As acknowledged in the response to Question 12 comments on the previous BES definition, the BES definition is expansive compared to the definition of the BPS in the FPA Section 215. The inclusion of the limited Exclusions is an attempt to remedy the situation. However, the Exclusions need to include a fifth one that if, based on studies or other assessments, it can be shown that any transmission or generator element otherwise identified as part of the BES is not important to the reliability of the BPS, then that element should be excluded from the mandatory standards program. There has never been a study to show that elements, such as a 20 MW wind farm, 60 MW merchant generator (which operates infrequently in the depressed market) in a large BA (eg NYISO) or a radial transmission line connecting a small generator are important to the reliability of the BPS. They are covered by the mandatory standards program through the registration criteria. The BES Definition is the opportunity to permit an entity to demonstrate that an element is unimportant to reliability of the BPS. The SDT has identified a small subset of elements that it is willing to exclude. By their very nature, these exclusions dim the bright line that is the stated goal of this project. However, the SDT's foresight seems limited in its selections. Analytical studies are used to evaluate contingencies that could lead to

the Big Three (cascading outages, instability or voltage collapse). Such a study showing that a transmission or generation element is bounded by the N-1 or N-2 contingency would exclude it from the BES definition. For example, in a BA with a NERC definition Reportable Disturbance of approximately 400 MW (eg NYISO), a 20 MW wind farm, 60 MW merchant generator or numerous other smaller facilities would be bounded by larger contingencies. It would take more than six 60 MW merchant generators with close location and common mode failure to even be a Reportable Disturbance, much less become the N-1 contingency for the Big Three. Exclusion E5 should be "E5 - Any facility that can be demonstrated to the Regional Entity by analytical study or other assessment to be unimportant to the reliability of the BPS (with periodic reports by the Regional Entity to NERC of any such assessments)."

Yes

As acknowledged in the response to Question 12 comments on the previous BES definition, the BES definition is expansive compared to the definition of the BPS in the FPA Section 215. The inclusion of the limited Exclusions is an attempt to remedy the situation. Tacoma Power

Yes

Tacoma Power supports the instructions as written.

Yes

Tacoma Power supports the information requested on page 2 and 3.

Yes

Tacoma Power supports the information requested on page 4.

No

Tacoma Power supports the expectation that entities will be able to supply the information requested.

No

Tacoma Power does not know of any characteristics to add at this time.

No

Tacoma Power is not aware of any conflicts at this time.

Yes

Tacoma Power has a concern that the form may be too general in nature. The task before NERC and the industry is to promote consistency in the application of the BES definition. The form will require the regions to develop individual criteria for assessing an exception request and making a recommendation on the request. We recommend in Phase 2 that the SDT develop specific evaluation criteria for the regions to apply to an exception request. Thank you for consideration of our comments.

The requirement to base flow studies on an "interconnection-wide base case" is likely to include many more lines and buses than necessary to model the impact of a facility that is not material to the BES. MPPA and its members request the words "or regional reduction of such a case" be added after "interconnection-wide base case" to avoid unnecessary expense and detail if a more limited study set is adequate to demonstrate the lack of material impact of the facility(ies) in question.
Yes
Yes
Yes
On Page 4 Question 1, information on the host Balancing Authority's most severe single contingency may not be publically available and therefore difficult or impossible for a smaller entity to obtain. Even if the data is available, it may not be meaningful in a larger Balancing Authority area such as within MISO where the most severe contingency may be geographically and electrically remote. A more readily available and meaningful measure would be a comparison of the generator's capability as a percent of the peak load for the local Balancing Authority or sub-Balancing Authority, as applicable.
No
No
Yes
The following revisions should be made to the procedures: 1. The Technical Review Panel (TRP) provided for in Section 5.3 should not include any staff from the host Regional Entity. 2. The Regional Entity should be required to include an attestation of a qualified individual or individuals to support the factual and technical bases for the decision. This is necessary for purposes of establishing a record in the event of an appeal. If a dispute is appealed, there must be someone at the Regional Entity level that serves as the witness supporting the Regional Entity decision. Currently, there is no accountability for the arguments and suppositions put forth by the Regional Entity; no individuals that stand behind the technical bases proffered in the Regional Entity's written decision. Requiring a qualified individual to attest to the facts and technical arguments relied upon in arriving at the decision will ensure that someone at the Regional Entity level is prepared to take responsibility for reviewing a decision before it is issued, to stand behind the assertions and conclusions reached by the Regional Entity, and whom the Submitting Party may cross examine at hearing. 3. A party seeking an exception should have the right to request a hearing and should not be limited to a paper process. 4. The procedures should not permit the TRP or the Regional Entity to make a decision based upon information that is outside of the record placed before it. That is, the TRP and the Regional Entity may not, on their own, conduct an investigation or seek information independently from what has been presented to it. If the TRP or the Regional Entity requires additional information, it must be requested and provided transparently, and the Submitting Party must have an opportunity to comment upon or challenge that information before the TRP or the Regional Entity relies upon it in any way. This is not currently happening at the Regional Entity and NERC level – decisions have been made based upon

documents and information that are not part of the record; the information is not shared with the Submitting Party (the party challenging registration) prior to (or after) a decision is made. 5. Section 5.2.2. should be revised as follows: "Upon Acceptance of the Exception Request, the Regional Entity and Submitting Party (and Owner, if different) shall confer to establish milestones in order to complete the substantive review of the Exception Request within six months after Acceptance of the Exception Request or within an alternative time period under Section 5.0. The Regional Entity and the Submitting Party (and Owner, if different) shall also discuss whether and to what extent a reduced compliance burden is appropriate during the review period. At the conclusion of the review period, the Regional Entity shall issue a notice (in accordance with Sections 5.2.3) stating its Recommendation that the Exception Request be approved or disapproved."

#### Additional Comments Submitted: Salt River Project

##### Detailed Information to Support BES Exceptions Request:

SRP agrees with the WECC Staff recommendation on the "Detailed Information to Support BES Exceptions Request."

*"WECC Staff believes that the proposed Technical Principles for Demonstrating BES Exceptions Request does not provide the necessary clarity as to what applying entities must provide to support their request, nor does it provide any criteria for consistency among regions in their assessment of requests. We believe that the checklist items for transmission and generation facilities are appropriate questions that must be answered in considering all requests. However, without objective criteria defining what must be submitted and how to assess the materials submitted, the current methodology leaves it to each region to develop their own methodology and criteria for evaluating the submittals. We believe the lack of clarity regarding what studies must be submitted and what must be demonstrated by the studies submitted will be overly burdensome on the submitting entity and the*

*Region, as multiple studies may be required for the two to agree that there is sufficient justification for an exemption request.*

*We believe that additional work is necessary to develop clear, objective methods and criteria for identifying which facilities may be excluded from or should be included in the Bulk Electric System. Clear, objective methods and criteria will enable the submitter of requests to understand what is necessary for submitting an exception request and will provide for consistency among the regions in their initial assessment and recommendations to the ERO."*

# Consideration of Comments on Initial Ballot Project 2010-17 BES Technical Exceptions

Date of Initial Ballot: September 30 – October 10, 2011

**Summary Consideration:** Many commenters followed instructions and cast their ballot while simply pointing to their detailed comments in the posted comment report. The SDT thanks those commenters as this greatly reduces the administrative workload on the SDT. Those who decided to place comments in the ballot report for the most part echoed comments that had already been seen by the SDT in the posted comment report which was administered first by the SDT. As a result, there were no changes to the definition due to comments received in the ballot report. However, for ease of reference, the changes to the definition made as a result of those comments are repeated here.

The SDT made the following changes to the request form due to industry comments received:

- **General** – Clarified the use of facility versus Element(s).
- **Page 1** – Deleted ‘s’ : List any attached supporting documents and any additional information that is included to support ts the request:
- **Generation - Q1.** Replaced ‘generator’s or generator’s facility’ with ‘generation resource’: What is the MW value of the host Balancing Authority’s most severe single Contingency and what is the generator’s, or generator facility’s generation resource’s, percent of this value?
- **Generation - Q2.** Replaced ‘generator’s or generator’s facility’ with ‘generation resource’: Is the generator or generator facility generation resource used to provide reliability-related Ancillary Services?
- **Generation - Q3.** Replaced ‘generator’s or generator’s facility’ with ‘generation resource’: Is the generator-generation resource designated as a must run unit for reliability?

The SDT feels that it is important to remind the industry that Phase II of this project will begin immediately after the conclusion of Phase I as SDT resources clear up. The same SDT will follow through with Phase II.

The SDT is recommending that this project be moved forward to the recirculation ballot stage.

There were two comments that were repeated multiple times throughout the various documents. The first topic was about how to sort through the definition inclusions and exclusions, i.e., which takes precedence. The SDT offers this guidance on that issue:

The application of the draft 'bright-line' BES definition is a three (3) step process that when appropriately applied will identify the vast majority of BES Elements in a consistent manner that can be applied on a continent-wide basis.

Initially, the BES 'core' definition is used to establish the bright-line of 100 kV, which is the overall demarcation point between BES and non-BES Elements. Additionally, the 'core' definition identifies the Real Power and Reactive Power resources connected at 100 kV or higher as included in the BES. To fully appreciate the scope of the 'core' definition an understanding of the term Element is needed. Element is defined in the NERC Glossary of Terms as:

"Any electrical device with terminals that may be connected to other electrical devices such as a generator, transformer, circuit breaker, bus section, or transmission line. An element may be comprised of one or more components. "

Element is basically any electrical device that is associated with the transmission or the generation (generating resources) of electric energy.

Step two (2) provides additional clarification for the purposes of identifying specific Elements that are included through the application of the 'core' definition. The Inclusions address transmission Elements and Real Power and Reactive Power resources with specific criteria to provide for a consistent determination of whether an Element is classified as BES or non-BES.

Step three (3) is to evaluate specific situations for potential exclusion from the BES (classification as non-BES Elements). The exclusion language is written to specifically identify Elements or groups of Elements for potential exclusion from the BES.

Exclusion E1 provides for the exclusion of 'transmission Elements' from radial systems that meet the specific criteria identified in the exclusion language. This does not include the exclusion of Real Power and Reactive Power resources captured by Inclusions I2 – I5. The exclusion (E1) only speaks to the transmission component of the radial system. Similarly, Exclusion E3 (local networks) should be applied in the same manner. Therefore, the only inclusion that Exclusions E1 and E3 supersede is Inclusion I1.

Exclusion E2 provides for the exclusion of the Real Power resources that reside behind the retail meter (on the customer's side) and supersedes inclusion I2.

Exclusion E4 provides for the exclusion of retail customer owned and operated Reactive Power devices and supersedes Inclusion I5.

In the event that the BES definition incorrectly designates an Element as BES that is not necessary for the reliable operation of the interconnected transmission network or an Element as non-BES that is necessary for the reliable operation of the interconnected transmission network, the Rules of Procedure exception process may be utilized on a case-by-case basis to either include or exclude an Element.

The second item is about providing specific guidance on how the information on the exception request form will be used in making decisions on inclusions/exclusions in the exception process. The SDT provides the following information on this item:

The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. If the SDT could have come up with the simple answer, it would have been supplied within the bright-line. The SDT would also like to point out to the commenters that it directly solicited assistance in this matter in the first posting of the criteria and received very little in the form of substantive comments. There are so many individual variables that will apply to specific cases that there is no way to cover everything up front. There are always going to be extenuating circumstances that will influence decisions on individual cases. One could take this statement to say that the regional discretion hasn't been removed from the process as dictated in the Order. However, the SDT disagrees with this position. The exception request form has to be taken in concert with the changes to the ERO Rules of Procedure and looked at as a single package. When one looks at the rules being formulated for the exception process, it becomes clear that the role of the Regional Entity has been drastically reduced in the proposed revision. The role of the Regional Entity is now one of reviewing the submittal for completion and making a recommendation to the ERO Panel, not to make the final determination. The Regional Entity plays no role in actually approving or rejecting the submittal. It simply acts as an intermediary. One can counter that this places the Regional Entity in a position to effectively block a submittal by being arbitrary as to what information needs to be supplied. In addition, the SDT believes that the visibility of the process would belie such an action by the Regional Entity and also believes that one has to have faith in the integrity of the Regional Entity in such a process. Moreover, Appendix 5C of the proposed NERC Rules of Procedure, Sections 5.1.5, 5.3, and 5.2.4, provide an added level of protection requiring an independent Technical Review Panel assessment where a Regional Entity decides to reject or disapprove an exception request. This panel's findings become part of the exception request record submitted to NERC. Appendix 5C of the proposed NERC Rules of Procedure, Section 7.0, provides NERC the option to remand the request to the Regional Entity with the mandate to process the exception if it finds the Regional Entity erred in rejecting or disapproving the exception request. On the other side of this equation, one could make an argument that the Regional Entity has no basis for what constitutes an acceptable submittal. Commenters point out that the explicit types of studies to be provided and how to interpret the information aren't shown in the request process. The SDT again points to the variations that will abound in the requests as negating any hard and fast rules in this regard. However, one is not dealing with amateurs here. This is not something that hasn't been handled before by either party and there is a great deal of professional experience involved on both the submitter's and the Regional Entity's side of this equation. Having viewed the request details, the SDT believes that both sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to travel upward to the ERO Panel for adjudication.

Now, the commenters could point to lack of direction being supplied to the ERO Panel as to specific guidelines for them to follow in making their decision. The SDT re-iterates the problem with providing such hard and fast rules. There are just too many variables to take into account. Providing concrete guidelines is going to tie the hands of the ERO Panel and inevitably result in bad decisions being made. The SDT also refers the commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.1 where the basic premise on evaluating an exception request must be based on whether the Elements are necessary for the reliable operation of the interconnected transmission system. Further,

reliable operation is defined in the Rules of Procedure as operating the elements of the bulk power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cyber security incident, or unanticipated failure of system elements. The SDT firmly believes that the technical prowess of the ERO Panel, the visibility of the process, and the experience gained by having this same panel review multiple requests will result in an equitable, transparent, and consistent approach to the problem. The SDT would also point out that there are options for a submitting entity to pursue that are outlined in the proposed ERO Rules of Procedure changes if they feel that an improper decision has been made on their submittal.

Some commenters have asked whether a single ‘yes’ or ‘no’ response to an item on the exception request form will mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.2 of the proposed Rules of Procedure that states “No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved.”

The SDT would like to point out several changes made to the specific items in the form that were made in response to industry comments. The SDT believes that these clarifications will make the process tighter and easier to follow and improve the quality of the submittals.

Finally, the SDT would point to the draft SAR for Phase II of this project that calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. Given the complexity of the technical aspects of this problem and the filing deadline that the SDT is working under for Phase I of this project, the SDT believes that it has developed a fair and equitable method of approaching this difficult problem. The SDT asks the commenter to consider all of these facts in making your decision and casting your ballot and hopes that these changes will result in a favorable outcome.

If you feel that the drafting team overlooked your comments, please let us know immediately. Our goal is to give every comment serious consideration in this process. If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herb Schrayshuen, at 404-446-2560 or at [herb.schrayshuen@nerc.net](mailto:herb.schrayshuen@nerc.net). In addition, there is a NERC Reliability Standards Appeals Process.<sup>1</sup>

---

<sup>1</sup> The appeals process is in the Standards Processes Manual: [http://www.nerc.com/docs/standards/sc/Standard\\_Processes\\_Manual\\_Approved\\_May\\_2010.pdf](http://www.nerc.com/docs/standards/sc/Standard_Processes_Manual_Approved_May_2010.pdf).

Stuart Sloan	Consumers Power Inc.	1	Affirmative	Please see CPI's separate comment form.
<p><b>Response:</b> The SDT thanks you for following the instructions with regard to comments. This greatly reduces the administrative burden for the SDT and will help accelerate the process.</p>				
Paul Morland	Colorado Springs Utilities	1	Negative	Colorado Springs Utilities believes that the proposed Technical Information to Support BES Exceptions Request does not provide the necessary clarity as to what applying entities must provide to support their request. We believe that the checklist items for transmission and generation facilities are appropriate questions that must be answered in considering all requests. We believe the lack of clarity regarding what studies must be submitted and what must be demonstrated by the

Voter	Entity	Segment	Vote	Comment
				<p>studies submitted will be overly burdensome on our staff. We believe that additional work is necessary to develop clear, objective methods and criteria for identifying which facilities may be excluded from or should be included in the Bulk Electric System. Clear, objective methods and criteria will enable us to understand what is necessary for submitting an exception request.</p> <p>To allow sufficient time to complete this difficult task, we believe that the Detailed Information to Support BES Exceptions Request should not be part of the Phase 1 Bulk Electric System Definition effort, but should be postponed and included in the Phase 2 effort.</p>
<p><b>Response:</b> The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. If the SDT could have come up with the simple answer, it would have been supplied within the bright-line. The SDT would also like to point out to the commenters that it directly solicited assistance in this matter in the first posting of the criteria and received very little in the form of substantive comments.</p> <p>There are so many individual variables that will apply to specific cases that there is no way to cover everything up front. There are always going to be extenuating circumstances that will influence decisions on individual cases. One could take this statement to say that the regional discretion hasn't been removed from the process as dictated in the Order. However, the SDT disagrees with this position. The exception request form has to be taken in concert with the changes to the ERO Rules of Procedure and looked at as a single package. When one looks at the rules being formulated for the exception process, it becomes clear that the role of the Regional Entity has been drastically reduced in the proposed revision. The role of the Regional Entity is now one of reviewing the submittal for completion and making a recommendation to the ERO Panel, not to make the final determination. The Regional Entity plays no role in actually approving or rejecting the submittal. It simply acts as an intermediary. One can counter that this places the Regional Entity in a position to effectively block a submittal by being arbitrary as to what information needs to be supplied. In addition, the SDT believes that the visibility of the process would belie such an action by the Regional Entity and also believes that one has to have faith in the integrity of the Regional Entity in such a process. Moreover, Appendix 5C of the proposed NERC Rules of Procedure, Sections 5.1.5, 5.3, and 5.2.4, provide an added level of protection requiring an independent Technical Review Panel assessment where a Regional Entity decides to reject or disapprove an exception request. This panel's findings become part of the exception request record submitted to NERC. Appendix 5C of the proposed NERC Rules of Procedure, Section 7.0, provides NERC the option to remand the request to the Regional Entity with the mandate to process the exception if it finds the Regional Entity erred in rejecting or disapproving the exception request. On the other side of this equation, one could make an argument that the Regional Entity has no basis for what constitutes an acceptable submittal. Commenters point out that the explicit types of studies to be provided and how to interpret the information aren't shown in the request process. The SDT again points to the variations that will abound in the requests as negating any hard and fast rules in this regard. However, one is not dealing with amateurs here. This is not something that hasn't been handled before by either</p>				

Voter	Entity	Segment	Vote	Comment
				<p>party and there is a great deal of professional experience involved on both the submitter’s and the Regional Entity’s side of this equation. Having viewed the request details, the SDT believes that both sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to travel upward to the ERO Panel for adjudication.</p> <p>Now, the commenters could point to lack of direction being supplied to the ERO Panel as to specific guidelines for them to follow in making their decision. The SDT re-iterates the problem with providing such hard and fast rules. There are just too many variables to take into account. Providing concrete guidelines is going to tie the hands of the ERO Panel and inevitably result in bad decisions being made. The SDT also refers the commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.1 where the basic premise on evaluating an exception request must be based on whether the Elements are necessary for the reliable operation of the interconnected transmission system. Further, reliable operation is defined in the Rules of Procedure as operating the elements of the bulk power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cyber security incident, or unanticipated failure of system elements. The SDT firmly believes that the technical prowess of the ERO Panel, the visibility of the process, and the experience gained by having this same panel review multiple requests will result in an equitable, transparent, and consistent approach to the problem. The SDT would also point out that there are options for a submitting entity to pursue that are outlined in the proposed ERO Rules of Procedure changes if they feel that an improper decision has been made on their submittal.</p> <p>Some commenters have asked whether a single ‘yes’ or ‘no’ response to an item on the exception request form will mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.2 of the proposed Rules of Procedure that states “No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved.”</p> <p>The SDT would like to point out several changes made to the specific items in the form that were made in response to industry comments. The SDT believes that these clarifications will make the process tighter and easier to follow and improve the quality of the submittals.</p> <p>Finally, the SDT would point to the draft SAR for Phase II of this project that calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. Given the complexity of the technical aspects of this problem and the filing deadline that the SDT is working under for Phase I of this project, the SDT believes that it has developed a fair and equitable method of approaching this difficult problem. The SDT asks the commenter to consider all of these facts in making your decision and casting your ballot and hopes that these changes will result in a favorable outcome.</p> <p>The SDT is required to submit the exception process as part of the revised definition on January 25, 2012 as specified in Order743.</p>

				<p>Yes: No: X Comments: This exclusion conflicts with inclusion item 15. Which one takes priority?</p> <p>11. Are there any other concerns with this definition that haven't been covered in previous questions and comments remembering that the exception criteria are posted separately for comment? Yes: X No: Comments: LCRA TSC supports the direction the standards drafting team taking with this project on the BES Definition and encourages further clarification as noted in these comments for proper application.</p>
<p><b>Response:</b> The SDT directs LCRA to the detailed responses in the regular comment form as these comments are identical to those contained there.</p>				
Greg C. Parent	Manitoba Hydro	3	Negative	<p>Manitoba Hydro strongly disagrees with the proposed 'Detailed Information to Support an Exception Request' document and associated exception process for the following reasons: -It is not clear what elements or situations beyond what is covered in the core definition and associated inclusions and exclusions that the drafting team is hoping to capture through the exception process. Further, it is unclear what the benefit to reliability would be by allowing an impact based exception process given that entities will be extremely unlikely to use the exception process to include elements in the BES. -The exception process will be extremely resource intensive, particularly in the absence of any Industry approved threshold criteria. The costs to properly administer and monitor the process to ensure that impact based modeling is done accurately and that it captures the frequent changes on a dynamic system will occupy a wealth of Industry, NERC and Regional Entity time to the detriment of reliability. -It is not reasonable for industry to approve the exception process without knowing what thresholds are required to demonstrate an element as being part of the BES or not. We are concerned that BES determinations would be subjective and would vary from case to case with the particular staff examining the request. BES elements should be established and agreed upon by Industry, not set by a NERC panel. We understand that the drafting team has made this change in the interests of time, but the impact of the BES definition is too broad for this project to be rushed. -The 2010-17 project goals to increase the clarity of the BES definition and establish a 'bright-line' are compromised by the exception process. Changes and alterations to the BES</p>

				<p>checklist items for transmission and generation facilities are appropriate questions that must be answered in considering all requests. However, without objective criteria defining what must be submitted and how to assess the materials submitted, the current methodology leaves it to each region to develop their own methodology and criteria for evaluating the submittals. We believe the lack of clarity regarding what studies must be submitted and what must be demonstrated by the studies submitted will be overly burdensome on the submitting entity and the Region, as multiple studies may be required for the two to agree that there is sufficient justification for an exemption request. We believe that additional work is necessary to develop clear, objective methods and criteria for identifying which facilities may be excluded from or should be included in the Bulk Electric System. Clear, objective methods and criteria will enable the submitter of requests to understand what is necessary for submitting an exception request and will provide for consistency among the regions in their initial assessment and recommendations to the ERO. We believe that a Yes vote for the Technical Principles for Demonstrating BES Exceptions Request will result in minimal or no changes to today’s process under the current definition which includes the language “as defined by the Regional Reliability Organization.” While the proposed Technical Principles for Demonstrating BES Exceptions Request includes a checklist that must be submitted with exception requests, a yes vote will still require each region to develop their own methods and criteria for assessing materials submitted with exemption requests. We believe that a No vote with guidance to the drafting team that objective methods and criteria must be developed and applied continent-wide will result in the desired uniformity and consistency among regions in their assessment of exception requests. To allow sufficient time to complete this difficult task, we believe that the Detailed Information to Support BES Exceptions Request should not be part of the Phase 1 Bulk Electric System Definition effort, but should be postponed and included in the Phase 2 effort.</p>
Ernest Hahn	Metropolitan Water District of Southern California	1	Negative	<p>MWDSC supports WECC's comments that proposed Technical Information to Support BES Exceptions does not provide the necessary clarity, nor does it provide any criteria for consistency among regions. This detail should be postponed and included in the Phase 2 SAR effort.</p>

Kevin Smith	Balancing Authority of Northern California	1	Negative	We believe that additional work is necessary to develop clear, objective methods and criteria for identifying which facilities may be excluded from or should be included in the Bulk Electric System. Clear, objective methods and criteria will enable the submitter of requests to understand what is necessary for submitting an exception request and will provide for consistency among the regions in their initial assessment and recommendations to the ERO.
Terry L Baker	Platte River Power Authority	3	Negative	Platte River believes that a Yes vote for the Technical Principles for Demonstrating BES Exceptions Request will result in minimal changes to today’s process under the current definition which includes the language “as defined by the Regional Reliability Organization.” While the proposed Technical Principles for Demonstrating BES Exceptions Request includes a checklist that must be submitted with exception requests, a yes vote will still require each region to develop their own methods and criteria for assessing materials submitted with exemption requests. We believe that a No vote with guidance to the drafting team that objective methods and criteria must be developed and applied continent-wide will result in the desired uniformity and consistency among regions in their assessment of exception requests.
Roland Thiel	Platte River Power Authority	5	Negative	Definition of BES Platte River believes that the SDT has made substantial progress towards a clear and workable definition of the BES. Although Platte River ballots “Negative” we strongly support the approach to defining the Bulk Electric System as proposed here. Platte River recognizes that, given the deadlines imposed by FERC in Order No. 743, it will not be possible for the SDT to conduct a technical analysis within the time available. Accordingly, Platte River agrees with the approach taken by the SDT, which is to propose a Phase II of the standards development process that would address the generator threshold level and other issues. However, it is our opinion that the second draft would benefit from further clarification or modification. That said, Platte River is prepared to support the BES definition as proposed by the SDT going forward. Platte River has taken the opportunity to provide this industry feedback, as it is our understanding that we will be afforded another ballot opportunity. If this were to be our sole occasion to ballot, we would vote “Affirmative” at this time. We are encouraged by the work that has been completed and we commend the SDT for their commitment and extensive work thus far. Detailed Information to Support BES Exceptions Requests

However, SCL finds that the Principles as written do not provide the necessary clarity as what applying entities must provide to support their request, nor do they provide adequate criteria for consistency among regions in their assessment of requests. SCL recommends the development of objective methods and criteria for identifying which facilities may be excluded from or included in the BES. SCL also recommends the development of one or more examples that illustrate what studies must be submitted and what must be documented as part of an exception request. SCL recognizes that, given the deadlines imposed by FERC in Order No. 743, it will not be possible for the SDT to conduct a technical analysis within the time available. Accordingly, SCL agrees with the approach taken by the SDT, which is to propose a Phase II of the standards development process that would address issues such as the exception process. SCL has taken the opportunity</p>

Voter	Entity	Segment	Vote	Comment
				to provide this industry feedback, as it is our understanding that we will be afforded another ballot opportunity. If this were to be our sole occasion to ballot, we would vote “Affirmative” at this time. We are encouraged by the work that has been completed and we commend the SDT for their commitment and extensive work thus far. SCL is prepared to support the BES Exception process as proposed by the SDT going forward.
Tim Kelley	Sacramento Municipal Utility District	1	Negative	We believe that additional work is necessary to develop clear, objective methods and criteria for identifying which facilities may be excluded from or should be included in the Bulk Electric System. Clear, objective methods and criteria will enable the submitter of requests to understand what is necessary for submitting an exception request and will provide for consistency among the regions in their initial assessment and recommendations to the ERO.
Richard K Vine	California ISO	2	Negative	The ISO believes that the proposed Technical Principles for Demonstrating BES Exceptions Request does not provide the necessary clarity as to what applying entities must provide to support their request, nor does it provide any criteria for consistency among regions in their assessment of requests. We believe that the checklist items for transmission and generation facilities are appropriate questions that must be answered in considering all requests. However, without objective criteria defining what must be submitted and how to assess the materials submitted, the current methodology leaves it to each region to develop their own methodology and criteria for evaluating the submittals. The lack of clarity regarding what studies must be submitted and what must be demonstrated by the studies submitted will be overly burdensome on the submitting entity and the Region, as multiple studies may be required for the two to agree that there is sufficient justification for an exemption request. The ISO believes that additional work is necessary to develop clear, objective methods and criteria for identifying which facilities may be excluded from or should be included in the Bulk Electric System. Clear, objective methods and criteria will enable the submitter of requests to understand what is necessary for submitting an exception request and will provide for consistency among the regions in their initial assessment and recommendations to the ERO.
Barbara Constantinescu	Independent Electricity	2	Negative	We believe that the SDT proposed approach for exception criteria is reasonable recognizing that one method/criteria cannot be applicable to everyone and every

