U.S. Fish and Wildlife Service Land-Based Wind Energy Guidelines

Paperwork Reduction Act Statement: The Land-Based Wind Energy Guidelines contain reporting and recordkeeping requirements that require Office of Management and Budget approval in accordance with the Paperwork Reduction Act of 1995. Your response is voluntary. We collect this information in order to provide technical assistance related to addressing wildlife conservation concerns at all stages of land-based wind energy development. For each response, we estimate the time necessary to provide the information as follows:

- Tier 1 – 83 hours
- Tier 2 – 375 hours
- Tier 3 – 2,880 hours
- Tier 4 – 2,550 hours
- Tier 5 – 2,400 hours

The above estimates include time for reviewing instructions, gathering and maintaining data, and preparing and transmitting reports. Send comments regarding these estimates or any other aspect of the requirements to the Service Information Collection Clearance Officer, Fish and Wildlife Service, 4401 N. Fairfax Drive, MS 2042-PDM, Arlington, VA 22203.

1 We may not conduct and you are not required to respond to a collection of information unless it displays a currently
2 valid OMB control number.

1 Executive Summary

2

3 As the Nation shifts to renewable energy production to supplant the need for carbon-based fuel,
4 wind energy will be an important source of power. As wind energy production increases, both
5 developers and wildlife agencies have recognized the need for a system to evaluate and address
6 the potential negative impacts of wind energy projects on species of concern. These voluntary
7 Guidelines provide a structured, scientific process for addressing wildlife conservation concerns
8 at all stages of land-based wind energy development. They also promote effective
9 communication among wind energy developers and federal, state, and local conservation
10 agencies and tribes. When used in concert with appropriate regulatory tools, the Guidelines form
11 the best practical approach for conserving species of concern. The Guidelines have been
12 developed by the Interior Department's U.S. Fish and Wildlife Service (Service) working with
13 the Wind Turbine Guidelines Advisory Committee. They replace interim voluntary guidance
14 published by the Service in 2003.

15

16 The Guidelines discuss various risks to "species of concern" from wind energy projects,
17 including collisions with wind turbines and associated infrastructure; loss and degradation of
18 habitat from turbines and infrastructure; fragmentation of large habitat blocks into smaller
19 segments that may not support sensitive species; displacement and behavioral changes; and
20 indirect effects such as increased predator populations or introduction of invasive plants. The
21 Guidelines assist developers in identifying species of concern that may potentially be affected by
22 their proposed project, including migratory birds; bats; bald and golden eagles and other birds of
23 prey; prairie and sage grouse; and listed, proposed, or candidate endangered and threatened
24 species. Wind energy development in some areas may be precluded by federal law; other areas
25 may be inappropriate for development because they have been recognized as having high
26 wildlife value based on their ecological rarity and intactness.

27

28 The Guidelines use a "tiered approach" for assessing potential adverse effects to species of
29 concern and their habitats. The tiered approach is an iterative decision-making process for
30 collecting information in increasing detail; quantifying the possible risks of proposed wind
31 energy projects to species of concern and their habitats; and evaluating those risks to make siting,
32 construction, and operation decisions. During the pre-construction tiers (Tiers 1, 2, and 3),

1 developers are working to identify, avoid and minimize risks to species of concern. During post-
2 construction tiers (Tiers 4 and 5), developers are assessing whether actions taken in earlier tiers
3 to avoid and minimize impacts are successfully achieving the goals and, when necessary, taking
4 additional steps to compensate for impacts. Subsequent tiers refine and build upon issues raised
5 and efforts undertaken in previous tiers. Each tier offers a set of questions to help the developer
6 evaluate the potential risk associated with developing a project at the given location.

7

8 Briefly, the tiers address:

- 9 • Tier 1 – Preliminary site evaluation (landscape-scale screening of possible project sites)
- 10 • Tier 2 – Site characterization (broad characterization of one or more potential project
11 sites)
- 12 • Tier 3 – Field studies to document site wildlife and habitat and predict project impacts
- 13 • Tier 4 – Post-construction studies to estimate impacts¹
- 14 • Tier 5 – Other post-construction studies and research

15

16 The tiered approach provides the opportunity for evaluation and decision-making at each stage,
17 enabling a developer to abandon or proceed with project development, or to collect additional
18 information if required. This approach does not require that every tier, or every element within
19 each tier, be implemented for every project. The Service anticipates that many distributed or
20 community facilities will not need to follow the Guidelines beyond Tiers 1 and 2. Instead, the
21 tiered approach allows efficient use of developer and wildlife agency resources with increasing
22 levels of effort.

23

24 If sufficient data are available at a particular tier, the following outcomes are possible:

- 25 1. The project proceeds to the next tier in the development process without additional
26 data collection.
- 27 2. The project proceeds to the next tier in the development process with additional data
28 collection.

1 ¹ The Service anticipates these studies will include fatality monitoring as well as studies to evaluate habitat impacts.

1 3. An action or combination of actions, such as project modification, mitigation, or
2 specific post-construction monitoring, is indicated.

3 4. The project site is abandoned because the risk is considered unacceptable.

4 If data are deemed insufficient at a tier, more intensive study is conducted in the subsequent tier
5 until sufficient data are available to make a decision to modify the project, proceed with the
6 project, or abandon the project.

7

8 The most important thing a developer can do is to consult with the Service as early as possible in
9 the development of a wind energy project. Early consultation offers the greatest opportunity for
10 avoiding areas where development is precluded or where wildlife impacts are likely to be high
11 and difficult or costly to remedy or mitigate at a later stage. By consulting early, project
12 developers can also incorporate appropriate wildlife conservation measures and monitoring into
13 their decisions about project siting, design, and operation.

14

15 Adherence to the Guidelines is voluntary and does not relieve any individual, company, or
16 agency of the responsibility to comply with laws and regulations. However, if a violation occurs
17 the Service will consider a developer's documented efforts to communicate with the Service and
18 adhere to the Guidelines. The Guidelines include a Communications Protocol which provides
19 guidance to both developers and Service personnel regarding appropriate communication and
20 documentation.

21

22 The Guidelines also provide Best Management Practices for site development, construction,
23 retrofitting, repowering, and decommissioning. For additional reference, a glossary of terms and
24 list of literature cited are included in the appendices.

1 **Chapter 1 - General Overview**

2

3 The mission of the U.S. Fish and Wildlife Service is working with others to conserve, protect
4 and enhance fish, wildlife, plants and their habitats for the continuing benefit of the American
5 people. As part of this, the Service implements statutes including the Endangered Species Act,
6 Migratory Bird Treaty Act, and Bald and Golden Eagle Protection Act. These statutes prohibit
7 taking of federally listed species, migratory birds, and eagles unless otherwise authorized.

8

9 Recent studies have documented that wind energy facilities can kill birds and bats. Mortality
10 rates vary among facilities and regions. Studies have indicated that relatively low raptor (e.g.,
11 hawks, eagles) fatality rates exist at most modern wind energy developments with the exception
12 of some facilities in California and Wyoming. Bat fatalities are a common phenomenon at wind
13 energy facilities with several developments reporting numerous bat fatalities. Most studies,
14 however, have reported low rates of such incidents. There is still much uncertainty regarding
15 geographic distribution and causes of bat fatalities (NWCC 2010).

16

17 These Guidelines are intended to:

- 18 (1) Promote compliance with relevant wildlife laws and regulations;
- 19 (2) Encourage scientifically rigorous survey, monitoring, assessment, and research
20 designs proportionate to the risk to species of concern;
- 21 (3) Produce potentially comparable data across the Nation;
- 22 (4) Mitigate, including avoid, minimize, and compensate for potential adverse effects
23 on species of concern and their habitats; and,
- 24 (5) Improve the ability to predict and resolve effects locally, regionally, and
25 nationally.

26 As the United States moves to expand wind energy production, it also must maintain and protect
27 the Nation's fish, wildlife, and their habitats, which wind energy production can negatively
28 affect. As with all responsible energy development, wind energy projects should adhere to high
29 standards for environmental protection. With proper diligence paid to siting, operations, and

1 management of projects, it is possible to mitigate for adverse effects to fish, wildlife, and their
2 habitats. This is best accomplished when the wind energy project developer communicates as
3 early as possible with the Service and other stakeholders. Such early communication allows for
4 the greatest range of development and mitigation options. The following website contains
5 contact information for the Service Regional and Field offices as well as State wildlife agencies:
6 <http://www.fws.gov/offices/statelinks.html>

7

8 In response to increasing wind energy development in the United States, the U.S. Fish and
9 Wildlife Service (Service) released a set of voluntary, interim guidelines for reducing adverse
10 effects to fish and wildlife resources from wind energy projects for public comment in July 2003.
11 After the Service reviewed the public comments, the Secretary of the Interior (Secretary)
12 established a Federal Advisory Committee² to provide recommendations to revise the guidelines
13 related to land-based wind energy facilities. In March 2007, the U.S. Department of the Interior
14 established the Wind Turbine Guidelines Advisory Committee (the Committee). The Committee
15 submitted its final Recommended Guidelines (Recommendations) to the Secretary on March 4,
16 2010. The Service used the Recommendations to develop its Land-Based Wind Energy
17 Guidelines.

18

19 The Service encourages project proponents to use the process described in these voluntary Land-
20 based Wind Energy Guidelines (Guidelines) to address risks to species of concern. The Service
21 intends that these Guidelines, when used in concert with the appropriate regulatory tools, will
22 form the best practical approach for conservation of species of concern.

23

1 ² Committee membership, from 2008 to 2011, has included: Taber Allison, Massachusetts Audubon; Dick
2 Anderson, California Energy Commission; Ed Arnett, Bat Conservation International; Michael Azeka, AES Wind
3 Generation; Thomas Bancroft, National Audubon; Kathy Boydston, Texas Parks and Wildlife Department; René
4 Braud, EDP Renewables; Scott Darling, Vermont Fish and Wildlife Department; Michael Daulton, National
5 Audubon; Aimee Delach, Defenders of Wildlife; Karen Douglas, California Energy Commission; Sam Enfield,
6 MAP Royalty; Greg Hueckel, Washington Department of Fish and Wildlife; Jeri Lawrence, Blackfeet Nation; Steve
7 Lindenberg, U.S. Department of Energy; Andy Linehan, Iberdrola Renewables; Rob Manes, The Nature
8 Conservancy, Kansas; Winifred Perkins, NextEra Energy Resources; Steven Quarles, Crowell & Moring; Rich
9 Rayhill, Ridgeline Energy; Robert Robel, Kansas State University; Keith Sexson, Association of Fish and Wildlife
10 Agencies; Mark Sinclair, Clean Energy States Alliance; David Stout, U.S. Fish and Wildlife Service; Patrick
11 Traylor, Hogan Lovells.

1 Statutory Authorities

2 These Guidelines are not intended nor shall they be construed to limit or preclude the Service
3 from exercising its authority under any law, statute, or regulation, or from conducting
4 enforcement action against any individual, company, or agency. They are not meant to relieve
5 any individual, company, or agency of its obligations to comply with any applicable federal,
6 state, tribal, or local laws, statutes, or regulations. The Guidelines do not prevent the Service
7 from referring cases for enforcement when a company has not followed the Guidelines.

8

9 Ultimately it is the responsibility of those involved with the planning, design, construction,
10 operation, maintenance, and decommissioning of wind projects to conduct relevant wildlife and
11 habitat evaluation (e.g., siting guidelines, risk assessment, etc.) and determine, which, if any,
12 species may be affected. The results of these analyses will inform all efforts to achieve
13 compliance with the appropriate jurisdictional statutes. Project proponents are responsible for
14 complying with applicable state and local laws.

15

16 *Migratory Bird Treaty Act*

17 The Migratory Bird Treaty Act (MBTA) is the cornerstone of migratory bird conservation and
18 protection in the United States. The MBTA implements four treaties that provide for
19 international protection of migratory birds. It is a strict liability statute, meaning that proof of
20 intent, knowledge, or negligence is not an element of an MBTA violation. The statute's
21 language is clear that actions resulting in a "taking" or possession (permanent or temporary) of a
22 protected species, in the absence of a Service permit or regulatory authorization, are a violation
23 of the MBTA.

24

25 The MBTA states, "Unless and except as permitted by regulations ... it shall be unlawful at any
26 time, by any means, or in any manner to pursue, hunt, take, capture, kill ... possess, offer for
27 sale, sell ... purchase ... ship, export, import ... transport or cause to be transported ... any
28 migratory bird, any part, nest, or eggs of any such bird [The Act] prohibits the taking,
29 killing, possession, transportation, import and export of migratory birds, their eggs, parts, and
30 nests, except when specifically authorized by the Department of the Interior." 16 U.S.C. 703.

1 The word “take” is defined by regulation as “to pursue, hunt, shoot, wound, kill, trap, capture, or
2 collect, or attempt to pursue, hunt, shoot, wound, kill, trap, capture, or collect.” 50 CFR 10.12.

3

4 The MBTA provides criminal penalties for persons who commit any of the acts prohibited by the
5 statute in section 703 on any of the species protected by the statute. *See* 16 U.S.C. 707. The
6 Service maintains a list of all species protected by the MBTA at 50 CFR 10.13. This list
7 includes over one thousand species of migratory birds, including eagles and other raptors,
8 waterfowl, shorebirds, seabirds, wading birds, and passerines. The MBTA does not protect
9 introduced species such as the house (English) sparrow, European starling, rock dove (pigeon),
10 Eurasian collared-dove, and non-migratory upland game birds. The Service maintains a list of
11 introduced species not protected by the Act. *See* 70 Fed. Reg. 12,710 (Mar. 15, 2005).

12

13 ***Bald and Golden Eagle Protection Act***

14 Under authority of the Bald and Golden Eagle Protection Act (BGEPA), 16 U.S.C. 668–668d,
15 bald eagles and golden eagles are afforded additional legal protection. BGEPA prohibits the
16 take, sale, purchase, barter, offer of sale, purchase, or barter, transport, export or import, at any
17 time or in any manner of any bald or golden eagle, alive or dead, or any part, nest, or egg thereof.
18 16 U.S.C. 668. BGEPA also defines take to include “pursue, shoot, shoot at, poison, wound, kill,
19 capture, trap, collect, molest, or disturb,” 16 U.S.C. 668c, and includes criminal and civil
20 penalties for violating the statute. *See* 16 U.S.C. 668. The Service further defined the term
21 “disturb” as agitating or bothering an eagle to a degree that causes, or is likely to cause, injury, or
22 either a decrease in productivity or nest abandonment by substantially interfering with normal
23 breeding, feeding, or sheltering behavior. 50 CFR 22.3. BGEPA authorizes the Service to
24 permit the take of eagles for certain purposes and under certain circumstances, including
25 scientific or exhibition purposes, religious purposes of Indian tribes, and the protection of
26 wildlife, agricultural, or other interests, so long as that take is compatible with the preservation of
27 eagles. 16 U.S.C. 668a.

28 In 2009, the Service promulgated a final rule on two new permit regulations that, for the first
29 time, specifically authorize the incidental take of eagles and eagle nests in certain situations
30 under BGEPA. *See* 50 CFR 22.26 & 22.27. The permits authorize limited, non-purposeful

1 (incidental) take of bald and golden eagles; authorizing individuals, companies, government
2 agencies (including tribal governments), and other organizations to disturb or otherwise take
3 eagles in the course of conducting lawful activities such as operating utilities and airports.
4 Removal of active eagle nests would usually be allowed only when it is necessary to protect
5 human safety or the eagles. Removal of inactive nests can be authorized when necessary to
6 ensure public health and safety, when a nest is built on a human-engineered structure rendering it
7 inoperable, and when removal is necessary to protect an interest in a particular locality, but only
8 if the take or mitigation for the take will provide a clear and substantial benefit to eagles.

9 To facilitate issuance of permits under these new regulations, the Service has drafted Eagle
10 Conservation Plan (ECP) Guidance. The ECP Guidance is compatible with these Land-Based
11 Wind Energy Guidelines. The Guidelines guide developers through the process of project
12 development and operation. If eagles are identified as a potential risk at a project site,
13 developers are strongly encouraged to refer to the ECP Guidance. The ECP Guidance describes
14 specific actions that are recommended to comply with the regulatory requirements in BGEPA for
15 an eagle take permit, as described in 50 CFR 22.26 and 22.27. The ECP Guidance provides a
16 national framework for assessing and mitigating risk specific to eagles through development of
17 ECPs and issuance of programmatic incidental takes of eagles at wind turbine facilities. The
18 Service will make its final ECP Guidance available to the public through its website.

19

20 ***Endangered Species Act***

21 The Endangered Species Act (16 U.S.C. 1531–1544; ESA) was enacted by Congress in 1973 in
22 recognition that many of our Nation’s native plants and animals were in danger of becoming
23 extinct. The ESA directs the Service to identify and protect these endangered and threatened
24 species and their critical habitat, and to provide a means to conserve their ecosystems. To this
25 end, federal agencies are directed to utilize their authorities to conserve listed species, and ensure
26 that their actions are not likely to jeopardize the continued existence of these species or destroy
27 or adversely modify their critical habitat. Federal agencies are encouraged to do the same with
28 respect to “candidate” species that may be listed in the near future. The law is administered by
29 the Service and the Commerce Department’s National Marine Fisheries Service (NMFS). For
30 information regarding species protected under the ESA, see: <http://www.fws.gov/endangered/>

31

1 The Service has primary responsibility for terrestrial and freshwater species, while NMFS
2 generally has responsibility for marine species. These two agencies work with other agencies to
3 plan or modify federal projects so that they will have minimal impact on listed species and their
4 habitats. Protection of species is also achieved through partnerships with the states, through
5 federal financial assistance and a system of incentives available to encourage state participation.
6 The Service also works with private landowners, providing financial and technical assistance for
7 management actions on their lands to benefit both listed and non-listed species.

8

9 Section 9 of the ESA makes it unlawful for a person to “take” a listed species. Take is defined as
10 “... to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect or attempt to engage
11 in any such conduct.” 16 U.S.C. 1532(19). The terms harass and harm are further defined in our
12 regulations. See 50 CFR 17.3. However, the Service may authorize “incidental take” (take that
13 occurs as a result of an otherwise legal activity) in two ways.

14

15 Take of federally listed species incidental to a lawful activity may be authorized through formal
16 consultation under section 7(a)(2) of the ESA, whenever a federal agency, federal funding, or a
17 federal permit is involved. Otherwise, a person may seek an incidental take permit under section
18 10(a)(1)(B) of the ESA upon completion of a satisfactory habitat conservation plan (HCP) for
19 listed species. Developers not receiving federal funding or authorization should contact the
20 Service to obtain an incidental take permit if a wind energy project is likely to result in take of
21 listed threatened or endangered wildlife species. For more information regarding formal
22 consultation and the requirements of obtaining HCPs, please see the Endangered Species
23 Consultation Handbook at <http://www.fws.gov/endangered/esa-library/index.html#consultations>
24 and the Service's HCP website, <http://www.fws.gov/endangered/what-we-do/hcp-overview.html>.

25

26 **Implementation of the Guidelines**

27 Because these Guidelines are voluntary, the Service encourages developers to use them as soon
28 as possible after publication. To receive the considerations discussed below regarding
29 enforcement priorities, a wind energy project would fall into one of three general categories
30 relative to timing and implementation:

- 1 • For projects initiated after publication, the developer has applied the Guidelines,
2 including the tiered approach, through site selection, design, construction, operation and
3 post-operation phases of the project, and has communicated and shared information with
4 the Service and considered its advice.
- 5 • For projects initiated prior to publication, the developer should consider where they are in
6 the planning process relative to the appropriate tier and inform the Service of what
7 actions they will take to apply the Guidelines.
- 8 • For projects operating at the time of publication, the developer should confer with the
9 Service regarding the appropriate period of fatality monitoring consistent with Tier 4,
10 communicate and share information with the Service on monitoring results, and consider
11 Tier 5 studies and mitigation options where appropriate.

12
13 Projects that are already under development or are in operation are not expected to start over or
14 return to the beginning of a specific tier. Instead, these projects should implement those portions
15 of the Guidelines relevant to the current phases of the project per the bullets above.

16
17 The Service is aware that it will take time for Service staff and other personnel, including wind
18 energy developers and their biologists, to develop expertise in the implementation of these
19 Guidelines. Service staff and many staff associated with the wind energy industry have been
20 involved with developing these Guidelines. Therefore, they have a working knowledge of the
21 Guidelines. To further refine their training, the Service will make every effort to offer an in-
22 depth course within 6 months of the final Guidelines being published in the Federal Register.

23
24 The Communications Protocol below (Table 1) provides guidance to Service staff and
25 developers in the exchange of information and recommendations at each tier in the process.
26 Although the advice of the Service is not binding, a developer should review such advice, and
27 either accept or reject it. If they reject it, they should contemporaneously document with
28 reasoned justification why they did so. Although the Guidelines leave decisions up to the
29 developer, the Service retains authority to evaluate whether developer efforts to mitigate impacts
30 are sufficient, to determine significance, and to refer for prosecution any unlawful take that it

1 believes to be reasonably related to lack of incorporation of Service recommendations or
 2 insufficient adherence with the Guidelines.

3

4 **Table 1. Suggested Communications Protocol**

5 This table provides examples of potential communication opportunities between a wind energy
 6 project developer and the Service. Not all projects will follow all steps indicated below.

TIER	Project developer/operator Role	Service Role
Tier 1: Preliminary site evaluation	<ul style="list-style-type: none"> • Landscape level assessment of habitat for species of concern • Request data sources for existing information and literature 	<ul style="list-style-type: none"> • Provide lists of data sources and references, if requested (within a certain amount of time?)
Tier 2: Site characterization	<ul style="list-style-type: none"> • Assess potential presence of species of concern, including species of habitat fragmentation concern, likely to be on site • Assess potential presence of plant communities present on site that may provide habitat for species of concern • Assess potential presence of critical congregation areas for species of concern • One or more reconnaissance level site visit by biologist • Communicate results of site visits and other assessments with the Service • Provide general information about the size and location of the project to the Service 	<ul style="list-style-type: none"> • Provide species lists, for species of concern, including species of habitat fragmentation concern, for general area, if available • Provide information regarding plant communities of concern, if available • Respond to information provided about findings of biologist from site visit • Identify initial concerns about site(s) based on available information • Inform lead federal agencies of communications with wind project developers
Tier 3: Field studies and impact prediction	<ul style="list-style-type: none"> • Discuss extent and design of field studies to conduct with the Service • Conduct biological studies • Communicate results of all studies to Service field office in a timely manner • Evaluate risk to species of concern from project construction and operation • Identify ways to mitigate potential direct and indirect impacts of building and operating the project 	<ul style="list-style-type: none"> • Respond to requests to discuss field studies • Advise project proponent about studies to conduct and methods for conducting them • Communicate with project proponent(s) about results of field studies and risk assessments • Communicate with project proponents(s) ways to mitigate potential impacts of building and operating the project • Inform lead federal agencies of communications with wind project developers
Tier 4: Post construction studies to estimate impacts	<ul style="list-style-type: none"> • Discuss extent and design of post-construction studies to conduct with the Service • Conduct post-construction studies to assess fatalities and habitat-related impacts • Communicate results of all studies to Service field office in a timely manner • If necessary, discuss potential mitigation strategies with Service • Maintain appropriate records of data collected from studies 	<ul style="list-style-type: none"> • Advise project operator on study design, including duration of studies to collect adequate information • Communicate with project operator about results of studies • Advise project operator of potential mitigation strategies, when appropriate
Tier 5: Other post-construction studies and research	<ul style="list-style-type: none"> • Communicate with the Service about the need for and design of other studies and research to conduct with the Service, when appropriate, particularly when impacts exceed predicted levels • Communicate with the Service about ways to 	<ul style="list-style-type: none"> • Advise project proponents as to need for Tier 5 studies to address specific topics, including cumulative impacts, based on information collected in Tiers 3 and 4 • Advise project proponents of methods and metrics to use in Tier 5 studies

	<p>evaluate cumulative impacts on species of concern, particularly species of habitat fragmentation concern</p> <ul style="list-style-type: none"> • Conduct appropriate studies as needed • Communicate results of studies with the Service • Identify potential mitigation strategies to reduce impacts and discuss them with the Service 	<ul style="list-style-type: none"> • Communicate with project operator and consultants about results of Tier 5 studies • Advise project operator of potential mitigation strategies, when appropriate, based on Tier 5 studies

2 ***Consideration of the Guidelines in MBTA and BGEPA Enforcement***

3 The Service urges voluntary adherence to the Guidelines and communication with the Service
 4 when planning and operating a facility. While it is not possible to absolve individuals or
 5 companies from MBTA or BGEPA liability, the Office of Law Enforcement focuses its
 6 resources on investigating and prosecuting those who take migratory birds without identifying
 7 and implementing reasonable and effective measures to avoid the take. The Service will regard a
 8 developer’s or operator’s adherence to these Guidelines, including communication with the
 9 Service, as appropriate means of identifying and implementing reasonable and effective
 10 measures to avoid the take of species protected under the MBTA and BGEPA.³ The Chief of
 11 Law Enforcement or more senior official of the Service will make any decision whether to refer
 12 for prosecution any alleged take of such species, and will take such adherence and
 13 communication fully into account when exercising discretion with respect to such potential
 14 referral. Each developer or operator will be responsible for maintaining internal records
 15 sufficient to demonstrate adherence to the Guidelines and response to communications from the
 16 Service. Examples of these records could include: studies performed in the implementation of
 17 the tiered approach; an internal or external review or audit process; a bird and bat conservation
 18 strategy; or a wildlife management plan.

19

20 If a developer and operator are not the same entity, the Service expects the operator to maintain
 21 sufficient records to demonstrate adherence to the Guidelines.

22

1 ³ With regard to eagles, this paragraph will only apply when a project is not likely to result in take. If Tiers 1, 2,
 2 and/or 3 identify a potential to take eagles, developers should consider developing an ECP and, if necessary, apply
 3 for a take permit.

1 Scope and Project Scale of the Guidelines

2 The Guidelines are designed for “utility-scale” land-based wind energy projects to reduce
3 potential impacts to species of concern, regardless of whether they are proposed for private or
4 public lands. A developer of a distributed or community scale wind project may find it useful to
5 consider the general principles of the tiered approach to assess and reduce potential impacts to
6 species of concern, including answering Tier 1 questions using publicly available information.
7 In the vast majority of situations, appropriately sited small wind projects are not likely to pose
8 significant risks to species of concern. Answering Tier 1 questions will assist a developer of
9 distributed or community wind projects, as well as landowners, in assessing the need to further
10 communicate with the Service, and precluding, in many cases, the need for full detailed pre-
11 construction assessments or monitoring surveys typically called for in Tiers 2 and 3. If
12 landowners or community/distributed wind developers encounter problems locating information
13 about specific sites they can contact the Service and/or state wildlife agencies to determine
14 potential risks to species of concern for their particular project.

15
16 The tiered approach is designed to lead to the appropriate amount of evaluation in proportion to
17 the anticipated level of risk that a project may pose to species of concern and their habitats.
18 Study plans and the duration and intensity of study efforts should be tailored specifically to the
19 unique characteristics of each site and the corresponding potential for significant adverse impacts
20 on species of concern and their habitats as determined through the tiered approach. This is why
21 the tiered approach begins with an examination of the potential location of the project, not the
22 size of the project. In all cases, study plans and selection of appropriate study methods and
23 techniques may be tailored to the relative scale, location, and potential for significant adverse
24 impacts of the proposed site.