Voter	Entity	Segment	Vote	Comment
	System Operator			situation within the ERO foot print. However, we believe that there is huge gap and lack of any transparency on how the exception application will be evaluated and processed. We strongly suggest that SDT develop a reference or a guidance document as part of the RoP that should provide some guidance to Registered Entities, Regional Entities and the ERO on how an exception application should be processed. The absence of such guidance will pose a challenge for each entity including the ERO, and may result in discrepancies amongst Regional Entities. The process may be perceived by registered entities as being non-transparency.
Alden Briggs	New Brunswick System Operator	2	Negative	The NBSO has concern about the lack of clarity and specificity with respect to what analyses and study results are required. This lack of clarity and specificity may lead to inconsistent application of the Technical Principles by both Registered Entities and Regional Entities.
Steven Grego	MEAG Power	5	Negative	We believe that the proposed Technical Principles for Demonstrating BES Exceptions Request does not provide the necessary clarity as to what applying entities must provide to support their request, nor does it provide any criteria for consistency among regions in their assessment of requests. We believe that the checklist items for transmission and generation facilities are appropriate questions that must be answered in considering all requests. However, without objective criteria defining what must be submitted and how to assess the materials submitted, the current methodology leaves it to each region to develop their own methodology and criteria for evaluating the submittals. We believe the lack of clarity regarding what studies must be submitted and what must be demonstrated by the studies submitted will be overly burdensome on the submitting entity and the Region, as multiple studies may be required for the two to agree that there is sufficient justification for an exemption request. We believe that additional work is necessary to develop clear, objective methods and criteria for identifying which facilities may be excluded from or should be included in the Bulk Electric System. Clear, objective methods and criteria will enable the submitter of requests to understand what is necessary for submitting an exception request and will provide for consistency among the regions in their initial assessment and recommendations to the ERO. We believe that a Yes vote for the Technical Principles for Demonstrating BES Exceptions Request will result in minimal or no changes to today's process under the current definition which includes the

To allow sufficient time to complete this difficult task, we believe that the Detailed Information to Support BES Exceptions Request should not be part of the Phase 1 Bulk Electric System Definition effort, but should be postponed and included in the Phase 2 effort.
John H Hagen	Pacific Gas and Electric Company	3	Negative	This does not provide clarity on the criteria that will be used to manage the inclusion/exclusion process. Leaving it up to the regions will only create variances that this effort was chartered to eliminate. To support a bright line BES definition, the exclusion process must not have subjective results based on regional variances. We may be better off without an exclusion process and include the exclusions as written into the definition.
Mike Ramirez	Sacramento Municipal Utility District	4	Negative	We believe that additional work is necessary to develop clear, objective methods and criteria for identifying which facilities may be excluded from or should be included in the Bulk Electric System. Clear, objective methods and criteria will enable the submitter of requests to understand what is necessary for submitting an exception request and will provide for consistency among the regions in their initial assessment and recommendations to the ERO.
Bethany Hunter	Sacramento Municipal Utility District	5	Negative	We believe that additional work is necessary to develop clear, objective methods and criteria for identifying which facilities may be excluded from or should be included in the Bulk Electric System. Clear, objective methods and criteria will enable the submitter of requests to understand what is necessary for submitting an exception request and will provide for consistency among the regions in their initial assessment and recommendations to the ERO.
Claire Warshaw	Sacramento Municipal Utility District	6	Negative	We believe that additional work is necessary to develop clear, objective methods and criteria for identifying which facilities may be excluded from or should be included in the Bulk Electric System. 				<p>technical specificity will help ensure consistency between regions and transparency for registered entities on the technical studies and data required to support exception requests. These issues should be addressed in Phase 2.</p>
<p><b>Response:</b> The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. If the SDT could have come up with the simple answer, it would have been supplied within the bright-line. The SDT would also like to point out to the commenters that it directly solicited assistance in this matter in the first posting of the criteria and received very little in the form of substantive comments.</p> <p>There are so many individual variables that will apply to specific cases that there is no way to cover everything up front. There are always going to be extenuating circumstances that will influence decisions on individual cases. One could take this statement to say that the regional discretion hasn't been removed from the process as dictated in the Order. However, the SDT disagrees with this position. The exception request form has to be taken in concert with the changes to the ERO Rules of Procedure and looked at as a single package. When one looks at the rules being formulated for the exception process, it becomes clear that the role of the Regional Entity has been drastically reduced in the proposed revision. The role of the Regional Entity is now one of reviewing the submittal for completion and making a recommendation to the ERO Panel, not to make the final determination. The Regional Entity plays no role in actually approving or rejecting the submittal. It simply acts as an intermediary. One can counter that this places the Regional Entity in a position to effectively block a submittal by being arbitrary as to what information needs to be supplied. In addition, the SDT believes that the visibility of the process would belie such an action by the Regional Entity and also believes that one has to have faith in the integrity of the Regional Entity in such a process. Moreover, Appendix 5C of the proposed NERC Rules of Procedure, Sections 5.1.5, 5.3, and 5.2.4, provide an added level of protection requiring an independent Technical Review Panel assessment where a Regional Entity decides to reject or disapprove an exception request. This panel's findings become part of the exception request record submitted to NERC. Appendix 5C of the proposed NERC Rules of Procedure, Section 7.0, provides NERC the option to remand the request to the Regional Entity with the mandate to process the exception if it finds the Regional Entity erred in rejecting or disapproving the exception request. On the other side of this equation, one could make an argument that the Regional Entity has no basis for what constitutes an acceptable submittal. Commenters point out that the explicit types of studies to be provided and how to interpret the information aren't shown in the request process. The SDT again points to the variations that will abound in the requests as negating any hard and fast rules in this regard. However, one is not dealing with amateurs here. This is not something that hasn't been handled before by either party and there is a great deal of professional experience involved on both the submitter's and the Regional Entity's side of this equation. Having viewed the request details, the SDT believes that both sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to travel upward to the ERO Panel for adjudication.</p> <p>Now, the commenters could point to lack of direction being supplied to the ERO Panel as to specific guidelines for them to follow in making their decision. The SDT re-iterates the problem with providing such hard and fast rules. There are just too many variables to take into account. Providing concrete guidelines is going to tie the hands of the ERO Panel and inevitably result in bad decisions being made. The SDT also refers</p>				

Voter	Entity	Segment	Vote	Comment
<p>the commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.1 where the basic premise on evaluating an exception request must be based on whether the Elements are necessary for the reliable operation of the interconnected transmission system. Further, reliable operation is defined in the Rules of Procedure as operating the elements of the bulk power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cyber security incident, or unanticipated failure of system elements. The SDT firmly believes that the technical prowess of the ERO Panel, the visibility of the process, and the experience gained by having this same panel review multiple requests will result in an equitable, transparent, and consistent approach to the problem. The SDT would also point out that there are options for a submitting entity to pursue that are outlined in the proposed ERO Rules of Procedure changes if they feel that an improper decision has been made on their submittal.</p> <p>Some commenters have asked whether a single ‘yes’ or ‘no’ response to an item on the exception request form will mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.2 of the proposed Rules of Procedure that states “No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved.”</p> <p>The SDT would like to point out several changes made to the specific items in the form that were made in response to industry comments. The SDT believes that these clarifications will make the process tighter and easier to follow and improve the quality of the submittals.</p> <p>Finally, the SDT would point to the draft SAR for Phase II of this project that calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. Given the complexity of the technical aspects of this problem and the filing deadline that the SDT is working under for Phase I of this project, the SDT believes that it has developed a fair and equitable method of approaching this difficult problem. The SDT asks the commenter to consider all of these facts in making your decision and casting your ballot and hopes that these changes will result in a favorable outcome.</p>

				<p>with your comments. Yes: X No: Comments: Completing the exception form does not provide the entity with any indication of whether the Exception will be granted or rejected. It would be more effective and efficient to revise the Exception request questions to provide confirmation or rejection after completion of the form. Consistent application of the exception process across regions may become challenging with separate exception request review teams.</p>
<p><b>Response:</b> 1. Thank you for your support.</p> <p>2. See response to #10 below. Material is an unmeasurable concept. No change made. The SDT believes that an entity should follow the TPL methodology in formulating its request. If the entity believes that an n-1 analysis is all that is needed then it can submit just an n-1 analysis. No change made. Cranking Path information is just one piece of information that may be of value to the ERO Panel in making its decision. No change made. If two years worth of data are not available, the SDT believes that a Regional Entity will accept what is available and will work with the submitter to come up with an acceptable plan to move forward.</p> <p>3. Ancillary service products differ from region to region so providing a list in the form would be problematic. The form has sufficient flexibility for the entity to specify which products it is dealing with. However, the SDT has clarified the language concerning ancillary service products and must run units to indicate that only reliability-based information is pertinent.</p> <p>Q2. Is the <del>generator or generator facility</del> <u>generation resource</u> used to provide <u>reliability--related</u> Ancillary Services?</p> <p>Q3. Is the <del>generator</del> <u>generation resource</u> designated as a must run unit <u>for reliability</u>?</p> <p>4. 5. &amp; 6. Without a specific comment, the SDT is unable to respond.</p> <p>7. The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. If the SDT could have come up with the simple answer, it would have been supplied within the bright-line. The SDT would also like to point out to the commenters that it directly solicited assistance in this matter in the first posting of the criteria and received very little in the form of substantive comments.</p> <p>There are so many individual variables that will apply to specific cases that there is no way to cover everything up front. There are always going to be extenuating circumstances that will influence decisions on individual cases. One could take this statement to say that the regional discretion hasn't been removed from the process as dictated in the Order. However, the SDT disagrees with this position. The exception request form has to be taken in concert with the changes to the ERO Rules of Procedure and looked at as a single package. When one looks at the rules being formulated for the exception process, it becomes clear that the role of the Regional Entity has been drastically reduced in the proposed revision. The role of the Regional Entity is now one of reviewing the submittal for completion and making a recommendation to the</p>				

Voter	Entity	Segment	Vote	Comment
				<p>ERO Panel, not to make the final determination. The Regional Entity plays no role in actually approving or rejecting the submittal. It simply acts as an intermediary. One can counter that this places the Regional Entity in a position to effectively block a submittal by being arbitrary as to what information needs to be supplied. In addition, the SDT believes that the visibility of the process would belie such an action by the Regional Entity and also believes that one has to have faith in the integrity of the Regional Entity in such a process. Moreover, Appendix 5C of the proposed NERC Rules of Procedure, Sections 5.1.5, 5.3, and 5.2.4, provide an added level of protection requiring an independent Technical Review Panel assessment where a Regional Entity decides to reject or disapprove an exception request. This panel’s findings become part of the exception request record submitted to NERC. Appendix 5C of the proposed NERC Rules of Procedure, Section 7.0, provides NERC the option to remand the request to the Regional Entity with the mandate to process the exception if it finds the Regional Entity erred in rejecting or disapproving the exception request. On the other side of this equation, one could make an argument that the Regional Entity has no basis for what constitutes an acceptable submittal. Commenters point out that the explicit types of studies to be provided and how to interpret the information aren’t shown in the request process. The SDT again points to the variations that will abound in the requests as negating any hard and fast rules in this regard. However, one is not dealing with amateurs here. This is not something that hasn’t been handled before by either party and there is a great deal of professional experience involved on both the submitter’s and the Regional Entity’s side of this equation. Having viewed the request details, the SDT believes that both sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to travel upward to the ERO Panel for adjudication.</p> <p>Now, the commenters could point to lack of direction being supplied to the ERO Panel as to specific guidelines for them to follow in making their decision. The SDT re-iterates the problem with providing such hard and fast rules. There are just too many variables to take into account. Providing concrete guidelines is going to tie the hands of the ERO Panel and inevitably result in bad decisions being made. The SDT also refers the commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.1 where the basic premise on evaluating an exception request must be based on whether the Elements are necessary for the reliable operation of the interconnected transmission system. Further, reliable operation is defined in the Rules of Procedure as operating the elements of the bulk power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cyber security incident, or unanticipated failure of system elements. The SDT firmly believes that the technical prowess of the ERO Panel, the visibility of the process, and the experience gained by having this same panel review multiple requests will result in an equitable, transparent, and consistent approach to the problem. The SDT would also point out that there are options for a submitting entity to pursue that are outlined in the proposed ERO Rules of Procedure changes if they feel that an improper decision has been made on their submittal.</p> <p>Some commenters have asked whether a single ‘yes’ or ‘no’ response to an item on the exception request form will mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.2 of the proposed Rules of Procedure that states “No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved.”</p>

<p>The SDT would like to point out several changes made to the specific items in the form that were made in response to industry comments. The SDT believes that these clarifications will make the process tighter and easier to follow and improve the quality of the submittals.</p>				
<p>Finally, the SDT would point to the draft SAR for Phase II of this project that calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. Given the complexity of the technical aspects of this problem and the filing deadline that the SDT is working under for Phase I of this project, the SDT believes that it has developed a fair and equitable method of approaching this difficult problem. The SDT asks the commenter to consider all of these facts in making your decision and casting your ballot and hopes that these changes will result in a favorable outcome.</p>				
Doug Peterchuck	Omaha Public Power District	1	Negative	<p>The technical document on exceptions is appropriate, but there should be a guideline on what a typical exception is. The guideline can easily be created by what is now listed within the four-item “Exclusion List”. For example when looking at the current Local Network exclusion (E3), it looks to be based on a regional request and thus is in direct conflict with FERC’s order. We interpret the creation of a technical document regarding a proposed BES exclusion as a case that should be examined during the Exception Process and not during the BES definition process. The simple question that FERC could eventually ask is why don’t all listed exclusions include a technical justification?</p>
<p><b>Response:</b> The SDT did not provide a technical justification for items that are simply being copied from the existing definition. Technical justification was only provided for items that are new with this revision.</p>				
John T. Underhill	Salt River Project	3	Negative	<p>Definition of Bulk Electric System (BES) The Blackstart “Cranking Path” has been deleted from Inclusion 3 of the BES definition. However, NERC standards EOP-005 and CIP-002, R1.2.4 require documenting the Cranking Path. In addition, CIP-002-4 identifies the Cranking Path as a Critical Asset in Attachment 1. Compliance to the NERC Standards needs to be an exact science whenever possible. SRP does not argue the inclusion or exclusion of Cranking Path. However, if it is excluded, guidance must be provided on whether or not a Cranking Path is subject to the previously mentioned Standards. Detailed Information to Support BES Exceptions Request SRP agrees with the WECC Staff recommendation on the “Detailed Information to Support BES Exceptions Request.” “WECC Staff believes that the proposed Technical Principles for Demonstrating BES Exceptions Request does not provide the necessary clarity as to what applying entities must provide to support</p>

Marie Knox	Midwest ISO, Inc.	2	Negative	We support the SDT’s decision to exclude the cranking paths from the BES definition since testing and verification of the use of facilities in the cranking path is already covered by the appropriate EOP standards. However Inclusion I3 (blackstart) is extraneous given there is already designation specific for system restoration covered by an existing standard; EOP-005-2. Therefore, information on whether the facility is part of a Cranking Path associated with a Blackstart Resource, should not be required to receive consideration for an exception.
<p><b>Response:</b> The SDT disagrees that Blackstart Resources should not be included in the BES Definition. The Commission directed NERC to revise its BES definition to ensure that the definition encompasses all facilities necessary for operating an interconnected electric transmission network. The SDT interprets this to include operation under both normal and emergency conditions, which includes situations related to black starts and system restoration. Blackstart Resources have the ability to be started without support from the System or can be energized without</p>				

Voter	Entity	Segment	Vote	Comment
<p>connection to the remainder of the System, in order to meet a Transmission Operator’s restoration plan requirements for Real and Reactive Power capability, frequency, and voltage control. The associated resources of the electric system that can be isolated and then energized to deliver electric power during a restoration event are essential to enable the startup of one or more other generating units as defined in the Transmission Operator’s restoration plan. For these reasons, the SDT continues to include Blackstart Resources indentified in the Transmission Operator’s restoration plan as BES elements. No change made.</p> <p>Cranking Path information is just one piece of information that may be of value to the ERO Panel in making its decision. EOP-005-2 has no relevance in this regard. No change made.</p>				
Linda Jacobson	City of Farmington	3	Negative	FEUS appreciates the efforts of the SDT. However, the Detailed Information to Support an Exception Request does not align with the Draft Appendix 5C as it is applied to ‘Facilities’ rather than ‘Elements’ and is unclear how it is applied for an Inclusion Exception. Additional Comments have been submitted using the comment form.
<p><b>Response:</b> Please see the detailed responses to comments for Farmington in the general consideration of comments document for the technical criteria.</p>				
Gregg R Griffin	City of Green Cove Springs	3	Affirmative	GCS appreciates the SDT’s work on this project. For the most part,GCS supports what it believes to be the intent of the proposed language. The proposed specific exclusion of facilities used in the local distribution of electric energy is appropriate and consistent with Section 215 of the Federal Power Act. However, we have suggestions to better carry out what we believe to be the SDT’s intent. The first sentence can be read as: “... all ... Real Power and Reactive Power resources connected at 100 kV or higher”, which is surely not what the SDT intends. The basic problem is that Inclusions I2 and I4 do not modify the first sentence, e.g., from a set theory perspective, the set described by the first sentence includes the sets described in inclusions I2 and I4; hence, I2 and I4 do not modify the first sentence. From a literal reading, this would cause any size generator connected at 100 kV to be included, which is surely not the intent of the SDT. For similar reasons, the core definition and Inclusion I5 now has the effect of including all generators connected at 100 kV since a generator is a “dynamic device ... supplying or absorbing Reactive Power”. The word “dedicated” in I5 is not sufficient in GCS’s mind to unambiguously exclude generators from this statement. FMPA suggests the following wording to address these issues: "Transmission Elements (not including elements used in the local distribution of electric energy) and Real Power

Voter	Entity	Segment	Vote	Comment
				<p>and Reactive Power resources as described in the list below, unless excluded by Exclusion or Exception: a. Transmission Elements other than transformers and reactive resources operated at 100 kV or higher. b. Transformers with primary and secondary terminals operated at 100 kV or higher. c. Generating resource(s) (with gross individual or gross aggregate nameplate rating per the ERO Statement of Compliance Registry Criteria) including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100 kV or above. d. Blackstart Resources identified in the Transmission Operator’s restoration plan. e. Dispersed power producing resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating) utilizing a system designed primarily for aggregating capacity, connected at a common point at a voltage of 100 kV or above, but not including generation on the retail side of the retail meter. f. Non-generator static or dynamic devices dedicated to supplying or absorbing more than 6 MVAR of Reactive Power that are connected at 100 kV or higher, or through a dedicated transformer with a high-side voltage of 100 kV or higher, or through a transformer that is designated in bullet 2 above." 2. The SDT has revised the specific inclusions to the core definition in response to industry comments. Do you agree with Inclusion I1 (transformers)? If you do not support this change or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments. Yes: Yes No: Comments: Please see comments to Question 1 3. The SDT has revised the specific inclusions to the core definition in response to industry comments. Do you agree with Inclusion I2 (generation) including the reference to the ERO Statement of Compliance Registry Criteria? If you do not support this change or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments. Yes: yes No: Comments: Please see comments to Question 1 4. The SDT has revised the specific inclusions to the core definition in response to industry comments. Do you agree with Inclusion I3 (blackstart)? If you do not support this change or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments. Yes: Yes No: Comments: Please see comments to Question 1. 5. The SDT has revised the specific inclusions to the core definition in response to industry comments. Do you agree with Inclusion I4 (dispersed power)?</p>

Voter	Entity	Segment	Vote	Comment
				<p>If you do not support this change or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments. Yes: Yes No: Comments: We recommend clarifying that the dispersed power resources covered by this inclusion do not include generators on the retail side of the retail meter. Specifically, we recommend that the Inclusion read: “Dispersed power producing resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating) utilizing a system designed primarily for aggregating capacity, connected at a common point at a voltage of 100kV or above, but not including generation on the retail side of the retail meter.” 6. The SDT has added specific inclusions to the core definition in response to industry comments. Do you agree with Inclusion 15 (reactive resources)? If you do not support this change or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments. Yes: No: Comments: To help clarify and to avoid inclusion of de minimis reactive resources, we propose a size threshold of 6 MVAR consistent with the smallest size generator included in the BES at a 0.95 power factor, which is a common leading power factor used in Facility Connection Requirements for generators. In other words, 6 MVAR is consistent with typically the least amount of MVAR required to be absorbed by the smallest generator meeting the registry criteria. 7. The SDT has revised the specific exclusions to the core definition in response to industry comments. Do you agree with Exclusion E1 (radial system)? If you do not support this change or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments. Yes: Yes No: Comments: FMPA supports the exclusion of radial systems from the BES Definition. Such systems are generally not “necessary for operating an interconnected electric transmission network,” the standard in Orders 743 and 743-A. We have several suggestions to clarify the proposed language for this Exclusion. Proposed Exclusion E1 refers to “[a] group of contiguous transmission Elements that emanates from a single point of connection of 100 kV or higher.” We appreciate the SDT’s clarification of the point of connection requirement, but the term “a single point of connection” should be further defined (more clearly than just by voltage), and should be generic enough to encompass the various bus configurations. It is not the case, for example, that each individual breaker position</p>

Voter	Entity	Segment	Vote	Comment
				<p>in a ring bus is a separate point of connection for this purpose; in that situation, a bus at one voltage level at one substation should be considered “a single point of connection.” Some examples of configurations that should be considered a single point of connection for this purpose are at <a href="https://www.frc.com/Standards/StandardDocs/BES/BESAppendixA_V4_clean.pdf">https://www.frc.com/Standards/StandardDocs/BES/BESAppendixA_V4_clean.pdf</a>, Examples 1-6. Although the core definition (appropriately) refers to “Transmission Elements” (with a capital “T”), proposed Exclusion E1 refers to “transmission Elements” (with a lowercase “t”). To avoid confusion, either “Transmission” should be capitalized in both locations, or the word “transmission” should simply be deleted from Exclusion E1, leaving a “group of contiguous Elements.” We understand that the lack of capitalization may have been a deliberate choice by the SDT in an attempt to avoid confusion that SDT members believe exists in the Glossary definition. If the Glossary definition of Transmission is unclear-which GCS does not necessarily believe is the case-the answer is not to simply abandon the Glossary definition in favor of an entirely und</p>

Jose Escamilla	CPS Energy	3	Negative	The sample form "Request for Exception to the Bulk Electric System Definition" developed by the BES ROP Team is a more complete form.
<p><b>Response:</b> The SDT believes that the indicated form was an early draft and is no longer applicable. The SDT has worked closely with the Rules of Procedure team to make certain that the form is coordinated with the proposed ERO Rules of Procedure changes.</p>				
David Kiguel	Hydro One Networks, Inc.	3	Negative	After careful analysis of the proposed documents, Hydro One Networks Inc. is casting a negative vote. We commend the SDT for the effort in facing the challenge. However, we believe that the proposed definition and the exception request criteria still needs further work. Some issues need to be resolved before a final approval is granted. Please see our detailed comments as provided in the on-line system.
<p><b>Response:</b> Please see the detailed responses to comments for Hydro One in the general consideration of comments document for the technical criteria.</p>				
Jack W Savage	Modesto Irrigation	3	Negative	MID is voting No with the following comments. Inclusions and exclusions are based upon the ERO Statement of Compliance Registry Criteria - currently 75MVA. What

Voter	Entity	Segment	Vote	Comment
	District			<p>is the SDT's technical justification for using this generation level? If 75MVA is the criteria for including facilities as part of the BES, why is that same criteria not applied at voltages below 100kv? Is 75MVA of generation within an area whose load far exceeds that 75MVA cause to classify that entire area as part of the BES and not exclude it as a Local Network?</p> <p>Why are customer owned generators treated differently than other generators? Where is "non-retail generation" defined?</p> <p>The Detailed Information to Support an Exception Request requests information that is not included or mentioned in the definition of the BES. One example is reference to a Balancing Authorities most severe single contingency outage. How does the SDT justify inclusion of these type of questions which are not supported by the actual definition of the BES?</p>
<p><b>Response:</b> The SDT recognizes that some candidate local networks will have far in excess of 75 MVA of load demand, yet it believes that the 75 MVA threshold value given in Exclusion E3.a is an appropriate level regardless of the amount of load. This value is consistent with the existing threshold of aggregate generation in the ERO Statement of Compliance Registry Criteria. The generation values used in the BES definition will receive more attention and refinement as part of Phase 2 of this Project 2010-17.</p> <p>The SDT assumes the commenter is referring to Exclusion E2. This exclusion is simply clarifying what already exists in the ERO Statement of Compliance Registry Criteria for behind-the-meter generation.</p> <p>Non-retail generation is the generation on the system (supply) side of the meter.</p> <p>The indicated information is simply one piece of data that the SDT felt might be of value in the decision process and does not believe that data requested has to match one for one with the actual language of the definition.</p>				
Jeff Nelson	Springfield Utility Board	3	Negative	<p>Excellent progress has been made, but the technical information to support BES exceptions needs strengthening. For example, unscheduled flows in or out of a local network should not be used as a determination of whether a network is excluded.</p> <p>Reactive devices needs clarification as there are some reactive devices used for power factor correction, for example, on systems above 100kV that SUB believes should be exempt from the BES</p>
<p><b>Response:</b> The SDT believes it is vital to ensure both that power flow is always in the direction from the BES toward the LN at all points of connection, and that the LN facilities not be used for "wheeling" type transactions. The SDT believes the existing language accomplishes this. The suggested language in this comment touches on an important aspect, the scheduled use of the facilities, but the SDT believes that the existing language is more appropriate to express this point. No change made.</p> <p>Special circumstances such as described by SUB will need to be submitted to the exception process. In general, the SDT believes that reactive</p>

<p>devices above 100 kV should be part of the BES.</p>				
Mark Ringhausen	Old Dominion Electric Coop.	4	Negative	I cannot vote for this as it references in I2 the ERO Statement of Compliance Registry Criteria, which can be changed without stakeholder review and approval. The industry would be held to a changing standard that is not included in the Standards itself.
<p><b>Response:</b> This is a factor for the definition and not the criteria. Voting on the two separate issues should be done separately on their own individual merits.            In response to comments, the SDT has deleted the reference to the ERO Statement of Compliance Registry and replaced it with the existing numeric values. This way, any changes to the ERO Statement of Compliance Registry prior to resolution of threshold values in Phase II will not affect the definition</p>				
Michelle R DAntuono	Occidental Chemical	5	Negative	<p>1. Page 1 of the Detailed Information to Support an Exception Request contains general instructions. Do you agree with the instructions presented or is there information that you believe needs to be on page one and is missing? Please be as specific as possible with your comments. No: X Comments: It would be helpful to specify what the “key performance measures of BES reliability” are in the instructions (or at least examples of what these measures are in relation to the TPL Table 1). There must be some guidance on the relative level that should be considered acceptable to exclude a facility. Since the Regional Entities are responsible under the proposed Rules of Procedure to recommend the approval or disapproval of an exception request, it makes sense that they should provide this guidance. However, the DBESSDT should suggest an acceptable minimum - perhaps 10% of the allowed voltage transient dip or frequency excursion as assessed under a single contingency scenario.</p> <p>2. Pages two and three of the Detailed Information to Support an Exception Request contain a checklist of items that deal with transmission facilities. Do you agree with the information being requested or is there information that you believe needs to be on page three and is missing? Please be as specific as possible with your comments. No: X Comments: Item 4 needs to be expanded to provide some guidance on what an acceptable “impact to the over-all reliability of the BES” is. Also, there needs to be some sort of qualifier for the request to specify the “most severe system impact of an outage of the facility,” i.e., at least add the</p>