25
26 The Service considers a “project” to include all phases of wind energy development, including,
27 but not limited to, prospecting, site assessment, construction, operation, and decommissioning, as
28 well as all associated infrastructure and interconnecting electrical lines. A “project site” is the
29 land and airspace where development occurs or is proposed to occur, including the turbine pads,
30 roads, power distribution and transmission lines on or immediately adjacent to the site; buildings
31 and related infrastructure, ditches, grades, culverts; and any changes or modifications made to

1 the original site before development occurs. Project evaluations should consider all potential
2 effects to species of concern, which includes species (1) protected by the MBTA, BGEPA, and
3 ESA (including candidate species), designated by law, regulation or other formal process for
4 protection and/or management by the relevant agency or other authority, or that have been shown
5 to be significantly adversely affected by wind energy development, and 2) determined to be
6 possibly affected by the project.

8 These Guidelines are not designed to address power transmission beyond the point of
9 interconnection to the transmission system.

10

11 ***Service Review Period***

12 The Service is committed to providing timely responses. Service Field Offices should typically
13 respond to requests by a wind energy developer for information and consultation on proposed
14 site locations (Tiers 1 and 2), pre- and post-construction study designs (Tiers 3 and 4), and
15 proposed mitigation (Tier 3) within 60 calendar days. The request should be in writing to the
16 field office and copied to the Regional Office with information about the proposed project,
17 location(s) under consideration, and point of contact. The request should contain a description of
18 the information needed from the Service. The Service will provide a response, even if it is to
19 notify a developer of additional review time, within the 60 calendar day review period. If the
20 Service does not respond within 60 calendar days of receipt of the document, then the developer
21 can proceed through Tier 3 without waiting for Service input. If the Service provides comments
22 at a later time, the developer should incorporate the comments if feasible. It is particularly
23 important, that if data from Tier 1-3 studies predict that the project is likely to produce
24 significant adverse impacts on species of concern, the developer inform the Service of the
25 actions it intends to implement to mitigate those impacts. If the Service cannot respond within
26 60 calendar days, this does not relieve developers from their MBTA, BGEPA, and ESA
27 responsibilities.

28 The tiered approach allows a developer in certain limited circumstances to move directly from
29 Tier 2 to construction (e.g., adequate survey data for the site exists). The developer should notify
30 the Service of this decision and to give the Service 60 calendar days to comment on the proposed
31 project prior to initiating construction activities.

1

2 Introduction to the Decision Framework Using a Tiered Approach

3 The tiered approach provides a decision framework for collecting information in increasing
4 detail to evaluate risk and make siting and operational decisions. It provides the opportunity for
5 evaluation and decision-making at each tier, enabling a developer to proceed or abandon with
6 project development, or to collect additional information if necessary. This approach does not
7 require that every tier, or every element within each tier, be implemented for every project.
8 Instead, it allows efficient use of developer and wildlife agency resources with increasing levels
9 of effort until sufficient information and the desired precision is acquired for the risk assessment.

10

11 Figure 1 (“General Framework for Minimizing Impacts of Wind Development on Wildlife in the
12 Context of the Siting and Development of Wind Energy Projects”) illustrates the tiered approach,
13 which consists of up to five iterative stages, or tiers:

14 Tier 1 – Preliminary site evaluation (landscape-scale screening of possible project sites)

15 Tier 2 – Site characterization (broad characterization of one or more potential project
16 sites)

17 Tier 3 – Field studies to document site wildlife and habitat and predict project impacts

18 Tier 4 – Post-construction studies to estimate impacts⁴

19 Tier 5 – Other post-construction studies and research

20

21 At each tier, potential issues associated with developing or operating a project are identified and
22 questions formulated to guide the decision process. Chapters Two through Six outline the
23 questions to be posed at each tier, and describe recommended methods and metrics for gathering
24 the data needed to answer those questions.

25

26 The first three tiers correspond to the pre-construction evaluation phase of wind energy
27 development. At each of the three tiers, the Guidelines provide questions that developers should
28 answer, followed by recommended methods and metrics to use in answering the questions.

29 Some questions are repeated at each tier, with successive tiers requiring a greater investment in

1 ⁴ The Service anticipates these studies will include fatality monitoring as well as studies to evaluate habitat impacts.

1 data collection to answer certain questions. For example, while Tier 2 investigations may
2 discover some existing information on federal or state-listed species and their use of the
3 proposed development site, it may be necessary to collect empirical data in Tier 3 studies to
4 determine the presence of federal or state-listed species.

5

6 Developers decide whether to proceed to the next tier. Timely communication and sharing of
7 information will allow opportunities for the Service to provide, and developers to consider,
8 technical advice. A developer should base the decision on the information obtained from
9 adequately answering the questions in this tier, whether the methods used were appropriate for
10 the site selected, and the resulting assessment of risk posed to species of concern and their
11 habitats.

12

13 If sufficient data are available at a particular tier, the following outcomes are possible based on
14 analysis of the information gathered:

- 15 1. The project proceeds to the next tier in the development process without additional data
16 collection.
- 17 2. An action or combination of actions, such as project modification, mitigation, or specific
18 post-construction monitoring, is indicated.
- 19 3. The project site is abandoned because of the level of risk to species of concern.

20

21 If data are deemed insufficient at a tier, more intensive study is conducted in the subsequent tier
22 until sufficient data are available to make a decision to modify the project, proceed with the
23 project, or abandon the project.

24

25 The tiered approach used in these Guidelines embodies adaptive management by collecting
26 increasingly detailed information that is used to make decisions about project design,
27 construction, and operation as the developer progresses through the tiers. Adaptive management
28 is an iterative learning process producing improved understanding and improved management
29 over time (Williams et al 2007). DOI has determined that its resource agencies, and the natural
30 resources they oversee, could benefit from adaptive management. Use of adaptive management

1 in DOI is guided by the DOI Policy on Adaptive Management. DOI has adopted the National
2 Research Council’s 2004 definition of adaptive management, which states:

3
4 Adaptive management [is a decision process that] promotes flexible decision making that
5 can be adjusted in the face of uncertainties as outcomes from management actions and
6 other events become better understood. Careful monitoring of these outcomes both
7 advances scientific understanding and helps adjust policies or operations as part of an
8 iterative learning process. Adaptive management also recognizes the importance of
9 natural variability in contributing to ecological resilience and productivity. It is not a
10 ‘trial and error’ process, but rather emphasizes learning while doing. Adaptive
11 management does not represent an end in itself, but rather a means to more effective
12 decisions and enhanced benefits. Its true measure is in how well it helps meet
13 environmental, social, and economic goals, increases scientific knowledge, and reduces
14 tensions among stakeholders.

15

16 This definition gives special emphasis to uncertainty about management effects, iterative
17 learning to reduce uncertainty, and improved management as a result of learning. The DOI
18 Adaptive Management Technical Guide is located on the web at:

19 www.doi.gov/initiatives/AdaptiveManagement/index.html.

1 **Figure 1. General Framework of Tiered Approach**

- 2
- 3 **TIER 1**
- 4 A. Species of concern known to be present? 40
- 5 1. Noproceed to Tier 2 41
- 6 2. Unknown - Insufficient or inconclusive dataproceed to Tier 2 42
- 7 3. Yes.....abandon site or proceed to Tier 2 43

- 8 **TIER 2**
- 9 A. Probability of significant adverse impacts? 44
- 10 1. Unknown - Insufficient or inconclusive dataproceed to Tier 3 45
- 11 2. Low.....proceed to obtain state and local permit (if required), 46
- 12 design, and construction following BMPs 47
- 13 3. Moderateproceed to Tier 3 and mitigate 48
- 14 4. High, and: 49
- 15 a. can be adequately mitigated...modify project and proceed to Tier 3 50
- 16 b. cannot be adequately mitigate.....abandon project 51

- 17 **TIER 3**
- 18 A. Probability of significant adverse impacts? 52
- 19 1. Lowproceed to Tier 4 53
- 20 2. Moderate to high, and: 54
- 21 a. certainty regarding mitigation proceed to Tier 4 55
- 22 b. uncertainty regarding mitigationproceed to Tier 4 56
- 23 3. High, and: 57
- 24 c. can be adequately mitigated.....proceed to Tier 4 58
- 25 d. cannot be adequately mitigatedmodify or abandon project 59

- 26 **TIER 4a (See Table 2, page 73)** 60
- 27 A. Tier 3 studies indicate low probability of significant adverse impacts 61
- 28 1. Documented fatalities are equal to or lower than 62
- 29 predicted.....no further studies or mitigation needed 63
- 30 2. Documented fatalities are higher than predicted, but not significant, 64
- 31 and: 65
- 32 a. comparable data are available that support findings of not 66
- 33 significant.....no further studies needed 67
- 34 b. comparable data not available to support findings of not 68
- 35 significant.....additional year(s) of monitoring recommended 69
- 36 3. Documented fatalities are higher than predicted and are 70
- 37 significant.....communicate with Service 71

- B. Tier 3 studies indicate moderate probability of significant adverse 72
- impacts 73
- 1. Documented fatalities are lower than or no different predicted, and: 74
- a. are not significant and no ESA or BGEPA species are affected 75
-no further monitoring or mitigation needed 76
- b. are significant OR ESA or BGEPA species are 77
- affectedcommunicate with Service 78
- 2. Documented fatalities are greater than predicted and are likely to be 79
- significant OR ESA or BGEPA species are affected. 80
-communicate with Service 81
- C. Tier 3 studies indicate high probability of significant adverse impacts 82
- 1. Documented fatalities are less than predicted and are not 83
- significant, and no ESA or BGEPA species are affected..... 84
-no further monitoring or mitigation needed 85
- 2. Documented fatalities are less than predicted but are still significant, 86
- and no ESA or BGEPA species are affected.....further 87
- monitoring or mitigation needed 88
- 3. Fatalities are equal to or greater than predicted and are significant 89
- OR ESA or BGEPA species are affected.....communicate 90
- with Service regarding additional mitigation 91

- 62 **TIER 4b (See Table 3, pg 78)**
- 63 A. Species of habitat fragmentation concern potentially present? 92
- 1. No.....no further studies needed 93
- 2. Yes, and: 94
- a. Tier 3 studies do not confirm presence...no further studies needed 95
- b. Tier 3 studies confirm presence, but no significant adverse 96
- impacts predicted, and: 97
- i. Tier 4b studies confirm Tier 3 predictions.....no further 98
- studies or mitigation needed 99
- ii. Tier 4b studies indicate potentially significant adverse impacts 100
-Tier 5 studies and mitigation may be needed 101
- c. Tier 3 studies confirm presence, and significant adverse impacts 102
- predicted and mitigation plan is developed and implemented, 103
- and: 104
- i. Tier 4b studies determine mitigation is effectiveno 105
- further studies or mitigation needed 106

- 1 ii. Tier 4b studies determine mitigation not effective.....further
- 2 mitigation and, where appropriate, Tier 5 studies needed

1 **Considering Risk in the Tiered Approach**

2 In the context of these guidelines risk refers to the likelihood that adverse impacts will occur to
3 individuals or populations of species of concern as a result of wind energy development and
4 operation. Estimates of fatality risk can be used in a relative sense, allowing comparisons among
5 projects, alternative development designs, and in the evaluation of potential risk to populations.
6 Because there are relatively few methods available for direct estimation of risk, a weight-of-
7 evidence approach is often used (Anderson et al. 1999). Until such time that reliable risk
8 predictive models are developed regarding avian and bat fatality and wind energy projects,
9 estimates of risk would typically be qualitative, but should be based upon quantitative site
10 information.

11

12 For the purposes of these guidelines, risk can also be defined in the context of populations, but
13 that calculation is more complicated as it could involve estimating the reduction in population
14 viability as indicated by demographic metrics such as growth rate, size of the population, or
15 survivorship, either for local populations, metapopulations, or entire species. For most
16 populations, risk cannot easily be reduced to a strict metric, especially in the absence of
17 population viability models for most species. Consequently, estimating the quantitative risk to
18 populations is usually beyond the scope of project studies due to the difficulties in evaluating
19 these metrics, and therefore risk assessment will be qualitative.

20

21 Risk to habitat is a component of the evaluation of population risk. In this context, the estimated
22 loss of habitat is evaluated in terms of the potential for population level effects (e.g., reduced
23 survival or reproduction).

24

25 The assessment of risk should synthesize sufficient data collected at a project to estimate
26 exposure and predict impact for individuals and their habitats for the species of concern, with
27 what is known about the population status of these species, and in communication with the
28 relevant wildlife agency and industry wildlife experts. Predicted risk of these impacts could
29 provide useful information for determining appropriate mitigation measures if determined to be
30 necessary. In practice in the tiered approach, risk assessments conducted in Tiers 1 and 2 require
31 less information to reach a risk-based decision than those conducted at higher tiers.

1

2 Cumulative Impacts of Project Development

3 Cumulative impacts are the comprehensive effect on the environment that results from the
4 incremental impact of a project when added to other past, present, and reasonably foreseeable
5 future actions. Developers are encouraged to work closely with federal and state agencies early
6 in the project planning process to access any existing information on the cumulative impacts of
7 individual projects on species and habitats at risk, and to incorporate it into project development
8 and any necessary wildlife studies. To achieve that goal, it is important that agencies and
9 organizations take the following actions to improve cumulative impacts analysis:

- 10 • review the range of development-related significant adverse impacts;
- 11 • determine which species of concern or their habitats within the landscape are most at risk
12 of significant adverse impacts from wind development in conjunction with other
13 reasonably foreseeable significant adverse impacts; and
- 14 • make that data available for regional or landscape level analysis.

15

16 The magnitude and extent of the impact on a resource depend on whether the cumulative impacts
17 exceed the capacity for resource sustainability and productivity.

18

19 For projects that require a federal permit, funding, or other federal nexus, the lead federal agency
20 is required to include a cumulative impacts analysis in their National Environmental Policy Act
21 (NEPA) review. The federal action agency coordinates with the developer to obtain the
22 necessary information for the NEPA review and cumulative impacts analysis. To avoid project
23 delays, federal and state agencies are encouraged to use existing wildlife data for the cumulative
24 impacts analysis until improved data are available.

25

26 Where there is no federal nexus, individual developers are not expected to conduct their own
27 cumulative impacts analysis. However, a cumulative impacts analysis would help developers
28 and other stakeholders better understand the significance of potential impacts on species of
29 concern and their habitats.

1

2 Other Federal Agencies

3 Other federal agencies, such as the Bureau of Land Management, National Park Service, U.S.
4 Department of Agriculture Forest Service and Rural Utility Service, Federal Energy Regulatory
5 Commission and Department of Energy are often interested in and involved with wind project
6 developments. These agencies have a variety of expertise and authorities they implement. Wind
7 project developers on public lands will have to comply with applicable regulations and policies
8 of those agencies. State and local agencies and Tribes also have additional interests and
9 knowledge. The Service recommends that, where appropriate, wind project developers contact
10 these agencies early in the tiered process and work closely with them throughout project
11 planning and development to assure that projects address issues of concern to those agencies.
12 The definition of “species of concern” in these Guidelines includes species which are trust
13 resources of States, but not necessarily of federal agencies. In those instances where a project
14 may significantly affect State trust resources, wind energy developers should work closely with
15 appropriate State agencies.

16

17 Relationship to Other Guidelines

18 These Guidelines replace the Service’s 2003 interim voluntary guidelines. The Service intends
19 that these Guidelines, when used in concert with the appropriate regulatory tools, will form the
20 best practical approach for conservation of species of concern. For instance, when developers
21 find that a project may affect an endangered or threatened species, they should comply with
22 Section 7 or 10 of the ESA to obtain incidental take authorization. Other federal, state, tribal and
23 local governments may use these Guidelines to complement their efforts to address wind energy
24 development/wildlife interactions. They are not intended to supplant existing regional or local
25 guidance, or landscape-scale tools for conservation planning, but were developed to provide a
26 means of improving consistency with the goals of the wildlife statutes that the Service is
27 responsible for implementing. The Service will continue to work with states, tribes, and other
28 local stakeholders on map-based tools, decision-support systems, and other products to help
29 guide future development and conservation. Additionally, project proponents should utilize any
30 relevant guidance of the appropriate jurisdictional entity, which will depend on the species and
31 resources potentially affected by proposed development.

1 **Chapter 2: Tier 1 – Preliminary Site Evaluation**

2

3 For developers taking a first look at a broad geographic area, a preliminary evaluation of the
4 general ecological context of a potential site or sites can serve as useful preparation for working
5 with the federal, state, tribal, and/or local agencies. The Service is available to assist wind
6 energy project developers to identify potential wildlife and habitat issues and should be
7 contacted as early as possible in the company's planning process. With this internal screening
8 process, the developer can begin to identify broad geographic areas of high sensitivity due to the
9 presence of: 1) large blocks of intact native landscapes; 2) intact ecological communities; 3)
10 fragmentation-sensitive species' habitats; or 4) other important landscape-scale wildlife values.

11 Tier 1 may be used in any of the following three ways:

12

- 13 1. To identify regions where wind energy development poses significant risks to species of
14 concern or their habitats, including the fragmentation of large-scale habitats and threats to
15 regional populations of federal- or state-listed species.
- 16 2. To “screen” a landscape or set of multiple potential sites to avoid those with the highest
17 habitat values.
- 18 3. To begin to determine if a single identified potential site poses serious risk to species of
19 concern or their habitats.

20

21 Tier 1 can offer early guidance about the sensitivity of the site within a larger landscape context;
22 it can help direct development away from sites that will be associated with additional study need,
23 greater mitigation requirements, and uncertainty; or it can identify those sensitive resources that
24 will need to be studied further to determine if the site can be developed without significant
25 adverse impacts to the species of concern or local population(s). This may facilitate discussions
26 with the federal, state, tribal, and/or local agencies in a region being considered for development.
27 In some cases, Tier 1 studies could reveal serious concerns indicating that a site should not be
28 developed.

29

1 Developers of distributed or community scale wind projects are typically considering limited
2 geographic areas to install turbines. Therefore, they would not likely consider broad geographic
3 areas. Nevertheless, they should consider the presence of habitats or species of concern before
4 siting projects.

5

6 Development in some areas may be precluded by federal law. This designation is separate from
7 a determination through the tiered approach that an area is not appropriate for development due
8 to feasibility, ecological reasons, or other issues. Developers are encouraged to visit Service and
9 other publicly available databases or other available information during Tier 1 or Tier 2 to see if
10 a potential wind energy area is precluded from development by federal law. Some areas may be
11 protected from development through state or local laws or ordinances, and the appropriate
12 agency should be contacted accordingly. Service field offices are available to answer questions
13 where they are knowledgeable, guide developers to databases, and refer developers to other
14 agency contacts.

15

16 Some areas may be inappropriate for large scale development because they have been recognized
17 according to scientifically credible information as having high wildlife value, based solely on
18 their ecological rarity and intactness (e.g., Audubon Important Bird Areas, The Nature
19 Conservancy portfolio sites, state wildlife action plan priority habitats). It is important to
20 identify such areas through the tiered approach, as reflected in Tier 1, Question 2 below. Many
21 of North America's native landscapes are greatly diminished, with some existing at less than 10
22 percent of their pre-settlement occurrence. Herbaceous scrub-shrub steppe in the Pacific
23 Northwest and old growth forest in the Northeast represent such diminished native resources.
24 Important remnants of these landscapes are identified and documented in various databases held
25 by private conservation organizations, state wildlife agencies, and, in some cases, by the
26 Service. Developers should collaborate with such entities specifically about such areas in the
27 vicinity of a prospective project site.

28

29 **Tier 1 Questions**

30 Questions at each tier help determine potential environmental risks at the landscape scale for Tier
31 1 and project scale for Tiers 2 and 3. Suggested questions to be considered for Tier 1 include:

- 1 **1. Are there species of concern present on the potential site(s), or is habitat (including**
2 **designated critical habitat) present for these species?**
- 3 **2. Does the landscape contain areas where development is precluded by law or areas**
4 **designated as sensitive according to scientifically credible information? Examples of**
5 **designated areas include, but are not limited to: federally-designated critical habitat;**
6 **high-priority conservation areas for non-government organizations (NGOs); or other**
7 **local, state, regional, federal, tribal, or international categorizations.**
- 8 **3. Are there known critical areas of wildlife congregation, including, but not limited to:**
9 **maternity roosts, hibernacula, staging areas, winter ranges, nesting sites, migration**
10 **stopovers or corridors, leks, or other areas of seasonal importance?**
- 11 **4. Are there large areas of intact habitat with the potential for fragmentation, with**
12 **respect to species of habitat fragmentation concern needing large contiguous blocks of**
13 **habitat?**

14

15 **Tier 1 Methods and Metrics**

16 Developers who choose to conduct Tier 1 investigations would generally be able to utilize
17 existing public or other readily available landscape-level maps and databases from sources such
18 as federal, state, or tribal wildlife or natural heritage programs, the academic community,
19 conservation organizations, or the developers' or consultants' own information. The Service
20 recommends that developers conduct a review of the publicly available data. The analysis of
21 available sites in the region of interest will be based on a blend of the information available in
22 published and unpublished reports, wildlife range distribution maps, and other such sources. The
23 developer should check with the Service Field Office for data specific to wind energy
24 development and wildlife at the landscape scale in Tier 1.

25

26 **Tier 1 Decision Points**

27 The objective of the Tier 1 process is to help the developer identify a site or sites to consider
28 further for wind energy development. Possible outcomes of this internal screening process
29 include the following:

- 1 1. One or more sites are found within the area of investigation where the answer to each of
2 the above Tier 1 questions is “no,” indicating a low probability of significant adverse
3 impact to wildlife. The developer proceeds to Tier 2 investigations and characterization
4 of the site or sites, answering the Tier 2 questions with site-specific data to confirm the
5 validity of the preliminary indications of low potential for significant adverse impact.
- 6 2. If a developer answers “yes” to one or more of the Tier 1 questions, they should proceed
7 to Tier 2 to further assess the probability of significant adverse impacts to wildlife. A
8 developer may consider abandoning the area or identifying possible means by which the
9 project can be modified to avoid or minimize potential significant adverse impacts.
- 10 3. The data available in the sources described above are insufficient to answer one or more
11 of the Tier 1 questions. The developer proceeds to Tier 2, with a specific emphasis on
12 collecting the data necessary to answer the Tier 2 questions, which are inclusive of those
13 asked at Tier 1.

1 **Chapter 3: Tier 2 – Site Characterization**

2

3 At this stage, the developer has narrowed consideration down to specific sites, and additional
4 data may be necessary to systematically and comprehensively characterize a potential site in
5 terms of the risk wind energy development would pose to species of concern and their habitats.
6 In the case where a site or sites have been selected without the Tier 1 preliminary evaluation of
7 the general ecological context, Tier 2 becomes the first stage in the site selection process. The
8 developer will address the questions asked in Tier 1; if addressing the Tier 1 questions here, the
9 developer will evaluate the site within a landscape context. However, a distinguishing feature of
10 Tier 2 studies is that they focus on site-specific information and should include at least one visit
11 by a knowledgeable biologist to each of the prospective site(s). Because Tier 2 studies are
12 preliminary, normally one reconnaissance level site visit will be adequate as a “ground-truth” of
13 available information. Notwithstanding, if key issues are identified that relate to varying
14 conditions and/or seasons, Tier 2 studies should include enough site visits during the appropriate
15 times of the year to adequately assess these issues for the prospective site(s).

16 If the results of the site assessment indicate that one or more species of concern are present, a
17 developer should consider applicable regulatory or other agency processes for addressing them.
18 For instance, if migratory birds and bats are likely to experience significant adverse impacts by a
19 wind project at the proposed site, a developer should identify and document possible actions that
20 will avoid or compensate for those impacts. Such actions might include, but not be limited to,
21 altering locations of turbines or turbine arrays, operational changes, or compensatory mitigation.
22 As soon as a developer anticipates that a wind energy project is likely to result in a take of bald
23 or golden eagles, a developer should prepare an ECP and, if necessary, apply for a programmatic
24 take permit. As soon as a developer realizes endangered or threatened species are present and
25 likely to be affected by a wind project located there, a federal agency should consult with the
26 Service under Section 7(a)(2) of the ESA if the project has a federal nexus or the developer
27 should apply for a section 10(a)(1)(B) incidental take permit if there is not a federal nexus, and
28 incidental take of listed wildlife is anticipated. State, tribal, and local jurisdictions may have
29 additional permitting requirements.

30

1 Developers of distributed or community scale wind projects are typically considering limited
2 geographic areas to install turbines. Therefore, they would likely be familiar with conditions at
3 the site where they are considering installing a turbine. Nevertheless, they should do preliminary
4 site evaluations to determine the presence of habitats or species of concern before siting projects.

5 **Tier 2 Questions**

6 Questions suggested for Tier 2 can be answered using credible, publicly available information
7 that includes published studies, technical reports, databases, and information from agencies, local
8 conservation organizations, and/or local experts. Developers or consultants working on their
9 behalf should contact the federal, state, tribal, and local agencies that have jurisdiction or
10 management authority and responsibility over the potential project.

11

- 12 **1. Are known species of concern present on the proposed site, or is habitat (including**
13 **designated critical habitat) present for these species?**
- 14 **2. Does the landscape contain areas where development is precluded by law or**
15 **designated as sensitive according to scientifically credible information? Examples of**
16 **designated areas include, but are not limited to: federally-designated critical**
17 **habitat; high-priority conservation areas for NGOs; or other local, state, regional,**
18 **federal, tribal, or international categorizations.**
- 19 **3. Are there plant communities of concern present or likely to be present at the site(s)?**
- 20 **4. Are there known critical areas of congregation of species of concern, including, but**
21 **not limited to: maternity roosts, hibernacula, staging areas, winter ranges, nesting**
22 **sites, migration stopovers or corridors, leks, or other areas of seasonal importance?**
- 23 **5. Using best available scientific information has the developer or relevant federal,**
24 **state, tribal, and/or local agency identified the potential presence of a population of**
25 **a species of habitat fragmentation concern?**
- 26 **6. Which species of birds and bats, especially those known to be at risk by wind energy**
27 **facilities, are likely to use the proposed site based on an assessment of site**
28 **attributes?**

1 **7. Is there a potential for significant adverse impacts to species of concern based on**
2 **the answers to the questions above, and considering the design of the proposed**
3 **project?**

4
5
6 **Tier 2 Methods and Metrics**

7 Obtaining answers to Tier 2 questions will involve a more thorough review of the existing site-
8 specific information than in Tier 1. Tier 2 site characterizations studies will generally contain
9 three elements:

- 10 1. A review of existing information, including existing published or available literature and
11 databases and maps of topography, land use and land cover, potential wetlands, wildlife,
12 habitat, and sensitive plant distribution. If agencies have documented potential habitat
13 for species of habitat fragmentation concern, this information can help with the analysis.
- 14 2. Contact with agencies and organizations that have relevant scientific information to
15 further help identify if there are bird, bat or other wildlife issues. The Service
16 recommends that the developer make contact with federal, state, tribal, and local agencies
17 that have jurisdiction or management authority over the project or information about the
18 potentially affected resources. In addition, because key NGOs and relevant local groups
19 are often valuable sources of relevant local environmental information, the Service
20 recommends that developers contact key NGOs, even if confidentiality concerns preclude
21 the developer from identifying specific project location information at this stage. These
22 contacts also provide an opportunity to identify other potential issues and data not already
23 identified by the developer.
- 24 3. One or more reconnaissance level site visits by a wildlife biologist to evaluate current
25 vegetation/habitat coverage and land management/use. Current habitat and land use
26 practices will be noted to help in determining the baseline against which potential
27 impacts from the project would be evaluated. The vegetation/habitat will be used for
28 identifying potential bird and bat resources occurring at the site and the potential
29 presence of, or suitable habitat for, species of concern. Vegetation types or habitats will
30 be noted and evaluated against available information such as land use/land cover

1 mapping. Any sensitive resources located during the site visit will be noted and mapped
2 or digital location data recorded for future reference. Any individuals or signs of species
3 of concern observed during the site visit will be noted.