Voter	Entity	Segment	Vote	Comment
				<p>qualifier that it only requires a credible scenario. For example, what is the status of the BES when the outage of the facility occurs such that it represents the “most severe impact.” Most Regional Entities have settled on Transmission Planning models and thresholds that any new transmission deployment must minimally meet before it goes online. In some Regions, power transfer distribution factor may be gating factor - others may look at transient response. Whatever the case, the Regions should use those same criteria for BES exceptions - reduced to some conservative percentage level; perhaps 10% of the available margin.</p> <p>3. Page four of the Detailed Information to Support an Exception Request contains a checklist of items that deal with generation facilities. Do you agree with the information being requested or is there information that you believe needs to be on page four and is missing? Please be as specific as possible with your comments. No: X Comments: Item 4 needs to be expanded to provide some guidance on what an acceptable “impact to the over-all reliability of the BES” is. Also, there needs to be some sort of qualifier for the request to specify the “most severe system impact of an outage of the facility,” i.e., at least add the qualifier that it only requires a credible scenario. For example, what is the status of the BES when the outage of the facility occurs such that it represents the “most severe impact.” Most Regional Entities have settled on Transmission Planning models and thresholds that any new generation deployment must minimally meet before it goes online. Whatever the case, the Regions should use those same criteria for BES exceptions - reduced to some conservative percentage level; perhaps 10% of the available margin.</p> <p>4. Do you have concerns about an entity’s ability to obtain the data they would need to file the Detailed Information to Support an Exception Request? If so, please be specific with your concerns so that the SDT can fully understand the problem. Yes: X Comments: Having the data to perform studies of generator outage effects on the BES may require sharing of potentially confidential and/or classified information between the generator and transmission entities. Obviously, “base case” and possibly “N-1” information would need to be shared. Hence, there needs to be some assurance that information will be provided (Possibly in the proposed Appendix 5C of the NERC Rules of Procedure).</p>

				<p>5. Are there other specific characteristics that you feel would be important for presenting a case and generic enough that they belong in the request? If so, please identify them here and provide suggested language that could be added to the document. Yes: No: Comments:</p> <p>6. Are you aware of any conflicts between the proposed approach and any regulatory function, rule order, tariff, rate schedule, legislative requirement or agreement, or jurisdictional issue? If so, please identify them here and provide suggested language changes that may clarify the issue. Yes: X Comments: This Detailed Information to Support an Exemption Request document obviously does not conform to FERC Order 743, Sections 115,116 “NERC should develop an exemption process that includes clear, objective, transparent, and uniformly applicable criteria for exemption of facilities that are not necessary for operating the grid.” The question is will the justification for declining to observe this FERC directive be sufficient. We would assert that is it a lesser consequence for the BES to raise the single generation threshold to 75 MVA than it is to violate this FERC directive by not providing clear, objective, transparent and uniform criteria for the exemption process. We understand that the FERC directive was not well conceived in that if a bright line criteria could be developed for the exemption process, it should be included in the BES Definition itself. However, it leaves the exemption process that FERC had originally conceived non-attainable and causes angst to the industry.</p> <p>7. Are there any other concerns with this approach that haven’t been covered in previous questions and comments bearing in mind that the definition itself and the proposed Rules of Procedure changes are posted separately for comments? Please be as specific as possible with your comments. Yes: No: Comments:</p>
<p><b>Response:</b> 1. 2. &amp; 3. The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. If the SDT could have come up with the simple answer, it would have been supplied within the bright-line. The SDT would also like to point out to the commenters that it directly solicited assistance in this matter in the first posting of the criteria and received very little in the form of substantive comments.</p> <p>There are so many individual variables that will apply to specific cases that there is no way to cover everything up front. There are always going to be extenuating circumstances that will influence decisions on individual cases. One could take this statement to say that the regional</p>

				<p>discretion hasn't been removed from the process as dictated in the Order. However, the SDT disagrees with this position. The exception request form has to be taken in concert with the changes to the ERO Rules of Procedure and looked at as a single package. When one looks at the rules being formulated for the exception process, it becomes clear that the role of the Regional Entity has been drastically reduced in the proposed revision. The role of the Regional Entity is now one of reviewing the submittal for completion and making a recommendation to the ERO Panel, not to make the final determination. The Regional Entity plays no role in actually approving or rejecting the submittal. It simply acts as an intermediary. One can counter that this places the Regional Entity in a position to effectively block a submittal by being arbitrary as to what information needs to be supplied. In addition, the SDT believes that the visibility of the process would belie such an action by the Regional Entity and also believes that one has to have faith in the integrity of the Regional Entity in such a process. Moreover, Appendix 5C of the proposed NERC Rules of Procedure, Sections 5.1.5, 5.3, and 5.2.4, provide an added level of protection requiring an independent Technical Review Panel assessment where a Regional Entity decides to reject or disapprove an exception request. This panel's findings become part of the exception request record submitted to NERC. Appendix 5C of the proposed NERC Rules of Procedure, Section 7.0, provides NERC the option to remand the request to the Regional Entity with the mandate to process the exception if it finds the Regional Entity erred in rejecting or disapproving the exception request. On the other side of this equation, one could make an argument that the Regional Entity has no basis for what constitutes an acceptable submittal. Commenters point out that the explicit types of studies to be provided and how to interpret the information aren't shown in the request process. The SDT again points to the variations that will abound in the requests as negating any hard and fast rules in this regard. However, one is not dealing with amateurs here. This is not something that hasn't been handled before by either party and there is a great deal of professional experience involved on both the submitter's and the Regional Entity's side of this equation. Having viewed the request details, the SDT believes that both sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to travel upward to the ERO Panel for adjudication.</p> <p>Now, the commenters could point to lack of direction being supplied to the ERO Panel as to specific guidelines for them to follow in making their decision. The SDT re-iterates the problem with providing such hard and fast rules. There are just too many variables to take into account. Providing concrete guidelines is going to tie the hands of the ERO Panel and inevitably result in bad decisions being made. The SDT also refers the commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.1 where the basic premise on evaluating an exception request must be based on whether the Elements are necessary for the reliable operation of the interconnected transmission system. Further, reliable operation is defined in the Rules of Procedure as operating the elements of the bulk power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cyber security incident, or unanticipated failure of system elements. The SDT firmly believes that the technical prowess of the ERO Panel, the visibility of the process, and the experience gained by having this same panel review multiple requests will result in an equitable, transparent, and consistent approach to the problem. The SDT would also point out that there are options for a submitting entity to pursue that are outlined in the proposed ERO Rules of Procedure changes if they feel that an improper decision has been made on their submittal.</p>

Voter	Entity	Segment	Vote	Comment
<p>Some commenters have asked whether a single ‘yes’ or ‘no’ response to an item on the exception request form will mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.2 of the proposed Rules of Procedure that states “No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved.”</p> <p>The SDT would like to point out several changes made to the specific items in the form that were made in response to industry comments. The SDT believes that these clarifications will make the process tighter and easier to follow and improve the quality of the submittals.</p> <p>Finally, the SDT would point to the draft SAR for Phase II of this project that calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. Given the complexity of the technical aspects of this problem and the filing deadline that the SDT is working under for Phase I of this project, the SDT believes that it has developed a fair and equitable method of approaching this difficult problem. The SDT asks the commenter to consider all of these facts in making your decision and casting your ballot and hopes that these changes will result in a favorable outcome.</p> <p>4. If confidential data is involved in the submittal, the SDT expects the Regional Entity to work with the submitter to get around this problem.                      5. &amp; 7. Thank you for your response.                      6. The SDT believes the process is in alignment with Order 743 directives as explained above.</p>				
Colin Anderson	Ontario Power Generation Inc.	5	Negative	<p>OPG has cast a negative ballot in the BES Definition poll. Since we disagree with the Definition, and the justification for it, we don't see the need for an exception process. OPG continues to question the need for the changes required (and costs imposed) as a result of the new BES definition. OPG disagrees in general with proceeding to implement a 100 kV brightline definition in the absence of a properly quantified cost/benefit analysis. Entities are being asked to incur a high cost for no demonstrated benefit in wide-area reliability.</p>

The SDT asks the commenter to consider all of these facts in making your decision and casting your ballot and hopes that these changes will result in a favorable outcome.</p> <p>The responsibilities assigned to the SDT included the revision of the definition of BES contained in the NERC Glossary of Terms to improve clarity, to reduce ambiguity, and to establish consistency across all Regions in distinguishing between BES and non-BES Elements. The SDT’s efforts are directed at fulfilling their responsibilities and developing a definition that addresses the Commission’s concerns as expressed in the directives contained in Orders No. 743 &amp; 743-A. To accomplish these goals, the SDT has pursued a definition that remains as consistent as possible with the existing definition, while not significantly expanding or contracting the current scope of the BES or driving registration or de-registration. With this in mind, the SDT acknowledges that the current BES definition has varying degrees of Regional application and has resulted in different conclusions on what is currently considered to be part of the BES. This inconsistency in the application and subsequent results were also identified by the Commission in Orders No. 743 &amp; 743-A as a significant concern. The SDT acknowledges that by developing a bright-line definition coupled with the inconsistency in application of the current definition there is a potential for varying degrees of impact on Regions. Without an approved BES definition any assumptions utilized in a cost benefit analysis would be purely speculative and the results would have little meaning in regards to potential improvements in the reliable operation of the interconnected transmission grid on a continent-wide basis. Therefore, the SDT believes that best opportunity to address cost concerns will be through the development of Regional transition plans once the definition has been approved by the Commission.</p>				
Steven Grega	Public Utility District No. 1 of Lewis County	5	Negative	Process should make it easier to prove facility is a non-BES; process should take into account the plant load factor, if the plant is dispatchable and if it critical resource as determine by the BA. Most facilities should be able to prove they are not part of the BES. In WECC, only critical cranking paths are part of BES.
<p><b>Response:</b> The SDT has attempted to make the exception process as easy as possible while still providing the information necessary to properly process a request. Factors such as described by the commenter can be supplied with the submittal as there is no limit or constraint on additional information that can be supplied by the submitter.</p>				

Voter	Entity	Segment	Vote	Comment
Larry Nordell	Montana Consumer Counsel	8	Negative	The BES exception process must be cognizant of costs and benefits. In addition to the explicit information required in the current proposal it needs to provide an opportunity for an exception for elements whose failure would have no consequential impacts on the bulk system, and a process for an exception for elements for which the costs inclusion can be shown to be clearly in excess of the benefits of inclusion.
<p><b>Response:</b> The responsibilities assigned to the SDT included the revision of the definition of BES contained in the NERC Glossary of Terms to improve clarity, to reduce ambiguity, and to establish consistency across all Regions in distinguishing between BES and non-BES Elements. Therefore, the SDT believes that best opportunity to address cost concerns will be through the development of Regional transition plans once the definition has been approved by the Commission.</p>				
Diane J Barney	National Association of Regulatory Utility Commissioners	9	Negative	The draft definition has a circularity issue with the Registry, lacks clarity in some aspects, and lacks a technical basis and cost/benefit analysis. (See specific comments submitted.)
<p><b>Response:</b> Please see the specific responses provided.</p>				
John D Varnell	Tenaska Power Services Co.	6	Abstain	Which part of this definition has the highest priority inclusions or exclusions.
<p><b>Response:</b> The application of the draft 'bright-line' BES definition is a three (3) step process that when appropriately applied will identify the vast majority of BES Elements in a consistent manner that can be applied on a continent-wide basis.</p> <p>Initially, the BES 'core' definition is used to establish the bright-line of 100 kV, which is the overall demarcation point between BES and non-BES Elements. Additionally, the 'core' definition identifies the Real Power and Reactive Power resources connected at 100 kV or higher as included</p>				

Voter	Entity	Segment	Vote	Comment
<p>in the BES. To fully appreciate the scope of the ‘core’ definition an understanding of the term Element is needed. Element is defined in the NERC Glossary of Terms as:</p> <p>“Any electrical device with terminals that may be connected to other electrical devices such as a generator, transformer, circuit breaker, bus section, or transmission line. An element may be comprised of one or more components. “</p> <p>Element is basically any electrical device that is associated with the transmission or the generation (generating resources) of electric energy.</p> <p>Step two (2) provides additional clarification for the purposes of identifying specific Elements that are included through the application of the ‘core’ definition. The Inclusions address transmission Elements and Real Power and Reactive Power resources with specific criteria to provide for a consistent determination of whether an Element is classified as BES or non-BES.</p> <p>Step three (3) is to evaluate specific situations for potential exclusion from the BES (classification as non-BES Elements). The exclusion language is written to specifically identify Elements or groups of Elements for potential exclusion from the BES.</p> <p>Exclusion E1 provides for the exclusion of ‘transmission Elements’ from radial systems that meet the specific criteria identified in the exclusion language. This does not include the exclusion of Real Power and Reactive Power resources captured by Inclusions I2 – I5. The exclusion (E1) only speaks to the transmission component of the radial system. Similarly, Exclusion E3 (local networks) should be applied in the same manner. Therefore, the only inclusion that Exclusions E1 and E3 supersede is Inclusion I1.</p> <p>Exclusion E2 provides for the exclusion of the Real Power resources that reside behind the retail meter (on the customer’s side) and supersedes inclusion I2.</p> <p>Exclusion E4 provides for the exclusion of retail customer owned and operated Reactive Power devices and supersedes Inclusion I5.</p> <p>In the event that the BES definition incorrectly designates an Element as BES that is not necessary for the reliable operation of the interconnected transmission network or an Element as non-BES that is necessary for the reliable operation of the interconnected transmission network, the Rules of Procedure exception process may be utilized on a case-by-case basis to either include or exclude an Element.</p>				
Brenda Powell	Constellation Energy Commodities Group	6	Affirmative	While the Technical Principles for BES Exception are acceptable, they are quite complicated. Further simplification may ease the process.

Voter	Entity	Segment	Vote	Comment
<p><b>Response:</b> The SDT has attempted to make the exception process as easy as possible while still providing the information necessary to properly process a request.</p>				
Greg Lange	Public Utility District No. 2 of Grant County	3	Affirmative	<p>Public Utility District No. 2 of Grant County (GCPD) agrees that the General Instructions set forth the basic information that would be necessary to support an Exception Request. GCPD is concerned, however, that the statement “diagram(s) supplied should also show the Protection Systems at the interface points associated with the Elements for which the exception is being requested” may be subject to differing interpretations. GCPD envisions that at least four different kinds of documents would be responsive to the description: one-line diagrams with breakers and switches (status); identification of relays by their ANSI device numbers; details of the DC control logic for ANSI devices; and, operational scheme descriptions of the type used by system operators. Accordingly, we suggest that the language be refined to identify the specific kinds of diagrams necessary to identify protection systems at the interface with the Elements for which the Exception is sought, including any required details.</p> <p>GCPD suggests that a generic example of a completed form be available to the industry to help ensure that Exception Requests are supported by consistent and complete information. Such a generic example could be addressed in the Phase 2 BES efforts.</p> <p>GCPD agrees that the items listed on page 4 of the Detailed Information to Support an Exception Request capture the information that generally would be necessary to make a reasoned determination concerning the BES status of a generation facility. GCPD suggests three refinements to the questions: (1) Question 2 should be modified by adding “necessary for the operation of the interconnected bulk transmission system” to the end of the question, so that it reads: “Is the generator or the generator facility used to provide Ancillary Services necessary for the operation of the interconnected bulk transmission system?” The italicized language is necessary to distinguish between a generator that provides, for example, reactive power or regulating reserves that support operation of the interconnected bulk grid, and, for example, a behind-the-meter generator that provides back-up generation to a specific industrial facility. The former may be necessary for the reliable operation of the interconnected bulk transmission system, but the latter is not.</p>

Voter	Entity	Segment	Vote	Comment
				<p>(2) The current draft of the BES Definition contains Exclusions for radials and for Local Networks. To be consistent with these aspects of the revised BES definition, GCPD suggests modifying question 5 by adding “radial, or Local Network” to the question, so that it would read: “Does the generator use the BES, a radial system, or a Local Network to deliver its actual or scheduled output, or a portion of its actual or scheduled output, to Load?”</p> <p>(3) For reasons similar to those explained in our response to Question 2, a general “catch-all” question should be added that will prompt an entity submitting an Exception Request for a generator to submit any information it believes is relevant to the Exception that is not captured in the previous questions. We suggest the following language: Is there additional information not covered in questions 1 through 5 that supports the Exception Request? If yes, please provide the information and explain why it is relevant to the Exception Request. This will allow an entity seeking an Exception for a generator to identify any unusual circumstances or non-standard information that might support its Exception Request. An entity seeking such an Exception should have the opportunity to present any information it believes is relevant.</p>
<p><b>Response:</b> The SDT believes that the form allows for the flexibility of an entity supplying any types of diagrams that it believes will support its request. This is a preferable situation to coming up with a hard coded list. No change made.                      The SDT will consider completing a sample form in Phase II.                      The SDT has modified the wording of the question to clarify the intent.</p> <p><b>Q2.</b> Is the <del>generator or generator facility</del> <u>generation resource</u> used to provide <del>reliability--related</del> Ancillary Services?</p> <p>The SDT does not believe that the suggested wording change provides any additional clarification and may even cause confusion. No change made.                      The SDT agrees that any information that might support a request should be allowed and has clarified the wording on page 1 to that effect.</p> <p><b>Page 1 - List any attached supporting documents and any additional information that is included to supports the request:</b></p>				
Jeffrey S Brame	North Carolina Electric Membership Corp.	5	Affirmative	In general, we support the “Detailed Information to Support an Exception Request”. However, we have identified a few concerns that warrant the SDT’s consideration. Q1, Q5 and Q6 in the Transmission Facilities section have a “Description/Comments” section. What type of information should be included

Voter	Entity	Segment	Vote	Comment
				<p>under the Description for each of these questions? Providing more guidance here would help achieve the “standardization, clarity and continuity of process” that we seek. Regarding Q2: A permanent flowgate should not be part of the detailed information to support an exception. First, there is no definition for what constitutes a permanent flowgate. Second, flowgates are often created for a myriad of reasons that have nothing to do with them being necessary to operate the BES. While section c) in E3 attempts to limit the applicability to permanent flowgates, there is no definition for what constitutes a permanent flowgate particularly since no flowgate is truly permanent. The NERC Glossary of Terms definition of flowgate includes flowgates in the IDC. This is a problem because flowgates are included in the IDC for many reasons not just because reliability issues are identified. Flowgates could be included to simply study the impact of schedules on a particular interface as an example. It does not mean the interface is critical. As an example, it could be used to generate evidence that there are no transactional impacts to support exclusion from the BES. Furthermore, the list of flowgates in the IDC is dynamic. The master list of IDC flowgates is updated monthly and IDC users can add temporary flowgates at anytime. While the permanent adjective applied to flowgates probably limits the applicability from the “temporary” flowgates, it is not clear which of the monthly flowgates would be included from the IDC since they might be added one month and removed another. In the Transmission Facilities section, we are unclear about what “an appropriate list” in Q3 is supposed to be. Is it supposed to be a list of all IROLs or only those for which the answer is yes? Why is a list even necessary since the answer to the question answers Exclusion E3.c? If the answer to Q3 is no, is this asking the submitter to prove the negative? For Q2 in the Generation Facilities section, the definition of ancillary services varies and can be quite broad. It can include reactive power and voltage support for example. All generators provide some reactive power and voltage support. Thus, ancillary services should be further defined or one could construe it to limit any generator from being excluded. For Q1 in the Generation Facilities section, some generation owners may not be able to obtain their BA’s most severe single Contingency. Many generator owners will not have access to the data necessary to demonstrate the reliability impact to the BES. This is particularly true for transmission dependent utilities.</p>

Doug White	North Carolina Electric Membership Corp.	3	Affirmative	<p>In general, we support the proposed definition of the BES. However, we have identified a few concerns that warrant the SDT’s consideration. We’d prefer to see the language from the ERO Statement of Compliance Registry Criteria repeated within the BES Definition itself instead of referencing an outside document. As it stands right now, the Compliance Registry Criteria needs to stay intact for Phase I of this project. That makes the Compliance Registry Criteria reliant on the BES Definition and vice versa. We understand that the Statement of Compliance Registry Criteria may be reviewed/revised at the same time Phase 2 of this project is being developed, therefore we agree with Inclusion I2 of this draft.</p> <p>Blackstart Resources can actually be on the distribution system. There is still the question of whether the distribution system would then be subjected to the enforceable standards. If so, there would most likely be a significant cost increase associated with tracking compliance for these distribution systems without a commensurate increase in reliability since Blackstart Resources are rarely used. This could very well cause entities to un-designate Blackstart Resources on distribution systems to avoid these distribution systems from becoming part of the BES. The same rationale that was used for eliminating cranking paths could also be applied to Blackstart Resources.</p> <p>A flowgate should not be used to limit applicability of E3. First, there is no definition for what constitutes a permanent flowgate. Second, flowgates are often created for a myriad of reasons that have nothing to do with them being necessary to operate the BES. While section c) in E3 attempts to limit the applicability to permanent flowgates, there is no definition for what constitutes a permanent flowgate particularly since no flowgate is truly permanent. The NERC Glossary of Terms definition of flowgate includes flowgates in the IDC. This is a problem because flowgates are included in the IDC for many reasons not just because reliability issues are identified. Flowgates could be included to simply study the impact of schedules on a particular interface as an example. It does not mean the interface is critical. As an example, it could be used to generate evidence that there are no transactional impacts to support exclusion from the BES.</p> <p>Furthermore, the list of flowgates in the IDC is dynamic. The master list of IDC flowgates is updated monthly and IDC users can add temporary flowgates at anytime. While the “permanent” adjective applied to flowgates probably limits the</p>

				<p>applicability from the “temporary” flowgates, it is not clear which of the monthly flowgates would be included from the IDC since they might be added one month and removed another. Flowgates are created for many reasons that have nothing to do with them being necessary to operate the BES. First, flowgates are created to manage congestion. The IDC is more of a congestion management tool than a reliability tool. FERC recognized this in Order 693, when they directed NERC to make clear in IRO-006 that the IDC should not be relied upon to relieve IROLs that have been violated. Rather, other actions such as re-dispatch must be used in conjunction. Second, flowgates are used as a convenient point to calculate flows to sell transmission service. The characteristics of the flowgate make it a good proxy for estimating how much contractual use has been sold not necessarily how much flow will actually occur. While some flowgates definitely are created for reliability issues such as IROLs, many simply are not.</p> <p>The term “non-retail generation” used in Exclusion E1 (item c) and again in E3 (item a) should be clarified (see comments for question 8 below). The Note after item c should also be clarified to indicate that closing a normally open switch doesn’t affect this exclusion.</p> <p>Detailed Information to Support an Exception Request: Vote affirmative with the comments below Comments for Ballot (these may be copied and pasted ): In general, we support the “Detailed Information to Support an Exception Request”. However, we have identified a few concerns that warrant the SDT’s consideration. Q1, Q5 and Q6 in the Transmission Facilities section have a “Description/Comments” section. What type of information should be included under the Description for each of these questions? Providing more guidance here would help achieve the “standardization, clarity and continuity of process” that we seek. Sam Nietfeld	Snohomish County PUD No. 1	5	Affirmative	<p>Below are SNPD's responses to the NERC comment form for the Definition of the BES (Project 2010-17) Technical Principles for Demonstrating BES Exceptions). SNPD believes the refinements below will clarify the current draft of the BES definition, without hanging the current intent. 1. Page one of the 'Detailed Information to Support an Exception Request' contains general instructions. Do you agree with the instructions presented or is there information that you believe needs to be on page one that is missing? Please be as specific as possible with your comments. Comments: SNPD agrees generally that the General Instructions set forth the basic information that would be necessary to support an Exception Request. SNPD is concerned, however, that the statement "diagram(s) supplied should also show the Protection Systems at the interface points associated with the Elements for which the exception is being requested" may be subject to differing interpretations. SNPD envisions that at least four different kinds of documents would be responsive to the description: one-line diagrams with breakers and switches (status); identification of relays by their ANSI device numbers; details of the DC control logic for ANSI devices; and, operational scheme descriptions of the type used by system operators. Accordingly, we suggest that the language be refined to identify the specific kinds of diagrams necessary to identify protection systems at the interface with the Elements for which the Exception is sought, including any required details, such as breaker settings. SNPD suggests that a generic example of a completed form be available to the industry to help ensure that Exception Requests are supported by consistent and complete information. Such a generic example could be addressed in the Phase 2 BES efforts. 2. Pages two and three of the Detailed Information to Support an Exception Request contain a checklist of items that deal with transmission facilities. Do you agree with the information being requested or is there</p>

Voter	Entity	Segment	Vote	Comment
				<p>information that you believe needs to be on page two or three that is missing? Please be as specific as possible with your comments. Comments: SNPD agrees that the checklist of items on pages two and three lists most of the information that would be necessary to determine if an Exceptions Request is justified. We suggest three modifications to the proposed language to ensure consistency with Section 215 of the Federal Power Act, with the BES Definition, and to provide an entity seeking an Exception with the opportunity to submit all relevant information: 1) SNPD suggests that a new question should be added concerning the function of the facility, which would read: "Does the facility function as a local distribution facility rather than a Transmission facility? If yes, please provide a detailed explanation of your answer." Section 215(a)(1) of the FPA makes clear that "facilities used in the local distribution of electric energy" are excluded from the BES, 16 U.S.C. Â§ 824o(a)(1), and the most recent draft of the BES definition incorporates the same language. SNPD believes a question to address the function of the Element or system subject to an Exception Request is necessary to determine whether the Element or system is "used" in local distribution and thereby to ensure that this statutory limit on the BES is observed in the Exceptions process. Further, we believe a variety of information may be relevant to determining whether a particular facility functions as local distribution rather than as part of the BES. For example, if power is not scheduled across the facility or if capacity on the system is not posted on the relevant OASIS, it is likely to function as local distribution, not transmission. Similarly, if power enters the system and is delivered to load within the system rather than moving to load located on another system, its function is local distribution rather than transmission. SNPD proposes the language above as an open-ended question so that the entity submitting the Exceptions Request can provide this and any other information it deems relevant to facility function. 2) SNPD suggests modifying question 6 to "Is the facility part a designated Cranking Path associated with a Blackstart Resource identified in a Transmission Operator's restoration plan." This language reflects the most recent revision of the BES Definition and also helps distinguish between generators which have Blackstart capability and those generators that are designated as a Blackstart Resource in the Transmission Operator's restoration plan. It is only the latter that are included in the BES under the current draft of the definition. 3) A general</p>

Voter	Entity	Segment	Vote	Comment
				<p>“catch-all” question should be added that will prompt the entity submitting an Exception Request to submit any information it believes is relevant to the Exception that is not captured in the other questions. We suggest the following language: Is there additional information not covered in the questions above that supports the Exception Request? If yes, please provide the information and explain why it is relevant to the Exception Request. While SNPD believes the questions set forth in the draft capture the information that generally would be necessary to determine whether an Exception Request should be granted, it is foreseeable that there may be unusual circumstances where the information called for either does not capture the full picture or where studies other than the specific types called for in the draft form support the Exception. An entity seeking an Exception should have the opportunity to present any information it believes is relevant. 3. Page four of the ‘Detailed Information to Support an Exception Request’ contains a checklist of items that deal with generation facilities. Do you agree with the information being requested or is there information that you believe needs to be on page four that is missing? Please be as specific as possible with your comments. Comments: SNPD agrees that the items listed on page 4 of the Detailed Information to Support an Exception Request capture the information that generally would be necessary to make a reasoned determination concerning the BES status of a generation facility. SNPD suggests three refinements to the questions: 1) Question 2 should be modified by adding “necessary for the operation of the interconnected bulk transmission system” to the end of the question, so that it reads: “Is the generator or the generator facility used to provide Ancillary Services necessary for the operation of the interconnected bulk transmission system?” The italicized language is necessary to distinguish between a generator that provides, for example, reactive power or regulating reserves that support operation of the interconnected bulk grid, and, for example, a behind-the-meter generator that provides back-up generation to a specific industrial facility. The former may be necessary for the reliable operation of the interconnected bulk transmission system, but the latter is not. 2) The current draft of the BES Definition contains Exclusions for radials and for Local Networks. To be consistent with these aspects of the revised BES definition, SNPD suggests modifying question 5 by adding “radial, or Local Network” to the question, so that it would read: “Does the</p>