4
5 Specific resources that can help answer each Tier 2 question include:

6 **1. Are known species of concern present on the proposed site, or is habitat (including**
7 **designated critical habitat) present for these species?**

8 Information review and agency contact: locations of state and federally listed, proposed
9 and candidate species and species of concern are frequently documented in state and
10 federal wildlife databases. Examples include published literature such as: Natural
11 Heritage Databases, State Wildlife Action Plans, NGOs publications, and developer and
12 consultant information, or can be obtained by contacting these entities.

13 Site Visit: To the extent practicable, the site visit(s) should evaluate the suitability of
14 habitat at the site for species identified and the likelihood of the project to adversely
15 affect the species of concern that may be present.

16 **2. Does the landscape contain areas where development is precluded by law or**
17 **designated as sensitive according to scientifically credible information?** Examples of
18 designated areas include, but are not limited to: federally-designated critical habitat;
19 high-priority conservation areas for NGOs; or other local, state, regional, federal, tribal,
20 or international categorizations.

21 Information review and agency contact such as: maps of political and administrative
22 boundaries; National Wetland Inventory data files; USGS National Land Cover data
23 maps; state, federal and tribal agency data on areas that have been designated to preclude
24 development, including wind energy development; State Wildlife Action Plans; State
25 Land and Water Resource Plans; Natural Heritage databases; scientifically credible
26 information provided by NGO and local resources; and the additional resources listed in
27 **Appendix C: Sources of Information Pertaining to Methods to Assess**
28 **Impacts to Wildlife** of this document, or through contact of agencies and NGOs, to
29 determine the presence of high priority habitats for species of concern or conservation
30 areas.

1 Site Visit: To the extent practicable, the site visit(s) should characterize and evaluate the
2 uniqueness of the site vegetation relative to surrounding areas.

3 **3. Are plant communities of concern present or likely to be present at the site(s)?**

4 Information review and agency contact such as: Natural Heritage Data of state rankings
5 (S1, S2, S3) or globally (G1, G2, G3) ranked rare plant communities.

6 Site Visit: To the extent practicable, the site visit should evaluate the topography,
7 physiographic features and uniqueness of the site vegetation in relation to the surrounding
8 region. If plant communities of concern are present, developers should also assess in Tier
9 3 whether the proposed project poses risk of significant adverse impacts and
10 opportunities for mitigation.

11 **4. Are there known critical areas of wildlife congregation, including, but not limited to,**
12 **maternity roosts, hibernacula, staging areas, winter ranges, nesting sites, migration**
13 **stopovers or corridors, leks, or other areas of seasonal importance?**

14 Information review and agency contact such as: existing databases, State Wildlife Action
15 Plan, Natural Heritage Data, and NGO and agency information regarding the presence of
16 Important Bird Areas, migration corridors or stopovers, leks, bat hibernacula or maternity
17 roosts, or game winter ranges at the site and in the surrounding area.

18 Site Visit: To the extent practicable, the site visit should, *during appropriate times to*
19 *adequately assess these issues for prospective site(s)*, evaluate the topography,
20 physiographic features and uniqueness of the site in relation to the surrounding region to
21 assess the potential for the project area to concentrate resident or migratory birds and
22 bats.

23 **5. Using best available scientific information, has the relevant federal, state, tribal,**
24 **and/or local agency determined the potential presence of a population of a species of**
25 **habitat fragmentation concern?** If not, the developer need not assess impacts of the
26 proposed project on habitat fragmentation.

27 Habitat fragmentation is defined as the separation of a block of habitat for a species into
28 segments, such that the genetic or demographic viability of the populations surviving in
29 the remaining habitat segments is reduced; and risk, in this case, is defined as the

1 probability that this fragmentation will occur as a result of the project. Site clearing,
2 access roads, transmission lines and turbine tower arrays remove habitat and displace
3 some species of wildlife, and may fragment continuous habitat areas into smaller, isolated
4 tracts. Habitat fragmentation is of particular concern when species require large expanses
5 of habitat for activities such as breeding and foraging.

6 Consequences of isolating local populations of some species include decreased
7 reproductive success, reduced genetic diversity, and increased susceptibility to chance
8 events (e.g. disease and natural disasters), which may lead to extirpation or local
9 extinctions. In addition to displacement, development of wind energy infrastructure may
10 result in additional loss of habitat for some species due to “edge effects” resulting from
11 the break-up of continuous stands of similar vegetation resulting in an interface (edge)
12 between two or more types of vegetation. The extent of edge effects will vary by species
13 and may result in adverse impacts from such effects as a greater susceptibility to
14 colonization by invasive species, increased risk of predation, and competing species
15 favoring landscapes with a mosaic of vegetation.

16 Site Visit: If the answer to Tier 2 Question 5 is yes, developers should use the general
17 framework for evaluating habitat fragmentation at a project site in Tier 2 outlined below.
18 Developers and the Service may use this method to analyze the impacts of habitat
19 fragmentation at wind development project sites on species of habitat fragmentation
20 concern. Service field offices may be able to provide the available information on habitat
21 types, quality and intactness. Developers may use this information in combination with
22 site-specific information on the potential habitats to be impacted by a potential
23 development and how they will be impacted.

24 General Framework for Evaluating Habitat Fragmentation at a Project Site (Tier 2)

- 25 A. The developer should define the study area. The study area should not only
26 include the project site for the proposed project, but be based on the distribution
27 of habitat for the local population of the species of habitat fragmentation concern.
- 28 B. The developer should analyze the current habitat quality and spatial configuration
29 of the study area for the species of habitat fragmentation concern.

- 1 i. Use recent aerial and remote imagery to determine distinct habitat patches, or
2 boundaries, within the study area, and the extent of existing habitat
3 fragmenting features (e.g., highways).
4 ii. Assess the level of fragmentation of the existing habitat for the species of
5 habitat fragmentation concern and categorize into three classes:
6 ▪ High quality: little or no apparent fragmentation of intact habitat
7 ▪ Medium quality: intact habitat exhibiting some recent disturbance activity
8 ▪ Low quality: Extensive fragmentation of habitat (e.g., row-cropped
9 agricultural lands, active surface mining areas)

10
11 C. The developer should determine potential changes in quality and spatial
12 configuration of the habitat in the study area if development were to proceed as
13 proposed using existing site information.

14
15 D. The developer should provide the collective information from steps A-C for all
16 potential developments to the Service for use in assessing whether the habitat
17 impacts, including habitat fragmentation, are likely to affect population viability
18 of the potentially affected species of habitat fragmentation concern.

19
20 **6. Which species of birds and bats, especially those known to be at risk by wind energy**
21 **facilities, are likely to use the proposed site based on an assessment of site**
22 **attributes?**

23 Information review and agency contact: existing published information and databases
24 from NGOs and federal and state resource agencies regarding the potential presence
25 of:

- 26 • Raptors: species potentially present by season
27 • Prairie grouse and sage grouse: species potentially present by season and location
28 of known leks
29 • Other birds: species potentially present by season that may be at risk of collision
30 or adverse impacts to habitat, including loss, displacement and fragmentation

- 1 • Bats: species likely to be impacted by wind energy facilities and likely to occur
2 on or migrate through the site

3 Site Visit: To the extent practicable, the site visit(s) should identify landscape features or
4 habitats that could be important to raptors, prairie grouse, and other birds that may be at
5 risk of adverse impacts, and bats, including nesting and brood-rearing habitats, areas of
6 high prey density, movement corridors and features such as ridges that may concentrate
7 raptors. Raptors, prairie grouse, and other presence or sign of species of concern seen
8 during the site visit should be noted, with species identification if possible.

9 **7. Is there a potential for significant adverse impacts to species of concern based on**
10 **the answers to the questions above, and considering the design of the proposed**
11 **project?**

12 The developer has assembled answers to the questions above and should make an initial
13 evaluation of the probability of significant adverse impacts to species of concern and
14 their habitats. The developer should make this evaluation based on assessments of the
15 potential presence of species of concern and their habitats, potential presence of critical
16 congregation areas for species of concern, and any site visits. The developer is
17 encouraged to communicate the results of these assessments with the Service.

18

19 **Tier 2 Decision Points**

20 Possible outcomes of Tier 2 include the following:

- 21 1. The most likely outcome of Tier 2 is that the answer to one or more Tier 2 questions is
22 inconclusive to address wildlife risk, either due to insufficient data to answer the question
23 or because of uncertainty about what the answers indicate. The developer proceeds to
24 Tier 3, formulating questions, methods, and assessment of potential mitigation measures
25 based on issues raised in Tier 2 results.
- 26 2. Sufficient information is available to answer all Tier 2 questions, and the answer to each
27 Tier 2 question indicates a low probability of significant adverse impact to wildlife (for
28 example, infill or expansion of an existing facility where impacts have been low and Tier
29 2 results indicate that conditions are similar, therefore wildlife risk is low). The

- 1 developer may then decide to proceed to obtain state and local permit (if required),
2 design, and construction following best management practices (see Chapter 7: Best
3 Management Practices).
- 4 3. Sufficient information is available to answer all Tier 2 questions, and the answer to each
5 Tier 2 question indicates a moderate probability of significant adverse impacts to species
6 of concern or their habitats. The developer should proceed to Tier 3 and identify
7 measures to mitigate potential significant adverse impacts to species of concern.
- 8 4. The answers to one or more Tier 2 questions indicate a high probability of significant
9 adverse impacts to species of concern or their habitats that:
- 10 a) Cannot be adequately mitigated. The proposed site should be abandoned.
- 11 b) Can be adequately mitigated. The developer should proceed to Tier 3 and identify
12 measures to mitigate potential significant adverse impacts to species of concern or their
13 habitats.

1 **Chapter 4: Tier 3 – Field Studies to Document Site Wildlife and Habitat and** 2 **Predict Project Impacts**

3

4 Tier 3 is the first tier in which a developer would conduct quantitative and scientifically rigorous
5 studies to assess the potential risk of the proposed project. Specifically, these studies provide pre-
6 construction information to:

7

- 8 • Further evaluate a site for determining whether the wind energy project should be
9 developed or abandoned
- 10 • Design and operate a site to avoid or minimize significant adverse impacts if a decision is
11 made to develop
- 12 • Design compensatory mitigation measures if significant adverse habitat impacts cannot
13 acceptably be avoided or minimized
- 14 • Determine duration and level of effort of post-construction monitoring. If warranted,
15 provide the pre-construction component of post-construction studies necessary to
16 estimate and evaluate impacts

17

18 At the beginning of Tier 3, a developer should communicate with the Service on the pre-
19 construction studies. At the end of Tier 3, developers should communicate with the Service
20 regarding the results of the Tier 3 studies and consider the Service's comments and
21 recommendations prior to completing the Tier 3 decision process. The Service will provide
22 written comments to a developer that identify concerns and recommendations to resolve the
23 concerns based on study results and project development plans.

24

25 Not all Tier 3 studies will continue into Tiers 4 or 5. For example, surveys conducted in Tier 3
26 for species of concern may indicate one or more species are not present at the proposed project
27 site, or siting decisions could be made in Tier 3 that remove identified concerns, thus removing
28 the need for continued efforts in later tiers. Additional detail on the design issues for post-
29 construction studies that begin in Tier 3 is provided in the discussion of methods and metrics in
30 Tier 3.

1 **Tier 3 Questions**

2 Tier 3 begins as the other tiers, with problem formulation: what additional studies are necessary
3 to enable a decision as to whether the proposed project can proceed to construction or operation
4 or should be abandoned? This step includes an evaluation of data gaps identified by Tier 2
5 studies as well as the gathering of data necessary to:

6

7 • Design a project to avoid or minimize predicted risk

8 • Evaluate predictions of impact and risk through post-construction comparisons of
9 estimated impacts

10 • Identify compensatory mitigation measures, if appropriate, to offset significant adverse
11 impacts that cannot be avoided or minimized

12

13 The problem formulation stage for Tier 3 also will include an assessment of which species
14 identified in Tier 1 and/or Tier 2 will be studied further in the site risk assessment. This
15 determination is based on analysis of existing data from Tier 1 and existing site-specific data and
16 Project Site (see Glossary in Appendix A) visit(s) in Tier 2, and on the likelihood of presence
17 and the degree of adverse impact to species or their habitat. If the habitat is suitable for a species
18 needing further study and the site occurs within the historical range of the species, or is near the
19 existing range of the species but presence has not been documented, additional field studies may
20 be appropriate. Additional analyses should not be necessary if a species is unlikely to be present
21 or is present but adverse impact is unlikely or of minor significance.

22

23 Tier 3 studies address many of the questions identified for Tiers 1 and 2, but Tier 3 studies differ
24 because they attempt to quantify the distribution, relative abundance, behavior, and site use of
25 species of concern. Tier 3 data also attempt to estimate the extent that these factors expose these
26 species to risk from the proposed wind energy facility. Therefore, in answering Tier 3 questions
27 1-3, developers should collect data sufficient to analyze and answer Tier 3 questions 4-6. High
28 risk sites may warrant additional years of pre-construction studies. The duration and intensity of
29 studies needed should be determined through communication with the Service.

1

2 If Tier 3 studies identify species of concern or important habitats, e.g., wetlands, which have
3 specific regulatory processes and requirements, developers should work with appropriate state,
4 tribal, or federal agencies to obtain required authorizations or permits.

5

6 Tier 3 studies should be designed to answer the following questions:

- 7 **1. Do field studies indicate that species of concern are present on or likely to use the**
8 **proposed site?**
- 9 **2. Do field studies indicate the potential for significant adverse impacts on affected**
10 **population of species of habitat fragmentation concern?**
- 11 **3. What is the distribution, relative abundance, behavior, and site use of species of**
12 **concern identified in Tiers 1 or 2, and to what extent do these factors expose these**
13 **species to risk from the proposed wind energy project?**
- 14 **4. What are the potential risks of adverse impacts of the proposed wind energy project**
15 **to individuals and local populations of species of concern and their habitats? (In**
16 **the case of rare or endangered species, what are the possible impacts to such species**
17 **and their habitats?)**
- 18 **5. How can developers mitigate identified significant adverse impacts?**
- 19 **6. Are there studies that should be initiated at this stage that would be continued in**
20 **post-construction?**

21

22 The Service encourages the use of common methods and metrics in Tier 3 assessments for
23 measuring wildlife activity and habitat features. Common methods and metrics provide great
24 benefit over the long-term, allowing for comparisons among projects and for greater certainty
25 regarding what will be asked of the developer for a specific project. Deviation from commonly
26 used methods should be carefully considered, scientifically justifiable and discussed with federal,
27 tribal, or state natural resource agencies, or other credible experts, as appropriate. It may be
28 useful to consult other scientifically credible information sources.

29

1 Tier 3 studies will be designed to accommodate local and regional characteristics. The specific
2 protocols by which common methods and metrics are implemented in Tier 3 studies depend on
3 the question being addressed, the species or ecological communities being studied and the
4 characteristics of the study sites. Federally-listed threatened and endangered species, eagles, and
5 some other species of concern and their habitats, may have specific protocols required by local,
6 state or federal agencies. The need for special surveys and mapping that address these species
7 and situations should be discussed with the appropriate stakeholders.

8

9 In some instances, a single method will not adequately assess potential collision risk or habitat
10 impact. For example, when there is concern about moderate or high risk to nocturnally active
11 species, such as migrating passerines and local and migrating bats, a combination of remote
12 sensing tools such as radar, and acoustic monitoring for bats and indirect inference from diurnal
13 bird surveys during the migration period may be necessary. Answering questions about habitat
14 use by songbirds may be accomplished by relatively small-scale observational studies, while
15 answering the same question related to wide-ranging species such as prairie grouse and sage
16 grouse may require more time-consuming surveys, perhaps including telemetry.

17

18 Because of the points raised above and the need for flexibility in application, the Guidelines do
19 not make specific recommendations on protocol elements for Tier 3 studies. The peer-reviewed
20 scientific literature (such as the articles cited throughout this section) contains numerous recently
21 published reviews of methods for assessing bird and bat activity, and tools for assessing habitat
22 and landscape level risk. Details on specific methods and protocols for recommended studies are
23 or will be widely available and should be consulted by industry and agency professionals.

24

25 Many methods for assessing risk are components of active research involving collaborative
26 efforts of public-private research partnerships with federal, state and tribal agencies, wind energy
27 developers and NGOs interested in wind energy-wildlife interactions (e.g., Bats and Wind
28 Energy Cooperative and the Grassland Shrub Steppe Species Cooperative). It is important to
29 recognize the need to integrate the results of research that improves existing methods or
30 describes new methodological developments, while acknowledging the value of utilizing
31 common methods that are currently available.

1

2 The methods and metrics that may be appropriate for gathering data to answer Tier 3 questions
3 are compiled and outlined in the Study Design Considerations and Technical Resources section,
4 page 43. These are not meant to be all inclusive and other methods and metrics are available,
5 such as the NWCC Methods & Metrics document (Strickland et al. 2011) and others listed in
6 **Appendix C: Sources of Information Pertaining to Methods to Assess Impacts**
7 **to Wildlife**

8

9 Each question should be considered in turn, followed by a discussion of the methods and their
10 applicability.

11

12 **1. Do field studies indicate that species of concern are present on or likely to use the**
13 **proposed site?**

14 In many situations, this question can be answered based on information accumulated in Tier 2.
15 Specific presence/absence studies may not be necessary, and protocol development should focus
16 on answering the remaining Tier 3 questions. Nevertheless, it may be necessary to conduct field
17 studies to determine the presence, or likelihood of presence, when little information is available
18 for a particular site. The level of effort normally contemplated for Tier 3 studies should detect
19 common species and species that are relatively rare, but which visit a site regularly (e.g., every
20 year). In the event a species of concern is very rare and only occasionally visits a site, a
21 determination of “likely to occur” would be inferred from the habitat at the site and historical
22 records of occurrence on or near the site.

23

24 State, federal and tribal agencies often require specific protocols be followed when species of
25 concern are potentially present on a site. The methods and protocols for determining presence of
26 species of concern at a site are normally established for each species and required by federal,
27 state and tribal resource agencies. Surveys should sample the wind turbine sites and applicable
28 disturbance area during seasons when species are most likely present. Normally, the methods
29 and protocols by which they are applied also will include an estimate of relative abundance.

30 Most presence/absence surveys should be done following a probabilistic sampling protocol to
31 allow statistical extrapolation to the area and time of interest.

1

2 Determining the presence of diurnally or nocturnally active mammals, reptiles, amphibians, and
3 other species of concern will typically be accomplished by following agency-required protocols.
4 Most listed species have required protocols for detection (e.g., the black-footed ferret). State,
5 tribal and federal agencies should be contacted regarding survey protocols for those species of
6 concern. See Corn and Bury 1990, Olson et al. 1997, Bailey et al. 2004, Graeter et al. 2008 for
7 examples of reptile and amphibian protocols, survey and analytical methods. See Tier 3 Study
8 Design Considerations on page 43 for further details.

9

10 **2. Do field studies indicate the potential for significant adverse impacts on affected**
11 **populations of species of habitat fragmentation concern?**

12 If Tier 2 studies indicate the presence of species of habitat fragmentation concern, but existing
13 information did not allow for a complete analysis of potential impacts and decision-making, then
14 additional studies and analyses should take place in Tier 3.

15

16 As in Tier 2, the particulars of the analysis will depend on the species of habitat fragmentation
17 concern and how habitat block size and fragmentation are defined for the life cycles of that
18 species, the likelihood that the project will adversely affect a local population of the species and
19 the significance of these impacts to the viability of that population.

20

21 To assess habitat fragmentation in the project vicinity, developers should evaluate landscape
22 characteristics of the proposed site prior to construction and determine the degree to which
23 habitat for species of habitat fragmentation concern will be significantly altered by the presence
24 of a wind energy facility.

25 A general framework for evaluating habitat fragmentation at a project site, following that
26 described in Tier 2, is outlined on page 49. This framework should be used in those
27 circumstances when the developer, or a relevant federal, state, tribal and/or other local agency
28 determines the potential presence of a population of a species of habitat fragmentation concern
29 that may be adversely affected by the project. Otherwise, the developer need not assess the
30 impacts of the proposed project on habitat fragmentation. This method for analysis of habitat

1 fragmentation at project sites must be adapted to the local population of the species of habitat
2 fragmentation concern potentially affected by the proposed development.

3

4 **3. What is the distribution, relative abundance, behavior, and site use of species of**
5 **concern identified in Tiers 1 or 2, and to what extent do these factors expose these**
6 **species to risk from the proposed wind energy project?**

7

8 For those species of concern that are considered at risk of collisions or habitat impacts, the
9 questions to be answered in Tier 3 include: where are they likely to occur (i.e., where is their
10 habitat) within a project site or vicinity, when might they occur, and in what abundance. The
11 spatial distribution of species at risk of collision can influence how a site is developed. This
12 distribution should include the airspace for flying species with respect to the rotor-swept zone.
13 The abundance of a species and the spatial distribution of its habitat can be used to determine the
14 relative risk of impact to species using the sites, and the absolute risk when compared to existing
15 projects where similar information exists. Species abundance and habitat distribution can also be
16 used in modeling risk factors.

17

18 Surveys for spatial distribution and relative abundance require coverage of the wind turbine sites
19 and applicable site disturbance area, or a sample of the area using observational methods for the
20 species of concern during the seasons of interest. As with presence/absence (see Tier 3, question
21 1, above) the methods used to determine distribution, abundance, and behavior may vary with
22 the species and its ecology. Spatial distribution is determined by applying presence/absence or
23 using surveys in a probabilistic manner over the entire area of interest. Suggested survey
24 protocols for birds, bats, and other wildlife are found in the Study Design Considerations and
25 Technical Resources section on page 52.

26

27 **4. What are the potential risks of adverse impacts of the proposed wind energy project to**
28 **individuals and local populations of species of concern and their habitats? (In the case**
29 **of rare or endangered species, what are the possible impacts to such species and their**
30 **habitats?)**

1 Methods used for estimating risk will vary with the species of concern. For example, estimating
2 potential bird fatalities in Tier 3 may be accomplished by comparing exposure estimates
3 (described earlier in estimates of bird use) at the proposed site with exposure estimates and
4 fatalities at existing projects with similar characteristics (e.g., similar technology, landscape, and
5 weather conditions). If models are used, they may provide an additional tool for estimating
6 fatalities, and have been used in Australia (Organ and Meredith 2004), Europe (Chamberlin et al.
7 2006), and the United States (Madders and Whitfield 2006). As with other prediction tools,
8 model predictions should be evaluated and compared with post-construction fatality data to
9 validate the models. Models should be used as a subcomponent of a risk assessment based on
10 the best available empirical data. A statistical model based on the relationship of pre-
11 construction estimates of raptor abundance and post-construction raptor fatalities is described in
12 Strickland et al. (2011) and promises to be a useful tool for risk assessment.

13

14 Collision risk to individual birds and bats at a particular wind energy facility may be the result of
15 complex interactions among species distribution, relative abundance, behavior, weather
16 conditions (e.g., wind, temperature) and site characteristics. Collision risk for an individual may
17 be low regardless of abundance if its behavior does not place it within the rotor-swept zone. If
18 individuals frequently occupy the rotor-swept zone but effectively avoid collisions, they are also
19 at low risk of collision with a turbine (e.g., ravens). Alternatively, if the behavior of individuals
20 frequently places them in the rotor-swept zone, and they do not actively avoid turbine blade
21 strikes, they are at higher risk of collisions with turbines regardless of abundance. For a given
22 species (e.g., red-tailed hawk), increased abundance increases the likelihood that individuals will
23 be killed by turbine strikes, although the risk to individuals will remain about the same. The risk
24 to a population increases as the proportion of individuals in the population at risk to collision
25 increases.

26

27 At some projects, bat fatalities are higher than bird fatalities, but the exposure risk of bats at
28 these facilities is not fully understood (National Research Council (NRC) 2007). Horn et al.
29 (2008) and Cryan (2008) hypothesize that bats are attracted to turbines, which, if true, would
30 further complicate estimation of exposure. Further research is required to determine if bats are

1 attracted to turbines and if so, to evaluate 1) the influence on Tier 2 methods and predictions, and
2 2) if this increased individual risk translates into higher population-level impacts for bats.

3

4 The estimation of indirect impact risk requires an understanding of animal behavior in response
5 to a project and its infrastructure, and a pre-construction estimate of presence/absence of species
6 whose behavior would cause them to avoid areas in proximity to turbines, roads and other
7 components of the project. The amount of habitat that is lost to indirect impacts will be a
8 function of the sensitivity of individuals to the project and to the activity levels associated with
9 the project's operations. The population-level significance of this indirect impact will depend on
10 the amount of habitat available to the affected population. If the indirect impacts include habitat
11 fragmentation, then the risk to the demographic and genetic viability of the isolated animals is
12 increased. Quantifying cause and effect may be very difficult, however.

13

14 **5. How can developers mitigate identified significant adverse impacts?**

15 Results of Tier 3 studies should provide a basis for identifying measures to mitigate significant
16 adverse impacts predicted for species of concern. Information on wildlife use of the proposed
17 area is most useful when designing a project to avoid or minimize significant adverse impacts.
18 In cases of uncertainty with regard to impacts to species of concern, additional studies may be
19 necessary to quantify significant adverse impacts and determine the need for mitigation of those
20 impacts.

21

22 Chapter 7, Best Management Practices, and Chapter 8, Mitigation, outline measures that can be
23 taken to mitigate impacts throughout all phases of a project.

24

25 The following discussion of prairie grouse and sage grouse as species of concern illustrates the
26 uncertainty mentioned above by describing the present state of scientific knowledge relative to
27 these species, which should be considered when designing mitigation measures. The extent of
28 the impact of wind energy development on prairie grouse and sage grouse lekking activity (e.g.,
29 social structure, mating success, persistence) and the associated impacts on productivity (e.g.,
30 nesting, nest success, chick survival) is poorly understood (Arnett et al. 2007, NRC 2007,
31 Manville 2004). However, recent published research documents that anthropogenic features

1 (e.g., tall structures, buildings, roads, transmission lines) can adversely impact vital rates (e.g.,
2 nesting, nest success, lekking behavior) of lesser prairie-chickens (Pruett et al. 2009, Pitman et
3 al. 2005, Hagen et al. 2009, Hagen et al. 2011) and greater prairie-chickens over long distances.
4 Pitman et al. (2005) found that transmission lines reduced nesting of lesser prairie chicken by 90
5 percent out to a distance of 0.25 miles, improved roads at a distance of 0.25 miles, a house at 0.3
6 miles, and a power plant at >0.6 miles. Reduced nesting activity of lesser prairie chickens may
7 extend farther, but Pitman et al. (2005) did not analyze their data for lower impacts (less than 90
8 percent reduction in nesting) of those anthropogenic features on lesser prairie chicken nesting
9 activities at greater distances. Hagen et al. (2011) suggested that development within 1 to 1 ½
10 miles of active leks of prairie grouse may have significant adverse impacts on the affected grouse
11 population. It is not unreasonable to infer that impacts from wind energy facilities may be
12 similar to those from these other anthropogenic structures. Kansas State University, as part of
13 the National Wind Coordinating Collaborative's Grassland and Shrub Steppe Species Subgroup,
14 is undertaking a multi-year telemetry study to evaluate the effects of a proposed wind-energy
15 facility on displacement and demographic parameters (e.g., survival, nest success, brood success,
16 fecundity) of greater prairie-chickens in Kansas.⁵

17

18 The distances over which anthropogenic activities impact sage grouse are greater than for prairie
19 grouse. Based primarily on data documenting reduced fecundity (a combination of nesting,
20 clutch size, nest success, juvenile survival, and other factors) in sage grouse populations near
21 roads, transmissions lines, and areas of oil and gas development/production (Holloran 2005,
22 Connelly et al. 2000), development within three to five miles (or more) of active sage grouse leks
23 may have significant adverse impacts on the affected grouse population. Lyon and Anderson
24 (2003) found that in habitats fragmented by natural gas development, only 26 percent of hens
25 captured on disturbed leks nested within 1.8 miles of the lek of capture, whereas 91 percent of
26 hens from undisturbed areas nested within the same area. Holloran (2005) found that active
27 drilling within 3.1 miles of sage grouse lek reduced the number of breeding males by displacing
28 adult males and reducing recruitment of juvenile males. The magnitudes and proximal causes
29 (e.g., noise, height of structures, movement, human activity, etc.) of those impacts on vital rates
30 in grouse populations are areas of much needed research (Becker et al. 2009). Data accumulated

1 ⁵ www.nationalwind.org

1 through such research may improve our understanding of the buffer distances necessary to avoid
2 or minimize significant adverse impacts to prairie grouse and sage grouse populations.

3

4 When significant adverse impacts cannot be fully avoided or adequately minimized, some form
5 of compensatory mitigation may be appropriate to address the loss of habitat value. For
6 example, it may be possible to mitigate habitat loss or degradation for a species of concern by
7 enhancing or restoring nearby habitat value comparable to that potentially influenced by the
8 project.

9 **6. Are there studies that should be initiated at this stage that would be continued in post-**
10 **construction?**

11 During Tier 3 problem formulation, it is necessary to identify the studies needed to address the
12 Tier 3 questions. Consideration of how the resulting data may be used in conjunction with post-
13 construction Tier 4 and 5 studies is also recommended. The design of post-construction impact
14 or mitigation assessment studies will depend on the specific impact questions being addressed.
15 Tier 3 predictions will be evaluated using data from Tier 4 studies designed to estimate fatalities
16 for species of concern and impacts to their habitat, including species of habitat fragmentation
17 concern. Tier 3 studies may demonstrate the need for mitigation of significant adverse impacts.
18 Where Tier 3 studies indicate the potential for significant adverse direct and indirect impacts to
19 habitat, Tier 4 studies will provide data that evaluate predictions of those impacts, and Tier 5
20 studies, if necessary, will provide data to evaluate the effect of those impacts on populations and
21 the effectiveness of mitigation measures. Evaluations of the impacts of a project on
22 demographic parameters of local populations, habitat use, or some other parameter(s) are
23 considered Tier 5 studies, and typically will require data on these parameters prior to as well as
24 after construction of the project.

25

26 **Tier 3 Study Design Considerations**

27 Specific study designs will vary from site to site and should be adjusted to the circumstances of
28 individual projects. Study designs will depend on the types of questions, the specific project, and
29 practical considerations. The most common considerations include the area being studied, the
30 species of concern and potential risk to those species, potentially confounding variables, time
31 available to conduct studies, project budget, and the magnitude of the anticipated impacts.

1 Studies will be necessary in part to assess a) which species of concern are present within the
2 project area; b) how these species are using the area (behavior); and c) what risks are posed to
3 them by the proposed wind energy project.

4

5 ***Assessing Presence***

6 A developer should assess whether species of concern are likely to be present in the project area
7 during the life of the project. Assessing species use from databases and site characteristics is a
8 potential first step. However, it can be difficult to assess potential use by certain species from
9 site characteristics alone. Various species in different locations may require developers to use
10 specific survey protocols or make certain assumptions regarding presence. Project developers
11 should seek local wildlife expertise, such as Service Field Office staff, in using the proper
12 procedures and making assumptions.

13 Some species will present particular challenges when trying to determine potential presence. For
14 instance, species that a) are rare or cryptic; b) migrate, conduct other daily movements, or use
15 areas for short periods; c) are small or nocturnal; or d) have become extirpated in parts of their
16 historical range can be difficult to observe. One of these challenges is migration, broadly
17 defined as the act of moving from one spatial unit to another (Baker 1978), or as a periodic
18 movement of animals from one location to another. Migration is species-specific, and for birds
19 and bats occurs throughout the year.

20

21 ***Assessing Site Use/Behavior***

22 Developers should monitor potential sites to determine the types of migratory species present,
23 what type of spatial and temporal use these species make of the site (e.g., chronology of
24 migration or other use), and the ecological function the site may provide in terms of the
25 migration cycle of these species. Wind developers should determine not only what species may
26 migrate through a proposed development site and when, but also whether a site may function as a
27 staging area or stopover habitat for wildlife on their migration pathway.

28 For some species, movements between foraging and breeding habitat, or between sheltering and
29 feeding habitats, occur on a daily basis. Consideration of daily movements (morning and
30 evening; coming and going) is a critical factor when considering project development.

31

1 ***Duration/Intensity of Studies***

2 Where pre-construction assessments are warranted to help assess risk to wildlife, the studies
3 should be of sufficient duration and intensity to ensure adequate data are collected to accurately
4 characterize wildlife presence and use of the area. In ecological systems, resource quality and
5 quantity can fluctuate rapidly. These fluctuations occur naturally, but human actions can
6 significantly affect (i.e., increase or decrease) natural oscillations. Pre-construction monitoring
7 and assessment of proposed wind energy sites are “snapshots in time,” showing occurrence or no
8 occurrence of a species or habitat at the specific time surveyed. Often due to prohibitive costs,
9 assessments and surveys are conducted for very low percentages (e.g., less than 5 percent) of the
10 available sample time in a given year, however, these data are used to support risk analyses over
11 the projected life of a project (e.g., 30 years of operations).

12

13 To establish a trend in site use and conditions that incorporates annual and seasonal variation in
14 meteorological conditions, biological factors, and other variables, pre-construction studies may
15 need to occur over multiple years. However, the level of risk and the question of data
16 requirements will be based on site sensitivity, affected species, and the availability of data from
17 other sources. Accordingly, decisions regarding studies should consider information gathered
18 during the previous tiers, variability within and between seasons, and years where variability is
19 likely to substantially affect answers to the Tier 3 questions. These studies should also be
20 designed to collect data during relevant breeding, feeding, sheltering, staging, or migration
21 periods for each species being studied. Additionally, consideration for the frequency and
22 intensity of pre-construction monitoring should be site-specific and determined through
23 consultation with an expert authority based on their knowledge of the specific species, level of
24 risk and other variables present at each individual site.

25

26 ***Assessing Risk to Species of Concern***

27 Once likely presence and factors such as abundance, frequency of use, habitat use patterns, and
28 behavior have been determined or assumed, the developer should consider and/or determine the
29 consequences to the “populations” and species.

30 Below is a brief discussion of several types of risk factors that can be considered. This does not
31 include all potential risk factors for all species, but addresses the most common ones.

1

2 Collision

3 Collision likelihood for individual birds and bats at a particular wind energy facility may be the
4 result of complex interactions among species distribution, "relative abundance," behavior,
5 visibility, weather conditions, and site characteristics. Collision likelihood for an individual may
6 be low regardless of abundance if its behavior does not place it within the "rotor-swept zone."
7 Individuals that frequently occupy the rotor-swept zone but effectively avoid collisions are also
8 at low likelihood of collision with a turbine.

9

10 Alternatively, if the behavior of individuals frequently places them in the rotor-swept zone, and
11 they do not actively avoid turbine blade strikes, they are at higher likelihood of collisions with
12 turbines regardless of abundance. Some species, even at lower abundance, may have a higher
13 collision rate than similar species due to subtle differences in their ecology and behavior.

14 At many projects, the numbers of bat fatalities are higher than the numbers of bird fatalities, but
15 the exposure risk of bats at these facilities is not fully understood. Researchers (Horn et al. 2008
16 and Cryan 2008) hypothesize that some bats may be attracted to turbines, which, if true, would
17 further complicate estimation of exposure. Further research is required to determine whether
18 bats are attracted to turbines and if so, whether this increased individual risk translates into
19 higher population-scale effects.

20

21 Habitat Loss and Degradation

22 Wind project development results in direct habitat loss and habitat modification, especially at
23 sites previously undeveloped. Many of North America's native landscapes are greatly
24 diminished or degraded from multiple causes unrelated to wind energy. Important remnants of
25 these landscapes are identified and documented in various databases held by private conservation
26 organizations, state wildlife agencies, and, in some cases, by the Service. Species that depend on
27 these landscapes are susceptible to further loss of habitat, which will affect their ability to
28 reproduce and survive. While habitat lost due to footprints of turbines, roads, and other
29 infrastructure is obvious, less obvious is the potential reduction of habitat quality.

30

31 Habitat Fragmentation

1 Habitat fragmentation separates blocks of habitat for some species into segments, such that the
2 individuals in the remaining habitat segments may suffer from effects such as decreased survival,
3 reproduction, distribution, or use of the area. Site clearing, access roads, transmission lines, and
4 arrays of turbine towers may displace some species or fragment continuous habitat areas into
5 smaller, isolated tracts. Habitat fragmentation is of particular concern when species require large
6 expanses of habitat for activities such as breeding, foraging, and sheltering.

7

8 Habitat fragmentation can result in increases in “edge” resulting in direct effects of barriers and
9 displacement as well as indirect effects of nest parasitism and predation. Sensitivity to
10 fragmentation effects varies among species. Habitat fragmentation and site modification are
11 important issues that should be assessed at the landscape scale early in the siting process.
12 Identify areas of high sensitivity due to the presence of blocks of native habitats, paying
13 particular attention to known or suspected “species sensitive to habitat fragmentation.”

14

15 Displacement and Behavioral Changes

16 Estimating displacement risk requires an understanding of animal behavior in response to a
17 project and its infrastructure and activities, and a pre-construction estimate of presence/absence
18 of species whose behavior would cause them to avoid or seek areas in proximity to turbines,
19 roads, and other components of the project. Displacement is a function of the sensitivity of
20 individuals to the project and activity levels associated with operations.

21

22 Indirect Effects

23 Wind development can also have indirect effects to wildlife and habitats. Indirect effects include
24 reduced nesting and breeding densities and the social ramifications of those reductions; loss or
25 modification of foraging habitat; loss of population vigor and overall population density;
26 increased isolation between habitat patches, loss of habitat refugia; attraction to modified
27 habitats; effects on behavior, physiological disturbance, and habitat unsuitability. Indirect effects
28 can result from introduction of invasive plants; increased predator populations or facilitated
29 predation; alterations in the natural fire regime; or other effects, and can manifest themselves
30 later in time than the causing action.

31

1 When collection of both pre- and post-construction data in the areas of interest and reference
2 areas is possible, then the Before-After-Control-Impact (BACI) is the most statistically robust
3 design. The BACI design is most like the classic manipulative experiment.⁶ In the absence of a
4 suitable reference area, the design is reduced to a Before-After (BA) analysis of effect where the
5 differences between pre- and post-construction parameters of interest are assumed to be the
6 result of the project, independent of other potential factors affecting the assessment area. With
7 respect to BA studies, the key question is whether the observations taken immediately after the
8 incident can reasonably be expected within the expected range for the system (Manly 2009).
9 Reliable quantification of impact usually will include additional study components to limit
10 variation and the confounding effects of natural factors that may change with time.

11

12 The developer's timeline for the development of a wind energy facility often does not allow for
13 the collection of sufficient pre-construction data and/or identification of suitable reference areas
14 to complete a BACI or BA study. Furthermore, alterations in land use or disturbance over the
15 course of a multi-year BACI or BA study may complicate the analysis of study results.

16 Additional discussion of these issues can be found in Tier 5 Study Design Considerations.

17

18 **Tier 3 Technical Resources**

19 The following methods and metrics are provided as suggested sources for developers to use in
20 answering the Tier 3 questions.

21

22 ***Tier 3, Question 1***

23 Acoustic monitoring can be a practical method for determining the presence of threatened,
24 endangered or otherwise rare species of bats throughout a proposed project (Kunz et al. 2007).

25 There are two general types of acoustic detectors used for collection of information on bat
26 activity and species identification: the full-spectrum, time-expansion and the zero-crossing
27 techniques for ultrasound bat detection (see Kunz et al. 2007 for detailed discussion). Full-

28 spectrum time expansion detectors provide nearly complete species discrimination, while zero-

29 crossing detectors provide reliable and cost-effective estimates of total bat use at a site and some

1 ⁶ In this context, such designs are not true experiments in that the treatments (project development and control) are
2 not randomly assigned to an experimental unit, and there is often no true replication. Such constraints are not fatal
3 flaws, but do limit statistical inferences of the results.

1 species discrimination. *Myotis* species can be especially difficult to discriminate with zero-
2 crossing detectors (Kunz et al. 2007). Kunz et al. (2007) describe the strengths and weaknesses
3 of each technique for ultrasonic bat detection, and either type of detector may be useful in most
4 situations except where species identification is especially important and zero-crossing methods
5 are inadequate to provide the necessary data. Bat acoustics technology is evolving rapidly and
6 study objectives are an important consideration when selecting detectors. When rare or
7 endangered species of bats are suspected, sampling should occur during different seasons and at
8 multiple sampling stations to account for temporal and spatial variability.

9

10 Mist-netting for bats is required in some situations by state agencies, Tribes, and the Service to
11 determine the presence of threatened, endangered or otherwise rare species. Mist-netting is best
12 used in combination with acoustic monitoring to inventory the species of bats present at a site,
13 especially to detect the presence of threatened or endangered species. Efforts should concentrate
14 on potential commuting, foraging, drinking, and roosting sites (Kuenzi and Morrison 1998,
15 O'Farrell et al. 1999). Mist-netting and other activities that involve capturing and handling
16 threatened or endangered species of bats will require permits from state and/or federal agencies.

17

18 ***Tier 3, Question 2***

19 The following protocol should be used to answer Tier 3, Question 2. This protocol for analysis
20 of habitat fragmentation at project sites should be adapted to the species of habitat fragmentation
21 concern as identified in response to Question 5 in Tier 2 and to the landscape in which
22 development is contemplated. The developer should:

23

24 1. Define the study area. The study area for the site should include the “footprint” for the
25 proposed facility plus an appropriate surrounding area. The extent of the study area
26 should be based on the area where there is potential for significant adverse habitat
27 impacts, including indirect impacts, within the distribution of habitat for the species of
28 habitat fragmentation concern.

29

30 2. Determine the potential for occupancy of the study area based on the guidance provided
31 for the species of habitat fragmentation concern described above in Question 1.

30

3. Analyze current habitat quality and spatial configuration of the study area for the species of habitat fragmentation concern.
 - a. Use recent aerial or remote imagery to determine distinct habitat patches or boundaries within the study area, and the extent of existing habitat fragmenting features.
 - i. Assess the level of fragmentation of the existing habitat for the species of habitat fragmentation concern and categorize into three classes:
 - High quality: little or no apparent fragmentation of intact habitat
 - Medium quality: intact habitat exhibiting some recent disturbance activity
 - Low quality: extensive fragmentation of habitat (e.g., row-cropped agricultural lands, active surface mining areas)
 - ii. Determine edge and interior habitat metrics of the study area:
 - Identify habitat, non-habitat landscape features and existing fragmenting features relative to the species of habitat fragmentation concern, to estimate existing edge
 - Calculate area and acres of edge
 - Calculate area of intact patches of habitat and compare to needs of species of habitat fragmentation concern
 - b. Determine potential changes in quality and spatial configuration of the habitat in the study area if development proceeds as proposed using existing site information and the best available spatial data regarding placement of wind turbines and ancillary infrastructure:
 - i. Identify, delineate and classify all additional features added by the development that potentially fragment habitat for the species of habitat fragmentation concern (e.g., roads, transmission lines, maintenance structures, etc.)

- 1 ii. Assess the expected future size and quality of habitat patches for the
2 species of habitat fragmentation concern and the additional
3 fragmenting features, and categorize into three classes as described
4 above
- 5 iii. Determine expected future acreages of edge and interior habitats
- 6 iv. Calculate the area of the remaining patches of intact habitat
- 7
- 8 c. Compare pre-construction and expected post-construction fragmentation metrics:
- 9 i. Determine the area of intact habitat lost (to the displacement footprint
10 or by alteration due to the edge effect)
- 11 ii. Identify habitat patches that are expected to be moved to a lower
12 habitat quality classification as a result of the development
- 13
- 14 4. Assess the likelihood of a significant reduction in the demographic and genetic viability of
15 the local population of the species of habitat fragmentation concern using the habitat
16 fragmentation information collected under item 3 above and any currently available
17 demographic and genetic data. Based on this assessment, the developer makes the finding
18 whether or not there is significant reduction. The developer should share the finding with the
19 relevant agencies. If the developer finds the likelihood of a significant reduction, the
20 developer should consider items a, b or c below:
- 21 a. Consider alternative locations and development configurations to minimize
22 fragmentation of habitat in communication with species experts, for all species of
23 habitat fragmentation concern in the area of interest.
- 24
- 25 b. Identify high quality habitat parcels that may be protected as part of a plan to limit
26 future loss of habitat for the impacted population of the species of habitat
27 fragmentation concern in the area.
- 28 c. Identify areas of medium or low quality habitat within the range of the impacted
29 population that may be restored or improved to compensate for losses of habitat that
30 result from the project (e.g., management of unpaved roads and ORV trails).

1

2 **Tier 3, Question 3**

3 The following protocols are suggested for use in answering Tier 3, Question 3.

4

5 Bird distribution, abundance, behavior and site use

6

7 *Diurnal Avian Activity Surveys*

8 The commonly used data collection methods for estimating the spatial distribution and relative
9 abundance of diurnal birds includes counts of birds seen or heard at specific survey points (point
10 count), along transects (transect surveys), and observational studies. Both methods result in
11 estimates of bird use, which are assumed to be indices of abundance in the area surveyed.

12 Absolute abundance is difficult to determine for most species and is not necessary to evaluate
13 species risk. Depending on the characteristics of the area of interest and the bird species
14 potentially affected by the project, additional pre-construction study methods may be necessary.
15 Point counts or line transects should collect vertical as well as horizontal data to identify levels
16 of activity within the rotor-swept zone.

17

18 Avian point counts should follow the general methodology described by Reynolds et al. (1980)
19 for point counts within a fixed area, or the line transect survey similar to Schaffer and Johnson
20 (2008), where all birds seen within a fixed distance of a line are counted. These methods are
21 most useful for pre- and post-construction studies to quantify avian use of the project site by
22 habitat, determine the presence of species of concern, and to provide a baseline for assessing
23 displacement effects and habitat loss. Point counts for large birds (e.g., raptors) follow the same
24 point count method described by Reynolds et al. (1980), Ralph et al. (1993) and Ralph et al.
25 1995).

26

27 Point count plots, transects, and observational studies should allow for statistical extrapolation of
28 data and be distributed throughout the area of interest using a probability sampling approach
29 (e.g., systematic sample with a random start). For most projects, the area of interest is the area
30 where wind turbines and permanent meteorological (met) towers are proposed or expected to be
31 sited. Alternatively, the centers of the larger plots can be located at vantage points throughout

1 the potential area being considered with the objective of covering most of the area of interest.
2 Flight height should also be collected to focus estimates of use on activity occurring in the rotor-
3 swept zone.

4

5 Sampling duration and frequency will be determined on a project-by-project basis and by the
6 questions being addressed. The most important consideration for sampling frequency when
7 estimating abundance is the amount of variation expected among survey dates and locations and
8 the species of concern.

9

10 The use of comparable methods and metrics should allow data comparison from plot to plot
11 within the area of interest and from site to site where similar data exist. The data should be
12 collected so that avian activity can be estimated within the rotor-swept zone. Relating use to site
13 characteristics requires that samples of use also measure site characteristics thought to influence
14 use (i.e., covariates such as vegetation and topography) in relation to the location of use. The
15 statistical relationship of use to these covariates can be used to predict occurrence in unsurveyed
16 areas during the survey period and for the same areas in the future.

17

18 Surveys should be conducted at different intervals during the year to account for variation in
19 expected bird activity with lower frequency during winter months if avian activity is low.

20 Sampling frequency should also consider the episodic nature of activity during fall and spring
21 migration. Standardized protocols for estimating avian abundance are well-established and
22 should be consulted (e.g., Dettmers et al. 1999). If a more precise estimate of density is required
23 for a particular species (e.g., when the goal is to determine densities of a special-status breeding
24 bird species), the researcher will need more sophisticated sampling procedures, including
25 estimates of detection probability.

26 *Raptor Nest Searches*

27 An estimate of raptor use of the project site is obtained through appropriate surveys, but if
28 potential impacts to breeding raptors are a concern on a project, raptor nest searches are also
29 recommended. These surveys provide information to predict risk to the local breeding
30 population of raptors, for micro-siting decisions, and for developing an appropriate-sized non-

1 disturbance buffer around nests. Surveys also provide baseline data for estimating impacts and
2 determining mitigation requirements. A good source of information for raptor surveys and
3 monitoring is Bird and Bildstein (2007).

4

5 Searches for raptor nests or raptor breeding territories on projects with potential for impacts to
6 raptors should be conducted in suitable habitat during the breeding season. While there is no
7 consensus on the recommended buffer zones around nest sites to avoid disturbance of most
8 species (Sutter and Jones 1981), a nest search within at least one mile of the wind turbines and
9 transmission lines, and other infrastructure should be conducted. However, larger nest search
10 areas are needed for eagles, as explained in the Service's ECP Guidance, when bald or golden
11 eagles are likely to be present.

12

13 Methods for these surveys are fairly common and will vary with the species, terrain, and
14 vegetation within the survey area. The Service recommends that protocols be discussed with
15 biologists from the lead agency, Service, state wildlife agency, and Tribes where they have
16 jurisdiction. It may be useful to consult other scientifically credible information sources. At
17 minimum, the protocols should contain the list of target raptor species for nest surveys and the
18 appropriate search protocol for each site, including timing and number of surveys needed, search
19 area, and search techniques.

20

21 *Prairie Grouse and Sage Grouse Population Assessments*

22 Sage grouse and prairie grouse merit special attention in this context for three reasons:

23

24 1. The scale and biotic nature of their habitat requirements uniquely position them as reliable
25 indicators of impacts on, and needs of, a suite of species that depend on sage and grassland
26 habitats, which are among the nation's most diminished ecological communities (Vodehnal
27 and Haufler 2007).

28 2. Their ranges and habitats are highly congruent with the nation's richest inland wind
29 resources.

1 3. They are species for which some known impacts of anthropogenic features (e.g., tall
2 structures, buildings, roads, transmission lines, wind energy facilities, etc.) have been
3 documented.

4
5 Populations of prairie grouse and sage grouse generally are assessed by either lek counts (a count
6 of the maximum number of males attending a lek) or lek surveys (classification of known leks as
7 active or inactive) during the breeding season (e.g., Connelly et al. 2000). Methods for lek
8 counts vary slightly by species but in general require repeated visits to known sites and a
9 systematic search of all suitable habitat for leks, followed by repeated visits to active leks to
10 estimate the number of grouse using them.

11
12 Recent research indicates that viable prairie grouse and sage grouse populations are dependent
13 on suitable nesting and brood-rearing habitat (Connelly et al. 2000, Hagen et al. 2009). These
14 habitats generally are associated with leks. Leks are the approximate centers of nesting and
15 brood-rearing habitats (Connelly et al. 2000, but see Connelly et al. 1988 and Becker et al.
16 2009). High quality nesting and brood rearing habitats surrounding leks are critical to sustaining
17 viable prairie grouse and sage grouse populations (Giesen and Connelly 1993, Hagen et al. 2004,
18 Connelly et al. 2000). A population assessment study area should include nesting and brood
19 rearing habitats that may extend several miles from leks. For example, greater and lesser prairie-
20 chickens generally nest in suitable habitats within one to two miles of active leks (Hagen et al.
21 2004), whereas the average distances from nests to active leks of non-migratory sage grouse
22 range from 0.7 to four miles (Connelly et al. 2000), and potentially much more for migratory
23 populations (Connelly et al. 1988).

24
25 While surveying leks during the spring breeding season is the most common and convenient tool
26 for monitoring population trends of prairie grouse and sage grouse, documenting available
27 nesting and brood rearing habitat within and adjacent to the potentially affected area is
28 recommended. Suitable nesting and brood rearing habitats can be mapped based on habitat
29 requirements of individual species. The distribution and abundance of nesting and brood rearing
30 habitats can be used to help in the assessment of adverse impacts of the proposed project to
31 prairie grouse and sage grouse.

1

2 *Mist-Netting for Birds*

3 Mist-netting is not recommended as a method for assessing risk of wind development for birds.
4 Mist-netting cannot generally be used to develop indices of relative bird abundance, nor does it
5 provide an estimate of collision risk as mist-netting is not feasible at the heights of the rotor-
6 swept zone and captures below that zone may not adequately reflect risk. Operating mist-nets
7 requires considerable experience, as well as state and federal permits.

8

9 Occasionally mist-netting can help confirm the presence of rare species at documented fallout or
10 migrant stopover sites near a proposed project. If mist-netting is to be used, the Service
11 recommends that procedures for operating nets and collecting data be followed in accordance
12 with Ralph et al. (1993).

13

14 *Nocturnal and Crepuscular Bird Survey Methods*

15 Additional studies using different methods should be conducted if characteristics of the project
16 site and surrounding areas potentially pose a high risk of collision to night migrating songbirds
17 and other nocturnal or crepuscular species. For most of their flight, songbirds and other
18 nocturnal migrants are above the reach of wind turbines, but they pass through the altitudinal
19 range of wind turbines during ascents and descents and may also fly closer to the ground during
20 inclement weather (Able, 1970; Richardson, 2000). Factors affecting flight path, behavior, and
21 “fall-out” locations of nocturnal migrants are reviewed elsewhere (e.g., Williams et al., 2001;
22 Gauthreaux and Belser, 2003; Richardson, 2000; Mabee et al., 2006).

23

24 In general, pre-construction nocturnal studies are not recommended unless the site has features
25 that might strongly concentrate nocturnal birds, such as along coastlines that are known to be
26 migratory songbird corridors. Biologists knowledgeable about nocturnal bird migration and
27 familiar with patterns of migratory stopovers in the region should assess the potential risks to
28 nocturnal migrants at a proposed project site. No single method can adequately assess the spatial
29 and temporal variation in nocturnal bird populations or the potential collision risk. Following
30 nocturnal study methods in Kunz et al. (2007) is recommended to determine relative abundance,
31 flight direction and flight altitude for assessing risk to migrating birds, if warranted. If areas of

1 interest are within the range of nocturnal species of concern (e.g., marbled murrelet, northern
2 spotted owl, Hawaiian petrel, Newell's shearwater), surveyors should use species-specific
3 protocols recommended by state wildlife agencies, Tribes or Service to assess the species'
4 potential presence in the area of interest.

5

6 In contrast to the diurnal avian survey techniques previously described, considerable variation
7 and uncertainty exist on the optimal protocols for using acoustic monitoring devices, radar, and
8 other techniques to evaluate species composition, relative abundance, flight height, and trajectory
9 of nocturnal migrating birds. While an active area of research, the use of radar for determining
10 passage rates, flight heights and flight directions of nocturnal migrating animals has yet to be
11 shown as a good indicator of collision risk. Pre- and post-construction studies comparing radar
12 monitoring results to estimates of bird and bat fatalities will be necessary to evaluate radar as a
13 tool for predicting collision risk. Additional studies are also needed before making
14 recommendations on the number of nights per season or the number of hours per night that are
15 appropriate for radar studies of nocturnal bird migration (Mabee et al., 2006).