Voter	Entity	Segment	Vote	Comment
				<p>generator use the BES, a radial system, or a Local Network to deliver its actual or scheduled output, or a portion of its actual or scheduled output, to Load? 3) For reasons similar to those explained in our response to Question 2, a general “catch-all” question should be added that will prompt an entity submitting an Exception Request for a generator to submit any information it believes is relevant to the Exception that is not captured in the previous questions. We suggest the following language: Is there additional in</p>
John D Martinsen	Public Utility District No. 1 of Snohomish County	4	Affirmative	<p>Below are SNPD’s responses to the NERC comment form for the Definition of the BES (Project 2010-17) Technical Principles for Demonstrating BES Exceptions). SNPD believes the refinements below will clarify the current draft of the BES definition, without hanging the current intent. 1. Do you agree with the information being requested or is there information that you believe needs to be on page four that is missing? Please be as specific as possible with your comments. Comments: SNPD agrees that the items listed on page 4 of the Detailed Information to Support an Exception Request capture the information that generally would be necessary to make a reasoned determination concerning the BES status of a generation facility. SNPD suggests three refinements to the questions: 1) Question 2 should be modified by adding “necessary for the operation of the interconnected bulk transmission system” to the end of the question, so that it reads: “Is the generator or the generator facility used to provide Ancillary Services necessary for the operation of the interconnected bulk transmission system?” The italicized language is necessary to distinguish between a generator that provides, for example, reactive power or regulating reserves that support operation of the interconnected bulk grid, and, for example, a behind-the-meter generator that provides back-up generation to a specific industrial facility. The former may be necessary for the reliable operation of the interconnected bulk transmission system, but the latter is not. 2) The current draft of the BES Definition contains Exclusions for radials and for Local Networks. To be consistent with these aspects of the revised BES definition, SNPD suggests modifying question 5 by adding “radial, or Local Network” to the question, so that it would read: “Does the</p>

				<p>generator use the BES, a radial system, or a Local Network to deliver its actual or scheduled output, or a portion of its actual or scheduled output, to Load? 3) For reasons similar to those explained in our response to Question 2, a general “catch-all” question should be added that will prompt an entity submitting an Exception Request for a generator to submit any information it believes is relevant to the Exception that is not captured in the previous questions. We suggest the following language: Is there additional in</p>
William T Moojen	Snohomish County PUD No. 1	6	Affirmative	<p>Below are SNPD’s responses to the NERC comment form for the Definition of the BES (Project 2010-17) Technical Principles for Demonstrating BES Exceptions). SNPD believes the refinements below will clarify the current draft of the BES definition, without hanging the current intent. 1. Page one of the ‘Detailed Information to Support an Exception Request’ contains general instructions. Do you agree with the instructions presented or is there information that you believe needs to be on page one that is missing? Please be as specific as possible with your comments. Comments: SNPD agrees generally that the General Instructions set forth the basic information that would be necessary to support an Exception Request. SNPD is concerned, however, that the statement “diagram(s) supplied should also show the Protection Systems at the interface points associated with the Elements for which the exception is being requested” may be subject to differing interpretations. SNPD envisions that at least four different kinds of documents would be responsive to the description: one-line diagrams with breakers and switches (status); identification of relays by their ANSI device numbers; details of the DC control logic for ANSI devices; and, operational scheme descriptions of the type used by system operators. Accordingly, we suggest that the language be refined to identify the specific kinds of diagrams necessary to identify protection systems at the interface with the Elements for which the Exception is sought, including any required details, such as breaker settings. SNPD suggests that a generic example of a completed form be available to the industry to help ensure that Exception Requests are supported by consistent and complete information. Such a generic example could be addressed in the Phase 2 BES efforts. 2. Pages two and three of the Detailed Information to Support an Exception Request contain a checklist of items that deal with transmission facilities. Do you agree with the information being requested or is there</p>

Voter	Entity	Segment	Vote	Comment
				<p>information that you believe needs to be on page two or three that is missing? Please be as specific as possible with your comments. Comments: SNPD agrees that the checklist of items on pages two and three lists most of the information that would be necessary to determine if an Exceptions Request is justified. We suggest three modifications to the proposed language to ensure consistency with Section 215 of the Federal Power Act, with the BES Definition, and to provide an entity seeking an Exception with the opportunity to submit all relevant information: 1) SNPD suggests that a new question should be added concerning the function of the facility, which would read: "Does the facility function as a local distribution facility rather than a Transmission facility? If yes, please provide a detailed explanation of your answer." Section 215(a)(1) of the FPA makes clear that "facilities used in the local distribution of electric energy" are excluded from the BES, 16 U.S.C. Â§ 824o(a)(1), and the most recent draft of the BES definition incorporates the same language. SNPD believes a question to address the function of the Element or system subject to an Exception Request is necessary to determine whether the Element or system is "used" in local distribution and thereby to ensure that this statutory limit on the BES is observed in the Exceptions process. Further, we believe a variety of information may be relevant to determining whether a particular facility functions as local distribution rather than as part of the BES. For example, if power is not scheduled across the facility or if capacity on the system is not posted on the relevant OASIS, it is likely to function as local distribution, not transmission. Similarly, if power enters the system and is delivered to load within the system rather than moving to load located on another system, its function is local distribution rather than transmission. SNPD proposes the language above as an open-ended question so that the entity submitting the Exceptions Request can provide this and any other information it deems relevant to facility function. 2) SNPD suggests modifying question 6 to "Is the facility part a designated Cranking Path associated with a Blackstart Resource identified in a Transmission Operator's restoration plan." This language reflects the most recent revision of the BES Definition and also helps distinguish between generators which have Blackstart capability and those generators that are designated as a Blackstart Resource in the Transmission Operator's restoration plan. It is only the latter that are included in the BES under the current draft of the definition. 3) A general</p>

Voter	Entity	Segment	Vote	Comment
				<p>“catch-all” question should be added that will prompt the entity submitting an Exception Request to submit any information it believes is relevant to the Exception that is not captured in the other questions. We suggest the following language: Is there additional information not covered in the questions above that supports the Exception Request? If yes, please provide the information and explain why it is relevant to the Exception Request. While SNPD believes the questions set forth in the draft capture the information that generally would be necessary to determine whether an Exception Request should be granted, it is foreseeable that there may be unusual circumstances where the information called for either does not capture the full picture or where studies other than the specific types called for in the draft form support the Exception. An entity seeking an Exception should have the opportunity to present any information it believes is relevant. 3. Page four of the ‘Detailed Information to Support an Exception Request’ contains a checklist of items that deal with generation facilities. Do you agree with the information being requested or is there information that you believe needs to be on page four that is missing? Please be as specific as possible with your comments. Comments: SNPD agrees that the items listed on page 4 of the Detailed Information to Support an Exception Request capture the information that generally would be necessary to make a reasoned determination concerning the BES status of a generation facility. SNPD suggests three refinements to the questions: 1) Question 2 should be modified by adding “necessary for the operation of the interconnected bulk transmission system” to the end of the question, so that it reads: “Is the generator or the generator facility used to provide Ancillary Services necessary for the operation of the interconnected bulk transmission system?” The italicized language is necessary to distinguish between a generator that provides, for example, reactive power or regulating reserves that support operation of the interconnected bulk grid, and, for example, a behind-the-meter generator that provides back-up generation to a specific industrial facility. The former may be necessary for the reliable operation of the interconnected bulk transmission system, but the latter is not. 2) The current draft of the BES Definition contains Exclusions for radials and for Local Networks. To be consistent with these aspects of the revised BES definition, SNPD suggests modifying question 5 by adding “radial, or Local Network” to the question, so that it would read: “Does the</p>

				generator use the BES, a radial system, or a Local Network to deliver its actual or scheduled output, or a portion of its actual or scheduled output, to Load? 3) For reasons similar to those explained in our response to Question 2, a general “catch-all” question should be added that will prompt an entity submitting an Exception Request for a generator to submit any information it believes is relevant to the Exception that is not captured in the previous questions. We suggest the following language: Is there additional in
<p><b>Response:</b> Please see the detailed responses to comments for Snohomish in the general consideration of comments document for the technical criteria.</p>				
Harold Taylor	Georgia Transmission Corporation	1	Affirmative	Throughout the document, because it will be part of a larger Exception Request Form, it should, when possible, use terms consistent with the rest of that form (e.g., “Request” rather than “application”). Similarly, defined terms (even if only defined in the context of the Request Form in which these Principles will be used) such as “Exception,” “Request,” “Element” or “Facility” should be capitalized; if the use of lower case is intended to convey a different meaning than what is defined, another term should be used to avoid confusion. The Definition and Request Form generally use the term “Element,” so it is unclear why this document should so consistently use “facility.” For consistency, “Element(s)” or possibly “Element(s) or Facility” should be used.
<p><b>Response:</b> The SDT has attempted to clean up any inconsistencies in terminology.</p>				
Gregory S Miller	Baltimore Gas & Electric Company	1	Affirmative	While the Technical Principles for BES Exception are acceptable, they are quite complicated. Further simplification may ease the process.
<p><b>Response:</b> The SDT would point the commenter to the Phase II draft SAR which contains wording to allow for a review of the principles after a 12 month period of real-world experience.</p>				
Charles A. Freibert	Louisville Gas and Electric Co.	3	Affirmative	LG&E and KU Energy request clarification as to how the two year data requirement would apply to a new facility for which the owner/operator requests an exemption.
<p><b>Response:</b> If two years worth of data are not available, the SDT believes that a Regional Entity will accept what is available and will work with the submitter to come up with an acceptable plan to move forward.</p>				

Voter	Entity	Segment	Vote	Comment
Anthony Schacher	Salem Electric	3	Affirmative	Salem Electric is encouraged to see that the standard drafting team understands the reality that in many circumstances many small radially fed utilities have no effect on the bulk electric system. By permitting reasonable and prudent exceptions it will allow many of the small utilities to be able to spend our limited time and resources on the reliability of our systems for our end users, instead of undertaking unnecessary steps to protect a system upon which we have no effect. The exception process is thorough but still manageable for small utilities with limited resources. Salem Electric would like to thank the Standards Drafting Team for their hard work and dedication in defining the Bulk Electric System.
Thomas C Duffy	Central Hudson Gas & Electric Corp.	3	Affirmative	The 'Technical Principles for Demonstrating BES Exceptions' process was intended to establish technical exception 'criteria' which would be used by the industry to understand what facilities would qualify for inclusions and exclusions from the BES. What has been produced, however, is essentially a listing of 'electrical system indicators', identified on the form, which may be material to making a decision regarding, 'is it BES or not'. The thresholds (or acceptable values) for the indicators, however, have not been determined. It is understood that in Phase II of the BES Definition development process, the SDT will attempt to address these issues but until that work has been completed, the industry will remain enmeshed in confusion and inefficient application of resources and funding. Without these criteria, it is very difficult to believe that this process can be transparent and consistent.
Jason Fortik	Lincoln Electric System	3	Affirmative	No comments.
Benjamin Friederichs	Big Bend Electric Cooperative, Inc.	3	Affirmative	These principles seem reasonable.
<p><b>Response:</b> Thank you for your support.</p>

# Consideration of Comments

## Definition of the Bulk Electric System Exception Criteria (Project 2010-17)

The Bulk Electric System Drafting Team thanks all commenters who submitted comments on the second draft of the Project 2010-17: Definition of the Bulk Electric System (BES) Exception Criteria. These standards were posted for a 45-day public comment period from August 26, 2011 through October 10, 2011. Stakeholders were asked to provide feedback on the standards and associated documents through a special electronic comment form. There were 72 sets of comments, including comments from approximately 137 different people from approximately 83 companies representing all 10 Industry Segments as shown in the table on the following pages.

The SDT made the following changes to the request form due to industry comments received:

- **General** – Clarified the use of facility versus Element(s).
- **Page 1** – Corrected typo: List any attached supporting documents and any additional information that is included to support the request.
- **Generation - Q1**. Replaced 'generator's or generator facility's' with 'generation resource's': What is the MW value of the host Balancing Authority's most severe single Contingency and what is the ~~generator's, or generator facility's~~ generation resource's, percent of this value?
- **Generation - Q2**. Replaced 'generator's or generator facility's' with 'generation resource's': Is the ~~generator or generator facility~~ generation resource used to provide reliability-related Ancillary Services?
- **Generation - Q3**. Replace 'generator' with 'generation resource': Is the ~~generator~~ generation resource designated as a must run unit for reliability?

The SDT feels that it is important to remind the industry that Phase II of this project will begin immediately after the conclusion of Phase I as SDT resources clear up. The same SDT will follow through with Phase II.

The SDT is recommending that this project be moved forward to the recirculation ballot stage.

There were two comments that were repeated multiple times throughout the various documents. The first topic was about how to sort through the definition inclusions and exclusions, i.e., which takes precedence. The SDT offers this guidance on that issue:

The application of the draft 'bright-line' BES definition is a three (3) step process that when appropriately applied will identify the vast majority of BES Elements in a consistent manner that can be applied on a continent-wide basis.

Initially, the BES 'core' definition is used to establish the bright-line of 100 kV, which is the overall demarcation point between BES and non-BES Elements. Additionally, the 'core' definition identifies the Real Power and Reactive Power resources connected at 100 kV or higher as included in the BES. To fully appreciate the scope of the 'core' definition an understanding of the term Element is needed. Element is defined in the NERC Glossary of Terms as:

"Any electrical device with terminals that may be connected to other electrical devices such as a generator, transformer, circuit breaker, bus section, or transmission line. An element may be comprised of one or more components. "

Element is basically any electrical device that is associated with the transmission or the generation (generating resources) of electric energy.

Step two (2) provides additional clarification for the purposes of identifying specific Elements that are included through the application of the 'core' definition. The Inclusions address transmission Elements and Real Power and Reactive Power resources with specific criteria to provide for a consistent determination of whether an Element is classified as BES or non-BES.

Step three (3) is to evaluate specific situations for potential exclusion from the BES (classification as non-BES Elements). The exclusion language is written to specifically identify Elements or groups of Elements for potential exclusion from the BES.

Exclusion E1 provides for the exclusion of 'transmission Elements' from radial systems that meet the specific criteria identified in the exclusion language. This does not include the exclusion of Real Power and Reactive Power resources captured by Inclusions I2 – I5. The exclusion (E1) only speaks to the transmission component of the radial system. Similarly, Exclusion E3 (local networks) should be applied in the same manner. Therefore, the only inclusion that Exclusions E1 and E3 supersede is Inclusion I1.

Exclusion E2 provides for the exclusion of the Real Power resources that reside behind the retail meter (on the customer's side) and supersedes inclusion I2.

Exclusion E4 provides for the exclusion of retail customer owned and operated Reactive Power devices and supersedes Inclusion I5.

In the event that the BES definition incorrectly designates an Element as BES that is not necessary for the reliable operation of the interconnected transmission network or an Element as non-BES that is necessary for the reliable operation of the interconnected transmission network, the Rules of Procedure exception process may be utilized on a case-by-case basis to either include or exclude an Element.

The second item is about providing specific guidance on how the information on the exception request form will be used in making decisions on inclusions/exclusions in the exception process. The SDT provides the following information on this item:

The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. If the SDT could have come up with the simple answer, it would have been supplied within the bright-line. The SDT would also like to point out to the commenters that it directly solicited assistance in this matter in the first posting of the criteria and received very little in the form of substantive comments.

There are so many individual variables that will apply to specific cases that there is no way to cover everything up front. There are always going to be extenuating circumstances that will influence decisions on individual cases. One could take this statement to say that the regional discretion hasn't been removed from the process as dictated in the Order. However, the SDT disagrees with this position. The exception request form has to be taken in concert with the changes to the ERO Rules of Procedure and looked at as a single package. When one looks at the rules being formulated for the exception process, it becomes clear that the role of the Regional Entity has been drastically reduced in the proposed revision. The role of the Regional Entity is now one of reviewing the submittal for completion and making a recommendation to the ERO Panel, not to make the final determination. The Regional Entity plays no role in actually approving or rejecting the submittal. It simply acts as an intermediary. One can counter that this places the Regional Entity in a position to effectively block a submittal by

being arbitrary as to what information needs to be supplied. In addition, the SDT believes that the visibility of the process would belie such an action by the Regional Entity and also believes that one has to have faith in the integrity of the Regional Entity in such a process. Moreover, Appendix 5C of the proposed NERC Rules of Procedure, Sections 5.1.5, 5.3, and 5.2.4, provide an added level of protection requiring an independent Technical Review Panel assessment where a Regional Entity decides to reject or disapprove an exception request. This panel's findings become part of the exception request record submitted to NERC. Appendix 5C of the proposed NERC Rules of Procedure, Section 7.0, provides NERC the option to remand the request to the Regional Entity with the mandate to process the exception if it finds the Regional Entity erred in rejecting or disapproving the exception request. On the other side of this equation, one could make an argument that the Regional Entity has no basis for what constitutes an acceptable submittal. Commenters point out that the explicit types of studies to be provided and how to interpret the information aren't shown in the request process. The SDT again points to the variations that will abound in the requests as negating any hard and fast rules in this regard. However, one is not dealing with amateurs here. This is not something that hasn't been handled before by either party and there is a great deal of professional experience involved on both the submitter's and the Regional Entity's side of this equation. Having viewed the request details, the SDT believes that both sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to travel upward to the ERO Panel for adjudication.

Now, the commenters could point to lack of direction being supplied to the ERO Panel as to specific guidelines for them to follow in making their decision. The SDT re-iterates the problem with providing such hard and fast rules. There are just too many variables to take into account. Providing concrete guidelines is going to tie the hands of the ERO Panel and inevitably result in bad decisions being made. The SDT also refers the commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.1 where the basic premise on evaluating an exception request must be based on whether the Elements are necessary for the reliable operation of the interconnected transmission system. Further, reliable operation is defined in the Rules of Procedure as operating the elements of the bulk power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cyber security incident, or unanticipated failure of system elements. The SDT firmly believes that the technical prowess of the ERO Panel, the visibility of the process, and the experience gained by having this same panel review multiple requests will result in an equitable, transparent, and consistent approach to the problem. The SDT would also point out that there are options for a submitting entity to pursue that are outlined in the proposed ERO Rules of Procedure changes if they feel that an improper decision has been made on their submittal.

Some commenters have asked whether a single 'yes' or 'no' response to an item on the exception request form will mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.2 of the proposed Rules of Procedure that states "No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved."

The SDT would like to point out several changes made to the specific items in the form that were made in response to industry comments. The SDT believes that these clarifications will make the process tighter and easier to follow and improve the quality of the submittals.

Finally, the SDT would point to the draft SAR for Phase II of this project that calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. Given the complexity of the technical aspects of this problem and the filing deadline that the SDT is working under for Phase I of this project, the SDT believes that it has developed a fair and equitable method of approaching this difficult problem. The SDT asks the commenter to consider all of these facts in making your decision and casting your ballot and hopes that these changes will result in a favorable outcome.

All comments submitted may be reviewed in their original format on the standard's project page:

[http://www.nerc.com/filez/standards/Project2010-17\\_BES.html](http://www.nerc.com/filez/standards/Project2010-17_BES.html)

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herb Schrayshuen, at 404-446-2560 or at [herb.schrayshuen@nerc.net](mailto:herb.schrayshuen@nerc.net). In addition, there is a NERC Reliability Standards Appeals Process.<sup>1</sup>

---

<sup>1</sup> The appeals process is in the Standards Processes Manual:  
[http://www.nerc.com/docs/standards/sc/Standard\\_Processes\\_Manual\\_Approved\\_May\\_2010.pdf](http://www.nerc.com/docs/standards/sc/Standard_Processes_Manual_Approved_May_2010.pdf).

**Index to Questions, Comments, and Responses**

1. Page one of the ‘Detailed Information to Support an Exception Request’ contains general instructions. Do you agree with the instructions presented or is there information that you believe needs to be on page one that is missing? Please be as specific as possible with your comments. .... 13

2. Pages two and three of the Detailed Information to Support an Exception Request contain a checklist of items that deal with transmission facilities. Do you agree with the information being requested or is there information that you believe needs to be on page two or three that is missing? Please be as specific as possible with your comments. .... 49

3. Page four of the ‘Detailed Information to Support an Exception Request’ contains a checklist of items that deal with generation facilities. Do you agree with the information being requested or is there information that you believe needs to be on page four that is missing? Please be as specific as possible with your comments. .... 88

4. Do you have concerns about an entity’s ability to obtain the data they would need to file the ‘Detailed Information to Support an Exception Request’? If so, please be specific with your concerns so that the SDT can fully understand the problem. 108

5. Are there other specific characteristics that you feel would be important for presenting a case and which are generic enough that they belong in the request? If so, please identify them here and provide suggested language that could be added to the document. .... 120

6. Are you aware of any conflicts between the proposed approach and any regulatory function, rule order, tariff, rate schedule, legislative requirement or agreement, or jurisdictional issue? If so, please identify them here and provide suggested language changes that may clarify the issue. .... 133

7. Are there any other concerns with the proposed approach for demonstrating BES Exceptions that haven’t been covered in previous questions and comments (bearing in mind that the definition itself and the proposed Rules of Procedure changes are posted separately for comments)? Please be as specific as possible with your comments. .... 142

END OF REPORT ..... 167

**The Industry Segments are:**

- 1 — Transmission Owners
- 2 — RTOs, ISOs
- 3 — Load-serving Entities
- 4 — Transmission-dependent Utilities
- 5 — Electric Generators
- 6 — Electricity Brokers, Aggregators, and Marketers
- 7 — Large Electricity End Users
- 8 — Small Electricity End Users
- 9 — Federal, State, Provincial Regulatory or other Government Entities
- 10 — Regional Reliability Organizations, Regional Entities

1. **Page one of the ‘Detailed Information to Support an Exception Request’ contains general instructions. Do you agree with the instructions presented or is there information that you believe needs to be on page one that is missing? Please be as specific as possible with your comments.**

**Summary Consideration:** The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. If the SDT could have come up with the simple answer, it would have been supplied within the bright-line. The SDT would also like to point out to the commenters that it directly solicited assistance in this matter in the first posting of the criteria and received very little in the form of substantive comments.

There are so many individual variables that will apply to specific cases that there is no way to cover everything up front. There are always going to be extenuating circumstances that will influence decisions on individual cases. One could take this statement to say that the regional discretion hasn't been removed from the process as dictated in the Order. However, the SDT disagrees with this position. The exception application form has to be taken in concert with the changes to the ERO Rules of Procedure and looked at as a single package. When one looks at the rules being formulated for the exception process, it becomes clear that the role of the Regional Entity has been drastically reduced in the proposed revision. The role of the Regional Entity is now one of reviewing the submittal for completion and making a recommendation to the ERO panel, not to make the final determination. The Regional Entity plays no role in actually approving or rejecting the submittal. It simply acts as an intermediary. One can counter that this places the Regional Entity in a position to effectively block a submittal by being arbitrary as to what information needs to be supplied. In addition, the SDT believes that the visibility of the process would belie such an action by the Regional Entity and also believes that one has to have faith in the integrity of the Regional Entity in such a process. Moreover, Appendix 5C of the proposed NERC Rules of Procedure, Sections 5.1.5, 5.3, and 5.2.4, provide an added level of protection requiring an independent Technical Review Panel assessment where a Regional Entity decides to reject or disapprove an exception request. This panel's findings become part of the exception request record submitted to NERC. Appendix 5C of the proposed NERC Rules of Procedure, Section 7.0, provides NERC the option to remand the application to the Regional Entity with the mandate to process the exception if it finds the Regional Entity erred in rejecting or disapproving the exception request. On the other side of this equation, one could make an argument that the Regional Entity has no basis for what constitutes an acceptable submittal. Commenters point out that the explicit types of studies to be provided and how to interpret the information aren't shown in the application process. The SDT again points to the variations that will abound in the applications as negating any hard and fast rules in this regard. However, one is not dealing with amateurs here. This is not something that hasn't been handled before by either party and there is a great deal of professional experience involved on both the submitter's and the Regional Entity's side of this equation. Having viewed the application details, the SDT believes that both

sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to travel upward to the ERO panel for adjudication.

Now, the commenters could point to lack of direction being supplied to the ERO panel as to specific guidelines for them to follow in making their decision. The SDT re-iterates the problem with providing such hard and fast rules. There are just too many variables to take into account. Providing concrete guidelines is going to tie the hands of the ERO panel and inevitably result in bad decisions being made. The SDT also refers the commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.1 where the basic premise on evaluating an exception request must be based on whether the Elements are necessary for the reliable operation of the Bulk Electric System. The SDT firmly believes that the technical prowess of the ERO panel, the visibility of the process, and the experience gained by having this same panel review multiple applications will result in an equitable, transparent, and consistent approach to the problem. The SDT would also point out that there are options for a submitting entity to pursue that are outlined in the proposed ERO Rules of Procedure changes if they feel that an improper decision has been made on their submittal.

Some commenters have asked whether a single 'yes' or 'no' response to an item on the exception application form will mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.2 of the proposed Rules of Procedure that states "No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved."

The SDT would like to point out several changes made to the specific items in the form that were made in response to industry comments. The SDT believes that these clarifications will make the process tighter and easier to follow and improve the quality of the submittals.

Finally, the SDT would point to the SAR for Phase II of this project that calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. Given the complexity of the technical aspects of this problem and the filing deadline that the SDT is working under for Phase I of this project, the SDT believes that it has developed a fair and equitable method of approaching this difficult problem. The SDT asks the commenter to consider all of these facts in making your decision and casting your ballot and hopes that these changes will result in a favorable outcome.