16

17 Bat survey methods

18 The Service recommends that all techniques discussed below be conducted by biologists trained
19 in bat identification, equipment use, and the analysis and interpretation of data resulting from the
20 design and conduct of the studies. Activities that involve capturing and handling bats may
21 require permits from state and/or federal agencies.

22

23 *Acoustic Monitoring*

24 Acoustic monitoring provides information about bat presence and activity, as well as seasonal
25 changes in species occurrence and use, but does not measure the number of individual bats or
26 population density. The goal of acoustic monitoring is to provide a prediction of the potential
27 risk of bat fatalities resulting from the construction and operation of a project. Our current state
28 of knowledge about bat-wind turbine interactions, however, does not allow a quantitative link
29 between pre-construction acoustic assessments of bat activity and operations fatalities.
30 Discussions with experts, state wildlife trustee agencies, Tribes, and Service will be needed to
31 determine whether acoustic monitoring is warranted at a proposed project site.

1

2 The predominance of bat fatalities detected to date are migratory species and acoustic monitoring
3 should adequately cover periods of migration and periods of known high activity for other (i.e.,
4 non-migratory) species. Monitoring for a full year is recommended in areas where there is year
5 round bat activity. Data on environmental variables such as temperature and wind speed should
6 be collected concurrently with acoustic monitoring so these weather data can be used in the
7 analysis of bat activity levels.

8

9 The number and distribution of sampling stations necessary to adequately estimate bat activity
10 have not been well established but will depend, at least in part, on the size of the project area,
11 variability within the project area, and a Tier 2 assessment of potential bat occurrence.

12

13 The number of detectors needed to achieve the desired level of precision will vary depending on
14 the within-site variation (e.g., Arnett et al. 2006, Weller 2007, See also, Bat Conservation
15 International website for up-to-date survey methodologies). One frequently used method is to
16 place acoustic detectors on existing met towers, approximately every two kilometers across the
17 site where turbines are expected to be sited. Acoustic detectors should be placed at high
18 positions (as high as practicable, based on tower height) on each met tower included in the
19 sample to record bat activity at or near the rotor swept zone, the area of presumed greatest risk
20 for bats. Developers should evaluate whether it would be cost effective to install detectors when
21 met towers are first established on a site. Doing so might reduce the cost of installation later and
22 might alleviate time delays to conduct such studies.

23

24 If sampling at met towers does not adequately cover the study area or provide sufficient
25 replication, additional sampling stations can be established at low positions (~1.5-2 meters) at a
26 sample of existing met towers and one or more mobile units (i.e., units that are moved to
27 different locations throughout the study period) to increase coverage of the proposed project
28 area. When practical and based on information from Tier 2, it may be appropriate to conduct
29 some acoustic monitoring of features identified as potentially high bat use areas within the study
30 area (e.g., bat roosts and caves) to determine use of such features.

31

1 There is growing interest in determining whether “low” position samples (~1.5-2 meters) can
2 provide equal or greater correlation with bat fatalities than “high” position samples (described
3 above) because this would substantially lower cost of this work. Developers could then install a
4 greater number of detectors at lower cost resulting in improved estimates of bat activity and,
5 potentially, improved qualitative estimates of risk to bats. This is a research question that is not
6 expected to be addressed at a project.

7

8 Other bat survey techniques

9 Occasionally, other techniques may be needed to answer Tier 3 questions and complement the
10 information from acoustic surveys. Kunz et al. (2007), NAS (2007), Kunz and Parsons (2009)
11 provide comprehensive descriptions of bat survey techniques, including those identified below
12 that are relevant for Tier 3 studies at wind energy facilities.

13

14 *Roost Searches and Exit Counts*

15 Pre-construction survey efforts may be recommended to determine whether known or likely bat
16 roosts in mines, caves, bridges, buildings, or other potential roost sites occur within the project
17 vicinity, and to confirm whether known or likely bat roosts are present and occupied by bats. If
18 active roosts are detected, it may be appropriate to address questions about colony size and
19 species composition of roosts. Exit counts and roost searches are two approaches to answering
20 these questions, and Rainey (1995), Kunz and Parsons (2009), and Sherwin et al. (2009) are
21 resources that describe options and approaches for these techniques. Roost searches should be
22 performed cautiously because roosting bats are sensitive to human disturbance (Kunz et al.
23 1996). Known maternity and hibernation roosts should not be entered or otherwise disturbed
24 unless authorized by state and/or federal wildlife agencies. Internal searches of abandoned mines
25 or caves can be dangerous and should only be conducted by trained researchers. For mine
26 survey protocol and guidelines for protection of bat roosts, see the appendices in Pierson et al.
27 (1999). Exit surveys at known roosts generally should be limited to non-invasive observation
28 using low-light binoculars and infrared video cameras.

29

30 Multiple surveys should be conducted to determine the presence or absence of bats in caves and
31 mines, and the number of surveys needed will vary by species of bats, sex (maternity or bachelor

1 colony) of bats, seasonality of use, and type of roost structure (e.g., caves or mines). For
2 example, Sherwin et al. (2003) demonstrated that a minimum of three surveys are needed to
3 determine the absence of large hibernating colonies of Townsend's big-eared bats (*Corynorhinus*
4 *townsendii*) in mines (90 percent probability), while a minimum of nine surveys (during a single
5 warm season) are necessary before a mine could be eliminated as a bachelor roost for this species
6 (90 percent probability). An average of three surveys was needed before surveyed caves could
7 be eliminated as bachelor roosts (90 percent probability). The Service recommends that
8 decisions on level of effort follow discussion with relevant agencies and bat experts.

9

10 *Activity Patterns*

11 If active roosts are detected, it may be necessary to answer questions about behavior, movement
12 patterns, and patterns of roost use for bat species of concern, or to further investigate habitat
13 features that might attract bats and pose fatality risk. For some bat species, typically threatened,
14 endangered, or state-listed species, radio telemetry or radar may be recommended to assess both
15 the direction of movement as bats leave roosts, and the bats' use of the area being considered for
16 development. Kunz et al. (2007) describe the use of telemetry, radar and other tools to evaluate
17 use of roosts, activity patterns, and flight direction from roosts.

18

19 *Mist-Netting for Bats*

20 While mist-netting for bats is required in some situations by state agencies, Tribes, and the
21 Service to determine the presence of threatened, endangered or other bat species of concern,
22 mist-netting is not generally recommended for determining levels of activity or assessing risk of
23 wind energy development to bats for the following reasons: 1) not all proposed or operational
24 wind energy facilities offer conditions conducive to capturing bats, and often the number of
25 suitable sampling points is minimal or not closely associated with the project location; 2) capture
26 efforts often occur at water sources offsite or at nearby roosts and the results may not reflect
27 species presence or use on the site where turbines are to be erected; and 3) mist-netting isn't
28 feasible at the height of the rotor-swept zone, and captures below that zone may not adequately
29 reflect risk of fatality. If mist-netting is employed, it is best used in combination with acoustic
30 monitoring to inventory the species of bats present at a site.

31

1 *White-Nose Syndrome*

2 White-nose syndrome is a disease affecting hibernating bats. Named for the white fungus that
3 appears on the muzzle and other body parts of hibernating bats, WNS is associated with
4 extensive mortality of bats in eastern North America. All contractors and consultants hired by
5 developers should employ the most current version of survey and handling protocols to avoid
6 transmitting white-nose syndrome between bats.

7

8 Other wildlife

9 While the above guidance emphasizes the evaluation of potential impacts to birds and bats, Tier
10 1 and 2 evaluations may identify other species of concern. Developers are encouraged to assess
11 adverse impacts potentially caused by development for those species most likely to be negatively
12 affected by such development. Impacts to other species are primarily derived from potential
13 habitat loss or displacement. The general guidance on the study design and methods for
14 estimation of the distribution, relative abundance, and habitat use for birds is applicable to the
15 study of other wildlife. References regarding monitoring for other wildlife are available in
16 **Appendix C: Sources of Information Pertaining to Methods to Assess Impacts**
17 **to Wildlife**. Nevertheless, most methods and metrics will be species-specific and developers
18 are advised to work with the state, tribal, or federal agencies, or other credible experts, as
19 appropriate, during problem formulation for Tier 3.

20

21 **Tier 3 Decision Points**

22 Developers and the Service should communicate prior to completing the Tier 3 decision process.
23 A developer should inform the Service of the results of its studies and plans. The Service will
24 provide written comments to a developer on study and project development plans that identify
25 concerns and recommendations to resolve the concerns. The developer and, when applicable, the
26 permitting authority will make a decision regarding whether and how to develop the project. The
27 decision point at the end of Tier 3 involves three potential outcomes:

28

- 29 1. Development of the site has a low probability of significant adverse impact based on existing
30 and new information.

- 1 There is little uncertainty regarding when and how development should proceed, and
2 adequate information exists to satisfy any required permitting. The decision process
3 proceeds to permitting, when required, and/or development, and Tier 4.
- 4 2. Development of the site has a moderate to high probability of significant adverse impacts
5 without proper measures being taken to mitigate those impacts. This outcome may be
6 subdivided into two possible scenarios:
- 7 a. There is certainty regarding how to develop the site to adequately mitigate significant
8 adverse impacts. The developer bases their decision to develop the site adopting
9 proper mitigation measures and appropriate post-construction fatality and habitat
10 studies (Tier 4).
- 11 b. There is uncertainty regarding how to develop the site to adequately mitigate
12 significant adverse impacts, or a permitting process requires additional information
13 on potential significant adverse wildlife impacts before permitting future phases of
14 the project. The developer bases their decision to develop the site adopting proper
15 mitigation measures and appropriate post-construction fatality and habitat studies
16 (Tier 4).
- 17 3. Development of the site has a high probability of significant impact that:
- 18 a. Cannot be adequately mitigated.
- 19 Site development should be delayed until plans can be developed that satisfactorily
20 mitigate for the significant adverse impacts. Alternatively, the site should be
21 abandoned in favor of known sites with less potential for environmental impact, or
22 the developer begins an evaluation of other sites or landscapes for more acceptable
23 sites to develop.
- 24
- 25 b. Can be adequately mitigated.
- 26 Developer should implement mitigation measures and proceed to Tier 4.

1 **Chapter 5: Tier 4 – Post-construction Studies to Estimate Impacts**

2

3 The outcome of studies in Tiers 1, 2, and 3 will determine the duration and level of effort of
4 post-construction studies.

5

6 Tier 4 post-construction studies are designed to assess whether predictions of fatality risk and
7 direct and indirect impacts to habitat of species of concern were correct. Fatality studies involve
8 searching for bird and bat carcasses beneath turbines to estimate the number and species
9 composition of fatalities (Tier 4a). Habitat studies involve application of GIS and use data
10 collected in Tier 3 and Tier 4b and/or published information. Post-construction studies on direct
11 and indirect impacts to habitat of species of concern, including species of habitat fragmentation
12 concern need only be conducted if Tier 3 studies indicate the potential for significant adverse
13 impacts.

14

15 **Tier 4a – Fatality Studies**

16 At this time, community- and utility-scale projects should conduct at least one year of fatality
17 monitoring. The intensity of the studies should be related to risks of significant adverse impacts
18 identified in pre-construction assessments. As data collected with consistent methods and
19 metrics increases (see discussion below), it is possible that some future projects will not warrant
20 fatality monitoring, but such a situation is rare with the present state of knowledge.

21

22 Fatality monitoring should occur over all seasons of occupancy for the species being monitored,
23 based on information produced in previous tiers. The number of seasons and total length of the
24 monitoring may be determined separately for bats and birds, depending on the pre-construction
25 risk assessment, results of Tier 3 studies and Tier 4 monitoring from comparable sites (see
26 Glossary in Appendix A) and the results of first year fatality monitoring. Guidance on the
27 relationship between these variables and monitoring for fatalities is provided in Table 2.

28

29 It may be appropriate to conduct monitoring using different durations and intervals depending on
30 the species of concern. For example, if raptors occupy an area year-round, it may be appropriate

1 to monitor for raptors throughout the year (12 months). It may be warranted to monitor for bats
2 when they are active (spring, summer and fall or approximately eight months). It may be
3 appropriate to increase the search frequency during the months bats are active and decrease the
4 frequency during periods of inactivity. All fatality monitoring should include estimates of
5 carcass removal and carcass detection bias likely to influence those rates.

6

7 ***Tier 4a Questions***

8 Post-construction fatality monitoring should be designed to answer the following questions as
9 appropriate for the individual project:

10

11 **1. What are the bird and bat fatality rates for the project?**

12 **2. What are the fatality rates of species of concern?**

13 **3. How do the estimated fatality rates compare to the predicted fatality rates?**

14 **4. Do bird and bat fatalities vary within the project site in relation to site
15 characteristics?**

16 **5. How do the fatality rates compare to the fatality rates from existing projects in
17 similar landscapes with similar species composition and use?**

18 **6. What is the composition of fatalities in relation to migrating and resident birds and
19 bats at the site?**

20 **7. Do fatality data suggest the need for measures to reduce impacts?**

21

22 Tier 4a studies should be of sufficient statistical validity to address Tier 4a questions and enable
23 determination of whether Tier 3 fatality predictions were correct. Fatality monitoring results also
24 should allow comparisons with other sites, and provide a basis for determining if operational
25 changes or other mitigation measures at the site are appropriate. The Service encourages project
26 operators to discuss Tier 4 studies with local, state, federal, and tribal wildlife agencies. The
27 number of years of monitoring is based on outcomes of Tier 3 and Tier 4 studies and analysis of
28 comparable Tier 4 data from other projects as indicated in Table 2. The Service may recommend

1 multiple years of monitoring for projects located near a listed species or bald or golden eagle, or
2 other situations, as appropriate.

3

4 ***Tier 4a Protocol Design Considerations***

5 The basic method of measuring fatality rates is the carcass search. Search protocols should be
6 standardized to the greatest extent possible, especially for common objectives and species of
7 concern, and they should include methods for adequately accounting for sampling biases
8 (searcher efficiency and scavenger removal). However, some situations warrant exceptions to
9 standardized protocol. The responsibility of demonstrating that an exception is appropriate and
10 applicable should be on the project operator to justify increasing or decreasing the duration or
11 intensity of operations monitoring.

12

13 Some general guidance is given below with regard to the following fatality monitoring protocol
14 design issues:

- 15 • Duration and frequency of monitoring
- 16 • Number of turbines to monitor
- 17 • Delineation of carcass search plots, transects, and habitat mapping
- 18 • General search protocol
- 19 • Field bias and error assessment
- 20 • Estimators of fatality

21 More detailed descriptions and methods of fatality search protocols can be found in the
22 California (California Energy Commission 2007) and Pennsylvania (Pennsylvania Game
23 Commission 2007) state guidelines and in Kunz et al. (2007), Smallwood (2007), and Strickland
24 et al. (2011).

25

26 Duration and frequency of monitoring

27 Frequency of carcass searches (search interval) may vary for birds and bats, and will vary
28 depending on the questions to be answered, the species of concern, and their seasonal abundance

1 at the project site. The carcass searching protocol should be adequate to answer applicable Tier
2 4 questions at an appropriate level of precision to make general conclusions about the project,
3 and is not intended to provide highly precise measurements of fatalities. Except during low use
4 times (e.g. winter months in northern states), the Service recommends that protocols be designed
5 such that carcass searches occur at some turbines within the project area most days each week of
6 the study.

7

8 The search interval is the interval between carcass searches at individual turbines, and this
9 interval may be lengthened or shortened depending on the carcass removal rates. If the primary
10 focus is on fatalities of large raptors, where carcass removal is typically low, then a longer
11 interval between searches (e.g., 14-28 days) is sufficient. However, if the focus is on fatalities of
12 bats and small birds and carcass removal is high, then a shorter search interval will be necessary.

13

14 There are situations in which studies of higher intensity (e.g., daily searches at individual
15 turbines within the sample) may be appropriate. These would be considered only in Tier 5
16 studies or in research programs because the greater complexity and level of effort goes beyond
17 that recommended for typical Tier 4 post construction monitoring. Tier 5 and research studies
18 could include evaluation of specific measures that have been implemented to mitigate potential
19 significant adverse impacts to species of concern identified during pre-construction studies.

20

21 *Number of turbines to monitor*

22 If available, data on variability among turbines from existing projects in similar conditions
23 within the same region are recommended as a basis for determining needed sample size (see
24 Morrison et al., 2008). If data are not available, the Service recommends that an operator select
25 a sufficient number of turbines via a systematic sample with a random start point. Sampling
26 plans can be varied (e.g., rotating panels [McDonald 2003, Fuller 1999, Breidt and Fuller 1999,
27 and Urquhart et al. 1998]) to increase efficiency as long as a probability sampling approach is
28 used. If the project contains fewer than 10 turbines, the Service recommends that all turbines in
29 the area of interest be searched unless otherwise agreed to by the permitting or wildlife resource
30 agencies. When selecting turbines, the Service recommends that a systematic sample with a
31 random start be used when selecting search plots to ensure interspersed among turbines.

1 Stratification among different habitat types also is recommended to account for differences in
2 fatality rates among different habitats (e.g., grass versus cropland or forest); a sufficient number
3 of turbines should be sampled in each strata.

4

5 *Delineation of carcass search plots, transects, and habitat mapping*

6 Evidence suggests that greater than 80 percent of bat fatalities fall within half the maximum
7 distance of turbine height to ground (Erickson 2003 a, b), and a minimum plot width of 120
8 meters from the turbine should be established at sample turbines. Plots will need to be larger for
9 birds, with a width twice the turbine height to ground. Decisions regarding search plot size
10 should be made in discussions with the Service, state wildlife agency, permitting agency and
11 Tribes. It may be useful to consult other scientifically credible information sources.

12

13 The Service recommends that each search plot should be divided into oblong subplots or belt
14 transects and that each subplot be searched. The objective is to find as many carcasses as
15 possible so the width of the belt will vary depending on the ground cover and its influence on
16 carcass visibility. In most situations, a search width of 6 meters should be adequate, but this may
17 vary from 3-10 meters depending on ground cover.

18

19 Searchable area within the theoretical maximum plot size varies, and heavily vegetated areas
20 (e.g., eastern mountains) often do not allow surveys to consistently extend to the maximum plot
21 width. In other cases it may be preferable to search a portion of the maximum plot instead of the
22 entire plot. For example, in some landscapes it may be impractical to search the entire plot
23 because of the time required to do an effective search, even if it is accessible (e.g., croplands),
24 and data from a probability sample of subplots within the maximum plot size can provide a
25 reasonable estimate of fatalities. It is important to accurately delineate and map the area
26 searched for each turbine to adjust fatality estimates based on the actual area searched. It may be
27 advisable to establish habitat visibility classes in each plot to account for differential
28 detectability, and to develop visibility classes for different landscapes (e.g., rocks, vegetation)
29 within each search plot. For example, the Pennsylvania Game Commission (2007) identified
30 four classes based on the percentage of bare ground.

31

1 The use of visibility classes requires that detection and removal biases be estimated for each
2 class. Fatality estimates should be made for each class and summed for the total area sampled.
3 Global positioning systems (GPS) are useful for accurately mapping the actual total area
4 searched and area searched in each habitat visibility class, which can be used to adjust fatality
5 estimates. The width of the belt or subplot searched may vary depending on the habitat and
6 species of concern; the key is to determine actual searched area and area searched in each
7 visibility class regardless of transect width. An adjustment may also be needed to take into
8 account the density of fatalities as a function of the width of the search plot.

9

10 *General search protocol*

11 Personnel trained in proper search techniques should look for bird and bat carcasses along
12 transects or subplots within each plot and record and collect all carcasses located in the
13 searchable areas. The Service will work with developers and operators to provide necessary
14 permits for carcass possession. A complete search of the area should be accomplished and
15 subplot size (e.g., transect width) should be adjusted to compensate for detectability differences
16 in the search area. Subplots should be smaller when vegetation makes it difficult to detect
17 carcasses; subplots can be wider in open terrain. Subplot width also can vary depending on the
18 size of the species being looked for. For example, small species such as bats may require smaller
19 subplots than larger species such as raptors.

20

21 Data to be recorded include date, start time, end time, observer, which turbine area was searched
22 (including GPS coordinates) and weather data for each search. When a dead bat or bird is found,
23 the searcher should place a flag near the carcass and continue the search. After searching the
24 entire plot, the searcher returns to each carcass and records information on a fatality data sheet,
25 including date, species, sex and age (when possible), observer name, turbine number, distance
26 from turbine, azimuth from turbine (including GPS coordinates), habitat surrounding carcass,
27 condition of carcass (entire, partial, scavenged), and estimated time of death (e.g., ≤ 1 day, 2
28 days). The recorded data will ultimately be housed in the FWS Office of Law Enforcement Bird
29 Mortality Reporting System. A digital photograph of the carcass should be taken. Rubber
30 gloves should be used to handle all carcasses to eliminate possible transmission of rabies or other
31 diseases and to reduce possible human scent bias for carcasses later used in scavenger removal

1 trials. Carcasses should be placed in a plastic bag and labeled. Unless otherwise conditioned by
2 the carcass possession permit, fresh carcasses (those determined to have been killed the night
3 immediately before a search) should be redistributed at random points on the same day for
4 scavenging trials.

5

6 *Field bias and error assessment*

7 During searches conducted at wind turbines, actual fatalities are likely incompletely observed.
8 Therefore carcass counts must be adjusted by some factor that accounts for imperfect
9 detectability (Huso 2011). Important sources of bias and error include: 1) fatalities that occur on
10 a highly periodic basis; 2) carcass removal by scavengers; 3) differences in searcher efficiency;
11 4) failure to account for the influence of site (e.g. vegetation) conditions in relation to carcass
12 removal and searcher efficiency; and 5) fatalities or injured birds and bats that may land or move
13 outside search plots.

14

15 Some fatalities may occur on a highly periodic basis creating a potential sampling error (number
16 1 above). The Service recommends that sampling be scheduled so that some turbines are
17 searched most days and episodic events are more likely detected, regardless of the search
18 interval. To address bias sources 2-4 above, it is strongly recommended that all fatality studies
19 conduct carcass removal and searcher efficiency trials using accepted methods (Anderson 1999,
20 Kunz et al. 2007, Arnett et al. 2007, NRC 2007, Strickland et al. 2011). Bias trials should be
21 conducted throughout the entire study period and searchers should be unaware of which turbines
22 are to be used or the number of carcasses placed beneath those turbines during trials. Carcasses
23 or injured individuals may land or move outside the search plots (number 5 above). With respect
24 to Tier 4a fatality estimates, this potential sampling error is considered to be small and can be
25 assumed insignificant (Strickland et al. 2011).

26

27 Prior to a study's inception, a list of random turbine numbers and random azimuths and distances
28 (in meters) from turbines should be generated for placement of each bat or bird used in bias
29 trials. Data recorded for each trial carcass prior to placement should include date of placement,
30 species, turbine number, distance and direction from turbine, and visibility class surrounding the
31 carcass. Trial carcasses should be distributed as equally as possible among the different

1 visibility classes throughout the study period and study area. Studies should attempt to avoid
2 “over-seeding” any one turbine with carcasses by placing no more than one or two carcasses at
3 any one time at a given turbine. Before placement, each carcass must be uniquely marked in a
4 manner that does not cause additional attraction, and its location should be recorded. There is no
5 agreed upon sample size for bias trials, though some state guidelines recommend from 50 - 200
6 carcasses (e.g., PGC 2007).

7

8 *Estimators of fatality*

9 If there were a direct relationship between the number of carcasses observed and the number
10 killed, there would be no need to develop a complex estimator that adjusts observed counts for
11 detectability, and observed counts could be used as a simple index of fatality (Huso 2011). But
12 the relationship is not direct and raw carcass counts recorded using different search intervals and
13 under different carcass removal rates and searcher efficiency rates are not directly comparable.
14 It is strongly recommended that only the most contemporary equations for estimating fatality be
15 used, as some original versions are now known to be extremely biased under many commonly
16 encountered field conditions (Erickson et al. 2000b, Erickson et al. 2004, Johnson et al. 2003,
17 Kerns and Kerlinger 2004, Fiedler et al. 2007, Kronner et al. 2007, Smallwood 2007, Huso 2011,
18 Strickland et al. 2011).

19

20 *Tier 4a Study Objectives*

21 In addition to the monitoring protocol design considerations described above, the metrics used to
22 estimate fatality rates must be selected with the Tier 4a questions and objectives in mind.
23 Metrics considerations for each of the Tier 4a questions are discussed briefly below. Not all
24 questions will be relevant for each project, and which questions apply would depend on Tier 3
25 outcomes.

26

27 **1. What are the bird and bat fatality rates for the project?**

28 The primary objective of fatality searches is to determine the overall estimated fatality rates for
29 birds and bats for the project. These rates serve as the fundamental basis for all comparisons of
30 fatalities, and if studies are designed appropriately they allow researchers to relate fatalities to
31 site characteristics and environmental variables, and to evaluate mitigation measures. Several

1 metrics are available for expressing fatality rates. Early studies reported fatality rates per
2 turbine. However, this metric is somewhat misleading as turbine sizes and their risks to birds
3 vary significantly (NRC 2007). Fatalities are frequently reported per nameplate capacity (i.e.
4 MW), a metric that is easily calculated and better for comparing fatality rates among different
5 sized turbines. Even with turbines of the same name plate capacity, the size of the rotor swept
6 area may vary among manufacturers, and turbines at various sites may operate for different
7 lengths of time and during different times of the day and seasons. With these considerations in
8 mind, the Service recommends that fatality rates be expressed on a per-turbine and per-
9 nameplate MW basis until a better metric becomes available.

10

11 **2. What are the fatality rates of species of concern?**

12 This analysis simply involves calculating fatalities per turbine of all species of concern at a site
13 when sample sizes are sufficient to do so. These fatalities should be expressed on a per
14 nameplate MW basis if comparing species fatality rates among projects.

15

16 **3. How do the estimated fatality rates compare to the predicted fatality rates?**

17 There are several ways that predictions can be evaluated with actual fatality data. During the
18 planning stages in Tier 2, predicted fatalities may be based on existing data at similar facilities in
19 similar landscapes used by similar species. In this case, the assumption is that use is similar, and
20 therefore that fatalities may be similar at the proposed facility. Alternatively, metrics derived
21 from pre-construction assessments for an individual species or group of species – usually an
22 index of activity or abundance at a proposed project – could be used in conjunction with use and
23 fatality estimates from existing projects to develop a model for predicting fatalities at the
24 proposed project site. Finally, physical models can be used to predict the probability of a bird of
25 a particular size striking a turbine, and this probability, in conjunction with estimates of use and
26 avoidance behavior, can be used to predict fatalities.

27

28 The most current equations for estimating fatality should be used to evaluate fatality predictions.
29 Several statistical methods can be found in the revised Strickland et al. 2011 and used to evaluate
30 fatality predictions. Metrics derived from Tier 3 pre-construction assessments may be correlated
31 with fatality rates, and (using the project as the experimental unit), in Tier 5 studies it should be

1 possible to determine if different preconstruction metrics can in fact accurately predict fatalities
2 and, thus, risk.

3

4 **4. Do bird and bat fatalities vary within the project site in relation to site characteristics?**

5 Data from pre-construction studies can demonstrate patterns of activity that may depend upon
6 the site characteristics. Turbines placed near escarpments or cliffs may intrude upon airspace
7 used by raptors soaring on thermals. Pre-construction and post construction studies and
8 assessments can be used to avoid siting individual, specific turbines within an area used by
9 species of concern. Turbine-specific fatality rates may be related to site characteristics such as
10 proximity to water, forest edge, staging and roosting sites, known stop-over sites, or other key
11 resources, and this relationship may be estimated using regression analysis. This information is
12 particularly useful for evaluating micro-siting options when planning a future facility or, on a
13 broader scale, in determining the location of the entire project.