The SDT clarified the point that an entity may submit any information that it feels will help support its request as follows:

**Page 1** - List any attached supporting documents and any additional information that is included to supports the request:

Organization	Yes or No	Question 1 Comment
<p>Northeast Power Coordinating Council</p>	<p>No</p>	<p>How an exception application will be assessed by the RE and NERC is not addressed in the document. Stakeholders need to know how the exception application will be evaluated and processed. Suggest that the SDT develop a reference or a guidance document as part of the RoP that will provide guidance to Registered Entities, Regional Entities and the ERO on how an exception application will be processed. Of particular concern is the lack of clarity and specificity with respect to what analyses and study results are required under the third bullet on page 1 and under question 4 on both pages 2 and 4. This lack of clarity and specificity will lead to inconsistent application of the Technical Principles by both Registered Entities and Regional Entities.</p> <p>We recommend the following: the impact and performance analyses required by the 3rd bullet on page 1 and by #4 on pages 2 and 4 should be stipulated to be all analyses, scenarios, and contingencies required under NERC Standard TPL-002-1 with the “exception element” removed from the base system model. Entities shall report on all key performance measures of BES reliability specified in the TPL-002-1 attributable to the removed “exception element”.</p> <p>On page 1 under General Instructions, it is stated that:”A one-line breaker diagram identifying the facility for which the exception is requested must be supplied with every application. The diagram(s) supplied should also show the Protection Systems at the interface points associated with the Elements for which the exception is being requested.”What is meant by interface points?</p>
<p><b>Response:</b> The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. The SDT believes that these clarifications will make the process tighter and easier to follow and improve the quality of the submittals.</p> <p>Finally, the SDT would point to the draft SAR for Phase II of this project that calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. Given the complexity of the technical aspects of this problem and the filing deadline that the SDT is working under for Phase I of this project, the SDT believes that it has developed a fair and equitable method of approaching this difficult problem. The SDT asks the commenter to consider all of these facts in making your decision and casting your ballot and hopes that these changes will result in a favorable outcome.</p> <p>As far as developing reference or guidance documents, the SDT will consider this recommendation in Phase II of the project.</p> <p>The recommendation to use “the impact and performance analyses required by the 3rd bullet on page 1 and by #4 on pages 2 and 4 should be stipulated to be all analyses, scenarios, and contingencies required under NERC Standard TPL-002-1 with the “exception element” removed from the base system model” could be viable as a form of evidence an entity may want to submit if the entity believes this test provides evidence for the exception of an Element(s). The SDT encourages the submitting entity to provide any additional information or explanation in the comments section of the questions that it believes will assist in the review of its Exception Request. The SDT has made a clarifying change to the page 1 instructions to make this point clearer. Also see the answer to question #4.</p>

Organization	Yes or No	Question 1 Comment
<p><b>Page one:</b> List any attached supporting documents <u>and any additional information that is included to supports the request:</u></p> <p>As far as interface points, the SDT agrees with BPA’s suggestion that the interface point is the point requested by the entity seeking the exception where the Element or Elements interconnect(s) to Bulk Electric System Elements.</p>		
<p>ACES Power Marketing Standards Collaborators</p>	<p>No</p>	<p>The first sentence only refers to element(s) designated as excluded. Element(s) designated as included under the BES definition, shouldn’t have to go through the exception process either.</p>
<p>Response: The SDT agrees with this comment. This language was added to clarify that Elements that are excluded (or included) do not have to go through the Exception Process unless they are attempting to change to classification of their Elements.</p>		
<p>WECC Staff</p>	<p>No</p>	<p>WECC has several concerns with the instructions on the checklist regarding the studies:</p> <ul style="list-style-type: none"> <li>o Study Case - The instructions state the study case that should be used, “Be based on an Interconnection-wide base case that is suitably complete and detailed to reflect the facility’s electrical characteristics and system topology.” The phrase “suitably complete and detailed” is vague. WECC recommends clarification of this phrase and the addition of specific requirements for what will constitute an appropriate case. Allowing the entity requesting an exception to choose any Interconnection-wide case could allow an inappropriate choice of case and could lead to inconsistent study results. If there are no requirements for the chosen case, then it is possible that the most favorable case to an entity’s argument will be chosen. In some instances that choice would likely be appropriate, but in others it would not necessarily be appropriate. At a minimum, there should be further description - and preferably, specific requirements - guiding the determination of which study case is most appropriate.</li> </ul> <p>Of particular importance in clarifying what case is an appropriate case, is the timeliness of the case. WECC recommends requiring that a recent case be used. In addition, if each entity is able to chose its own case, without further</p>

Organization	Yes or No	Question 1 Comment
		<p>requirements, there will be no way for the Regional Entity or NERC to ensure consistency of determinations with respect to the elements tested.</p> <p>o The entities are asked to address key performance measures of BES reliability through the studies. This instruction is vague concerning what the study must investigate and it leaves it up to the entity to determine the key performance measures. The “key performance” measures should be consistent with respect to similar elements and there is no way to ensure that if there are no specifications regarding such measures. The exceptions process must be objective and clear as to what performance measures need to be met for the process to be implemented consistently. WECC recommends further clarification and the addition of specific requirements beyond the guidance related to consistency with Transmission Planning (TPL) standards.</p> <p>o The background information on the comment form states: “The same checklist will be utilized for exceptions dealing with inclusions or exclusions.” But there is no mention of this in the document. A note should be added to the checklist instruction to state that the same checklist will be used for exclusions and inclusions.</p>
<p><b>Response:</b> In response to the comment about an appropriate base case, the SDT expects the entity seeking an exception to supply an appropriate base case that the Regional Entity will acknowledge as appropriate. Not indicating the explicit types of studies or base cases to be provided and how to interpret the information in the application process does not fail to provide a basis for the Regional Entity to determine what constitutes an acceptable submittal.</p> <p>The SDT again points to the variations that will abound in the applications as negating any hard and fast rules in this regard. However, this is not something that hasn’t been handled before and there is a great deal of professional experience involved on both the submitter’s and the Regional Entity’s side of this equation. Having viewed the application details, the SDT believes that both sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to move upward to the ERO panel for a final determination.</p> <p>The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would</p>		

Organization	Yes or No	Question 1 Comment
		<p>like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. If the SDT could have come up with the simple answer, it would have been supplied within the bright-line. The SDT would also like to point out to the commenters that it directly solicited assistance in this matter in the first posting of the criteria and received very little in the form of substantive comments.</p> <p>There are so many individual variables that will apply to specific cases that there is no way to cover everything up front. There are always going to be extenuating circumstances that will influence decisions on individual cases. One could take this statement to say that the regional discretion hasn't been removed from the process as dictated in the Order. However, the SDT disagrees with this position. The exception request form has to be taken in concert with the changes to the ERO Rules of Procedure and looked at as a single package. When one looks at the rules being formulated for the exception process, it becomes clear that the role of the Regional Entity has been drastically reduced in the proposed revision. The role of the Regional Entity is now one of reviewing the submittal for completion and making a recommendation to the ERO Panel, not to make the final determination. The Regional Entity plays no role in actually approving or rejecting the submittal. It simply acts as an intermediary. One can counter that this places the Regional Entity in a position to effectively block a submittal by being arbitrary as to what information needs to be supplied. In addition, the SDT believes that the visibility of the process would belie such an action by the Regional Entity and also believes that one has to have faith in the integrity of the Regional Entity in such a process. Moreover, Appendix 5C of the proposed NERC Rules of Procedure, Sections 5.1.5, 5.3, and 5.2.4, provide an added level of protection requiring an independent Technical Review Panel assessment where a Regional Entity decides to reject or disapprove an exception request. This panel's findings become part of the exception request record submitted to NERC. Appendix 5C of the proposed NERC Rules of Procedure, Section 7.0, provides NERC the option to remand the request to the Regional Entity with the mandate to process the exception if it finds the Regional Entity erred in rejecting or disapproving the exception request. On the other side of this equation, one could make an argument that the Regional Entity has no basis for what constitutes an acceptable submittal. Commenters point out that the explicit types of studies to be provided and how to interpret the information aren't shown in the request process. The SDT again points to the variations that will abound in the requests as negating any hard and fast rules in this regard. However, one is not dealing with amateurs here. This is not something that hasn't been handled before by either party and there is a great deal of professional experience involved on both the submitter's and the Regional Entity's side of this equation. Having viewed the request details, the SDT believes that both sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to travel upward to the ERO Panel for adjudication.</p> <p>Now, the commenters could point to lack of direction being supplied to the ERO Panel as to specific guidelines for them to follow in making their decision. The SDT re-iterates the problem with providing such hard and fast rules. There are just too many variables to take into account. Providing concrete guidelines is going to tie the hands of the ERO Panel and inevitably result in bad decisions being</p>

Organization	Yes or No	Question 1 Comment
		<p>made. The SDT also refers the commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.1 where the basic premise on evaluating an exception request must be based on whether the Elements are necessary for the reliable operation of the interconnected transmission system. Further, reliable operation is defined in the Rules of Procedure as operating the elements of the bulk power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cyber security incident, or unanticipated failure of system elements. The SDT firmly believes that the technical prowess of the ERO Panel, the visibility of the process, and the experience gained by having this same panel review multiple requests will result in an equitable, transparent, and consistent approach to the problem. The SDT would also point out that there are options for a submitting entity to pursue that are outlined in the proposed ERO Rules of Procedure changes if they feel that an improper decision has been made on their submittal. Some commenters have asked whether a single ‘yes’ or ‘no’ response to an item on the exception request form will mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.2 of the proposed Rules of Procedure that states “No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved.”</p> <p>The SDT would like to point out several changes made to the specific items in the form that were made in response to industry comments. The SDT believes that these clarifications will make the process tighter and easier to follow and improve the quality of the submittals.</p> <p>Finally, the SDT would point to the draft SAR for Phase II of this project that calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. Given the complexity of the technical aspects of this problem and the filing deadline that the SDT is working under for Phase I of this project, the SDT believes that it has developed a fair and equitable method of approaching this difficult problem. The SDT asks the commenter to consider all of these facts in making your decision and casting your ballot and hopes that these changes will result in a favorable outcome.</p> <p>As to the last comment, the SDT finds this wording redundant and not providing any additional clarity. No change made.</p>
<p>Dominion</p>	<p>No</p>	<p>Given that the second sentence in the 1st paragraph of this comment form reads “This same process would be used by Registered Entities to justify including Elements in the BES that might otherwise be excluded according to the proposed definition and designations.”, Dominion suggests that the 1st</p>

Organization	Yes or No	Question 1 Comment
		<p>sentence under General Instructions be revised to read “A one-line breaker diagram identifying the facility for which the exception (or inclusion) is requested must be supplied with every application. The diagram(s) supplied should also show the Protection Systems at the interface points associated with the Elements for which the exception <b>(or inclusion)</b> is being requested.”</p>
<p><b>Response:</b> The SDT reviewed the suggestion to add the phrase “(or inclusion)” and has elected to keep the original language because the term Exception includes both Exclusions and Inclusions.</p>		
<p>Pepco Holdings Inc</p>	<p>No</p>	<ol style="list-style-type: none"> <li>1) Why must the one-line diagram supplied show the Protection Systems at the interface points associated with the elements for which the exception is being requested? Since Protection Systems are not part of the new bright-line BES definition why would their presence, or absence, on the one-line diagram influence the exception process?</li> <li>2) The third bullet needs additional detail of what is being requested. The phrase “...key performance measures..” and use of methodologies described in TPS Standards does not provide sufficient direction needed. (see question #4)</li> </ol>
<p><b>Response:</b> In response to the question about including Protection Systems, the SDT has used the term “should also show the Protection Systems”. This is not mandatory; however the SDT has suggested this because the criterion for the evaluation of an exception is “the Elements are necessary for the reliable operation of the interconnected bulk power transmission system”. As an example, the elements could be part of a Special Protection System or RAS thus they could help the ERO to identify the Elements “necessary for Reliable Operation...” No change made.</p> <p>The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. <p>Duke Energy</p>	<p>No</p>	<p>Need to include identification of any System Protection Coordination considerations per PRC-001-1.</p> <p>Also, we believe that a system map showing the geographical location of the facility(s) should be supplied with the request.</p>
<p><b>Response:</b> The detail of the diagrams and the type of diagrams suggested by Duke could be viable forms of evidence that an entity may want to submit if the entity believes they provide evidence to support the exception of an Element.</p> <p>Additionally, the SDT encourages the submitting entity to provide any additional information or explanation in the comments section of the questions that it believes will assist in the review of its Exception Request.</p>		

Organization	Yes or No	Question 1 Comment
Consolidated Edison Co. of NY, Inc.	No	<p>Con Edison’s overall concern is the lack of clarity and specificity with respect to what analyses and study results are required under the 3rd bullet on page 1 and under #4 on pages 2 and 4. This lack of clarity and specificity will lead to inconsistent application of the Technical Principles by both Registered Entities and Regional Entities. We recommend the following: the impact and performance analyses required by the 3rd bullet on page 1 and by #4 on pages 2 and 4 should be stipulated to be all analyses, scenarios, and contingencies required under NERC Standard TPL-002-1 with the “exception element” removed from the base system model. Entities shall report on all key performance measures of BES reliability specified in the TPL-002-1 attributable to the removed “exception element”.</p> <p>Note that references to NERC Standard TPL-001-2 should not be made in the Technical Principles document as TPL-001-2 has not yet been filed with (nor approved by) FERC.</p> <p>General Instructions One-Line Breaker Diagram questions and comments: Page 1, paragraph 2: Please explain the phrase “at the interface points.” Where is this location? Please provide several examples, i.e., for a radial, a local network, a generator, a transformer, a substation buss, and for other Elements (PARs, reactors, UFLS panels, relays and switches).</p>

Organization	Yes or No	Question 1 Comment
		assumed out of service, new facilities places in service and system load levels, etc.
<p><b>Response:</b> The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. If the SDT could have come up with the simple answer, it would have been supplied within the bright-line. The SDT would also like to point out to the commenters that it directly solicited assistance in this matter in the first posting of the criteria and received very little in the form of substantive comments.</p> <p>There are so many individual variables that will apply to specific cases that there is no way to cover everything up front. There are always going to be extenuating circumstances that will influence decisions on individual cases. One could take this statement to say that the regional discretion hasn't been removed from the process as dictated in the Order. However, the SDT disagrees with this position. The exception request form has to be taken in concert with the changes to the ERO Rules of Procedure and looked at as a single package. When one looks at the rules being formulated for the exception process, it becomes clear that the role of the Regional Entity has been drastically reduced in the proposed revision. The role of the Regional Entity is now one of reviewing the submittal for completion and making a recommendation to the ERO Panel, not to make the final determination. The Regional Entity plays no role in actually approving or rejecting the submittal. It simply acts as an intermediary. One can counter that this places the Regional Entity in a position to effectively block a submittal by being arbitrary as to what information needs to be supplied. In addition, the SDT believes that the visibility of the process would belie such an action by the Regional Entity and also believes that one has to have faith in the integrity of the Regional Entity in such a process. Moreover, Appendix 5C of the proposed NERC Rules of Procedure, Sections 5.1.5, 5.3, and 5.2.4, provide an added level of protection requiring an independent Technical Review Panel assessment where a Regional Entity decides to reject or disapprove an exception request. This panel's findings become part of the exception request record submitted to NERC. Appendix 5C of the proposed NERC Rules of Procedure, Section 7.0, provides NERC the option to remand the request to the Regional Entity with the mandate to process the exception if it finds the Regional Entity erred in rejecting or disapproving the exception request. On the other side of this equation, one could make an argument that the Regional Entity has no basis for what constitutes an acceptable submittal. Commenters point out that the explicit types of studies to be provided and how to interpret the information aren't shown in the request process. The SDT again points to the variations that will abound in the requests as negating any hard and fast rules in this regard. However, one is not dealing with amateurs here. This is not something that hasn't been handled before by either party and there is a great deal of professional experience involved on both the submitter's and the Regional Entity's side of this equation. Having viewed the request details, the SDT believes that both sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to travel upward to the ERO Panel for</p>		

Organization	Yes or No	Question 1 Comment
		<p>adjudication.</p> <p>Now, the commenters could point to lack of direction being supplied to the ERO Panel as to specific guidelines for them to follow in making their decision. The SDT re-iterates the problem with providing such hard and fast rules. There are just too many variables to take into account. Providing concrete guidelines is going to tie the hands of the ERO Panel and inevitably result in bad decisions being made. The SDT also refers the commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.1 where the basic premise on evaluating an exception request must be based on whether the Elements are necessary for the reliable operation of the interconnected transmission system. Further, reliable operation is defined in the Rules of Procedure as operating the elements of the bulk power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cyber security incident, or unanticipated failure of system elements. The SDT firmly believes that the technical prowess of the ERO Panel, the visibility of the process, and the experience gained by having this same panel review multiple requests will result in an equitable, transparent, and consistent approach to the problem. The SDT would also point out that there are options for a submitting entity to pursue that are outlined in the proposed ERO Rules of Procedure changes if they feel that an improper decision has been made on their submittal. Some commenters have asked whether a single ‘yes’ or ‘no’ response to an item on the exception request form will mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.2 of the proposed Rules of Procedure that states “No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved.”</p> <p>The SDT would like to point out several changes made to the specific items in the form that were made in response to industry comments. The SDT believes that these clarifications will make the process tighter and easier to follow and improve the quality of the submittals.</p> <p>Finally, the SDT would point to the draft SAR for Phase II of this project that calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. Given the complexity of the technical aspects of this problem and the filing deadline that the SDT is working under for Phase I of this project, the SDT believes that it has developed a fair and equitable method of approaching this difficult problem. The SDT asks the commenter to consider all of these facts in making your decision and casting your ballot and hopes that these changes will result in a favorable outcome.</p>
Manitoba Hydro	No	

Organization	Yes or No	Question 1 Comment
<p><b>Response:</b> Without any specific comment the SDT is unable to respond.</p>		
<p>Orange and Rockland Utilities, Inc.</p>	<p>No</p>	<p>In the first paragraph “Entities that have Element(s) designated as excluded, under the BES definition and designations, do not have to seek exception for those Elements under the Exception Procedure.”, before the “General Instruction” it should have had another sentence saying that “for those who do not clearly meet the Inclusions and Exclusions should use the following instructions”. Otherwise, it’s still not very clear.</p>
<p><b>Response:</b> The SDT would like to point out that the “Detailed Information to Support an Exception Request” is only one section of the Exception Form. For clarity, please refer to the complete form contained as part of the proposed ERO Rules of Procedure Appendix 5C; also, see the RoP’s flow chart that outlines the process.</p>		
<p>ISO New England Inc</p>	<p>No</p>	<p>It is unclear what the purpose of submitting diagrams showing the Protection Systems is and we do not feel that it should be a requirement at the onset of the exception process.</p> <p>In the first bullet, we do not feel that the term “Interconnection-wide base case” is required as the phrase “suitably complete and detailed” should provide enough guidance to the submitter that inappropriate equivalent representations would not be accepted. The concern is that one could interpret “Interconnection-wide base case” as the entire Eastern Interconnection model is a requirement.</p>
<p><b>Response:</b> In response to the question about including Protection Systems, the SDT used the term “should also show the Protection Systems”. This is not mandatory; however the SDT has suggested this because the criterion for the evaluation of an Exception is “the Elements are necessary for the Reliable Operation of the interconnected bulk power transmission system”. As an example, the elements could be part of a special protection system or RAS thus they could help the ERO to identify the Elements “necessary for Reliable Operation...” No change made.</p> <p>In response to the comment about a base case, the SDT expects the entity seeking an exception to supply a Base Case that the Regional Entity will acknowledge as appropriate. The SDT points to the variations that will abound in the applications as negating</p>		

Organization	Yes or No	Question 1 Comment
<p>any hard and fast rules in this regard. However, this is not something that hasn't been handled before and there is a great deal of professional experience involved on both the submitter's and the Regional Entity's side of this equation. Having viewed the application details, the SDT believes that both sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to move upward to the ERO panel for a final determination. No change made.</p>		
PSEg Services Corp	No	<p>What is meant by "key performance measures of BES reliability" in the third bullet? A descriptive list would be helpful.</p>
<p><b>Response:</b> As to the lack of key performance measures, the SDT refers the commenters to Appendix 5C of the proposed ERO Rules of Procedure, Section 3.1 where the basic premise on evaluating an exception request must be based on whether the Elements are necessary for the reliable operation of the interconnected transmission system. Further, reliable operation is defined in the Rules of Procedure as operating the elements of the bulk power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cyber security incident, or unanticipated failure of system elements. No change made.</p>		
Hydro-Quebec TransEnergie	No	<p>We believe that the new Technical Principles are better than the previous ones, as they allow flexibility for an Entity to make their case with technical justifications. However, without any guide or specific criteria, it does not allow an Entity to identify the real possibility to obtain an exception. It is not clear at all what will guide the Region or ERO to make their decision to grant or not the exception. In order give confidence to the Industry in the procedure, it would be necessary to define the elements that will guide the decision.</p> <p>Will impact base study be accepted?</p> <p>Will the threshold differences with Quebec Interconnection be accepted?</p>
<p><b>Response:</b> The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. Organization	Yes or No	Question 1 Comment
City of St. George	No	<p>While the general instruction information outlined is applicable, it lacks sufficient detail to know exactly what is needed to be submitted. More importantly the general instructions and the overall document lacks criteria that if met (through study and other documentation methods) would allow for exclusion from or inclusion to the BES. Something similar to the criteria or concepts used in the Appendix 1 of the Local Network Exclusion justification document is needed. Clear criteria should allow an entity to determine with a reasonable degree of certainty that if the criteria are met as demonstrated by the associated study effort that an exemption can be obtained. Otherwise without that criteria, the process will be not far from where the exemption process is today, which will be costly, time consuming and frustrating for the registered entities as well as the regions and NERC. The process needs to be repeatable and consistent between all regions and entities. Entities need to know what is expected and where the finish line is. As presently written each region and NERC would have to develop their own criteria individually and will be open to opinions which could change as personnel changes occur in a given position or panel.</p>
<p><b>Response:</b> The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. <p>Georgia System Operations Corporation</p>	<p>No</p>	<p>: The last half of the first sentence should be changed to “do not have to seek an Exclusion Exception under the Exception Procedure for the Element(s).” The use of “Element(s)” relates back to that term at the start of the sentence, and the reference to an “Exclusion Exception” is necessary because an entity (albeit probably not the Owner), still may choose to seek an Inclusion Exception for such an Element(s).</p> <p>In the 3rd bullet, the reference should be to TPL standards (plural).</p>
<p><b>Response:</b> In response to the suggestion to change the first sentence, the SDT would like to point out that the “Detailed Information to Support an Exception Request” is only one section of the Exception Form. For further clarity, please refer to the complete Exception form contained as part of the proposed ERO Rules of Procedure Appendix 5C; also, see the RoP’s flow chart that outlines</p>		

Organization	Yes or No	Question 1 Comment
<p>the process. No change made.                      The SDT notes that there is now only one TPL standard, TPL-001-2; TPL-001-2 has been approved by the NERC Board of Trustees. As per drafting team guidelines, this document is now to be used in all cases where the TPL standards are referenced in other standards projects. No change made.</p>		
<p>ATC LLC</p>	<p>No</p>	<p>Since an Exception Request may be for approval to designate identified Element(s) as either excluded from or included in the BES, the wording of the first sentence should be changed and the request should clearly indicate (e.g. exclusion/inclusion check boxes) whether the request regards exclusion or inclusion of the Element(s). Here is some draft wording for consideration: Entities that have Element(s) that are included under the BES definition and designations, but seek to have them designated as excluded from the BES or that that have Element(s) that are excluded under the BES definition and designations, but seek to have them designated as included in the BES should submit an Exception Request according to the NERC Exception Procedures and provide detailed information to support the Exception Request as indicated below.</p> <p>In addition, ATC suggests the following clarifying edit. Entities that have BES Element(s) considered as excluded under the BES definition and designations, do not have to seek exception for those Elements under the Exception Procedure.</p>
<p><b>Response:</b> In response to the suggestion to change the first sentence, the SDT would like to point out that the “Detailed Information to Support an Exception Request” is only one section of the Exception Form. For further clarity, please refer to the complete form contained as part of the proposed ERO Rules of Procedure Appendix 5C; also, see the RoP’s flow chart that outlines the process.</p> <p>The SDT would refer the commenter to the first line of page 1 which clearly states this fact. No change made.</p>		
<p>Farmington Electric Utility System</p>	<p>No</p>	<p>The general instructions presented are primarily components to substantiate an Exception Request. However, a cover sheet (template) should be created that includes overall identifying information of the Submitting Entity and the</p>

Organization	Yes or No	Question 1 Comment
		<p>and the Owner if the if they are not the same - the template should align with the draft Appendix 5C Section 4.5.1 of the NERC Rules of Procedure. An Exception Request can be submitted for Inclusion or Exclusion of the BES. The first sentence in the form, “Entities that have Element(s) designated as excluded, under the BES definition and designations, so not have to seek exception for those Element(s) under the Exception Procedure. This would not be true if a Submitting Entity is seeking an Inclusion Exception. FEUS recommends revising to include Inclusion Exception Requests.</p>
<p><b>Response:</b> The SDT acknowledges that the “Detailed Information to Support an Exception Request” is only one section of the Exception Form and in itself lacks required information; the complete form contains the information suggested by the commenter. The full Exception form is part of the proposed ERO Rules of Procedure Appendix 5C; also, see the RoP’s flow chart that outlines the process.</p>		
<p>Transmission Access Policy Study Group</p>		<p>Glossary terms should be capitalized throughout the document. Lowercase “facility,” especially, should not be used. The document should use “Element” instead.</p> <p>The term “interface points,” while common, may not have a sufficiently common understanding to be used in this context. “Boundaries of the Element(s) for which the exception is being requested” may express the SDT’s meaning more clearly.</p>
<p><b>Response:</b> The SDT agrees with the commenter and the form was edited to use the term Element instead of Facility where appropriate.</p> <p>In response to the comment about interface points, the SDT agrees with BPA’s suggestion that the interface point is the point requested by the entity seeking the exception were the Element or Elements interconnect(s) to Bulk Electric System Elements.</p>		
<p>Tri-State Generation and Transmission Assn., Inc. Energy Mangement</p>		<p>This question is actually asking two questions; Tri-State’s answers would be No &amp; Yes. There needs to be a better introduction to what and why the exception is being requested.</p>

Organization	Yes or No	Question 1 Comment
TSGT G&T		This question is actually asking two questions; Tri-State’s answers would be No & Yes. There needs to be a better introduction to what and why the exception is being requested.
<p><b>Response:</b> This is a question that relates to the proposed ERO Rules of Procedure Appendix 5C. This question was forwarded to the RoP team.</p>		
American Electric Power	Yes	<p>Though we have no objections to the proposed content, this is contingent on the number and type of elements eventually found included or excluded as a result of the BES definition itself which is still being drafted. Any changes in that definition could in turn cause us concern regarding these general instructions.</p> <p>There needs to some provision for cases where specific elements which are not specifically contained within the studies. It needs to be clear what additional analysis needs to be provided under those circumstances.</p> <p>We recommend that the owner of the asset be identified as part of the general instructions.</p> <p>In the case of wind resources, how is individual gross nameplate information to be reported?</p>
<p><b>Response:</b> In response to a provision for specific elements not contained in studies, the SDT encourages the submitting entity to provide any additional information or explanation in the comments section of the questions that it believes will assist in the review of its Exception Request. Additionally, the exception form has been clarified to bring home that point.</p> <p><b>Page one:</b> List any attached supporting documents <u>and any additional information that is included to supports the request:</u></p> <p>The owner of the asset is identified in the instructions that are being proposed as part of the ERO Rules of Procedures changes.</p> <p>This revised definition does not change the way that wind resources are reported.</p>

SNPD is concerned, however, that the statement “diagram(s) supplied should also show the Protection Systems at the interface points associated with the Elements for which the exception is being requested” may be subject to differing interpretations. SNPD envisions that at least four different kinds of documents would be responsive to the description: one-line diagrams with breakers and switches (status); identification of relays by their ANSI device numbers; details of the DC control logic for ANSI devices; and, operational scheme descriptions of the type used by system operators. Accordingly, we suggest that the language be refined to identify the specific kinds of diagrams necessary to identify protection systems at the interface with the Elements for which the Exception is sought, including any required details.</p> <p>SNPD suggests that a generic example of a completed form be provided to the industry to help ensure that Exception Requests are supported by consistent and complete information. Such a generic example could be addressed in the Phase 2 BES efforts.</p>

**Response:** The various diagrams suggested by SNPD could be viable as forms of evidence that an entity may want to submit if the

Organization	Yes or No	Question 1 Comment
<p>entity believes they provide evidence to support the exception of an Element. As far as developing generic examples, reference, or guidance documents, the SDT agrees with SNPD that this should be considered in Phase II of the project.</p>		
<p>Southern Company Generation</p>	<p>Yes</p>	<p>In the third bullet under the list of study attributes, it is very important to specifically list the "key performance indicators of BES reliability". This will assist in pointing the studies to focus on the issues relevant to determining the significance of the exception request.</p>
<p><b>Response:</b> The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. If the SDT could have come up with the simple answer, it would have been supplied within the bright-line. The SDT would also like to point out to the commenters that it directly solicited assistance in this matter in the first posting of the criteria and received very little in the form of substantive comments.</p> <p>There are so many individual variables that will apply to specific cases that there is no way to cover everything up front. There are always going to be extenuating circumstances that will influence decisions on individual cases. One could take this statement to say that the regional discretion hasn't been removed from the process as dictated in the Order. However, the SDT disagrees with this position. The exception request form has to be taken in concert with the changes to the ERO Rules of Procedure and looked at as a single package. When one looks at the rules being formulated for the exception process, it becomes clear that the role of the Regional Entity has been drastically reduced in the proposed revision. The role of the Regional Entity is now one of reviewing the submittal for completion and making a recommendation to the ERO Panel, not to make the final determination. The Regional Entity plays no role in actually approving or rejecting the submittal. It simply acts as an intermediary. One can counter that this places the Regional Entity in a position to effectively block a submittal by being arbitrary as to what information needs to be supplied. In addition, the SDT believes that the visibility of the process would belie such an action by the Regional Entity and also believes that one has to have faith in the integrity of the Regional Entity in such a process. Moreover, Appendix 5C of the proposed NERC Rules of Procedure, Sections 5.1.5, 5.3, and 5.2.4, provide an added level of protection requiring an independent Technical Review Panel assessment where a Regional Entity decides to reject or disapprove an exception request. This panel's findings become part of the exception request record submitted to NERC. Appendix 5C of the proposed NERC Rules of Procedure, Section 7.0, provides NERC the option to remand the request to the Regional Entity with the mandate to process the exception if it finds the Regional Entity erred in rejecting or disapproving the exception request. On the other side of this equation, one could make an argument that the Regional Entity has no basis for what constitutes an acceptable submittal. Commenters point out that the explicit types of studies to be</p>		

Organization	Yes or No	Question 1 Comment
		<p>provided and how to interpret the information aren't shown in the request process. The SDT again points to the variations that will abound in the requests as negating any hard and fast rules in this regard. However, one is not dealing with amateurs here. This is not something that hasn't been handled before by either party and there is a great deal of professional experience involved on both the submitter's and the Regional Entity's side of this equation. Having viewed the request details, the SDT believes that both sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to travel upward to the ERO Panel for adjudication.</p> <p>Now, the commenters could point to lack of direction being supplied to the ERO Panel as to specific guidelines for them to follow in making their decision. The SDT re-iterates the problem with providing such hard and fast rules. There are just too many variables to take into account. Providing concrete guidelines is going to tie the hands of the ERO Panel and inevitably result in bad decisions being made. The SDT also refers the commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.1 where the basic premise on evaluating an exception request must be based on whether the Elements are necessary for the reliable operation of the interconnected transmission system. Further, reliable operation is defined in the Rules of Procedure as operating the elements of the bulk power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cyber security incident, or unanticipated failure of system elements. The SDT firmly believes that the technical prowess of the ERO Panel, the visibility of the process, and the experience gained by having this same panel review multiple requests will result in an equitable, transparent, and consistent approach to the problem. The SDT would also point out that there are options for a submitting entity to pursue that are outlined in the proposed ERO Rules of Procedure changes if they feel that an improper decision has been made on their submittal. Some commenters have asked whether a single 'yes' or 'no' response to an item on the exception request form will mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.2 of the proposed Rules of Procedure that states "No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved."</p> <p>The SDT would like to point out several changes made to the specific items in the form that were made in response to industry comments. The SDT believes that these clarifications will make the process tighter and easier to follow and improve the quality of the submittals.</p> <p>Finally, the SDT would point to the draft SAR for Phase II of this project that calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. Given the complexity of the technical aspects of this problem and the filing deadline that the SDT is working under for Phase I of this project, the SDT believes that it has developed a fair and equitable method of approaching this difficult problem. The SDT asks the commenter to</p>

Organization	Yes or No	Question 1 Comment
<p>consider all of these facts in making your decision and casting your ballot and hopes that these changes will result in a favorable outcome.</p> <p>Also, see the answer to question #4.</p>		
Holland Board of Public Works	Yes	<p>The requirement to base flow studies on an “interconnection-wide base case” is likely to include many more lines and buses than necessary to model the impact of a facility that is not material to the BES. Holland BPW request the words “or regional reduction of such a case” be added after “interconnection-wide base case” to avoid unnecessary expense and detail if a more limited study set is adequate to demonstrate the lack of material impact of the facility(ies) in question.</p>
Michigan Public Power Agency	Yes	<p>The requirement to base flow studies on an “interconnection-wide base case” is likely to include many more lines and buses than necessary to model the impact of a facility that is not material to the BES. MPPA and its members request the words “or regional reduction of such a case” be added after “interconnection-wide base case” to avoid unnecessary expense and detail if a more limited study set is adequate to demonstrate the lack of material impact of the facility(ies) in question.</p>
<p><b>Response:</b> In response to the comment about a reduction base case, the SDT expects the entity seeking an exception to supply a Base Case that the Regional Entity will acknowledge as appropriate. The SDT points to the variations that will abound in the applications as negating any hard and fast rules in this regard. However, this is not something that hasn’t been handled before and there is a great deal of professional experience involved on both the submitter’s and the Regional Entity’s side of this equation. Having viewed the application details, the SDT believes that both sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to move upward to the ERO panel for a final determination. No change made.</p>		
Bonneville Power Administration	Yes	<p>BPA suggests clarifying that the interface point is the point where the entity seeking the exception’s facility or facilities interconnect(s) to the Bulk Electric System facility.</p>

Organization	Yes or No	Question 1 Comment
		Page 1 states “Supporting statements for your position from other entities are encouraged.” BPA believes coordination with affected systems should be required under the exemption process.
<p><b>Response:</b> In response to the comment about interface points, the SDT agrees with BPA’s suggestion that the interface point is the point requested by the entity seeking the exception were the Element or Elements interconnect(s) to Bulk Electric System Elements.</p> <p>As for the comment about coordination, the SDT refers the commenter to Appendix 5C of the proposed NERC Rules of Procedure, Section 4.5.2. This section requires the submitting entity to submit a copy of the Exception Request Form Section II to each Planning Coordinator, Reliability Coordinator, Transmission Operator, Transmission Planner, and Balancing Authority that has (or will have upon inclusion of the Element(s) in the BES) the Elements covered by an Exception Request within its Scope of Responsibility.</p>

2. **Pages two and three of the Detailed Information to Support an Exception Request contain a checklist of items that deal with transmission facilities. Do you agree with the information being requested or is there information that you believe needs to be on page two or three that is missing? Please be as specific as possible with your comments.**

**Summary Consideration:** The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it had become obvious to the SDT that the simple answer that so many sought is not achievable. If the SDT could have come up with the simple answer, it would have been supplied within the bright-line. The SDT would also like to point out to the commenters that it directly solicited assistance in this matter in the first posting of the criteria and received very little in the form of substantive comments.

There are many individual variables that will apply to specific cases that there is no way to cover everything up front. There are always going to be extenuating circumstances that will influence decisions on individual cases. One could take this statement to say that the regional discretion hasn't been removed from the process as dictated in the Order. However, the SDT disagrees with this position. The exception application form has to be taken in concert with the changes to the ERO Rules of Procedure and looked at as a single package. When one looks at the rules being formulated for the Exception process, it becomes clear that the role of the Regional Entity has been drastically reduced in the proposed revision. The role of the Regional Entity is now one of reviewing the submittal for completion and making a recommendation to the ERO panel, not to make the final determination. The Regional Entity plays no role in actually approving or rejecting the submittal. It simply acts as an intermediary. One can counter that this places the Regional Entity in a position to effectively block a submittal by being arbitrary as to what information needs to be supplied. The SDT believes that the visibility of the process would belie such an action by the Regional Entity and also believes that one has to have faith in the integrity of the Regional Entity in such a process. Moreover, Appendix 5C of the proposed NERC Rules of Procedure, Sections 5.1.5, 5.3, and 5.2.4, provide an added level of protection requiring an independent Technical Review Panel assessment where a Regional Entity decides to reject or disapprove an exception request. This panel's findings become part of the exception request record submitted to NERC. Appendix 5C of the proposed NERC Rules of Procedure, Section 7.0, provides NERC the option to remand the application to the Regional Entity with the mandate to process the exception if it finds the Regional Entity erred in rejecting or disapproving the Exception Request. Conversely, an argument could be raised that the Regional Entity has no basis for what constitutes an acceptable submittal. Commenters point out that the explicit types of studies to be provided and how to interpret the information are not shown in the application process. The SDT again points to the variations that will abound in the applications as negating any hard and fast rules. However, this is not something that has not been handled before and there is a great deal of professional experience involved on both the submitter's and the Regional Entity's side of the Exception process. Having viewed the application details, the SDT believes that both sides can quickly arrive at

a resolution as to what information needs to be supplied for the submittal to move upward to the ERO panel for a final determination.

While commenters point to lack of direction being supplied to the ERO panel as to specific guidelines for them to follow in making their decision, the SDT re-iterates the problem with providing such hard and fast rules. There are too many variables to consider. Providing concrete guidelines is going to tie the hands of the ERO panel and inevitably result in poor decisions. The SDT also refers the commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.1 where the basic premise on evaluating an exception request must be based on whether the Elements are necessary for the reliable operation of the interconnected transmission system. Further, reliable operation is defined in the Rules of Procedure as operating the elements of the bulk power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cyber security incident, or unanticipated failure of system elements. The SDT firmly believes that the technical expertise of the ERO panel, the visibility of the process, and the experience gained by having the hindsight resulting from reviewing multiple applications will result in an equitable, transparent, and consistent approach to the problem. The SDT would also point out that there are options for a submitting entity to pursue that are outlined in the proposed ERO Rules of Procedure changes if they feel that an improper decision has been made on their submittal.

Some commenters have asked whether a single 'yes' or 'no' response to an item on the exception application form will mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.2, which states "No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved."

The SDT has made several minor changes made to the specific items in the form in response to industry comments. The SDT believes that these clarifications will make the process tighter and easier to follow and improve the quality of the submittals.

Finally, the SDT would point to the SAR for Phase II of this project that calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. Given the complexity of the technical aspects of this problem and the filing deadline that the SDT is working under for Phase I of this project, the SDT believes that it has developed a fair and equitable method of approaching this difficult problem. The SDT asks the commenter to consider all of these facts in making your decision and casting your ballot and hopes that these changes will result in a favorable outcome.

The SDT affirms the requirement to provide the most recent consecutive two calendar year period minimum and maximum magnitude of the power flow out of the Element(s) for which an Exception is sought. The SDT believes that a single year's data is

insufficient to determine a pattern of flow on the Element(s). Moreover, many of the NERC Standards already require longer data retention periods; typically for a full audit period which is either three or six years. See NERC Compliance Process Bulletin #2009-005, Current In-Force Document Data Retention Requirements for Registered Entities, Version 1.0, at 1 (Jun.29, 2009). It should be noted that retaining three second data from an Energy Management System (EMS) or a Supervisory Control And Data Acquisition (SCADA) system is not sought in this instance.

The SDT declines to further define the “maximum magnitude of the power flow.” It is up to the submitting entity to determine how best to present the information supporting their request and any responses provided by the submitting entity can be further described or qualified under the comments section.

The SDT has determined that information on Flowgate impacts and whether Element(s) are included in an Interconnection Reliability Operating Limit (IROL) are necessary to the Regional Entity’s determination of whether an Element(s) is used to provide bulk power transfers within the Interconnections or whether the Element(s) is distribution. A number of interchange coordination Reliability Standards apply to these transfer paths and Flowgates. Accordingly, the SDT believes such facilities are necessary for the reliable operation of an interconnected electric transmission network and would not be excluded from the definition of the BES. Furthermore, the SDT understands that each Flowgate list may be added to or subtracted from based on prevailing system conditions, however, a core set of Flowgates will remain the same. It is up to the submitting entity to determine how best to present the information supporting their request and the nature of the Element(s) impact on a permanent flowgate can be further described or qualified under the comments section.

Due to comments received, the SDT made the following clarifying changes to the request form:

**Page 1** - List any attached supporting documents and any additional information that is included to supports the request:

**Q3.** Please provide the appropriate list for ~~your~~the operating area where the Element(s) is located:

**Q6.** Is ~~Are~~ the facility-Element(s) part of a Cranking Path ~~associated with a Blackstart Resource~~ identified in a Transmission Operator’s restoration plan?

**Q7.** If yes, then using metered or SCADA data for the most recent consecutive two calendar year period, what is the minimum and maximum magnitude of the power flow out of the facility-Element(s)? and d Describe the conditions and the time duration when this ~~could~~ occurs?

<p>Northeast Power Coordinating Council</p>	<p>No</p>	<p>For question 2 on page 2 For Transmission Facilities:</p> <ul style="list-style-type: none"> <li>o What standards will define the “impact”?</li> <li>o What is a material impact and a non-material impact?</li> <li>o What kinds and types of impacts are acceptable/unacceptable?</li> <li>o How are impacts determined?</li> </ul> <p>Question 6 on page 3 reads “Is the facility part of a Cranking Path associated with a Blackstart Resource?”, suggest removing the reference to “Cranking Path” because the Drafting Team does not require that the BES be contiguous, and black start resource Cranking Paths were deleted from Inclusion I3.</p> <p>Question 7 on page 3 asks, “Does power flow through this facility into the BES?” This can only apply to a Local Network with two or more connections to the BES. No power should normally flow through a Local Network (or Radial system) to another portion of the BES. There may be occasional, brief reverse power flows may be acceptable during short periods under abnormal operating conditions.</p> <p>Question 7 also requests “data for the most recent consecutive two calendar year period.” Why is two years worth of data necessary? One year of data would be sufficient.</p> <p>From Question 7, “what is the minimum and maximum magnitude of the power flow out of the facility ...” What is intended by the use of magnitude?</p> <p>Suggest that the Drafting Team adopt the FERC Seven Factor test for question 7.</p> <p>Suggest deleting the “% of the calendar year” check boxes in favor of a statement either that power does not flow through the Local Network, or alternatively, a blank space for reporting the net peak MWs and MWHs transferred annually through the facility, and the percentage of these transferred amounts to the peak and annual MWH demands served by the Local Network.</p> <p>Suggest requesting only one year (8,760 hours) of data covering four seasons,</p>

Organization	Yes or No	Question 2 Comment
		including Summer and Winter capability periods.
Consolidated Edison Co. of NY, Inc.	No	<p>Application Form Page 2For Transmission Facilities:Impacts:Flowgates: The Application form at 2 states, “How does the facility impact permanent Flowgates in the Eastern Interconnection ...”</p> <ul style="list-style-type: none"> <li>o What standards for “impact” does the BES SDT envision?</li> <li>o What is a material impact and a non-material impact?</li> <li>o What kinds and types of impacts are acceptable and/or unacceptable?</li> <li>o How are impacts determined, e.g., Power TFD method, short circuit analysis, A-10 method?</li> </ul> <p>Impact-Based Studies: Note that the FERC Seven Factor test is a time-tested method and FERC has identified it as an acceptable method for reliability purposes; for gauging the expected impact of an Element on the interconnected transmission grid. The NPCC A-10 method has been used extensively in the Northeastern U.S. and Canada, and is an impact-based approach. The power TDF (transfer distribution factor) method is also used by some to assess the impact of changing power flows on individual Elements within a system. FERC has studied using the ‘TIER’ method for classifying system Elements based on LBMP impacts. WECC uses a short circuit test.</p> <p>Page 3Cranking Path Issue: The Application form at 6 asks, “Is the facility part of a Cranking Path associated with a Blackstart Resource?”We understand that:(i) The drafting team does not require that the BES be contiguous, and (ii) Blackstart resource Cranking Paths were deleted from Inclusion I3. Recommendation: Delete the reference to “Cranking Paths” in this Application form.</p> <p>Power Flow Issue: The Application form at 7 asks, “Does power flow through this facility into the BES?” We assume that this can only apply to a Local Network with two or more connections to the BES. We believe that no power should normally flow through a Local Network (or Radial system) to another portion of the BES. Occasional, brief reverse power flows may be acceptable during short periods under abnormal operating conditions, e.g., a switch</p>

Organization	Yes or No	Question 2 Comment
		<p>normally open is briefly closed during a forced maintenance outage.</p> <p>The Application form at 7 requests the following: “data for the most recent consecutive two calendar year period.” o Please explain why the BES SDT felt that two years worth of data was necessary, as one year of data would appear sufficient? Our experience has been that one year (8,760 hours) of data covers four seasons, including Summer and Winter capability periods, and is therefore sufficient. Requiring an extra year is perhaps unnecessarily burdensome on filing Entities, whether asset owners or Regional Entities.</p> <p>The Application form at 7 asks, “[W]hat is the minimum and maximum magnitude of the power flow outflow of the facility ...” o Please explain why the BES SDT used the term “magnitude” when requesting power outflow data?</p> <p>Recommendations: 1) We strongly recommend that the BES SDT adopt the FERC Seven Factor test for these purposes. The FERC Seven Factor test states that, o “Power flows into local distribution systems, and rarely, if ever flows out,” and o “When power enters a local distribution system, it is not reconsigned or transported on to some other market.”</p> <p>2) We recommend deleting the “% of the calendar year” check boxes in favor of a statement either that power does not flow through the Local Network, or alternatively, a blank space for reporting the net peak MWs and MWH’s transferred annually, and the percentage of these transferred amounts to the peak and annual MWH demands served by with the Local Network.3) We recommend requesting only one year (8,760 hours) of data covering four seasons, including Summer and Winter capability periods.</p>
<p><b>Response:</b> The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on the Exception criteria. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that a simple answer is not achievable. If the SDT could have come up with the simple answer, it would have been supplied within the bright-line. The SDT would also like to point out to the commenters that it directly solicited assistance in this matter in the first posting of the criteria and</p>		

Organization	Yes or No	Question 2 Comment
		<p>received very little in the form of substantive comments.</p> <p>Not indicating the explicit types of studies to be provided and how to interpret the information in the application process does not fail to provide a basis for the Regional Entity to determine what constitutes an acceptable submittal. The SDT again points to the variations that will abound in the applications as negating any hard and fast rules in this regard. However, this is not something that hasn't been handled before and there is a great deal of professional experience involved on both the submitter's and the Regional Entity's side of this equation. Having viewed the application details, the SDT believes that both sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to move upward to the ERO panel for a final determination.</p> <p>As to the lack of direction being supplied to the ERO panel in the form of specific guidelines to follow, the SDT refers the commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.1 where the basic premise on evaluating an exception request must be based on whether the Elements are necessary for the reliable operation of the interconnected transmission system. Further, reliable operation is defined in the Rules of Procedure as operating the elements of the bulk power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cyber security incident, or unanticipated failure of system elements. The SDT firmly believes that the technical expertise of the ERO panel, the visibility of the process, and the experience gained by having the hindsight resulting from reviewing multiple applications will result in an equitable, transparent, and consistent approach to the problem.</p> <p>Finally, there are options for a submitting entity to pursue that are outlined in the proposed ERO Rules of Procedure changes if they feel that an improper decision has been made on their submittal.</p> <p>The SDT disagrees with eliminating the question pertaining to Cranking Path. It is important to realize a distinction between the BES definition and the Exception process. While the BES definition established bright-line criteria for the determination between BES and non-BES Element(s), the Exception Process requires an evaluation of all the responses and supporting materials provided as part of the Exception Request Form. No single response or piece of supporting information will be solely dispositive in an Exception Request evaluation. It is not correct to assume that simply because an evaluation criterion was removed from the bright-line definition it should also be eliminated from consideration in the Exception Process. The SDT believes that consideration of Cranking Paths is among the factors to be given consideration in the evaluation for an Exception Request application. Any further discussion of this issue is within the scope of the Phase II SAR. No change made.</p> <p>With respect to concerns about including power flowing through a local network in the Exception Request Form, these concerns fail to recognize the distinction between the BES definition and the Exception Process. As stated above, while the BES definition</p>

Organization	Yes or No	Question 2 Comment
		<p>established bright-line criteria for the determination between BES and non-BES Element(s), the Exception Process requires an evaluation of all the responses and supporting materials provided as part of the Exception Request Form. The SDT believes that power flow through an Element into the BES is among the factors to be given consideration in the evaluation of an Exception Request. In fact, the example identified by commenters identifies one situation that requires such consideration; where occasional, brief reverse power flows may be acceptable during short periods under abnormal operating conditions. Further discussion of this issue is within the scope of the Phase II SAR. No change made.</p> <p>The SDT affirms the requirement to provide the most recent consecutive two calendar year period minimum and maximum magnitude of the power flow out of the Element(s) for which an Exception is sought. The SDT believes that a single year’s data is insufficient to determine a pattern of flow on the Element(s). Moreover, many of the NERC Standards already require longer data retention periods; typically for a full audit period which is either three or six years. See NERC Compliance Process Bulletin #2009-005, Current In-Force Document Data Retention Requirements for Registered Entities, Version 1.0, at 1 (Jun.29, 2009). It should be noted that retaining three second data from an Energy Management System (EMS) or a Supervisory Control And Data Acquisition (SCADA) system is not sought in this instance. No change made.</p> <p>The SDT declines to further define the “maximum magnitude of the power flow.” It is up to the submitting entity to determine how best to present the information supporting their request and any responses provided by the submitting entity can be further described or qualified under the comments section. No change made.</p> <p>The General Instruction area on page one has been modified to clarify that a submitting entity may provide documents and any additional information, including Seven Factor Test related information, which supports their request. It is up to the Submitting entity to determine how best to present the information supporting their request. If the submitting entity wishes to provide this additional information it may do so by listing this information in the area provided under General Instructions in the Exception Request Form.</p> <p><b>Page one:</b> List any attached supporting documents <u>and any additional information that is included to supports the request:</u></p> <p>The SDT has deleted the checkboxes in Question 7. To replace the checkboxes, language has been added requesting the submitting entity to describe the conditions and the time duration when power flow through Element(s) into the BES. It is up to the submitting entity to determine how best to present the information supporting their request.</p> <p><b>Q7.</b> If yes, then using metered or SCADA data for the most recent consecutive two calendar year period, what is the minimum and maximum magnitude of the power flow out of the <u>facility-Element(s)? and d</u>Describe the conditions <u>and the time duration</u> when this <del>could</del> occurs?</p>

Organization	Yes or No	Question 2 Comment
<p>ACES Power Marketing Standards Collaborators</p>	<p>No</p>	<p>Q1, Q5 and Q6 have a “Description/Comments” section. What type of information should be included under the Description for each of these questions? Providing more guidance here would help achieve the “standardization, clarity and continuity of process” that we seek.</p> <p>Regarding Q2: A permanent flowgate should not be part of the detailed information to support an exception. First, there is no definition for what constitutes a permanent flowgate. Second, flowgates are often created for a myriad of reasons that have nothing to do with them being necessary to operate the BES. While section c) in E3 attempts to limit the applicability to permanent flowgates, there is no definition for what constitutes a permanent flowgate particularly since no flowgate is truly permanent. The NERC Glossary of Terms definition of flowgate includes flowgates in the IDC. This is a problem because flowgates are included in the IDC for many reasons not just because reliability issues are identified. Flowgates could be included to simply study the impact of schedules on a particular interface as an example. It does not mean the interface is critical. As an example, it could be used to generate evidence that there are no transactional impacts to support exclusion from the BES. Furthermore, the list of flowgates in the IDC is dynamic. The master list of IDC flowgates is updated monthly and IDC users can add temporary flowgates at anytime. While the "permanent" adjective applied to flowgates probably limits the applicability from the “temporary” flowgates, it is not clear which of the monthly flowgates would be included from the IDC since they might be added one month and removed another. Flowgates are created for many reasons that have nothing to do with them being necessary to operate the BES. First, flowgates are created to manage congestion. The IDC is more of a congestion management tool than a reliability tool. FERC recognized this in Order 693, when they directed NERC to make clear in IRO-006 that the IDC should not be relied upon to relieve IROs that have been violated. Rather, other actions such as re-dispatch must be used in conjunction. Second, flowgates are used as a convenient point to calculate flows to sell transmission service. The</p>

Organization	Yes or No	Question 2 Comment
		<p>characteristics of the flowgate make it a good proxy for estimating how much contractual use has been sold not necessarily how much flow will actually occur. While some flowgates definitely are created for reliability issues such as IROLs, many simply are not.</p> <p>We are unclear about what “an appropriate list” in Q3 is supposed to be. Is it supposed to be a list of all IROLs or only those for which the answer is yes? Why is a list even necessary since the answer to the question answers Exclusion E3.c? If the answer is no, is this asking the submitter to prove the negative?</p>
<p><b>Response:</b> The SDT believes the guidance provided on Page 1 of the Exception Request Form is sufficient. A submitting entity may provide any additional information or explanation in the comments section of the questions that it believes will assist in the review of its Exception Request. No single response or piece of supporting information will be solely dispositive in an Exception Request evaluation and all responses and supporting information provided will receive consideration. It is up to the submitting entity to determine how best to present the information supporting their request in the comment area provided for each question. No change made.</p> <p>The SDT has determined that information on Flowgate impacts and whether Element(s) are included in an Interconnection Reliability Operating Limit (IROL) are necessary to the Regional Entity’s determination of whether an Element(s) is used to provide bulk power transfers within the Interconnections or whether the Element(s) is distribution. A number of interchange coordination Reliability Standards apply to these transfer paths and Flowgates. Accordingly, the SDT believes such facilities are necessary for the reliable operation of an interconnected electric transmission network and would not be excluded from the definition of the BES. Furthermore, the SDT understands that each Flowgate list may be added to or subtracted from based on prevailing system conditions, however, a core set of Flowgates will remain the same. It is up to the submitting entity to determine how best to present the information supporting their request and the nature of the Element(s) impact on a permanent flowgate can be further described or qualified under the comments section. No change made.</p> <p>The SDT has clarified that the submitting entity is to provide the appropriate list of IROLs for the operating area where the Element(s) is/are located.</p> <p><b>Q3.</b> Please provide the appropriate list for <del>you</del><u>the</u> operating area <u>where the Element(s) is located</u>:</p>		
Bonneville Power	No	Regarding #4 on page 2: BPA believes the impact to the over-all reliability of

Organization	Yes or No	Question 2 Comment
Administration		<p>the BES needs to consider more than just an outage of the facility requesting exclusion. One example is a contingency outage of a parallel facility that could cause an overload. Item 4 needs to include impacts of either the outage of the facility, or with the facility in service. BPA believes that the entity requesting an exception may not have information on impacts of the facility on parallel higher-voltage facilities because the NERC requirements for data sharing for these types of facilities does not necessarily include owners and operators of lower voltage systems. The entity requesting an exemption would likely need to coordinate with affected systems, and this coordination should be required in the exemption process so that affected systems are aware of the possible exclusion.</p>
<p><b>Response:</b> The SDT will continue to monitor the process over next 12 months and if it is determined additional information is needed, such as how outages of BES facilities impact the Element(s) for which an exception is sought, it will be addressed in Phase II. Nevertheless, submitting entities are free to include information in response to any question that best supports their request for an exception. No change made.</p> <p>Coordination of an exception request with affected systems is already addressed in the Exception Rules of Procedure, Appendix 5C Sections 4.1, 4.4, 4.5.1, and 4.5.2, requiring the submitting entity, if not the facility owner, to provide a copy of the request to the facility owner, all involved Regional Entities if it is a cross-border facility, and to the Planning Coordinator, Reliability Coordinator, Transmission Operator, Transmission Planner, and Balancing Authority that has (or will have upon inclusion in the BES) the Elements covered by an exception request within its scope of responsibility.</p>		
Pepco Holdings Inc	No	<p>1) Why is Item 5 (Question pertaining to whether the facility is used for off-site power to a nuclear plant) included, since this criteria is not part of the proposed bright-line BES definition.</p> <p>2) Similarly, why is Item 6 (Question pertaining to whether the facility is part of a Cranking Path associated with a Black Start Resource) included, since Black Start Cranking Paths were removed from the latest BES definition.</p> <p>Both Items 5 and 6 should be removed from the Exception Request Form.</p>