14

15 **5. How do the fatality rates compare to the fatality rates from existing facilities in similar**
16 **landscapes with similar species composition and use?**

17 Comparing fatality rates among facilities with similar characteristics can be useful to determine
18 patterns and broader landscape relationships. Developers should communicate with the Service
19 to ensure that such comparisons are appropriate to avoid false conclusions. Fatality rates should
20 be expressed on a per nameplate MW or some other standardized metric basis for comparison
21 with other projects, and may be correlated with site characteristics – such as proximity to
22 wetlands, riparian corridors, mountain-foothill interface, wind patterns, or other broader
23 landscape features – using regression analysis. Comparing fatality rates from one project to
24 fatality rates of other projects provides insight into whether a project has relatively high,
25 moderate or low fatalities.

26

27 **6. What is the composition of fatalities in relation to migrating and resident birds and bats**
28 **at the site?**

29 The simplest way to address this question is to separate fatalities per turbine of known resident
30 species (e.g., big brown bat, prairie horned lark) and those known to migrate long distances (e.g.
31 hoary bat, red-eyed vireo). These data are useful in determining patterns of species composition

1 of fatalities and possible mitigation measures directed at residents, migrants, or perhaps both, and
 2 can be used in assessing potential population effects.

3

4 **7. Do fatality data suggest the need for measures to reduce impacts?**

5 The Service recommends that the wind project operator⁷ and the relevant agencies discuss the
 6 results from Tier 4 studies to determine whether these impacts are significant. If fatalities are
 7 considered significant, the wind project operator and the relevant agencies should develop a plan
 8 to mitigate the impacts.

9

10 **Table 2.** Decision Framework for Tier 4a Fatality Monitoring of Species of Concern.⁸

Probability of significant adverse impacts in Tier 3	Recommended Fatality Monitoring Duration and Effort	Possible outcomes of monitoring results
Tier 3 Studies indicate LOW probability of significant adverse impacts	Duration: At least one year of fatality monitoring to estimate fatalities of birds and bats. Field assessments should be sufficient to confirm that risk to birds and/or bats is indeed “low.”	1) Documented fatalities are approximately equal to or lower than predicted risk. No further fatality monitoring or mitigation is needed. 2) Fatalities are greater than predicted, but are not likely to be significant (i.e., unlikely to affect the long-term status of the population). If comparable fatality data at similar sites also supports that impacts are not likely to be high enough to affect population status, no further monitoring or mitigation is needed. If no comparable fatality data are available or such data indicates high risk, one additional year of fatality monitoring is recommended. If two years of fatality monitoring indicate levels of impacts that are not significant, no further fatality monitoring or mitigation is recommended. 3) Fatalities are greater than predicted and are likely to be significant OR federally endangered or threatened species or BGEPA species are affected. Communication with the Service is

1 ⁷ In situations where a project operator was not the developer, the Service expects that obligations of the developer
 2 for adhering to the Guidelines transfer with the project.

3 ⁸ Ensure that survey protocols, and searcher efficiency and scavenger removal bias correction factors are the most
 4 reliable, robust, and up to date (after Huso 2009).

		recommended. Further efforts to address impacts to BGEPA or ESA species may be warranted, unless otherwise addressed in an ESA or BGEPA take permit.
Tier 3 studies indicate MODERATE probability of significant adverse impacts	<p>Duration: Two or more years of fatality monitoring may be necessary.</p> <p>Field assessments should be sufficient to confirm that risk to birds and/or bats is indeed “moderate.” Closely compare estimated effects to species to those determined from the risk assessment protocol(s).</p>	<ol style="list-style-type: none"> 1) Documented fatalities after the first two years are lower or not different than predicted and are not significant and no federally endangered species or BGEPA species are affected - no further fatality monitoring or mitigation is needed. 2) Fatalities are greater than predicted and are likely to be significant OR federally endangered or threatened species or BGEPA species are affected, communication with the Service is recommended. Further efforts to address impacts to BGEPA or ESA species may be warranted, unless otherwise addressed in an ESA or BGEPA take permit.
Tier 3 studies indicate HIGH probability of significant adverse impacts	<p>Duration: Two or more years of fatality monitoring may be necessary to document fatality patterns.</p> <p>If fatality is high, developers should shift emphasis to exploring opportunities for mitigation rather than continuing to monitor fatalities. If fatalities are variable, additional years are likely warranted.</p>	<ol style="list-style-type: none"> 1) Documented fatalities during each year of fatality monitoring are less than predicted and are not likely to be significant, and no federally endangered or threatened species or BGEPA species are affected – no further fatality monitoring or mitigation is needed. 2) Fatalities are equal to or greater than predicted and are likely to be significant - further efforts to reduce impacts are necessary; communication with the Service are recommended. Further efforts, such as Tier 5 studies, to address impacts to BGEPA or ESA species may be warranted, unless otherwise addressed in an ESA or BGEPA take permit.

1

2 **Tier 4b – Assessing direct and indirect impacts of habitat loss, degradation, and**
 3 **fragmentation**

4 The objective of Tier 4b studies is to **evaluate Tier 3 predictions of direct and indirect**
 5 **impacts to habitat and the potential for significant adverse impacts on species of concern as**
 6 **a result of these impacts.** Tier 4b studies should be conducted if Tier 3 studies indicate the
 7 presence of species of habitat fragmentation concern, or if Tier 3 studies indicate significant

1 direct and indirect adverse impacts to species of concern (see discussion below). Tier 4b studies
2 should also inform project operators and the Service as to whether additional mitigation is
3 necessary.

4 Tier 4b studies should evaluate the following questions:

- 5 **1. How do post-construction habitat quality and spatial configuration of the study area**
6 **compare to predictions for species of concern identified in Tier 3 studies?**
- 7 **2. Were any behavioral modifications or indirect impacts noted in regard to species of**
8 **concern?**
- 9 **3. If significant adverse impacts were predicted for species of concern, and the project**
10 **was altered to mitigate for adverse impacts, were those efforts successful?**
- 11 **4. If significant adverse impacts were predicted for species of concern, and the project**
12 **was altered to mitigate for adverse impacts, were those efforts successful?**

13

14 The answers to these questions will be based on information estimating habitat loss, degradation,
15 and fragmentation information collected in Tier 3, currently available demographic and genetic
16 data, and studies initiated in Tier 3. As in the case of Tier 4a, the answers to these questions will
17 determine the need to conduct Tier 5 studies. For example, in the case that significant adverse
18 impacts to species of concern were predicted, but mitigation was not successful, then additional
19 mitigation and Tier 5 studies may be necessary. See Table 3 for further guidance.

20

- 21 **1. How do post-construction habitat quality and spatial configuration of the study**
22 **area compare to predictions for species of concern identified in Tier 3 studies?**

23 GIS and demographic data collected in Tier 3 and/or published information can be used to
24 determine predictions of impacts to species of concern from habitat loss, degradation, and
25 fragmentation. The developer can provide development assumptions based on Tier 3
26 information that can be compared to post-construction information. Additional post-construction
27 studies on impacts to species of concern due to direct and indirect impacts to habitat should only
28 be conducted if Tier 3 studies indicate the potential for significant adverse impacts.

29

1 **2. Were any behavioral modifications or indirect impacts noted in regard to affected**
2 **species?**

3
4 Evaluation of this question is based on the analysis of observed use of the area by species of
5 concern prior to construction in comparison with observed use during operation. Observations
6 and demographic data collected during Tier 3, and assessment of published information about the
7 potential for displacement and demographic responses to habit impacts could be the basis for this
8 analysis. If this analysis suggests that direct and/or indirect loss of habitat for a species of
9 concern leads to behavioral modifications or displacement that are significant, further studies of
10 these impacts in Tier 5 may be appropriate.

11
12 **3. If significant adverse impacts were not predicted in Tier 3 because of loss,**
13 **degradation, or fragmentation of habitat, but Tier 4b studies indicate such impacts**
14 **have the potential to occur, can these impacts be mitigated?**

15 When Tier 4b studies indicate significant impacts may be occurring, the developer may need to
16 conduct an assessment of these impacts and what opportunities exist for additional mitigation.

17
18 **4. If significant adverse impacts were predicted for species of concern, and the**
19 **project was altered to mitigate for adverse impacts, were those efforts successful?**

20 When Tier 4b studies indicate significant impacts may be occurring, the developer may need to
21 conduct an assessment of these impacts and what opportunities exist for additional mitigation.
22 Evaluation of the effectiveness of mitigation is a Tier 4 study and should follow design
23 considerations discussed in Tier 5 and from guidance in the scientific literature (e.g. Strickland et
24 al. 2011).

25
26 When Tier 3 studies identified potential moderate or high risks to species of concern that caused
27 a developer to incorporate mitigation measures into the project, Tier 4b studies should evaluate
28 the effectiveness of those mitigation measures. Determining such effectiveness is important for
29 the project being evaluated to ascertain whether additional mitigation measures are appropriate
30 as well as informing future decisions about how to improve mitigation at wind energy facilities
31 being developed.

Tier 4b Protocol Design Considerations

Impacts to a species of concern resulting from the direct and indirect loss of habitat are important and must be considered when a wind project is being considered for development. Some species of concern are likely to occur at every proposed wind energy facility. This occurrence may range from a breeding population, to seasonal occupancy, such as a brief occurrence while migrating through the area. Consequently the level of concern regarding impacts due to direct and indirect loss of habitat will vary depending on the species and the impacts that occur.

If a breeding population of a species of habitat fragmentation concern occurs in the project area and Tier 3 studies indicate that fragmentation of their habitat is possible, these predictions should be evaluated following the guidance indicated in Table 3 using the protocols described in Tier 3. If the analysis of post-construction GIS data on direct and indirect habitat loss suggests that fragmentation is likely, then additional displacement studies and mitigation may be necessary. These studies would typically begin immediately and would be considered Tier 5 studies using design considerations illustrated by examples in Tier 5 below and from guidance in the scientific literature (e.g. Strickland et al. 2011).

Significant direct or indirect loss of habitat for a species of concern may occur without habitat fragmentation if project impacts result in the reduction of a habitat resource that potentially is limiting to the affected population. Impacts of this type include loss of use of breeding habitat or loss of a significant portion of the habitat of a federally or state protected species. This would be evaluated by determining the amount of the resource that is lost and determining if this loss would potentially result in significant impacts to the affected population. Evaluation of potential significant impacts would occur in Tier 5 studies that measure the demographic response of the affected population.

The intention of the Guidelines is to focus industry and agency resources on the direct and indirect loss of habitat and limiting resources that potentially reduce the viability of a species of

1 concern. Not all direct and indirect loss of a species’ habitat will affect limiting resources for
 2 that species, and when habitat losses are minor or non-existent no further study is necessary.

3
 4 **Tier 4b Decision Points**

5 The developer should use the results of the Tier 4b studies to evaluate whether further studies
 6 and/or mitigation are needed. The developer should communicate the results of these studies,
 7 and decisions about further studies and mitigation, with the Service. Table 3 provides a
 8 framework for evaluating the need for further studies and mitigation. Level of effort for studies
 9 should be sufficient to answer all questions of interest. Refer to the relevant methods sections
 10 for Tier 2 Question 5 and Tier 3 Question 2 in the text for specific guidance on study protocols.

11

12 **Table 3.** Decision framework to guide studies for minimizing impacts to habitat and species of
 13 habitat fragmentation (HF) concern.

Outcomes of Tier 2	Outcomes of Tier 3	Outcomes of Tier 4b	Suggested Study/Mitigation
<ul style="list-style-type: none"> No species of HF concern potentially present 	<ul style="list-style-type: none"> No further studies needed 	<ul style="list-style-type: none"> n/a 	<ul style="list-style-type: none"> n/a

14

1 **Chapter 6: Tier 5 – Other Post-construction Studies**

2

3 Tier 5 studies will not be necessary for most wind energy projects. Tier 5 studies can be
4 complex and time consuming. The Service anticipates that the tiered approach will steer projects
5 away from sites where Tier 5 studies would be necessary.

6

7 When Tier 5 studies are conducted, they should be site-specific and intended to: 1) analyze
8 factors associated with impacts in those cases in which Tier 4 analyses indicate they are
9 potentially significant; 2) identify why mitigation measures implemented for a project were not
10 adequate; and 3) assess demographic effects on local populations of species of concern when
11 demographic information is important, including species of habitat fragmentation concern.

12

13 **Tier 5 Questions**

14 Tier 5 studies are intended to answer questions that fall in three major categories; answering yes
15 to any of these questions might indicate a Tier 5 study is needed:

16

17 **1. To the extent that the observed fatalities exceed anticipated fatalities, are those**
18 **fatalities potentially having a significant adverse impact on local populations? Are**
19 **observed direct and indirect impacts to habitat having a significant adverse impact**
20 **on local populations?**

21 For example, in the Tier 3 risk assessment, predictions of collision fatalities and habitat impacts
22 (direct and indirect) are developed. Post-construction studies in Tier 4 evaluate the accuracy of
23 those predictions by estimating impacts. If post-construction studies demonstrate potentially
24 significant adverse impacts, Tier 5 studies may also be warranted and should be designed to
25 understand observed versus predicted impacts.

26

27 **2. Were mitigation measures implemented (other than fee in lieu) not effective? This**
28 **includes habitat mitigation measures as well as measures undertaken to reduce**
29 **collision fatalities.**

1 Tier 4a and b studies can assess the effectiveness of measures taken to reduce direct and indirect
2 impacts as part of the project and to identify such alternative or additional measures as are
3 necessary. If alternative or additional measures were unsuccessful, the reasons why would be
4 evaluated using Tier 5 studies.

5

6 **3. Are the estimated impacts of the proposed project likely to lead to population**
7 **declines in the species of concern (other than federally-listed species)?**

8 Impacts of a project will have population level effects if the project causes a population decline
9 in the species of concern. For non-listed species, this assessment will apply only to the local
10 population.

11

12 Tier 5 studies may need to be conducted when:

13

14 1) Realized fatality levels for individual species of concern reach a level at which they are
15 considered significant adverse impacts by the relevant agencies.

16

17 For example, if Tier 4a fatality studies document that a particular turbine or set of
18 turbines exhibits bird or bat collision fatality higher than predicted, Tier 5 studies may be
19 useful in evaluating alternative mitigation measures at that turbine/turbine string.

20

21 2) There is the potential for significant fatality impacts or significant adverse impacts to
22 habitat for species of concern, there is a need to assess the impacts more closely, and
23 there is uncertainty over how these impacts will be mitigated.

24

25 3) Fatality and/or significant adverse habitat impacts suggest the potential for a reduction in
26 the viability of an affected population, in which case studies on the potential for
27 population impacts may be warranted.

28

29 4) A developer evaluates the effectiveness of a risk reduction measure before deciding to
30 continue the measure permanently or whether to use the measure when implementing
31 future phases of a project.

In the event additional turbines are proposed as an expansion of an existing project, results from Tier 4 and Tier 5 studies and the decision-making framework contained in the tiered approach can be used to determine whether the project should be expanded and whether additional information should be collected. It may also be necessary to evaluate whether additional measures are warranted to reduce significant adverse impacts to species.

Tier 5 Study Design Considerations

As discussed in Chapter 4 Tier 3, Tier 5 studies will be highly variable and unique to the circumstances of the individual project, and therefore these Guidelines do not provide specific guidance on all potential approaches, but make some general statements about study design. Specific Tier 5 study designs will depend on the types of questions, the specific project, and practical considerations. The most common practical considerations include the area being studied, the time period of interest, the species of concern, potentially confounding variables, time available to conduct studies, project budget, and the magnitude of the anticipated impacts. When possible it is usually desirable to collect data before construction to address Tier 5 questions. Design considerations for these studies are including in Tier 3.

One study design is based on an experimental approach to evaluating mitigation measures, where the project proponent will generally select several alternative management approaches to design, implement, and test. The alternatives are generally incorporated into sound experimental designs. Monitoring and evaluation of each alternative helps the developer to decide which alternative is more effective in meeting objectives, and informs adjustments to the next round of management decisions. The need for this type of study design can be best determined by communication between the project operator, the Service field office, and the state wildlife agency, on a project-by-project basis. This study design requires developers and operators to identify strategies to adjust management and/or mitigation measures if monitoring indicates that anticipated impacts are being exceeded. Such strategies should include a timeline for periodic reviews and adjustments as well as a mechanism to consider and implement additional mitigation measures as necessary after the project is developed.

1

2 When pre-construction data are unavailable and/or a suitable reference area is lacking, the
3 reference Control Impact Design (Morrison et al. 2008) is the recommended design. The lack of
4 a suitable reference area also can be addressed using the Impact Gradient Design, when habitat
5 and species use are homogenous in the assessment area prior to development. When applied
6 both pre- and post-construction, the Impact Gradient Design is a suitable replacement for the
7 classic BACI (Morrison et al. 2008).

8

9 In the study of habitat impacts, the resource selection function (RSF) study design (see Anderson
10 et al 1999; Morrison et al. 2008; Manly et al. 2002) is a statistically robust design, either with or
11 without pre-construction and reference data. Habitat selection is modeled as a function of
12 characteristics measured on resource units and the use of those units by the animals of interest.
13 The RSF allows the estimation of the probability of use as a function of the distance to various
14 environmental features, including wind energy facilities, and thus provides a direct quantification
15 of the magnitude of the displacement effect. RSF could be improved with pre-construction and
16 reference area data. Nevertheless, it is a relatively powerful approach to documenting
17 displacement or the effect of mitigation measures designed to reduce displacement even without
18 those additional data.

19

20 ***Tier 5 Examples***

21 As described earlier, Tier 5 studies will not be conducted at most projects, and the specific Tier 5
22 questions and methods for addressing these questions will depend on the individual project and
23 the concerns raised during pre-construction studies and during operational phases. Rather than
24 provide specific guidance on all potential approaches, these Guidelines offer the following case
25 studies as examples of studies that have attempted to answer Tier 5 questions.

26 Habitat impacts - displacement and demographic impact studies

27 Studies to assess impacts may include quantifying species' habitat loss (e.g., acres of lost
28 grassland habitat for grassland songbirds) and habitat modification. For example, an increase in
29 edge may result in greater nest parasitism and nest predation. Assessing indirect impacts may
30 include two important components: 1) indirect effects on wildlife resulting from displacement,

1 due to disturbance, habitat fragmentation, loss, and alteration; and 2) demographic effects that
2 may occur at the local, regional or population-wide levels due to reduced nesting and breeding
3 densities, increased isolation between habitat patches, and effects on behavior (e.g., stress,
4 interruption, and modification). These factors can individually or cumulatively affect wildlife,
5 although some species may be able to habituate to some or perhaps all habitat changes. Indirect
6 impacts may be difficult to quantify but their effects may be significant (e.g., Stewart et al. 2007,
7 Pearce-Higgins et al. 2008, Bright et al. 2008, Drewitt and Langston 2006, Robel et al. 2004,
8 Pruett et al. 2009).

9

10 Example: in southwestern Pennsylvania, development of a project is proceeding at a site located
11 within the range of a state-listed terrestrial species. Surveys were performed at habitat locations
12 appropriate for use by the animal, including at control sites. Post-construction studies are
13 planned at all locations to demonstrate any displacement effects resulting from the construction
14 and operation of the project.

15

16 The Service recognizes that indirect impact studies may not be appropriate for most individual
17 projects. Consideration should be given to developing collaborative research efforts with
18 industry, government agencies, and NGOs to conduct studies to address indirect impacts.

19

20 Indirect impacts are considered potentially significant adverse threats to species such as prairie
21 grouse (prairie chickens, sharp-tailed grouse), and sage grouse, and demographic studies may be
22 necessary to determine the extent of these impacts and the need for mitigation.

23

24 Displacement studies may use any of the study designs describe earlier. The most scientifically
25 robust study designs to estimate displacement effects are BACI, RSF, and impact gradient. RSF
26 and impact gradient designs may not require specialized data gathering during Tier 3.

27

28 Telemetry studies that measure impacts of the project development on displacement, nesting,
29 nest success, and survival of prairie grouse and sage grouse in different environments (e.g., tall
30 grass, mixed grass, sandsage, sagebrush) will require spatial and temporal replication,
31 undisturbed reference sites, and large sample sizes covering large areas. Examples of study

1 designs and analyses used in the studies of other forms of energy development are presented in
2 Holloran et al. (2005), Pitman et al. (2005), Robel et al. (2004), and Hagen et al. (2011).
3 Anderson et al. (1999) provides a thorough discussion of the design, implementation, and
4 analysis of these kinds of field studies and should be consulted when designing the BACI study.

5

6 Studies are being initiated to evaluate effects of wind energy development on greater sage grouse
7 in Wyoming. In addition to measuring demographic patterns, these studies will use the RSF
8 study design (see Sawyer et al. 2006) to estimate the probability of sage grouse use as a function
9 of the distance to environmental features, including an existing and a proposed project.

10

11 In certain situations, such as for a proposed project site that is relatively small and in a more or
12 less homogeneous landscape, an impact gradient design may be an appropriate means to assess
13 avoidance of the wind energy facility by resident populations (Strickland et al., 2002). For
14 example, Leddy et al. 1999 used the impact gradient design to evaluate grassland bird density as
15 a function of the distance from wind turbines. Data were collected at various distances from
16 turbines along transects.

17

18 This approach provides information on whether there is an effect, and may allow quantification
19 of the gradient of the effect and the distance at which the displacement effect no longer exists –
20 the assumption being that the data collected at distances beyond the influence of turbines are the
21 reference data (Erickson et al., 2007). An impact gradient analysis could also involve measuring
22 the number of breeding grassland birds counted at point count plots as a function of distance
23 from the wind turbines (Johnson et al. 2000).

24

25 *Sound and Wildlife*

26 Turbine blades at normal operating speeds can generate levels of sound beyond ambient
27 background levels. Construction and maintenance activities can also contribute to sound levels
28 by affecting communication distance, an animal's ability to detect calls or danger, or to forage.
29 Sound associated with developments can also cause behavioral and/or physiological effects,
30 damage to hearing from acoustic over-exposure, and masking of communication signals and
31 other biologically relevant sounds (Dooling and Popper 2007). Some birds are able to shift their

1 vocalizations to reduce the masking effects of noise. However, when shifts don't occur or are
2 insignificant, masking may prove detrimental to the health and survival of wildlife (Barber et al.
3 2010). Data suggest noise increases of 3 dB to 10 dB correspond to 30 percent to 90 percent
4 reductions in alerting distances for wildlife, respectively (Barber et al. 2010).

5

6 The National Park Service has been investigating potential impacts to wildlife due to alterations
7 in sound level and type. However, further research is needed to better understand this potential
8 impact. Research may include: how wind facilities affect background sound levels; whether
9 masking, disturbance, and acoustical fragmentation occur; and how turbine, construction, and
10 maintenance sound levels can vary by topographic area.

11

12 Levels of fatality beyond those predicted

13 More intensive post-construction fatality studies may be used to determine relationships between
14 fatalities and weather, wind speed or other covariates, which usually require daily carcass
15 searches. Fatalities determined to have occurred the previous night can be correlated with that
16 night's weather or turbine characteristics to establish important relationships that can then be
17 used to evaluate the most effective times and conditions to implement measures to reduce
18 collision fatality at the project.

19

20 Measures to address fatalities

21 The efficacy of operational changes (e.g. changing turbine cut-in speed) of a project to reduce
22 collision fatalities has only recently been evaluated (Arnett et al. 2009, Baerwald et al 2009).
23 Operational changes to address fatalities should be applied only at sites where collision fatalities
24 are predicted or demonstrated to have significant adverse impacts.

25

26 ***Tier 5 Studies and Research***

27 The Service makes a distinction between Tier 5 studies focused on project-specific impacts and
28 research (which is discussed earlier in the Guidelines). For example, developers may be
29 encouraged to participate in collaborative studies (see earlier discussion of Research) or asked to
30 conduct a study on an experimental mitigation technique, such as differences in turbine cut-in
31 speed to reduce bat fatalities. Such techniques may show promise in mitigating the impacts of

1 wind energy development to wildlife, but their broad applicability for mitigation purposes has
2 not been demonstrated. Such techniques should not be routinely applied to projects, but
3 application at appropriate sites will contribute to the breadth of knowledge regarding the efficacy
4 of such measures in addressing collision fatalities. In addition, studies involving multiple sites
5 and academic researchers can provide more robust research results, and such studies take more
6 time and resources than are appropriately carried out by one developer at a single site. Examples
7 below demonstrate collaborative research efforts to address displacement, operational changes,
8 and population level impacts.

9

10 Studies of Indirect Effects

11 The Service provides two examples below of ongoing studies to assess the effects of indirect
12 impacts related to wind energy facilities.

13

14 Kansas State University, as part of the NWCC Grassland Shrub-steppe Species Collaborative, is
15 undertaking a multi-year research project to assess the effects of wind energy facilities on
16 populations of greater prairie-chickens (GPCH) in Kansas. Initially the research was based on a
17 Before/After Control/Impact (BACI) experimental design involving three replicated study sites
18 in the Flint Hills and Smoky Hills of eastern Kansas. Each study site consisted of an impact area
19 where a wind energy facility was proposed to be developed and a nearby reference area with
20 similar rangeland characteristics where no development was planned. The research project is a
21 coordinated field/laboratory effort, i.e., collecting telemetry and observational data from adult
22 and juvenile GPCH in the field, and determining population genetic attributes of GPCH in the
23 laboratory from blood samples of birds and the impact and reference areas. Detailed data on
24 GPCH movements, demography, and population genetics were gathered from all three sites from
25 2007 to 2010. By late 2008, only one of the proposed wind energy facilities was developed (the
26 Meridian Way Wind Farm in the Smoky Hills of Cloud County), and on-going research efforts
27 are focused on that site. The revised BACI study design now will produce two years of pre-
28 construction data (2007 and 2008), and three years of post-construction data (2009, 2010, and
29 2011) from a single wind energy facility site (impact area) and its reference area. Several
30 hypotheses were formulated for testing to determine if wind energy facilities impacted GPCH
31 populations, including but not limited to addressing issues relating to: lek attendance, avoidance

1 of turbines and associated features, nest success and chick survival, habitat usage, adult mortality
2 and survival, breeding behavior, and natal dispersal. A myriad of additional significant avenues
3 are being pursued as a result of the rich database that has been developed for the GPCH during
4 this research effort. GPCH reproductive data will be collected through the summer of 2011
5 whereas collection of data from transmitter-equipped GPCH will extend through the lekking
6 season of 2012 to allow estimates of survival of GPCH over the 2011-2012 winter. At the
7 conclusion of the study, the two years of pre-construction data and three years of post-
8 construction data will be analyzed and submitted to peer-reviewed journals for publication.

9

10 Erickson et al. (2004) evaluated the displacement effect of a large wind energy facility in the
11 Pacific Northwest. The study was conducted in a relatively homogeneous grassland landscape.
12 Erickson et al. (2004) conducted surveys of breeding grassland birds along 300 meter transects
13 perpendicular to strings of wind turbines. Surveys were conducted prior to construction and after
14 commercial operation. The basic study design follows the Impact Gradient Design (Morrison et
15 al. 2008) and in this application, conformed to a special case of BACI where areas at the distal
16 end of each transect were considered controls (i.e., beyond the influence of the turbines). In this
17 study, there is no attempt to census birds in the area, and observations per survey are used as an
18 index of abundance. Additionally, the impact-gradient study design resulted in less effort than a
19 BACI design with offsite control areas. Erickson et al. (2004) found that grassland passerines as
20 a group, as well as grasshopper sparrows and western meadowlarks, showed reduced use in the
21 first 50 meter segment nearest the turbine string. About half of the area within that segment,
22 however, had disturbed vegetation and separation of behavior avoidance from physical loss of
23 habitat in this portion of the area was impossible. Horned larks and savannah sparrows
24 (*Passerculus sandwichensis*) appeared unaffected. The impact gradient design is best used when
25 the study area is relatively small and homogeneous.