Organization	Yes or No	Question 2 Comment
<p><b>Response:</b> The SDT disagrees with eliminating Questions 5 and 6. It is important to realize a distinction between the BES definition and the Exception Procedure. While the BES definition established bright-line criteria for the determination between BES and non-BES Element(s), the Exception Process requires an evaluation of all the responses and supporting materials provided as part of the Exception Request Form. No single response or piece of supporting information will be solely dispositive in an Exception Request evaluation. It is not correct to assume that simply because an evaluation criterion was removed from the bright-line definition it should also be eliminated from consideration in the Exception Process. The SDT believes that Cranking Paths and off-site power supply to a nuclear power plants are among the factors to be given consideration in the evaluation for an Exception Request. Further discussion of this issue is within the scope of the Phase II SAR. No change made.</p>		
<p>Electricity Consumers Resource Council (ELCON)</p>	<p>No</p>	<p>A sub-question should be added to Question 1 asking: (1) Does the generation serve all or a part of retail customer Load, and (2) If so, the maximum net capacity of each unit injected to the BES during non-emergency conditions.</p>
<p><b>Response:</b> The General Instruction area on page one has been modified to clarify that a submitting entity may provide documents and any additional information that supports their request. If the submitting entity wishes to provide this additional information it may do so by listing this information in the area provided under General Instructions. No change made.</p>		
<p>AECI and member G&amp;Ts</p>	<p>No</p>	<p>There is no basis in this draft Standard for including Item 6). Item 7) does appear appropriate within the Standard, but the intent of the four check-boxes is ambiguous.</p>
<p><b>Response:</b> The SDT disagrees with eliminating the question pertaining to Cranking Path. It is important to realize a distinction between the BES definition and the Exception Procedure. While the BES definition established bright-line criteria for the determination between BES and non-BES Element(s), the Exception Procedure requires an evaluation of all the responses and supporting materials provided as part of the Exception Request Application Form. No single response or piece of supporting information will be solely dispositive in an Exception Request evaluation. The SDT believes that the Cranking Path is among the factors to be given consideration in the evaluation for an Exception Request application. Further discussion of this issue is within the scope of the Phase II SAR. No change made.</p> <p>The SDT has deleted the checkboxes in Question 7. To replace the checkboxes, language has been added requesting the submitting entity to describe the conditions and the time duration when power flow through Element(s) into the BES. It is up to the submitting</p>		

Organization	Yes or No	Question 2 Comment
<p>entity to determine how best to present the information supporting their request.</p> <p><b>Q7.</b> If yes, then using metered or SCADA data for the most recent consecutive two calendar year period, what is the minimum and maximum magnitude of the power flow out of the <del>facility Element(s)? and e</del> Describe the conditions <u>and the time duration</u> when this <del>could</del> occurs?</p>		
NERC Staff Technical Review	No	<p>In addition to describing how an outage of the facility under consideration affects the rest of the BES, the Submitting entity also should be required to provide an assessment of how outages of BES facilities affect the facility under consideration. This could be achieved with powerflow studies or distribution factor analysis.</p>
<p><b>Response:</b> The SDT will continue to monitor the process over next 12 months and if it is determined additional information is needed, such as how outages of BES facilities impact the Element(s) for which an Exception is sought, it will be addressed in Phase II. Nevertheless, the General Instruction area on page one has been modified to clarify that a submitting entity may provide documents and any additional information that supports their request. If the submitting entity wishes to provide this additional information it may do so by listing this information in the area provided under General Instructions. No change made.</p>		
IRC Standards Review Committee	No	<p>We agree with most parts on P.2 and P.3, but question the need for Q6, which asks: "Is the facility part of a Cranking Path associated with a Blackstart Resource?" I3 in the BES definition stipulates that Blackstart Resources identified in the Transmission Operator's restoration plan be included (which we disagree and commented in the BES Definition Comment Form). There is no inclusion of any transmission facilities that are part of the cranking path. We suggest this item (Q6) be removed.</p>
<p><b>Response:</b> The SDT disagrees with eliminating the question pertaining to Cranking Path. It is important to realize a distinction between the BES definition and the Exception Procedure. While the BES definition established bright-line criteria for the determination between BES and non-BES Element(s), the Exception Procedure requires an evaluation of all the responses and supporting materials provided as part of the Exception Request Form. No single response or piece of supporting information will be solely dispositive in an Exception Request evaluation. It is not correct to assume that simply because an evaluation criterion was removed from the bright-line definition it should also be eliminated from consideration in the Exception Procedure. The SDT believes</p>		

Organization	Yes or No	Question 2 Comment
<p>that Cranking Path is among the factors to be given consideration in the evaluation for an Exception Request application. Further discussion of this issue is within the scope of the Phase II SAR. No change made.</p>		
PacifiCorp	No	<p>Question 6 implies that if the facility is part of a designated blackstart cranking path then an exception request would most likely be denied. To the extent that was the intent, such an assumption would only be reasonable if the blackstart cranking path is the only path available. However, PacifiCorp suggests modifying the current Question 6 to reflect a situation in which multiple cranking paths are available, as follows: "6A. Is the facility part of a Cranking Path associated with a Blackstart Resource? 6B. If yes, does the Blackstart Resource have other viable Cranking Paths?"</p>
<p><b>Response:</b> Several commenters have asked whether a single 'yes' or 'no' response to an item on the exception request form will mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed ERO Rules of Procedure, Section 3.2 that states "No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved."</p> <p>The SDT has adopted clarifying language to differentiate between multiple Cranking Paths by requiring the Cranking Path "identified in a Transmission Operator's restoration plan."</p> <p><b>Q6. Is/Are the <u>facility Element(s)</u> part of a Cranking Path <u>associated with a Blackstart Resource identified in a Transmission Operator's restoration plan</u>?</b></p>		
Snohomish County PUD	No	<p>SNPD agrees that the checklist of items on pages two and three lists most of the information that would be necessary to determine if an Exceptions Request is justified. We suggest three modifications to the proposed language to ensure consistency with Section 215 of the Federal Power Act, with the BES Definition, and to provide an entity seeking an Exception with the opportunity to submit all relevant information: (1) SNPD suggests that a new question should be added concerning the function of the facility, which would read: "Does the facility function as a local distribution facility rather than a Transmission facility? If yes, please provide a detailed explanation of your answer." Section 215(a)(1) of the</p>

Organization	Yes or No	Question 2 Comment
		<p>FPA makes clear that “facilities used in the local distribution of electric energy” are excluded from the BES, 16 U.S.C. Â§ 824o(a)(1), and the most recent draft of the BES definition incorporates the same language. SNPD believes a question to address the function of the Element or system subject to an Exception Request is necessary to determine whether the Element or system is “used” in local distribution and thereby to ensure that this statutory limit on the BES is observed in the Exceptions process. Further, we believe a variety of information may be relevant to determining whether a particular facility functions as local distribution rather than as part of the BES. For example, if power is not scheduled across the facility or if capacity on the system is not posted on the relevant OASIS, it is likely to function as local distribution, not transmission. Similarly, if power enters the system and is delivered to load within the system rather than moving to load located on another system, its function is local distribution rather than transmission. SNPD proposes the language above as an open-ended question so that the entity submitting the Exceptions Request can provide this and any other information it deems relevant to facility function.</p> <p>(2) SNPD suggests modifying question 6 to “Is the facility part a designated Cranking Path associated with a Blackstart Resource identified in a Transmission Operator’s restoration plan.” This language reflects the most recent revision of the BES Definition, which removes the reference to “Cranking Paths,” and also helps distinguish between generators which have Blackstart capability and those generators that are designated as a Blackstart Resource in the Transmission Operator’s restoration plan. It is only the latter that are included in the BES under the current draft of the definition.</p> <p>(3) A general “catch-all” question should be added that will prompt the entity submitting an Exception Request to submit any information it believes is relevant to the Exception that is not captured in the other questions. We suggest the following language: "Is there additional information not covered in the questions above that supports the Exception Request? If yes, please</p>

Organization	Yes or No	Question 2 Comment
		<p>provide the information and explain why it is relevant to the Exception Request."While SNPD believes the questions set forth in the draft capture the information that generally would be necessary to determine whether an Exception Request should be granted, it is foreseeable that there may be unusual circumstances where the information called for either does not capture the full picture or where studies other than the specific types called for in the draft form support the Exception. An entity seeking an Exception should have the opportunity to present any information it believes is relevant.</p>
<p><b>Response:</b> The General Instruction area on page one has been modified to clarify that a submitting entity may provide documents and any additional information that supports their request. It is up to the submitting entity to determine how best to present the information supporting their request. If the submitting entity wishes to provide this additional information it may do so by listing this information in the area provided under General Instructions.</p> <p><b>Page one:</b> List any attached supporting documents <u>and any additional information that is included to supports the request:</u></p> <p>The SDT has adopted clarifying language to differentiate between multiple Cranking Paths by requiring the Cranking Path “identified in a Transmission Operator’s restoration plan.”</p> <p><b>Q6.</b> Is/<u>Are</u> the <u>facility Element(s)</u> part of a Cranking Path <del>associated with a Blackstart Resource</del> <u>identified in a Transmission Operator’s restoration plan?</u></p>		
Duke Energy	No	<p>Modify wording on #3 as follows: “Please provide the appropriate list for the operating area where the facility is located.”</p> <p>Modify the wording on #6 as follows: “Is the facility part of a Cranking Path identified in an entity’s restoration plan for a Blackstart Resource as required by EOP-005-2?”</p>
<p><b>Response:</b> The SDT has accepted the recommended wording change to Question 3.</p> <p><b>Q3.</b> Please provide the appropriate list for <del>you</del><u>the</u> operating area <u>where the Element(s) is located:</u></p> <p>The SDT has adopted clarifying language to differentiate between multiple cranking paths by requiring the cranking path “identified</p>		

Organization	Yes or No	Question 2 Comment
<p>in a Transmission Operator’s restoration plan.”</p> <p><b>Q6. Is/Are the <u>facility-Element(s)</u> part of a Cranking Path <del>associated with a Blackstart Resource</del> <u>identified in a Transmission Operator’s restoration plan</u>?</b></p>		
<p>ReliabilityFirst</p>	<p>No</p>	<p>All generating units, to some degree, affect the transmission elements that make-up the BES. What role will this effect have on the determination? If the systems are planned properly and the day-ahead analysis is done for maintenance work, the outage of any one element is moot. What is the phrase “impact the over-all reliability” getting at? These studies and analysis will need to look at multiple outages and groups of elements being taken out and excluded. Will this be on a first come, first out process?</p> <p>As for the Nuclear Plant Interface Requirement (NPIR) question, ReliabilityFirst Staff believes these facilities should always be included as part of the BES and taken out of the Detailed Information to Support an Exception Request.</p> <p>For question 6 ReliabilityFirst Staff believes the Cranking Path should be included in the BES definition. . ReliabilityFirst Staff feels that without including the Cranking Paths, the reliability of the system could be jeopardized if a restoration is required and the Cranking Paths are unavailable due to non-adherence to Reliability Standards.</p> <p>Omit question 7, E3 (LN) of the definition already talks to power flow and even if there is a small percentage of flow, it makes that entity a user of the BES, which should be included.</p>
<p><b>Response:</b> The SDT refers the commenter to the phrase consistent ‘with TPL methodologies’ which the SDT believes will cover the item in question. The SDT reminds the commenter that the evaluation in question is not for removing the Element from service but simply from inclusion or exclusion in the BES. Therefore, there should be no problem with evaluating multiple requests in the same area and no first in, first out scenario.</p> <p>The questions on nuclear interface facilities and Cranking Paths will be retained. They are just one piece of information in the process</p>		

Organization	Yes or No	Question 2 Comment
<p>and the SDT considers them as important considerations. No change made.</p> <p>Question 7 will be retained. It is important to realize a distinction between the BES definition and the Exception Procedure. While the BES definition established bright-line criteria for the determination between BES and non-BES Element(s), the Exception Procedure requires an evaluation of all the responses and supporting materials provided as part of the Exception Request Form. No single response or piece of supporting information will be solely dispositive in an Exception Request evaluation. The SDT believes that power flow through this Element(s) into the BES is among the factors to be given consideration in the evaluation for an Exception Request application.</p>		
Hydro-Quebec TransEnergie	No	
Manitoba Hydro	No	
<p><b>Response:</b> Without additional information, the SDT is unable to respond.</p>		
Consumers Energy	No	<p>We believe that item 6, should read "Is the facility part of a Primary Cranking Path associated with a Blackstart Resource?" Currently, the word "Primary" is not included.</p>
<p><b>Response:</b> The SDT has adopted clarifying language to differentiate between multiple cranking paths by requiring the cranking path "identified in a Transmission Operator's restoration plan."</p> <p><b>Q6.</b> <u>Is/Are the facility-Element(s) part of a Cranking Path-associated with a Blackstart Resource identified in a Transmission Operator's restoration plan?</u></p>		
Orange and Rockland Utilities, Inc.	No	<p>Please clarify "facility" and include "N-1" for power-flow studying.</p>
<p><b>Response:</b> In order to maintain consistency with the nomenclature used in the Exception Process Document, draft Appendix 5C of the NERC Rules of Procedure, the SDT has replaced "facilities" with "Element(s)", where appropriate.</p> <p>The SDT has pointed to the TPL methodology in the document and that should address your comment. No change made.</p>		

Organization	Yes or No	Question 2 Comment
ISO New England Inc	No	<p>- Question 1o The use of the words “connected to” is unclear. Some may read this as generation “directly” connected to while others could interpret it more generically.</p> <p>o A generation cut-off should be included in the requirement to list all indiv</p>
<p><b>Response:</b> The SDT acknowledges and appreciates the comments but has determined no additional clarity is needed to Question 1. It is up to the submitting entity to determine how best to present the information supporting their request and any responses can be further described or qualified under the comments section to Question 1. No change made.</p> <p>The SDT does not believe a generation threshold is appropriate for listing all connected units. The SAR for Phase II of this project calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. No change made.</p>		
PSEg Services Corp	No	<p>Questions #4 requires an analysis of the “most severe impact” associated an outage of the Element proposed for exception. a. Both the newly Board approved TPL-001-2 standard and the existing TPL-004-1 require that severe contingencies be evaluated, but there are no performance requirements for them. If the team intended the “most-severe impact” analysis to only evaluate TPL outages that incorporate performance requirements, it should make that clear. b. The most-severe-outage impact question does not ask key relevant information such as: i. What is the probability that the “most severe impact “will occur? ii. Could the impact be readily mitigated and service restored? This point is critical because the impact of an outage lasting several minutes before restoration versus several hours before restoration should affect the analysis.</p> <p>What does question #7 (“Does power flow through this facility into the BES?”) with check boxes for various % of a calendar year that power flows into the BES) imply with respect to a transmission facility’s exception request? Also, is the % of a calendar year data intended to be forecasted data or historic data? It would seem that forecasted data would need to be supplied that is consistent</p>

Organization	Yes or No	Question 2 Comment
		<p>with the TPL models.</p> <p>Finally, why are historic flows requested - they have no relevance except for perhaps explaining historic and forecasted differences?</p>
<p><b>Response:</b> The document cites that the TPL methodology should be followed and that should address your concern. An entity does not have to duplicate TPL studies. No change made.</p> <p>The SDT has replaced the checkboxes and language has been added requesting the submitting entity to describe the conditions and the time duration when power flow through Element(s) into the BES. It is up to the submitting entity to determine how best to present the information supporting their request.</p> <p><b>Q7.</b> If yes, then using metered or SCADA data for the most recent consecutive two calendar year period, what is the minimum and maximum magnitude of the power flow out of the <del>facility-Element(s)? and dD</del> describe the conditions <u>and the time duration</u> when this <del>could</del> occurs?</p> <p>Historic flows are requested because they are an indication of power flow patterns. It is up to the submitting entity to determine how best to present the information supporting their request and any responses can be further described or qualified under the comments section.</p>		
City of St. George	No	<p>The questions for transmission facilities seem to be appropriate; however, how the answers are to be used by the region or NERC is unclear. Will a given response to a question make exclusion impossible? If so this needs to be known upfront and clearly documented.</p> <p>For example question 4, on page 2 is open for interpretation and debate as to what the impact to the over-all reliability of the BES is. The definition of “impact” is really the key to the whole definition effort. Load flow, voltage, frequency change limits may all be pieces to the puzzle. Are these criteria to be met in normal, N-1, N-2, etc. system configurations?</p>
<p><b>Response:</b> Several commenters have asked whether a single ‘yes’ or ‘no’ response to an item on the exception application form will mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.2 of the proposed Rules of Procedure that states “No single piece of evidence provided as part of an</p>		

Organization	Yes or No	Question 2 Comment
<p>Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved.”</p> <p>The document cites that an entity should follow the TPL methodology.</p>

resolved as part of the review process. No change made.		
National Grid	No	<p>We agree with the information requested on pages 2 and 3, however we would like more clarification regarding Item 7. When answering what % of the calendar year power flows through the facility into BES, should this be calculated on an hourly basis?</p> <p>We would also like clarification for Item 7 regarding the request for SCADA data from the last 2 years to determine the minimum and maximum magnitude of the power flow out of the facility. What data should be used in situations with new facilities or in situations or where the system configuration (topology) has changed in such a way that the power flows in the area have changed, so the last 2 years of SCADA data is no longer relevant</p>
<p><b>Response:</b> The SDT has deleted the checkboxes in Question 7. To replace the checkboxes, language has been added requesting the submitting entity to describe the conditions and the time duration when power flow through Element(s) into the BES. It is up to the submitting entity to determine how best to present the information supporting their request.</p> <p><b>Q7.</b> If yes, then using metered or SCADA data for the most recent consecutive two calendar year period, what is the minimum and maximum magnitude of the power flow out of the <del>facility-Element(s)? and eD</del> describe the conditions <u>and the time duration</u> when this <del>could</del> occurs?</p> <p>The SDT recommends that each submitting entity work with its Regional Entity to resolve issues with information availability or access and, in the event such information is not available, whether suitable replacement data is acceptable. The SDT further recommends that where information is unavailable, the submitting entity state such in the comment area and provide the reason for this unavailability. This will signal the Regional Entity that an issue concerning information availability will need to be resolved as part of the review process.</p>		
Ameren	No	<p>From our perspective, the first question should be “Is the facility connected at 100 kV or above?” The questions should be reordered. Of the questions listed, question #3 should be #1, and questions #1 should be the last question in this section.</p>

Organization	Yes or No	Question 2 Comment
		Regarding the word “permanent” as it is used to describe Flowgates, it is suggested that the word “limiting” or “constrained” be used instead.
<p><b>Response:</b> The SDT does not believe the order of the questions is significant since no single response or piece of supporting information will be solely dispositive in an Exception Request evaluation and all responses and supporting information provided will receive consideration. No change made.</p> <p>The SDT believes that the continued qualifier of “permanent” associated with the term “Flowgate” addresses the intent of the definition. No change made.</p>		
ATC LLC	No	ATC proposes the following changes to Item #7:7a. Are Firm Power Transfers scheduled to flow out of, or through, this facility into the BES in the operating horizon? [for BES designations applicable to the operating horizon] Note: The consideration for power flowing into the BES should be based on normal operating conditions or base case (n-0 contingency analysis), not on historical real-time telemetry. 7b. Are Firm Power Transfers reserved to flow out of, or through, this facility into the BES in the planning horizon? [for BES designations applicable to the planning horizon)
<p><b>Response:</b> The General Instruction area on page one has been modified to clarify that a submitting entity may provide documents and any additional information that supports the request. It is up to the submitting entity to determine how best to present the information supporting their request. If the submitting entity wishes to provide this additional information it may do so by listing this information in the area provided under General Instructions on the Exception Request Form.</p> <p><b>Page one:</b> List any attached supporting documents <u>and any additional information that is included to supports the request:</u></p>		
Farmington Electric Utility System	No	<p>The form should be titled “For Transmission Elements” rather than “Facilities” to align with the BES definition and Appendix 5C of the NERC Rules of Procedure.</p> <p>The form should align with section 4.5.1 and 4.5.2 of Appendix 5C. It should include a listing of the Element(s) and the status based on the application of the</p>

Organization	Yes or No	Question 2 Comment
		<p>BES Definition.</p> <p>Question 6 relates to a ‘facility’ that is part of a Cranking Path. The latest revision of the BES Definition removed the designated blackstart Cranking Paths from the Inclusion of the BES in I3. Having a question regarding the Cranking Path in the Exception Request makes it appear Cranking Paths are still automatically included in the BES.</p> <p>Question 7; what is an alternate method if a Requesting Entity does not have SCADA data for the most recent two consecutive calendar years.</p>
<p><b>Response:</b> In order to maintain consistency with the nomenclature used in the Exception Process Document, draft Appendix 5C of the NERC Rules of Procedure, the SDT has replaced “facilities” with “Element(s)”, where appropriate.</p> <p>A checkbox for indicating the current BES status and a space for listing elements for which an exception is sought is included in Sections I and II, respectively, of the Exception Request Form provided by the Rules of Procedure Team in their posting.</p> <p>The SDT disagrees with eliminating the question pertaining to Cranking Path. It is important to realize a distinction between the BES definition and the Exception process. While the BES definition established bright-line criteria for the determination between BES and non-BES Element(s), the Exception Process requires an evaluation of all the responses and supporting materials provided as part of the Exception Request Form. No single response or piece of supporting information will be solely dispositive in an Exception Request evaluation. It is not correct to assume that simply because an evaluation criterion was removed from the bright-line definition it should also be eliminated from consideration in the Exception process. The SDT believes that cranking paths is among the factors to be given consideration in the evaluation for an Exception Request application. Any further discussion of this issue is within the scope of the Phase II SAR. No change made.</p> <p>The SDT further disagrees that including Question 6 in the Exception Request Form, relating to Element(s) that are a part of a Cranking Path, makes it appear that Cranking Paths are automatically included in the BES. The BES definition and the Exception Request Procedure are separate processes.</p> <p>The SDT recommends that each submitting entity work with its Regional Entity to resolve issues with information availability or access and, in the event such information is not available, whether suitable replacement data is acceptable. The SDT further recommends that where information is unavailable, the submitting entity state such in the comment area and provide the reason for this unavailability. This will signal the Regional Entity that an issue concerning information availability will need to be resolved as part</p>

of the review process. No change made.		
Metropolitan Water District of Southern California	No	<p>General Comments: Metropolitan Water District of Southern California (“MWDSC”) believes that additional work is necessary to explain how this Detailed Information to Support an Exception Request will be used in evaluating whether a transmission facility will be an exception to the BES.</p> <p>In addition, MWDSC agrees WECC that the proposed Technical Principles for Demonstrating BES Exceptions Request is lack of clarity. It does not provide detail information as to what entities must provide to support their requests, nor does it provide any criteria for consistency among regions in their assessment of requests.</p> <p>Lastly, the current proposal leaves it to each region to develop its own methodology and criteria for evaluating the technical studies. MWDSC believes that drafting team should establish a common method and criteria to apply continent-wide in achieving uniformity and consistency among regions in their assessment of exception requests.</p> <p>Comments to Checklist #4: MWDSC recommends the following changes to emphasize facility impact on the interconnection of the BES:”How does an outage of the facility impact the over-all reliability of to the interconnection of the BES?”</p> <p>Comments to Checklist #7: What percentage of power flow through entity’s facility into the BES will be considered as an exception to the BES?</p>
<p><b>Response:</b> The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. If the SDT could have come up with the simple answer, it would have been supplied within the bright-line. The SDT would also like to point out to the commenters that it directly solicited assistance in this matter in the first posting of the criteria and received very little in the form of substantive comments.</p>		

Organization	Yes or No	Question 2 Comment
		<p>There are so many individual variables that will apply to specific cases that there is no way to cover everything up front. There are always going to be extenuating circumstances that will influence decisions on individual cases. One could take this statement to say that the regional discretion hasn't been removed from the process as dictated in the Order. However, the SDT disagrees with this position. The exception request form has to be taken in concert with the changes to the ERO Rules of Procedure and looked at as a single package. When one looks at the rules being formulated for the exception process, it becomes clear that the role of the Regional Entity has been drastically reduced in the proposed revision. The role of the Regional Entity is now one of reviewing the submittal for completion and making a recommendation to the ERO Panel, not to make the final determination. The Regional Entity plays no role in actually approving or rejecting the submittal. It simply acts as an intermediary. One can counter that this places the Regional Entity in a position to effectively block a submittal by being arbitrary as to what information needs to be supplied. In addition, the SDT believes that the visibility of the process would belie such an action by the Regional Entity and also believes that one has to have faith in the integrity of the Regional Entity in such a process. Moreover, Appendix 5C of the proposed NERC Rules of Procedure, Sections 5.1.5, 5.3, and 5.2.4, provide an added level of protection requiring an independent Technical Review Panel assessment where a Regional Entity decides to reject or disapprove an exception request. This panel's findings become part of the exception request record submitted to NERC. Appendix 5C of the proposed NERC Rules of Procedure, Section 7.0, provides NERC the option to remand the request to the Regional Entity with the mandate to process the exception if it finds the Regional Entity erred in rejecting or disapproving the exception request. On the other side of this equation, one could make an argument that the Regional Entity has no basis for what constitutes an acceptable submittal. Commenters point out that the explicit types of studies to be provided and how to interpret the information aren't shown in the request process. The SDT again points to the variations that will abound in the requests as negating any hard and fast rules in this regard. However, one is not dealing with amateurs here. This is not something that hasn't been handled before by either party and there is a great deal of professional experience involved on both the submitter's and the Regional Entity's side of this equation. Having viewed the request details, the SDT believes that both sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to travel upward to the ERO Panel for adjudication.</p> <p>Now, the commenters could point to lack of direction being supplied to the ERO Panel as to specific guidelines for them to follow in making their decision. The SDT re-iterates the problem with providing such hard and fast rules. There are just too many variables to take into account. Providing concrete guidelines is going to tie the hands of the ERO Panel and inevitably result in bad decisions being made. The SDT also refers the commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.1 where the basic premise on evaluating an exception request must be based on whether the Elements are necessary for the reliable operation of the interconnected transmission system. Further, reliable operation is defined in the Rules of Procedure as operating the elements of the bulk power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled</p>

Organization	Yes or No	Question 2 Comment
		<p>separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cyber security incident, or unanticipated failure of system elements. The SDT firmly believes that the technical prowess of the ERO Panel, the visibility of the process, and the experience gained by having this same panel review multiple requests will result in an equitable, transparent, and consistent approach to the problem. The SDT would also point out that there are options for a submitting entity to pursue that are outlined in the proposed ERO Rules of Procedure changes if they feel that an improper decision has been made on their submittal.</p> <p>Some commenters have asked whether a single ‘yes’ or ‘no’ response to an item on the exception request form will mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.2 of the proposed Rules of Procedure that states “No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved.”</p> <p>The SDT would like to point out several changes made to the specific items in the form that were made in response to industry comments. The SDT believes that these clarifications will make the process tighter and easier to follow and improve the quality of the submittals.</p> <p>Finally, the SDT would point to the draft SAR for Phase II of this project that calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. Given the complexity of the technical aspects of this problem and the filing deadline that the SDT is working under for Phase I of this project, the SDT believes that it has developed a fair and equitable method of approaching this difficult problem. The SDT asks the commenter to consider all of these facts in making your decision and casting your ballot and hopes that these changes will result in a favorable outcome.</p> <p>The SDT believes no further clarification is needed in Question 4. The General Instruction area on page one has been modified to clarify that a submitting entity may provide documents and any additional information that supports their request. It is up to the submitting entity to determine how best to present the information supporting their request. If the submitting entity wishes to provide this additional information it may do so by listing this information in the area provided under General Instructions on the Exception Request Form.</p> <p><b>Page one:</b> List any attached supporting documents <u>and any additional information that is included to supports the request:</u></p> <p>The Exception Process requires an evaluation of all the responses and supporting materials provided as part of the Exception Request Form. There are no set thresholds, the percentage of power flow through and entity’s facility into the BES will be but one factor</p>