26

27 Operational Changes to Reduce Collision Fatality

28 Arnett et al. (2009) conducted studies on the effectiveness of changing turbine cut-in speed on
29 reducing bat fatality at wind turbines at the Casselman Wind Project in Somerset County,
30 Pennsylvania. Their objectives were to: 1) determine the difference in bat fatalities at turbines
31 with different cut-in-speeds relative to fully operational turbines; and 2) determine the economic

1 costs of the experiment and estimated costs for the entire area of interest under different
2 curtailment prescriptions and timeframes. Arnett et al. (2009) reported substantial reductions in
3 bat fatalities with relatively modest power losses.

4

5 In Kenedy County, Texas, investigators are refining and testing a real-time curtailment protocol.
6 The projects use an avian profiling radar system to detect approaching “flying vertebrates” (birds
7 and bats), primarily during spring and fall bird and bat migrations. The blades automatically idle
8 when risk reaches a certain level and weather conditions are particularly risky. Based on
9 estimates of the number and timing of migrating raptors, feathering (real-time curtailment)
10 experiments are underway in Tehuantepec, Mexico, where raptor migration through a mountain
11 pass is extensive.

12

13 Other tools, such as thermal imaging (Horn et al. 2008) or acoustic detectors (Kunz et al. 2007),
14 have been used to quantify post-construction bat activity in relation to weather and turbine
15 characteristics for improving operational change efforts. For example, at the Mountaineer
16 project in 2003, Tier 4 studies (weekly searches at every turbine) demonstrated unanticipated and
17 high levels of bat fatalities (Kerns and Kerlinger 2004). Daily searches were instituted in 2004
18 and revealed that fatalities were strongly associated with low-average-wind-speed nights, thus
19 providing a basis for testing operational changes (Arnett 2005, Arnett et al. 2008). The program
20 also included behavioral observations using thermal imaging that demonstrated higher bat
21 activity at lower wind speeds (Horn et al. 2008).

22

23 Studies are currently underway to design and test the efficacy of an acoustic deterrent device to
24 reduce bat fatalities at wind facilities (E.B. Arnett, Bat Conservation International, under the
25 auspices of BWEC). Prototypes of the device have been tested in the laboratory and in the field
26 with some success. Spanjer (2006) tested the response of big brown bats (*Eptesicus fuscus*) to a
27 prototype eight speaker deterrent emitting broadband white noise at frequencies from 12.5–112.5
28 kHz and found that during non-feeding trials, bats landed in the quadrant containing the device
29 significantly less when it was broadcasting broadband noise. Spanjer (2006) also reported that
30 during feeding trials, bats never successfully took a tethered mealworm when the device
31 broadcast sound, but captured mealworms near the device in about 1/3 of trials when it was

1 silent. Szewczak and Arnett (2006, 2007) tested the same acoustic deterrent in the field and
2 found that when placed by the edge of a small pond where nightly bat activity was consistent,
3 activity dropped significantly on nights when the deterrent was activated. Horn et al. (2007)
4 tested the effectiveness of a larger, more powerful version of this deterrent device on reducing
5 nightly bat activity and found mixed results. In 2009, a new prototype device was developed and
6 tested at a project in Pennsylvania. Ten turbines were fitted with deterrent devices, daily fatality
7 searches were conducted, and fatality estimates were compared with those from 15 turbines
8 without deterrents (i.e., controls) to determine if bat fatalities were reduced. This experiment
9 found that estimated bat fatalities per turbine were 20 to 53 percent lower at treatment turbines
10 compared to controls. More experimentation is required. At the present time, there is not an
11 operational deterrent available that has demonstrated effective reductions in bat kills (E. B.
12 Arnett, Bat Conservation International, unpublished data).

13

14 Assessment of Population-level Impacts

15 The Altamont Pass Wind Resource Area (APWRA) has been the subject of intensive scrutiny
16 because of avian fatalities, especially for raptors, in an area encompassing more than 5,000 wind
17 turbines (e.g., Orloff and Flannery 1992; Smallwood and Thelander 2004, 2005). Field studies
18 on golden eagles, a long-lived raptor species, have been completed using radio telemetry at
19 APWRA to understand population demographics, assess impacts from wind turbines, and
20 explore measures to effectively reduce the incidence of golden eagle mortality for this area.
21 (Hunt et al. 1999, and Hunt 2002). Results from nesting surveys (Hunt 2002) indicated that there
22 was no decline in eagle territory occupancy. However Hunt (2002) also found that subadult and
23 floater components of golden eagle populations at APWRA are highly vulnerable to wind turbine
24 mortality and results from this study indicate that turbine mortality prevented the maintenance of
25 substantial reserves of nonbreeding adults characteristic of healthy populations elsewhere,
26 suggesting the possibility of an eventual decline in the breeding population (Hunt and Hunt
27 2006). Hunt conducted follow-up surveys in 2005 (Hunt and Hunt 2006) and determined that
28 all 58 territories occupied by eagle pairs in 2000 were occupied in 2005. It should be noted
29 however that golden eagle studies at APWRA (Hunt et al. 1999, Hunt 2002, and Hunt and Hunt
30 2006) were all conducted after the APWRA was constructed and the species does not nest within
31 the footprint of the APWRA itself (Figure 4; Hunt and Hunt 2006). The APWRA is an area of

- 1 about 160 sq. km (Hunt 2002) and presumably golden eagles formerly nested within this area.
- 2 The loss of breeding eagle pairs from the APWRA suggests these birds have all been displaced
- 3 by the project, or lost due to various types of mortality including collisions with turbine blades.

1 **Chapter 7: Best Management Practices**

2

3 **Site Construction and Operation**

4 During site planning and development, careful attention to reducing risk of adverse impacts to
5 species of concern from wind energy projects, through careful site selection and facility design,
6 is recommended. The following BMPs can assist a developer in the planning process to reduce
7 potential impacts to species of concern. Use of these BMPs should ensure that the potentially
8 adverse impacts to most species of concern and their habitats present at many project sites would
9 be reduced, although compensatory mitigation may be appropriate at a project level to address
10 significant site-specific concerns and pre-construction study results.

11

12 These BMPs will evolve over time as additional experience, learning, monitoring and research
13 becomes available on how to best minimize wildlife and habitat impacts from wind energy
14 projects. Service should work with the industry, stakeholders and states to evaluate, revise and
15 update these BMPs on a periodic basis, and the Service should maintain a readily available
16 publication of recommended, generally accepted best practices.

17

- 18 1. Minimize, to the extent practicable, the area disturbed by pre-construction site monitoring
19 and testing activities and installations.
- 20 2. Avoid locating wind energy facilities in areas identified as having a demonstrated and
21 unmitigatable high risk to birds and bats.
- 22 3. Use available data from state and federal agencies, and other sources (which could include
23 maps or databases), that show the location of sensitive resources and the results of Tier 2
24 and/or 3 studies to establish the layout of roads, power lines, fences, and other infrastructure.
- 25
- 26 4. Minimize, to the maximum extent practicable, roads, power lines, fences, and other
27 infrastructure associated with a wind development project. When fencing is necessary,
28 construction should use wildlife compatible design standards.

29

30

- 1 5. Use native species when seeding or planting during restoration. Consult with appropriate
2 state and federal agencies regarding native species to use for restoration.
- 3 6. To reduce avian collisions, place low and medium voltage connecting power lines associated
4 with the wind energy development underground to the extent possible, unless burial of the
5 lines is prohibitively expensive (e.g., where shallow bedrock exists) or where greater adverse
6 impacts to biological resources would result:
 - 7 a. Overhead lines may be acceptable if sited away from high bird crossing locations, to
8 the extent practicable, such as between roosting and feeding areas or between lakes,
9 rivers, prairie grouse and sage grouse leks, and nesting habitats. To the extent
10 practicable, the lines should be marked in accordance with Avian Power Line
11 Interaction Committee (APLIC) collision guidelines.
 - 12 b. Overhead lines may be used when the lines parallel tree lines, employ bird flight
13 diverters, or are otherwise screened so that collision risk is reduced.
 - 14 c. Above-ground low and medium voltage lines, transformers and conductors should
15 follow the 2006 or most recent APLIC “Suggested Practices for Avian Protection on
16 Power Lines.”
- 17 7. Avoid guyed communication towers and permanent met towers at wind energy project sites.
18 If guy wires are necessary, bird flight diverters or high visibility marking devices should be
19 used.
- 20 8. Where permanent meteorological towers must be maintained on a project site, use the
21 minimum number necessary.
- 22 9. Use construction and management practices to minimize activities that may attract prey
23 and predators to the wind energy facility.
- 24 10. Employ only red, or dual red and white strobe, strobe-like, or flashing lights, not steady
25 burning lights, to meet Federal Aviation Administration (FAA) requirements for visibility
26 lighting of wind turbines, permanent met towers, and communication towers. Only a portion
27 of the turbines within the wind project should be lighted, and all pilot warning lights should
28 fire synchronously.

- 1 11. Keep lighting at both operation and maintenance facilities and substations located within half
2 a mile of the turbines to the minimum required:
 - 3 a. Use lights with motion or heat sensors and switches to keep lights off when not
4 required.
 - 5 b. Lights should be hooded downward and directed to minimize horizontal and skyward
6 illumination.
 - 7 c. Minimize use of high-intensity lighting, steady-burning, or bright lights such as
8 sodium vapor, quartz, halogen, or other bright spotlights.
 - 9 d. All internal turbine nacelle and tower lighting should be extinguished when
10 unoccupied.
- 11 12. Establish non-disturbance buffer zones to protect sensitive habitats or areas of high risk for
12 species of concern identified in pre-construction studies. Determine the extent of the buffer
13 zone in consultation with the Service and state, local and tribal wildlife biologists, and land
14 management agencies (e.g., U.S. Bureau of Land Management (BLM) and U.S. Forest
15 Service (USFS)), or other credible experts as appropriate.
- 16 13. Locate turbines to avoid separating bird and bat species of concern from their daily roosting,
17 feeding, or nesting sites if documented that the turbines' presence poses a risk to species.
- 18 14. Avoid impacts to hydrology and stream morphology, especially where federal or state-listed
19 aquatic or riparian species may be involved. Use appropriate erosion control measures in
20 construction and operation to eliminate or minimize runoff into water bodies.
- 21 15. When practical use tubular towers or best available technology to reduce ability of birds to
22 perch and to reduce risk of collision.
- 23 16. After project construction, close roads not needed for site operations and restore these
24 roadbeds to native vegetation, consistent with landowner agreements.
- 25 17. Minimize the number and length of access roads; use existing roads when feasible.
- 26 18. Minimize impacts to wetlands and water resources by following all applicable provisions of
27 the Clean Water Act (33 USC 1251-1387) and the Rivers and Harbors Act (33 USC 301 et
28 seq.); for instance, by developing and implementing a storm water management plan and

- 1 taking measures to reduce erosion and avoid delivery of road-generated sediment into
2 streams and waters.
- 3 19. Reduce vehicle collision risk to wildlife by instructing project personnel to drive at
4 appropriate speeds, be alert for wildlife, and use additional caution in low visibility
5 conditions.
- 6 20. Instruct employees, contractors, and site visitors to avoid harassing or disturbing wildlife,
7 particularly during reproductive seasons.
- 8 21. Reduce fire hazard from vehicles and human activities (instruct employees to use spark
9 arrestors on power equipment, ensure that no metal parts are dragging from vehicles, use
10 caution with open flame, cigarettes, etc.). Site development and operation plans should
11 specifically address the risk of wildfire and provide appropriate cautions and measures to be
12 taken in the event of a wildfire.
- 13 22. Follow federal and state measures for handling toxic substances to minimize danger to water
14 and wildlife resources from spills. Facility operators should maintain Hazardous Materials
15 Spill Kits on site and train personnel in the use of these.
- 16 23. Reduce the introduction and spread of invasive species by following applicable local policies
17 for invasive species prevention, containment, and control, such as cleaning vehicles and
18 equipment arriving from areas with known invasive species issues, using locally sourced
19 topsoil, and monitoring for and rapidly removing invasive species at least annually.
- 20 24. Use invasive species prevention and control measures as specified by county or state
21 requirements, or by applicable federal agency requirements (such as Integrated Pest
22 Management) when federal policies apply.
- 23 25. Properly manage garbage and waste disposal on project sites to avoid creating attractive
24 nuisances for wildlife by providing them with supplemental food.
- 25 26. Promptly remove large animal carcasses (e.g., big game, domestic livestock, or feral animal).
- 26 27. Wildlife habitat enhancements or improvements such as ponds, guzzlers, rock or brush piles
27 for small mammals, bird nest boxes, nesting platforms, wildlife food plots, etc. should not be
28 created or added to wind energy facilities. These wildlife habitat enhancements are often

1 desirable but when added to a wind energy facility result in increased wildlife use of the
2 facility which may result in increased levels of injury or mortality to them.

3

4 **Retrofitting, Repowering, and Decommissioning**

5 As with project construction, these Guidelines offer BMPs for the retrofitting, repowering, and
6 decommissioning phases of wind energy projects.

7

8 ***Retrofitting***

9 Retrofitting is defined as replacing portions of existing wind turbines or project facilities so that
10 at least part of the original turbine, tower, electrical infrastructure or foundation is being utilized.

11 Retrofitting BMPs include:

12 1. Retrofitting of turbines should use installation techniques that minimize new site
13 disturbance, soil erosion, and removal of vegetation of habitat value.

14 2. Retrofits should employ shielded, separated or insulated electrical conductors that
15 minimize electrocution risk to avian wildlife per APLIC (2006).

16 3. Retrofit designs should prevent nests or bird perches from being established in or on the
17 wind turbine or tower.

18 4. FAA visibility lighting of wind turbines should employ only red, or dual red and white
19 strobe, strobe-like, or flashing lights, not steady burning lights.

20 5. Lighting at both operation and maintenance facilities and substations located within half
21 a mile of the turbines should be kept to the minimum required:

22 a. Use lights with motion or heat sensors and switches to keep lights off when
23 not required.

24 b. Lights should be hooded downward and directed to minimize horizontal and
25 skyward illumination.

26 c. Minimize use of high intensity lighting, steady-burning, or bright lights such
27 as sodium vapor, quartz, halogen, or other bright spotlights.

28 6. Remove wind turbines when they are no longer cost effective to retrofit.

1

2 **Repowering**

3 Repowering may include removal and replacement of turbines and associated infrastructure.

4 BMPs include:

- 5 1. To the greatest extent practicable, existing roads, disturbed areas and turbine strings
6 should be re-used in repower layouts.
- 7 2. Roads and facilities that are no longer needed should be demolished, removed, and their
8 footprint stabilized and re-seeded with native plants appropriate for the soil conditions
9 and adjacent habitat and of local seed sources where feasible, per landowner
10 requirements and commitments.
- 11 3. Existing substations and ancillary facilities should be re-used in repowering projects to
12 the extent practicable.
- 13 4. Existing overhead lines may be acceptable if located away from high bird crossing
14 locations, such as between roosting and feeding areas, or between lakes, rivers and
15 nesting areas. Overhead lines may be used when they parallel tree lines, employ bird
16 flight diverters, or are otherwise screened so that collision risk is reduced.
- 17 5. Above-ground low and medium voltage lines, transformers and conductors should follow
18 the 2006 or most recent APLIC “Suggested Practices for Avian Protection on Power
19 Lines.”
- 20 6. Guyed structures should be avoided. If use of guy wires is absolutely necessary, they
21 should be treated with bird flight diverters or high visibility marking devices, or are
22 located where known low bird use will occur.
- 23 7. FAA visibility lighting of wind turbines should employ only red, or dual red and white
24 strobe, strobe-like, or flashing lights, not steady burning lights.
- 25 8. Lighting at both operation and maintenance facilities and substations located within ½
26 mile of the turbines should be kept to the minimum required.
 - 27 a. Use lights with motion or heat sensors and switches to keep lights off when not
28 required.

- 1 b. Lights should be hooded downward and directed to minimize horizontal and skyward
2 illumination.
- 3 c. Minimize use of high intensity lighting, steady-burning, or bright lights such as
4 sodium vapor, quartz, halogen, or other bright spotlights.

5 ***Decommissioning***

6 Decommissioning is the cessation of wind energy operations and removal of all associated
7 equipment, roads, and other infrastructure. The land is then used for another activity. During
8 decommissioning, contractors and facility operators should apply BMPs for road grading and
9 native plant re-establishment to ensure that erosion and overland flows are managed to restore
10 pre-construction landscape conditions. The facility operator, in conjunction with the landowner
11 and state and federal wildlife agencies, should restore the natural hydrology and plant
12 community to the greatest extent practical.

13

- 14 1. Decommissioning methods should minimize new site disturbance and removal of native
15 vegetation, to the greatest extent practicable.
- 16 2. Foundations should be removed to a minimum of three feet below surrounding grade, and
17 covered with soil to allow adequate root penetration for native plants, and so that subsurface
18 structures do not substantially disrupt ground water movements. Three feet is typically
19 adequate for agricultural lands.
- 20 3. If topsoils are removed during decommissioning, they should be stockpiled and used as
21 topsoil when restoring plant communities. Once decommissioning activity is complete,
22 topsoils should be restored to assist in establishing and maintaining pre-construction native
23 plant communities to the extent possible, consistent with landowner objectives.
- 24 4. Soil should be stabilized and re-vegetated with native plants appropriate for the soil
25 conditions and adjacent habitat, and of local seed sources where feasible, consistent with
26 landowner objectives.
- 27 5. Surface water flows should be restored to pre-disturbance conditions, including removal of
28 stream crossings, roads, and pads, consistent with storm water management objectives and
29 requirements.

- 1 6. Surveys should be conducted by qualified experts to detect populations of invasive species,
2 and comprehensive approaches to preventing and controlling invasive species should be
3 implemented and maintained as long as necessary.
- 4 7. Overhead pole lines that are no longer needed should be removed.
- 5 8. After decommissioning, erosion control measures should be installed in all disturbance areas
6 where potential for erosion exists, consistent with storm water management objectives and
7 requirements.
- 8 9. Fencing should be removed unless the landowner will be utilizing the fence.
- 9 10. Petroleum product leaks and chemical releases should be remediated prior to completion of
10 decommissioning.

1 **Chapter 8: Mitigation**

2
3 Mitigation is defined in this document as avoiding or minimizing significant adverse impacts,
4 and when appropriate, compensating for unavoidable significant adverse impacts, as determined
5 through the tiered approach described in the recommended Guidelines. The Service places
6 emphasis in project planning on first avoiding, then minimizing, potential adverse impacts to
7 wildlife and their habitats. Several tools are available to determine appropriate mitigation,
8 including the Service Mitigation Policy (USFWS Mitigation Policy, 46 FR 7656 (1981)). The
9 Service policy provides a common basis for determining how and when to use different
10 mitigation strategies, and facilitates earlier consideration of wildlife values in wind energy
11 project planning.

12
13 CEQ issued guidance in February 2011 on compliance with the National Environmental Policy
14 Act (NEPA) entitled, "Appropriate Use of Mitigation and Monitoring and Clarifying the
15 Appropriate Use of Mitigated Findings of No Significant Impact." This new guidance clarifies
16 that when agencies premise their Finding of No Significant Impact on a commitment to mitigate
17 the environmental impacts of a proposed action, they should adhere to those commitments,
18 publicly report on those efforts, monitor how they are implemented, and monitor the
19 effectiveness of the mitigation.

20
21 To the extent that a federal nexus with a wind project exists, for example, developing a project
22 on federal lands or obtaining a federal permit, the lead federal action agency should make its
23 decision based in part on a developer's commitment to mitigate adverse environmental impacts.
24 The federal action agency should ensure that the developer adheres to those commitments,
25 monitors how they are implemented, and monitors the effectiveness of the mitigation.
26 Additionally, the lead federal action agency should make information on mitigation monitoring
27 available to the public through its web site; and should ensure that mitigation successfully
28 achieves its goals.

29
30 Under the Service Mitigation Policy, the highest priority is for mitigation to occur on-site within
31 the project planning area. The secondary priority is for the mitigation to occur off-site. Off-site

1 mitigation should first occur in proximity to the planning area within the same ecological region
2 and secondarily elsewhere within the same ecological region. Generally, the Service prefers on-
3 site mitigation over off-site mitigation because this approach most directly addresses project
4 impacts at the location where they actually occur. However, there may be individual cases
5 where off-site mitigation could result in greater net benefits to affected species and habitats.
6 Developers should work with the Service in comparing benefits among multiple alternatives.

7

8 In some cases, a project's effects cannot be forecast with precision. The developer and the
9 agencies may be unable to make some mitigation decisions until post-construction data have
10 been collected. If significant adverse effects have not been adequately addressed, additional
11 mitigation for those adverse effects from operations may need to be implemented.

12

13 Mitigation measures implemented post-construction, whether in addition to those implemented
14 pre-construction or whether they are new, are appropriate elements of the tiered approach. The
15 general terms and funding commitments for future mitigation and the triggers or thresholds for
16 implementing such compensation should be developed at the earliest possible stage in project
17 development. Any mitigation implemented after a project is operational should be well defined,
18 bounded, technically feasible, and commensurate with the project effects.

19

20 **Compensatory Mitigation**

21 Compensatory mitigation as defined in this document refers to replacement of project-induced
22 losses to fish and wildlife resources. Substitution or offsetting of fish and wildlife resource losses
23 with resources considered to be of equivalent biological value.

24 - **In-kind** – Providing or managing substitute resources to replace the value of the resources
25 lost, where such substitute resources are physically and biologically the same or closely
26 approximate to those lost.

27 - **Out-of-kind** – Providing or managing substitute resources to replace the value of the
28 resources lost, where such substitute resources are physically or biologically different from
29 those lost. This may include conservation or mitigation banking, research or other options.

30

1 The amount of compensation, if necessary, will depend on the effectiveness of any avoidance
2 and minimization measures undertaken. If a proposed wind development is poorly sited with
3 regard to wildlife effects, the most important mitigation opportunity is largely lost and the
4 remaining options can be expensive, with substantially greater environmental effects.

5

6 Compensation is most often appropriate for habitat loss under limited circumstances or for direct
7 take of wildlife (e.g., Habitat Conservation Plans). Compensatory mitigation may involve
8 contributing to a fund to protect habitat or otherwise support efforts to reduce existing impacts to
9 species affected by a wind project. Developers should communicate with the Service and state
10 agency prior to initiating such an approach.

11

12 Ideally, project impact assessment is a cooperative effort involving the developer, the Service,
13 tribes, local authorities, and state resource agencies. The Service does not expect developers to
14 provide compensation for the same habitat loss more than once. But the Service, state resource
15 agencies, tribes, local authorities, state and federal land management agencies may have different
16 species or habitats of concern, according to their responsibilities and statutory authorities.
17 Hence, one entity may seek mitigation for a different group of species or habitat than does
18 another.

19

20 **Migratory Birds and Eagles**

21 Some industries, such as the electric utilities, have developed operational and deterrent measures
22 that when properly used can avoid or minimize “take” of migratory birds. Many of these
23 measures to avoid collision and electrocution have been scientifically tested with publication in
24 peer-reviewed, scientific journals. The Service encourages the wind industry to use these
25 measures in siting, placing, and operating all power lines, including their distribution and grid-
26 connecting transmission lines.

27

28 E.O. 13186, which addresses responsibilities of federal agencies to protect migratory birds,
29 includes a directive to federal agencies to restore and enhance the habitat of migratory birds as
30 practicable. E.O. 13186 provides a basis and a rationale for compensating for the loss of

1 migratory bird habitat that results from developing wind energy projects that have a federal
2 nexus.

3

4 Regulations concerning eagle take permits in 50 CFR 22.26 and 50 CFR 22.27 may allow for
5 compensation as part of permit issuance. Compensation may be a condition of permit issuance
6 in cases of nest removal, disturbance or take resulting in mortality that will likely occur over
7 several seasons, result in permanent abandonment of one or more breeding territories, have large
8 scale impacts, occur at multiple locations, or otherwise contribute to cumulative negative effects.

9 The draft ECP Guidance has additional information on the use of compensation for
10 programmatic permits.

11

12 **Endangered Species**

13 The ESA has provisions that allow for compensation through the issuance of an Incidental Take
14 Permit (ITP). Under the ESA, mitigation measures are determined on a case by case basis, and
15 are based on the needs of the species and the types of effects anticipated. If a federal nexus
16 exists, or if a developer chooses to seek an ITP under the ESA, then effects to listed species need
17 to be evaluated through the Section 7 and/or Section 10 processes. If an ITP is requested, it and
18 the associated HCP must provide for minimization and mitigation to the maximum extent
19 practicable, in addition to meeting other necessary criteria for permit issuance. For further
20 information about compensation under federal laws administered by the Service, see the
21 Service's Habitat and Resource Conservation website <http://www.fws.gov/habitatconservation>.

1 **Chapter 9: Advancing Use, Cooperation and Effective Implementation**

2

3 This chapter discusses a variety of policies and procedures that may affect the way wind project
4 developers and the Service work with each other as well as with state and tribal governments and
5 non-governmental organizations. The Service recommends that wind project developers work
6 closely with field office staff for further elaboration of these policies and procedures.

7

8 **Conflict Resolution**

9 The Service and developers should attempt to resolve any issues arising from use of the
10 Guidelines at the Field Office level. Deliberations should be in the context of the intent of the
11 Guidelines and be based on the site-specific conditions and the best available data. However, if
12 there is an issue that cannot be resolved within a timely manner at the field level, the developer
13 and Service staff will coordinate to bring the matter up the chain of command in a stepwise
14 manner.

15

16 **Bird and Bat Conservation Strategies (BBCS)**

17 The Service has recommended that developers prepare written records of their actions to avoid,
18 minimize and compensate for potential adverse impacts. In the past, the Service has referred to
19 these as Avian and Bat Protection Plans (ABPP). However, ABPPs have more recently been
20 used for transmission projects and less for other types of development. For this reason the
21 Service is introducing a distinct concept for wind energy projects and calling them Bird and Bat
22 Conservation Strategies (BBCS).

23

24 Typically, a project-specific BBCS will explain the analyses, studies, and reasoning that support
25 progressing from one tier to the next in the tiered approach. A wind energy project-specific
26 BBCS is an example of a document or compilation of documents that describes the steps a
27 developer could or has taken to apply these Guidelines to mitigate for adverse impacts and
28 address the post-construction monitoring efforts the developer intends to undertake. A developer
29 may prepare a BBCS in stages, over time, as analysis and studies are undertaken for each tier. It
30 will also address the post-construction monitoring efforts for mortality and habitat effects, and
31 may use many of the components suggested in the Suggested Practices for Avian Protection on
32 Power Lines (APLIC 2006). Any Service review of, or discussion with a developer, concerning

1 its BBCS is advisory only, does not result in approval or disapproval of the BBCS by the
2 Service, and does not constitute a federal agency action subject to the National Environmental
3 Policy Act or other federal law applicable to such an action.

4

5 **Project Interconnection Lines**

6 The Guidelines are designed to address all elements of a wind energy facility, including the
7 turbine string or array, access roads, ancillary buildings, and the above- and below-ground
8 electrical lines which connect a project to the transmission system. The Service recommends
9 that the project evaluation include consideration of the wildlife- and habitat-related impacts of
10 these electrical lines, and that the developer include measures to reduce impacts of these lines,
11 such as those outlined in the Suggested Practices for Avian Protection on Power Lines (APLIC
12 2006). The Guidelines are not designed to address transmission beyond the point of
13 interconnection to the transmission system. The national grid and proposed smart grid system
14 are beyond the scope of these Guidelines.

15

16 **Confidentiality of Site Evaluation Process as Appropriate**

17 Some aspects of the initial pre-construction risk assessment, including preliminary screening and
18 site characterization, occur early in the development process, when land or other competitive
19 issues limit developers' willingness to share information on projects with the public and
20 competitors. Any consultation or coordination with agencies at this stage may include
21 confidentiality agreements.

22

23 **Collaborative Research**

24 Much uncertainty remains about predicting risk and estimating impacts of wind energy
25 development on wildlife. Thus there is a need for additional research to improve scientifically
26 based decision-making when siting wind energy facilities, evaluating impacts on wildlife and
27 habitats, and testing the efficacy of mitigation measures. More extensive studies are needed to
28 further elucidate patterns and test hypotheses regarding possible solutions to wildlife and wind
29 energy impacts.

30

1 It is in the interests of wind developers and wildlife agencies to improve these assessments to
2 better mitigate the impacts of wind energy development on wildlife and their habitats. Research
3 can provide data on operational factors (e.g. wind speed, weather conditions) that are likely to
4 result in fatalities. It could also include studies of cumulative impacts of multiple wind energy
5 projects, or comparisons of different methods for assessing avian and bat activity relevant to
6 predicting risk. Monitoring and research should be designed and conducted to ensure unbiased
7 data collection that meets technical standards such as those used in peer review. Research
8 projects may occur at the same time as project-specific Tier 4 and Tier 5 studies.

9

10 Research would usually result from collaborative efforts involving appropriate stakeholders, and
11 is not the sole or primary responsibility of any developer. Research partnerships (e.g., Bats and
12 Wind Energy Cooperative (BWEC)⁹, Grassland and Shrub Steppe Species Collaborative
13 (GS3C)¹⁰) involving diverse players will be helpful for generating common goals and objectives
14 and adequate funding to conduct studies (Arnett and Haufler 2003). The National Wind
15 Coordinating Collaborative (NWCC)¹¹, the American Wind Wildlife Institute (AWWI)¹², and the
16 California Energy Commission (CEC)'s Public Interest Energy Research Program¹³ all support
17 research in this area.

18

19 Study sites and access will be necessary to design and implement research, and developers are
20 encouraged to participate in these research efforts when possible. Subject to appropriations, the
21 Service also should fund priority research and promote collaboration and information sharing
22 among research efforts to advance science on wind energy-wildlife interactions, and to improve
23 these Guidelines.

24

25 **Service - State Coordination and Cooperation**

26 The Service encourages states to increase compatibility between state guidelines and these
27 voluntary Guidelines, protocols, data collection methods, and recommendations relating to
28 wildlife and wind energy. States that desire to adopt, or those that have formally adopted, wind

1 ⁹ www.batsandwind.org

2 ¹⁰ www.nationalwind.org

3 ¹¹ www.nationalwind.org

4 ¹² <http://www.awwi.org>

5 ¹³ <http://www.energy.ca.gov/research>

1 energy siting, permitting, or environmental review regulations or guidelines are encouraged to
2 cooperate with the Service to develop consistent state level guidelines. The Service may be
3 available to confer, coordinate and share its expertise with interested states when a state lacks its
4 own guidance or program to address wind energy-wildlife interactions. The Service will also use
5 states' technical resources as much as possible and as appropriate.

6
7 The Service will explore establishing a voluntary state/federal program to advance cooperation
8 and compatibility between the Service and interested state and local governments for coordinated
9 review of projects under both federal and state wildlife laws. The Service, and interested states,
10 will consider using the following tools to reach agreements to foster consistency in review of
11 projects:

- 12
- 13 • Cooperation agreements with interested state governments.
- 14
- 15 • Joint agency reviews to reduce duplication and increase coordination in project review.
- 16
- 17 • A communication mechanism:
 - 18 ▪ To share information about prospective projects
 - 19 ▪ To coordinate project review
 - 20 ▪ To ensure that state and federal regulatory processes, and/or mitigation
 - 21 requirements are being adequately addressed
 - 22 ▪ To ensure that species of concern and their habitats are fully addressed
 - 23
- 24 • Establishing consistent and predictable joint protocols, data collection methodologies,
25 and study requirements to satisfy project review and permitting.
- 26
- 27 • Designating a Service management contact within each Regional Office to assist Field
28 Offices working with states and local agencies to resolve significant wildlife-related
29 issues that cannot be resolved at the field level.
- 30

- 1 • Cooperative state/federal/industry research agreements relating to wind energy -wildlife
2 interactions.

3

4 The Service will explore opportunities to:

- 5 • Provide training to states.
6 • Foster development of a national geographic data base that identifies development-
7 sensitive ecosystems and habitats.
8 • Support a national database for reporting of mortality data on a consistent basis.
9 • Establish national BMPs for wind energy development projects.
10 • Develop recommended guidance on study protocols, study techniques, and measures and
11 metrics for use by all jurisdictions.
12 • Assist in identifying and obtaining funding for national research priorities.

13

14 Service - Tribal Consultation and Coordination

15 Federally-recognized Indian Tribes enjoy a unique government-to-government relationship with
16 the United States. The United States Fish and Wildlife Service (Service) recognizes Indian tribal
17 governments as the authoritative voice regarding the management of tribal lands and resources
18 within the framework of applicable laws. It is important to recall that many tribal traditional
19 lands and tribal rights extend beyond reservation lands.

20

21 The Service consults with Indian tribal governments under the authorities of Executive Order
22 13175 “Consultation and Coordination with Indian Tribal Governments” and supporting DOI
23 and Service policies. To this end, when it is determined that federal actions and activities may
24 affect a Tribe’s resources (including cultural resources), lands, rights, or ability to provide
25 services to its members, the Service must, to the extent practicable, seek to engage the affected
26 Tribe(s) in consultation and coordination.

27

28 ***Tribal Wind Energy Development on Reservation Lands***

29 Indian tribal governments have the authority to develop wind energy projects, permit their
30 development, and establish relevant regulatory guidance within the framework of applicable
31 laws.

1

2 The Service will provide technical assistance upon the request of Tribes that aim to establish
3 regulatory guidance for wind energy development for lands under the Tribe's jurisdiction. Tribal
4 governments are encouraged to strive for compatibility between their guidelines and these
5 Guidelines.

6

7 ***Tribal Wind Energy Development on Lands that are not held in Trust***

8 Indian tribal governments may wish to develop wind energy projects on lands that are not held in
9 trust status. In such cases, the Tribes should coordinate with agencies other than the Service. At
10 the request of a Tribe, the Service may facilitate discussions with other regulatory organizations.
11 The Service may also lend its expertise in these collaborative efforts to help determine the extent
12 to which tribal resource management plans and priorities can be incorporated into established
13 regulatory protocols.

14

15 ***Non-Tribal Wind Energy Development – Consultation with Indian Tribal Governments***

16 When a non-Tribal wind energy project is proposed that may affect a Tribe's resources
17 (including cultural resources), lands, rights, or ability to govern or provide services to its
18 members, the Service should seek to engage the affected Tribe(s) in consultation and
19 coordination as early as possible in the process. In siting a proposed project that has a federal
20 nexus, it is incumbent upon the regulatory agency to notify potentially affected Tribes of the
21 proposed activity. If the Service or other federal agency determines that a project may affect a
22 Tribe(s), they should notify the Tribe(s) of the action at the earliest opportunity. At the request
23 of a Tribe, the Service may facilitate and lend its expertise in collaborating with other
24 organizations to help determine the extent to which tribal resource management plans and
25 priorities can be incorporated into established regulatory protocols or project implementation.
26 This process ideally should be agreed to by all involved parties.

27

28 In the consultative process, Tribes should be engaged as soon as possible when a decision may
29 affect a Tribe(s). Decisions made that affect Indian Tribal governments without adequate federal
30 effort to engage Tribe(s) in consultation have been overturned by the courts. *See, e.g., Quechan*
31 *Tribe v. U.S. Dep't of the Interior*, No. 10cv2241 LAB (CAB), 2010 WL 5113197 (S.D. Cal.

1 Dec. 15, 2010). When a tribal government is consulted, it is neither required, nor expected that
2 all of the Tribe's issues can be resolved in its favor. However, the Service must listen and may
3 not arbitrarily dismiss concerns of the tribal government. Rather, the Service must seriously
4 consider and respond to all tribal concerns. Regional Native American Liaisons are able to
5 provide in-house guidance as to government-to-government consultation processes. (See Service
6 - State Coordination and Cooperation, above).

7

8 **Non-Governmental Organization Actions**

9 If a specific project involves actions at the local, state, or federal level that provide opportunities
10 for public participation, non-governmental organizations (NGOs) can provide meaningful
11 contributions to the discussion of biological issues associated with that project, through the
12 normal processes such as scoping, testimony at public meetings, and comment processes. In the
13 absence of formal public process, there are many NGOs that have substantial scientific
14 capabilities and may have resources that could contribute productively to the siting of wind
15 energy projects. Several NGOs have made significant contributions to the understanding of the
16 importance of particular geographic areas to wildlife in the United States. This work has
17 benefited and continues to benefit from extensive research efforts and from associations with
18 highly qualified biologists. NGO expertise can – as can scientific expertise in the academic or
19 private consulting sectors – serve highly constructive purposes. These can include:

20

- 21 • Providing information to help identify environmentally sensitive areas, during the
22 screening phases of site selection (Tiers 1 and 2, as described in this document)
- 23 • Providing feedback to developers and agencies with respect to specific sites and site and
24 impact assessment efforts
- 25 • Helping developers and agencies design and implement mitigation or offset strategies
- 26 • Participating in the defining, assessing, funding, and implementation of research efforts
27 in support of improved predictors of risk, impact assessments and effective responses
- 28 • Articulating challenges, concerns, and successes to diverse audiences

1 Non-Governmental Organization Conservation Lands

Implementation of these Guidelines by Service and other state agencies will recognize that lands owned and managed by non-government conservation organizations represent a significant investment that generally supports the mission of state and federal wildlife agencies. Many of these lands represent an investment of federal conservation funds, through partnerships between agencies and NGOs. These considerations merit extra care in the avoidance of wind energy development impacts to these lands. In order to exercise this care, the Service and allied agencies can coordinate and consult with NGOs that own lands or easements which might reasonably be impacted by a project under review.

1 **Appendix A: Glossary**

2

3 **Accuracy** – The agreement between a measurement and the true or correct value.

4

5 **Adaptive management** – An iterative decision process that promotes flexible decision-making
6 that can be adjusted in the face of uncertainties as outcomes from management actions and other
7 events become better understood. Comprehensively applying the tiered approach embodies the
8 adaptive management process.

9

10 **Anthropogenic** – Resulting from the influence of human beings on nature.

11

12 **Area of interest** – For most projects, the area where wind turbines and meteorological (met)
13 towers are proposed or expected to be sited, and the area of potential impact.

14

15 **Avian** – Pertaining to or characteristic of birds.

16

17 **Avoid** – To not take an action or parts of an action to avert the potential effects of the action or
18 parts thereof. First of three components of “mitigation,” as defined in Service Mitigation Policy.
19 (See **mitigation**.)

20

21 **Before-after/control-impact (BACI)** – A study design that involves comparisons of
22 observational data, such as bird counts, before and after an environmental disturbance in a
23 disturbed and undisturbed site. This study design allows a researcher to assess the effects of
24 constructing and operating a wind turbine by comparing data from the “control” sites (before and
25 undisturbed) with the “treatment” sites (after and disturbed).

26

27 **Best management practices (BMPs)** – Methods that have been determined by the stakeholders
28 to be the most effective, practicable means of avoiding or minimizing significant adverse impacts
29 to individual species, their habitats or an ecosystem, based on the best available information.

30

31 **Buffer zone** – A zone surrounding a resource designed to protect the resource from adverse
32 impact, and/or a zone surrounding an existing or proposed wind energy project for the purposes
33 of data collection and/or impact estimation.

34

35 **Community-scale** – Wind energy projects greater than 1 MW, but generally less than 20 MW,
36 in name-plate capacity, that produce electricity for off-site use, often partially or totally owned
37 by members of a local community or that have other demonstrated local benefits in terms of
38 retail power costs, economic development, or grid issues.

39

40 **Comparable site** – A site similar to the project site with respect to topography, vegetation, and
41 the species under consideration.

42

43 **Compensatory mitigation** – Replacement of project-induced losses to fish and wildlife
44 resources. Substitution or offsetting of fish and wildlife resource losses with resources
45 considered to be of equivalent biological value.

- 1 - **In-kind** – Providing or managing substitute resources to replace the value of the resources
2 lost, where such substitute resources are physically and biologically the same or closely
3 approximate to those lost.
- 4 - **Out-of-kind** – Providing or managing substitute resources to replace the value of the
5 resources lost, where such substitute resources are physically or biologically different from
6 those lost. This may include conservation or mitigation banking, research or other options.
7
- 8 **Cost effective** – Economical in terms of tangible benefits produced by money spent.
9
- 10 **Covariate** – Uncontrolled random variables that influence a response to a treatment or impact,
11 but do not interact with any of the treatments or impacts being tested.
12
- 13 **Critical habitat** – For listed species, consists of the specific areas designated by rule making
14 pursuant to Section 4 of the Endangered Species Act and displayed in 50 CFR § 17.11 and 17.12.
15
- 16 **Cumulative impacts** – *See impact.*
- 17
- 18 **Curtailement** – The act of limiting the supply of electricity to the grid during conditions when it
19 would normally be supplied. This is usually accomplished by cutting-out the generator from the
20 grid and/or feathering the turbine blades.
21
- 22 **Cut-in Speed** – The wind speed at which the generator is connected to the grid and producing
23 electricity. It is important to note that turbine blades may rotate at full RPM in wind speeds
24 below cut-in speed.
25
- 26 **Displacement** – The loss of habitat as result of an animal’s behavioral avoidance of otherwise
27 suitable habitat. Displacement may be short-term, during the construction phase of a project,
28 temporary as a result of habituation, or long-term, for the life of the project.
- 29 **Distributed wind** – Small and mid-sized turbines between 1 kilowatt and 1 megawatt that are
30 installed and produce electricity at the point of use to off-set all or a portion of on-site energy
31 consumption.
- 32 **Ecosystem** – A system formed by the interaction of a community of organisms with their
33 physical and chemical environment. All of the biotic elements (i.e., species, populations, and
34 communities) and abiotic elements (i.e., land, air, water, energy) interacting in a given
35 geographic area so that a flow of energy leads to a clearly defined trophic structure, biotic
36 diversity, and material cycles. Service Mitigation Policy adopted definition from E. P. Odum
37 1971 *Fundamentals of Ecology*.
38
- 39 **Edge effect** – The effect of the juxtaposition of contrasting environments on an ecosystem.
40
- 41 **Endangered species** – *See listed species.*
42
- 43 **Extirpation** – The species ceases to exist in a given location; the species still exists elsewhere.
44

- 1 **Fatality** – An individual instance of death.
2
- 3 **Fatality rate** – The ratio of the number of individual deaths to some parameter of interest such
4 as megawatts of energy produced, the number of turbines in a wind project, the number of
5 individuals exposed, etc., within a specified unit of time.
6
- 7 **Feathering** – Adjusting the angle of the rotor blade parallel to the wind, or turning the whole
8 unit out of the wind, to slow or stop blade rotation.
9
- 10 **Federal action agency** – A department, bureau, agency or instrumentality of the United States
11 which plans, constructs, operates or maintains a project, or which reviews, plans for or approves
12 a permit, lease or license for projects, or manages federal lands.
13
- 14 **Federally listed species** – *See listed species.*
15
- 16 **Footprint** – The geographic area occupied by the actual infrastructure of a project such as wind
17 turbines, access roads, substation, overhead and underground electrical lines, and buildings, and
18 land cleared to construct the project.
19
- 20 **G1 (Global Conservation Status Ranking) Critically Imperiled** – At very high risk of
21 extinction due to extreme rarity (often five or fewer populations), very steep declines, or other
22 factors.
23
- 24 **G2 (Global Conservation Status Ranking) Imperiled** – At high risk of extinction or
25 elimination due to very restricted range, very few populations, steep declines, or other factors.
26
- 27 **G3 (Global Conservation Status Ranking) Vulnerable** – At moderate risk of extinction or
28 elimination due to a restricted range, relatively few populations, recent and widespread declines,
29 or other factors.
30
- 31 **Guy wire** – Wires used to secure wind turbines or meteorological towers that are not self-
32 supporting.
33
- 34 **Habitat** – The area which provides direct support for a given species, including adequate food,
35 water, space, and cover necessary for survival.
36
- 37 **Habitat fragmentation** – Habitat fragmentation separates blocks of habitat for some species into
38 segments, such that the individuals in the remaining habitat segments may suffer from effects
39 such as decreased survival, reproduction, distribution, or use of the area.
40
- 41 **Impact** – An effect or effects on natural resources and on the components, structures, and
42 functioning of affected ecosystems.
- 43 - **Cumulative** – Changes in the environment caused by the aggregate of past, present and
44 reasonably foreseeable future actions on a given resource or ecosystem.
 - 45 - **Direct** – Effects on individual species and their habitats caused by the action, and occur at
46 the same time and place.

- 1 - **Indirect impact** – Effects caused by the action that are later in time or farther removed in
2 distance, but are still reasonably foreseeable. Indirect impacts include displacement and
3 changes in the demographics of bird and bat populations.
4
- 5 **Infill** – Add an additional phase to the existing project, or build a new project adjacent to
6 existing projects.
7
- 8 **In-kind compensatory mitigation** – See **compensatory mitigation**.
9
- 10 **Intact habitat** – An expanse of habitat for a species or landscape scale feature, unbroken with
11 respect to its value for the species or for society.
12
- 13 **Intact landscape** – Relatively undisturbed areas characterized by maintenance of most original
14 ecological processes and by communities with most of their original native species still present.
15
- 16 **Lattice design** – A wind turbine support structure design characterized by horizontal or diagonal
17 lattice of bars forming a tower rather than a single tubular support for the nacelle and rotor.
18
- 19 **Lead agency** – Agency that is responsible for federal or non-federal regulatory or environmental
20 assessment actions.
21
- 22 **Lek** – A traditional site commonly used year after year by males of certain species of birds (e.g.,
23 greater and lesser prairie-chickens, sage and sharp-tailed grouse, and buff-breasted sandpiper),
24 within which the males display communally to attract and compete for female mates, and where
25 breeding occurs.
26
- 27 **Listed species** – Any species of fish, wildlife or plant that has been determined to be endangered
28 or threatened under section 4 of the Endangered Species Act (50 CFR §402.02), or similarly
29 designated by state law or rule.
30
- 31 **Local population** – A subdivision of a population of animals or plants of a particular species
32 that is in relative proximity to a project.
33
- 34 **Loss** – As used in this document, a change in wildlife habitat due to human activities that is
35 considered adverse and: 1) reduces the biological value of that habitat for species of concern; 2)
36 reduces population numbers of species of concern; 3) increases population numbers of invasive
37 or exotic species; or 4) reduces the human use of those species of concern.
38
- 39 **Megawatt (MW)** – A measurement of electricity-generating capacity equivalent to 1,000
40 kilowatts (kW), or 1,000,000 watts.
41
- 42 **Migration** – Regular movements of wildlife between their seasonal ranges necessary for
43 completion of the species lifecycle.
44
- 45 **Migration corridor** – Migration routes and/or corridors are the relatively predictable pathways
46 that a migratory species travel between seasonal ranges, usually breeding and wintering grounds.

- 1
2 **Migration stopovers** – Areas where congregations of wildlife assemble during migration. Such
3 areas supply high densities of food or shelter.
- 5 **Minimize** – To reduce to the smallest practicable amount or degree.
6
- 7 **Mitigation** – (*Specific to these Guidelines*) Avoiding or minimizing significant adverse impacts,
8 and when appropriate, compensating for unavoidable significant adverse impacts.
9
- 10 **Monitoring** – 1) A process of project oversight such as checking to see if activities were
11 conducted as agreed or required; 2) making measurements of uncontrolled events at one or more
12 points in space or time with space and time being the only experimental variable or treatment; 3)
13 making measurements and evaluations through time that are done for a specific purpose, such as
14 to check status and/or trends or the progress towards a management objective.
15
- 16 **Mortality rate** – Population death rate, typically expressed as the ratio of deaths per 100,000
17 individuals in the population per year (or some other time period).
18
- 19 **Operational changes** – Deliberate changes to wind energy project operating protocols, such as
20 the wind speed at which turbines “cut in” or begin generating power, undertaken with the object
21 of reducing collision fatalities. Considered separately from standard mitigation measures due to
22 the fact that operational changes are considered as a last resort and will rarely be implemented if
23 a project is properly sited.
24
- 25 **Passerine** – Describes birds that are members of the Order *Passeriformes*, typically called
26 “songbirds.”
27
- 28 **Plant communities of concern** – Plant communities of concern are unique habitats that are
29 critical for the persistence of highly specialized or unique species and communities of organisms.
30 Often restricted in distribution or represented by a small number of examples, these communities
31 are biological hotspots that significantly contribute to the biological richness and productivity of
32 the entire region. Plant communities of concern often support rare or uncommon species
33 assemblages, provide critical foraging, roosting, nesting, or hibernating habitat, or perform vital
34 ecosystem functions. These communities often play an integral role in the conservation of
35 biological integrity and diversity across the landscape. (Fournier et al. 2007) Also, any plant
36 community with a Natural Heritage Database ranking of S1, S2, S3, G1, G2, or G3.
37
- 38 **Population** – A demographically and genetically self-sustaining group of animals and/or plants
39 of a particular species.
40
- 41 **Practicable** – Capable of being done or accomplished; feasible.
42
- 43 **Prairie grouse** – A group of gallinaceous birds, includes the greater prairie-chicken, the lesser
44 prairie-chicken, and the sharp-tailed grouse.
45

- 1 **Project area** – The area that includes the project site as well as contiguous land that shares
2 relevant characteristics.
3
- 4 **Project commencement** – The point in time when a developer begins its preliminary evaluation
5 of a broad geographic area to assess the general ecological context of a potential site or sites for
6 wind energy project(s). For example, this may include the time at which an option is acquired to
7 secure real estate interests, an application for federal land use has been filed, or land has been
8 purchased.
9
- 10 **Project Site** – The land that is included in the project where development occurs or is proposed
11 to occur.
12
- 13 **Project transmission lines** – Electrical lines built and owned by a project developer.
14
- 15 **Raptor** – As defined by the American Ornithological Union, a group of predatory birds
16 including hawks, eagles, falcons, osprey, kites, owls, vultures and the California condor.
17
- 18 **Relative abundance** – The number of organisms of a particular kind in comparison to the total
19 number of organisms within a given area or community.
20
- 21 **Risk** – The likelihood that adverse effects may occur to individual animals or populations of
22 species of concern, as a result of development and operation of a wind energy project. For
23 detailed discussion of risk and risk assessment as used in this document see Chapter One -
24 General Overview.
25
- 26 **Rotor** – The part of a wind turbine that interacts with wind to produce energy. Consists of the
27 turbine's blades and the hub to which the blades attach.
28
- 29 **Rotor-swept area** – The area of the circle or volume of the sphere swept by the turbine blades.
30
- 31 **Rotor-swept zone** – The altitude within a wind energy project which is bounded by the upper
32 and lower limits of the rotor-swept area and the spatial extent of the project.
33
- 34 **S1 (Subnational Conservation Status Ranking) Critically Imperiled** – Critically imperiled in
35 the jurisdiction because of extreme rarity or because of some factor(s) such as very steep
36 declines making it especially vulnerable to extirpation from the jurisdiction.
37
- 38 **S2 (Subnational Conservation Status Ranking) Imperiled** – Imperiled in the jurisdiction
39 because of rarity due to very restricted range, very few populations, steep declines, or other
40 factors making it very vulnerable to extirpation from jurisdiction.
41
- 42 **S3 (Subnational Conservation Status Ranking) Vulnerable** – Vulnerable in the jurisdiction
43 due to a restricted range, relatively few populations, recent and widespread declines, or other
44 factors making it vulnerable to extirpation.
45

- 1 **Sage grouse** – A large gallinaceous bird living in the sage steppe areas of the intermountain
2 west, includes the greater sage grouse and Gunnison’s sage grouse.
3
- 4 **Significant** – For purposes of characterizing impacts to species of concern and their habitats,
5 “significance” takes into account the duration, scope, and intensity of an impact. Impacts that
6 are very brief or highly transitory, do not extend beyond the immediate small area where they
7 occur, and are minor in their intensity are not likely to be significant. Conversely, those that
8 persist for a relatively long time, encompass a large area or extend well beyond the immediate
9 area where they occur, or have substantial consequences are almost certainly significant. A
10 determination of significance may include cumulative impacts of other actions. There is
11 probably some unavoidable overlap among these three characteristics, as well as some inherent
12 ambiguity in these terms, requiring the exercise of judgment and the development of a consistent
13 approach over time.
14
- 15 **Species of concern** – For a particular wind energy project, any species which 1) is either a) listed
16 as an endangered, threatened or candidate species under the Endangered Species Act, subject to
17 the Migratory Bird Treaty Act or Bald and Golden Eagle Protection Act; b) is designated by law,
18 regulation, or other formal process for protection and/or management by the relevant agency or
19 other authority; or c) has been shown to be significantly adversely affected by wind energy
20 development, and 2) is determined to be possibly affected by the project.
21
- 22 **Species of habitat fragmentation concern**—Species of concern for which a relevant federal,
23 state, tribal, and/or local agency has found that separation of their habitats into smaller blocks
24 reduces connectivity such that the individuals in the remaining habitat segments may suffer from
25 effects such as decreased survival, reproduction, distribution, or use of the area. Habitat
26 fragmentation from a wind energy project may create significant barriers for such species.
27
- 28 **String** – A number of wind turbines oriented in close proximity to one another that are usually
29 sited in a line, such as along a ridgeline.
30
- 31 **Strobe** – Light consisting of pulses that are high in intensity and short in duration.
32
- 33 **Threatened species** – *See listed species.*
34
- 35 **Tubular design** – A type of wind turbine support structure for the nacelle and rotor that is
36 cylindrical rather than lattice.
37
- 38 **Turbine height** – The distance from the ground to the highest point reached by the tip of the
39 blades of a wind turbine.
- 40 **Utility-scale** – Wind projects generally larger than 20 MW in nameplate generating capacity that
41 sell electricity directly to utilities or into power markets on a wholesale basis.
- 42 **Voltage (low and medium)** – Low voltages are generally below 600 volts, medium voltages are
43 commonly on distribution electrical lines, typically between 600 volts and 110 kV, and voltages
44 above 110 kV are considered high voltages.

10
11

Wildlife – Birds, fishes, mammals, and all other classes of wild animals and all types of aquatic and land vegetation upon which wildlife is dependent.

Wildlife management plan – A document describing actions taken to identify resources that may be impacted by proposed development; measures to mitigate for any significant adverse impacts; any post-construction monitoring; and any other studies that may be carried out by the developer.

Wind turbine – A machine for converting the kinetic energy in wind into mechanical energy, which is then converted to electricity.