Organization	Yes or No	Question 2 Comment
among others considered when evaluating a BES Exception Request.		
Transmission Access Policy Study Group		<p>Question 7 asks, “[d]oes power flow through this facility into the BES?” As in the rest of the document, the reference should be to an “Element(s),” rather than to a “facility.” In addition, we suggest that the meaning of power flowing “through” the Element(s) be clarified, consistent with clarification of the same point in Exclusion E3 of the BES Definition.</p> <p>In TAPS’ comments on the BES Definition, also submitted today, TAPS suggests that the first sentence of Exclusion E3 be revised to state: “Power flows only into the LN, that is, at each individual connection at 100 kV or higher, the pre-contingency flow of power is from outside the LN into the LN for all hours of the previous 2 years.” We propose that Question 7 in the Detailed Information to Support an Exception Requests be similarly revised: “Does power flow from this facility into the BES, i.e., at any individual connection at 100kV or higher, is the pre-contingency flow of power from the LN to the BES for any hour of the previous 2 years?”</p>
<p><b>Response:</b> In order to maintain consistency with the nomenclature used in the Exception Process Document, draft Appendix 5C of the NERC Rules of Procedure, the SDT has replaced “facilities” with “Element(s)” where appropriate.</p> <p>The SDT disagrees with the use of parallel language for exclusions in the BES Definition and Exception Request Form. It is important to realize a distinction between the BES definition and the Exception process. While the BES definition established bright-line criteria for the determination between BES and non-BES Element(s), the Exception Process requires an evaluation of all the responses and supporting materials provided as part of the Exception Request Application Form.</p>		
Tri-State Generation and Transmission Assn., Inc. Energy Mangement		<p>Again Yes/No is conflicting in the question. The requested information in#2 is too vague and may be subjective. If the information in#7 is requested in the planning stage the data would not be available.</p> <p>What objective criteria would be used to determine the state of the exception request?</p>

Organization	Yes or No	Question 2 Comment
TSGT G&T		<p>Again Yes/No is conflicting in the question. The requested information in#2 is too vague and may be subjective.</p> <p>If the information in#7 is requested in the planning stage the data would not be available.</p> <p>What objective criteria would be used to determine the state of the exception request?</p>
<p><b>Response:</b> The SDT disagrees that the information requested in Question 2 is too vague and subjective but understands the concerns raised by the commenters in not receiving hard and fast guidance on the Exception criteria. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. This is not something that hasn’t been handled before by either party and there is a great deal of professional experience involved on both the submitter’s and the Regional Entity’s side of this equation. Having viewed the request details, the SDT believes that both sides</p>		

Organization	Yes or No	Question 2 Comment
		<p>can quickly arrive at a resolution as to what information needs to be supplied for the submittal to travel upward to the ERO Panel for adjudication.</p> <p>Now, the commenters could point to lack of direction being supplied to the ERO Panel as to specific guidelines for them to follow in making their decision. The SDT re-iterates the problem with providing such hard and fast rules. There are just too many variables to take into account. Providing concrete guidelines is going to tie the hands of the ERO Panel and inevitably result in bad decisions being made. The SDT also refers the commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.1 where the basic premise on evaluating an exception request must be based on whether the Elements are necessary for the reliable operation of the interconnected transmission system. Further, reliable operation is defined in the Rules of Procedure as operating the elements of the bulk power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cyber security incident, or unanticipated failure of system elements. The SDT firmly believes that the technical prowess of the ERO Panel, the visibility of the process, and the experience gained by having this same panel review multiple requests will result in an equitable, transparent, and consistent approach to the problem. The SDT would also point out that there are options for a submitting entity to pursue that are outlined in the proposed ERO Rules of Procedure changes if they feel that an improper decision has been made on their submittal.</p> <p>Some commenters have asked whether a single ‘yes’ or ‘no’ response to an item on the exception request form will mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.2 of the proposed Rules of Procedure that states “No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved.”</p> <p>The SDT would like to point out several changes made to the specific items in the form that were made in response to industry comments. The SDT believes that these clarifications will make the process tighter and easier to follow and improve the quality of the submittals.</p> <p>Finally, the SDT would point to the draft SAR for Phase II of this project that calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. Given the complexity of the technical aspects of this problem and the filing deadline that the SDT is working under for Phase I of this project, the SDT believes that it has developed a fair and equitable method of approaching this difficult problem. The SDT asks the commenter to consider all of these facts in making your decision and casting your ballot and hopes that these changes</p>

Organization	Yes or No	Question 2 Comment
will result in a favorable outcome.		
American Electric Power	Yes	We recommend capitalizing “facility”.
<p><b>Response:</b> In order to maintain consistency with the nomenclature used in the Exception Process Document, draft Appendix 5C of the NERC Rules of Procedure, the SDT has replaced “facilities” with “Element(s)”, where appropriate.</p>		
Long Island Power Authority	Yes	On page 3 why reference if a facility is part of a Cranking Path after the SDT has deleted Cranking Paths from the Inclusion list as part of the BES definition.
<p><b>Response:</b> It is important to realize a distinction between the BES definition and the Exception Procedure. While the BES definition established bright-line criteria for the determination between BES and non-BES Element(s), the Exception Procedure requires an evaluation of all the responses and supporting materials provided as part of the Exception Request Application Form. No single response or piece of supporting information will be solely dispositive in an Exception Request evaluation. It is not correct to assume that simply because an evaluation criterion was removed from the bright-line definition it should also be eliminated from consideration in the Exception process. The SDT believes that Cranking Path is among the factors to be given consideration in the evaluation for an Exception Request application. Further discussion of this issue is within the scope of the Phase II SAR. No change made.</p>

<b>Response:</b> Thank you for your support.		

3. **Page four of the ‘Detailed Information to Support an Exception Request’ contains a checklist of items that deal with generation facilities. Do you agree with the information being requested or is there information that you believe needs to be on page four that is missing? Please be as specific as possible with your comments.**

**Summary Consideration:** Several respondents suggested better clarity on whether responses should be market or reliability related. The SDT made slight modifications to the “Detailed Information to Support an Exception Request” form to request responses that are specifically reliability related.

Based on the comments received and past history for such situations, the SDT believes that entities will be able to obtain the requisite information necessary to submit a request. However, should an entity have difficulty, they will need to obtain the assistance of their Regional Entity to secure the data. If the entity still can’t obtain the needed data, then the SDT fully expects that entity’s Regional Entity to work with them to come up with a plan that will allow that entity to fill out the request form in a manner that will be acceptable to the Regional Entity so that processing of the request can continue.

The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. If the SDT could have come up with the simple answer, it would have been supplied within the bright-line. The SDT would also like to point out to the commenters that it directly solicited assistance in this matter in the first posting of the criteria and received very little in the form of substantive comments.

There are so many individual variables that will apply to specific cases that there is no way to cover everything up front. There are always going to be extenuating circumstances that will influence decisions on individual cases. One could take this statement to say that the regional discretion hasn’t been removed from the process as dictated in the Order. However, the SDT disagrees with this position. The exception request form has to be taken in concert with the changes to the ERO Rules of Procedure and looked at as a single package. When one looks at the rules being formulated for the exception process, it becomes clear that the role of the Regional Entity has been drastically reduced in the proposed revision. The role of the Regional Entity is now one of reviewing the submittal for completion and making a recommendation to the ERO Panel, not to make the final determination. The Regional Entity plays no role in actually approving or rejecting the submittal. It simply acts as an intermediary. One can counter that this places the Regional Entity in a position to effectively block a submittal by being arbitrary as to what information needs to be supplied. In addition, the SDT believes that the visibility of the process would belie such an action by the Regional Entity and also believes that one has to have faith in the integrity of the Regional Entity in such a process. Moreover, Appendix 5C of the proposed NERC Rules of Procedure, Sections 5.1.5, 5.3, and 5.2.4, provide an added level of protection requiring an independent Technical Review Panel assessment where a Regional Entity decides to reject or disapprove an exception request. This panel’s findings become part of the exception request record submitted to

NERC. Appendix 5C of the proposed NERC Rules of Procedure, Section 7.0, provides NERC the option to remand the request to the Regional Entity with the mandate to process the exception if it finds the Regional Entity erred in rejecting or disapproving the exception request. On the other side of this equation, one could make an argument that the Regional Entity has no basis for what constitutes an acceptable submittal. Commenters point out that the explicit types of studies to be provided and how to interpret the information aren't shown in the request process. The SDT again points to the variations that will abound in the requests as negating any hard and fast rules in this regard. However, one is not dealing with amateurs here. This is not something that hasn't been handled before by either party and there is a great deal of professional experience involved on both the submitter's and the Regional Entity's side of this equation. Having viewed the request details, the SDT believes that both sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to travel upward to the ERO Panel for adjudication.

Now, the commenters could point to lack of direction being supplied to the ERO Panel as to specific guidelines for them to follow in making their decision. The SDT re-iterates the problem with providing such hard and fast rules. There are just too many variables to take into account. Providing concrete guidelines is going to tie the hands of the ERO Panel and inevitably result in bad decisions being made. The SDT also refers the commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.1 where the basic premise on evaluating an exception request must be based on whether the Elements are necessary for the reliable operation of the interconnected transmission system. Further, reliable operation is defined in the Rules of Procedure as operating the elements of the bulk power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cyber security incident, or unanticipated failure of system elements. The SDT firmly believes that the technical prowess of the ERO Panel, the visibility of the process, and the experience gained by having this same panel review multiple requests will result in an equitable, transparent, and consistent approach to the problem. The SDT would also point out that there are options for a submitting entity to pursue that are outlined in the proposed ERO Rules of Procedure changes if they feel that an improper decision has been made on their submittal.

Some commenters have asked whether a single 'yes' or 'no' response to an item on the exception request form will mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.2 of the proposed Rules of Procedure that states "No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved."

The SDT would like to point out several changes made to the specific items in the form that were made in response to industry comments. The SDT believes that these clarifications will make the process tighter and easier to follow and improve the quality of the submittals.

Finally, the SDT would point to the draft SAR for Phase II of this project that calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. Given the

complexity of the technical aspects of this problem and the filing deadline that the SDT is working under for Phase I of this project, the SDT believes that it has developed a fair and equitable method of approaching this difficult problem. The SDT asks the commenter to consider all of these facts in making your decision and casting your ballot and hopes that these changes will result in a favorable outcome.

**Page 1** - List any attached supporting documents and any additional information that is included to supports the request:

**Generation - Q1.** What is the MW value of the host Balancing Authority’s most severe single Contingency and what is the ~~generator’s, or generator facility’s~~ generation resource’s, percent of this value?

**Generation - Q2.** Is the ~~generator or generator facility~~ generation resource used to provide reliability-related Ancillary Services?

**Generation - Q3.** Is the ~~generator~~ generation resource designated as a must run unit for reliability?

Organization	Yes or No	Question 3 Comment
Northeast Power Coordinating Council	No	<p>This Application generally applies to traditionally fueled generating facilities. Application form and justifications would be required for non-traditional resources such as solar and wind?</p> <p>Question 2 on page 4 asks, “Is the generator or generator facility used to provide Ancillary Services?” If some of these Generator check list items are market-related and not reliability-related, they should not be present. If the Ancillary Services are reliability-related, please explain their relation to BES reliability.</p> <p>Suggest inserting the word “reliability” before the words “must run” in question 3.</p> <p>Question 5 on page 4 asks, “Does the generator use the BES to deliver its actual or scheduled output, or a portion of its actual or scheduled output, to Load?” This could mean the generator may serve local loads through non-BES facilities. In order to serve these local loads the generator would need to be connected to a Radial system, a Local Network or to local distribution facilities. Is this what is intended? Were there any other possibilities envisioned by the BES SDT?</p>
<p><b>Response:</b> The SDT believes the form can be used for any type of generation resource as there are no restrictions on type in the</p>		

Organization	Yes or No	Question 3 Comment
<p>questions. No change made.</p> <p>The form has been modified to request only reliability related functions be included.</p> <p><b>Q2.</b> Is the <del>generator or generator facility</del> <u>generation resource</u> used to provide <u>reliability--related</u> Ancillary Services?</p> <p><b>Q3.</b> Is the <del>generator</del> <u>generation resource</u> designated as a must run unit <u>for reliability</u>?</p> <p>If the entity serves the indicated Load through a radial system, etc., it should supply that information as part of its supporting information. No change made.</p>		
<p>ACES Power Marketing Standards Collaborators</p>	<p>No</p>	<p>Q5 has a “Description/Comments” section. Further clarification on what type of information to include under the Description would help “standardize” the supporting information and “will provide more clarity and continuity to the process.”</p> <p>The definition of ancillary services varies and can be quite broad. It can include reactive power and voltage support for example. All generators provide some reactive power and voltage support. Thus, ancillary services should be further defined or one could construe it to limit any generator from being excepted.</p>
<p><b>Response:</b> Entities applying for an exception can include any information they deem appropriate in the general and specific sections of the form. It would be difficult to establish specific criteria that would be applicable to all systems.</p> <p>Questions regarding ancillary services have been further clarified.</p> <p><b>Q2.</b> Is the <del>generator or generator facility</del> <u>generation resource</u> used to provide <u>reliability--related</u> Ancillary Services?</p>		
<p>Farmington Electric Utility System</p>	<p>No</p>	<p>Question 1, the SDT team should consider if the Submitting entity or Owner is part of a Reserve Sharing Group. The host BA’s most single severe Contingency vs the obligation of reserves required as part of a Reserve Sharing Group may be substantial.</p> <p>The SDT team should clarify if it is a single generator or if it is the aggregate at a facility.</p>

Organization	Yes or No	Question 3 Comment
<p><b>Response:</b> An entity can supply that information as part of its supporting information in its request. No change made.</p> <p>The assumption is that the request is being made as a result of the application of the definition which is for single units or aggregate as appropriate.</p>		
<p>Dominion</p>	<p>No</p>	<p>The SDT language specifying services acceptable for inclusion in an exclusion request references ancillary services identified under a Transmission Service Provider’s OATT. However, there is great variation in the services that have actually been implemented and posted across North America under those OATTs. There is no consistent description or terminology to characterize those services. In short, Transmission Providers have been permitted to individualize OATT services to fit regional market structures and vernacular. For example, PJM’s OATT includes a schedule for Blackstart Service. The FERC pro-forma tariff does not. ISO-NE’s tariff includes the following ancillary services (which are performed by the ISO and TSP):</p> <ul style="list-style-type: none"> <li>o Scheduling, System Control and Dispatch Service</li> <li>o Energy Imbalance Service</li> <li>o Generator Imbalance Service</li> </ul> <p>Therefore, Dominion suggests that the SDT provide a specific list of ancillary services that would be eligible for exclusion, rather than rely on OATT references. Examples might include: reactive, voltage control or regulation services, frequency response and blackstart services.</p> <p>Dominion is also aware that the phrase “ ‘must run” is used in some RTO/ISO market systems to indicate intent to self-schedule the generator. Dominion suggests that question 3 be revised to read “Is the generator designated as a “must run” unit by either the Balancing Authority, Resource Planner or Reliability Coordinator?”</p>
<p><b>Response:</b> The form has been modified to request only reliability related functions are included.</p> <p><b>Q2.</b> Is the <del>generator or generator facility</del> <u>generation resource</u> used to provide <u>reliability--related</u> Ancillary Services?</p> <p><b>Q3.</b> Is the <del>generator</del> <u>generation resource</u> designated as a must run unit <u>for reliability</u>?</p>		
<p>Southern Company</p>	<p>No</p>	<p>We do not agree completely with the information being requested. For checklist item #2, please specify what is included in "providing Ancillary Services" for a</p>

Organization	Yes or No	Question 3 Comment
Generation		<p>generator.</p> <p>For #4, can the question include a measure of evaluating the "most severe system impact"? Can the specific study that is required to be evaluated be outlined?</p>
<p><b>Response:</b> Questions regarding ancillary services have been further clarified.</p> <p><b>Q2.</b> Is the <del>generator or generator facility</del> <u>generation resource</u> used to provide <del>reliability--related</del> Ancillary Services?                      The SDT refers the commenter to the statement that TPL methodologies should be followed in formulating the supporting information for the request.</p>		
AECI and member G&Ts	No	<p>Most of these questions appear relevant to the LN concept paper, but irrelevant to this standard's requirements. The last conditional of Item 5) must always be answered Yes, unless the local-network is islanded.</p>
<p><b>Response:</b> The SDT does not see a need for a one-to-one correspondence between the definition items and the information requested. The form contains questions that will supply information the review panel will need to evaluate the request.</p>		
NERC Staff Technical Review	No	<p>For units designated as must run, the Submitting entity should be required to describe the reasons for which the unit has been so designated. We believe the general requirement to provide an appropriate reference is too vague, and should be appended with “. . . including a description of why the unit has been designated as must run and if applicable, the contingencies that would result in violation of the NERC Reliability Standards if the unit was not must run.”</p>
<p><b>Response:</b> The form has been modified to request only reliability related functions are included. Information such as shown in the comment can be entered as needed by the requesting entity. In general, an entity should supply any and all information that it feels is needed to support its request.</p> <p><b>Q3.</b> Is the <del>generator</del> <u>generation resource</u> designated as a must run unit <u>for reliability</u>?</p>		

Organization	Yes or No	Question 3 Comment
Duke Energy	No	Modify wording on #3 as follows: "Please provide the appropriate reference for the operating area where the facility is located."
<p><b>Response:</b> The SDT does not believe that the suggested wording provides any additional clarity. No change made.</p>		
NV Energy	No	<p>In question #7 of the form, it would be useful to the analysis for technical exception to include not only the minimum and maximum power flow out of the candidate facility, but also a description or demonstration of the "typical" magnitude or the "average" of such flow. An entity may provide this sort of information anyhow, but a prompt for this type of information could be useful and prevent having to solicit more information during the review.</p> <p>Should be included in Question 2.</p>
New York State Dept. of Public Service	No	<p>Question 6 should be dropped. Facilities in a cranking path for a blackstart resource should not be a consideration.</p> <p>Question 7 is circular. If a facility is used to flow power into the BES, by definition it is outside the BES. Needs clarification as to the information the question is seeking.</p> <p>Should be question 2.</p>
<p><b>Response:</b> Please see the response to Q2.</p>		
Consolidated Edison Co. of NY, Inc.	No	<p>For Generation Facilities: This Application form would appear to generally apply to traditional generating facilities.</p> <ul style="list-style-type: none"> <li>o What Application form and justifications would be required for non-traditional resources, e.g., solar and wind?</li> <li>o The Application form at 2 asks, "Is the generator or generator facility used to provide Ancillary Services?" If some of these Generator check list items are market-related and not reliability-related, then they should not be present.</li> <li>o If the Ancillary Services are reliability-related, please explain their relation to BES</li> </ul>

Organization	Yes or No	Question 3 Comment
		<p>reliability.</p> <p>Recommendation: Insert the word “reliability” before the words “must run” in question 3.</p> <p>The Application form at 5 asks, “Does the generator use the BES to deliver its actual or scheduled output, or a portion of its actual or scheduled output, to Load?” We assume this mean the generator may serve local loads through non-BES facilities. In order to serve these local loads the generator would need to be connected to a Radial system, a Local Network or to local distribution facilities. o Is this meaning above implied and intended by this question? o Were there any other possibilities envisioned by the BES SDT?</p>
<p><b>Response:</b> The SDT believes the form can be used for any type of generation resource as there are no restrictions on type in the questions.</p> <p>The form has been modified to request only reliability related functions be included.</p> <p><b>Q2.</b> Is the <del>generator or generator facility</del> <u>generation resource</u> used to provide <u>reliability--related</u> Ancillary Services?</p> <p><b>Q3.</b> Is the <del>generator</del> <u>generation resource</u> designated as a must run unit <u>for reliability</u>?</p> <p>Entities applying for an exception can include any information they deem appropriate in the general and specific sections of the form.</p> <p>If the entity serves the indicated Load through a radial system, etc., it should supply that information as part of its supporting information. No change made.</p>		
American Electric Power	No	<p>It is unclear how the process will work with the interaction among the various NERC Functions. For instance, an exception request from generation might require collaboration among other functional entities, i.e. GOP, TOP, and RC.</p> <p>The question “How does an outage of the generator impact the over-all reliability of the BES” may be subjective and dependent on contingencies at any given time. It would be dependent on what state the BES would be in the area the generator is located. More detail would be needed in describing the study required to have</p>

Organization	Yes or No	Question 3 Comment
		consistent results.
<p><b>Response:</b> Please refer to the Rules of Procedure for clarity on how the process will provide consistency.</p> <p>As every generator will have different impact it is up to the entity to complete the studies and to respond appropriately in the written section of the question.</p>		
ReliabilityFirst	No	<p>If the systems are planned properly and the day-ahead analysis is done for maintenance work, the outage of any one unit and even with the most serve outage happening, the system should be capable of withstanding. These studies and analysis will need to look at multiple outages and groups of units being taken out and excluded before any could be exempt. What is the phrase “impact the over-all reliability” getting at?</p> <p>These studies and analysis will need to look at multiple outages and groups of elements being taken out and excluded. Will this be on a first come, first out process?</p> <p>As for the Ancillary Services question, ReliabilityFirst Staff believes that if a unit provides this service, it should be included in the BES.</p> <p>The same applies for the “must run units” in question 3.</p> <p>Omit question 5, E3 (LN) of the definition already talks to power flow and even if there is a small percentage of unit’s output flowing onto the BES, it makes that entity a user of the BES, which should be included.</p>
<p><b>Response:</b> The SDT refers the commenter to the phrase consistent ‘with TPL methodologies’ which the SDT believes will cover the item in question.</p> <p>The SDT reminds the commenter the evaluation in question is not for removing the Element from service but simply from inclusion or exclusion in the BES. Therefore, there should be no problem with evaluating multiple requests in the same area and no first in, first out scenario.</p> <p>Ancillary services or must run status is only one piece of information in a total review of the impact of the Element on the BES. The</p>		

Organization	Yes or No	Question 3 Comment
<p>SDT does not believe that simply because a generator provides ancillary services or that it is must run that it should be automatically included.</p> <p>There is more to the BES than just the local networks. No change made.</p>		
Hydro-Quebec TransEnergie	No	
Manitoba Hydro	No	
<p><b>Response:</b> Without any specific comments, the SDT is unable to respond.</p>		
ISO New England Inc	No	<p>- Question 1o The question would be better worded as “How many MW are lost following the host Balancing Authority’s most severe single Contingency...”o The question becomes difficult to answer when the most severe single Contingency can change on a</p>
<p><b>Response:</b> A slight revision has been made to Question 1 which should provide more clarity in this regard.</p> <p><b>Q1.</b> What is the MW value of the host Balancing Authority’s most severe single Contingency and what is the <del>generator’s, or generator facility’s, generation resource’s,</del> percent of this value?</p>		
PSEg Services Corp	No	<p>With regards to question #2 (“Is the generator or generating facility used to provide Ancillary Services”), the answer for most synchronous generators is probably “yes” unless they are in a bid-based market that selects specific generators for Reactive Power delivery. Since most generators (with the exception of those with nuclear prime movers) provide Reactive Power to meet a Transmission Operator-specified voltage, they would provide that Ancillary Service. Other generators (again, with the exception of generators with nuclear prime movers) may be eligible to provide other Ancillary Services such as Spinning Reserve, but may have rarely done so. However, they still may be “used do provide” Spinning Reserve at any time. How would those generators respond to question #2?</p> <p>Questions #4 requires an analysis of the “most severe impact” associated an outage</p>

Organization	Yes or No	Question 3 Comment
		<p>of the Element proposed for exception. a. Both the newly Board approved TPL-001-2 standard and the existing TPL-004-1 require that severe contingencies be evaluated, but there are no performance requirements for them. For consistency, performance requirements for the most-severe-impact analysis needed to be defined by the team. If the team intended the “most-severe impact” analysis to only evaluate TPL outages that incorporate performance requirements, it should make that clear.b. The most-severe-outage impact question does not ask key relevant information such as: i. What is the probability that the “most severe impact “will occur?ii. Could the impact be readily mitigated and service restored? This point is critical because the impact of an outage lasting several minutes before restoration versus several hours before restoration should affect the analysis.</p> <p>What does the answer to the question #5 in the Generator Facilities section (“Does the generator use the BES to deliver its actual or scheduled output, or a portion of its actual or scheduled output, to Load?”) imply with respect to a generator’s exclusion? Also, the phrase “deliver its actual or scheduled output ...to load” needs explanation. The use of “actual output” and “scheduled output” may have several contexts. a. For example, in a market, a generator’s actual output may suddenly go to zero due a forced outage, but the generator has financial obligations that accrue for delivering its scheduled output, which is in fact provided by other sources since the generator is unavailable. Is the question asking about the use of BPS facilities by resources that may be substituted for delivery of a generator’s scheduled output when it differs from its actual output?b. Now assume that a generator’s actual output equals its scheduled output and that several generators are forced out of service in another Balancing Authority, resulting in a frequency decline. Generators within the interconnection with active governors and available spinning capacity will automatically increase their output above their scheduled output, resulting in Inadvertent Interchange. Is the question related to the BES facilities used to deliver such Inadvertent Interchange?c. Again assume that a generator’s actual output equals its scheduled output. Is the question related to the actual BES facilities that may be used to deliver the generator’s power to Load? That would require an</p>

Organization	Yes or No	Question 3 Comment
		<p>analysis of generator and load shift factors to determine what actual facilities carry the power generated from a generator to a specific load for a given set of assumptions on the system topology. In a market, this analysis would not be possible for generators that do not self-schedule for delivery to specific loads.</p>
<p><b>Response:</b> The form has been modified to request only reliability related functions are included.</p> <p><b>Q2.</b> Is the <del>generator or generator facility</del> <u>generation resource</u> used to provide <u>reliability-related</u> Ancillary Services?</p> <p>The SDT reminds the commenter the requirement is only to follow the TPL methodologies which have been spelled out in TPL-001-2. An entity can supply any and all information that it thinks will support its request.</p> <p>Entities applying for an exception can include any information they deem appropriate in the general and specific sections of the form. It is simply just one piece of information that is considered as useful for the review panel in making its ultimate decision. Any clarifying points an entity wants to make in its request can be supplied as the entity thinks appropriate.</p>		
City of St. George	No	<p>The questions for generation facilities seem to be appropriate; however, how the answers are to be used by the region or NERC is unclear. Will a given response to a question make exclusion impossible? If so this needs to be known upfront and clearly documented. For example question 4, on page 4 is open for interpretation and debate as to what the impact to the over-all reliability of the BES is. The definition of “impact” is really the key to the whole definition effort. Load flow, voltage, frequency change limits may all be pieces to the puzzle.</p> <p>Are these criteria to be met in normal, N-1, N-2, etc. system configurations?</p>
<p><b>Response:</b> Some commenters have asked whether a single ‘yes’ or ‘no’ response to an item on the exception request form will mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.2 of the proposed Rules of Procedure that states “No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved.”</p> <p>The SDT refers the commenter to the statement that TPL methodologies should be followed in formulating the supporting</p>		

Organization	Yes or No	Question 3 Comment
information for the request.		
Ameren	No	It is suggested that question #2 be deleted and replaced with “Is the generator designated as a black-start unit in an entity’s restoration plan?”
<p><b>Response:</b> The SDT assumes the commenter is actually referring to the sixth question for transmission. Please see the detailed response to Q2.</p>		
Georgia System Operations Corporation	No	Item 2 asks about “the generator or generator Facility,” but 3, 4 and 5 only refer to the generator. There is no immediately apparent reason for them to be different. The language in Item 2 seems preferable.
<p><b>Response:</b> The SDT has reviewed all of the terminology for consistency and made clarifying changes as necessary. For example:</p> <p><b>Q1.</b> What is the MW value of the host Balancing Authority’s most severe single Contingency and what is the <del>generator’s, or generator facility’s, generation resource’s,</del> percent of this value?</p>		
IRC Standards Review Committee		We do not agree with the detailed information requirements for generators. In a deregulated environment, generators are free to bid into the market or offer their availability, to dispatched based on bid price and resource needs, or overall generation dispatch plans. A generator may be on line but not dispatched, or not on line at all due to maintenance outage or a decision to not start. Its status and generation level have little to do in determining whether or not it needs to be included as a BES facility. Rather, it is the generator’s active contribution to the BES performance, namely, its protective relay setting and coordination with those of related facilities and its ability to control voltage, respond to contingencies, ride through frequency and voltage excursion, provide accurate model with verification, etc., are critical to BES reliability performance. There are currently no standards or requirements that mandate a generator to be on line or to attain a specific level of output, and we do not see such a need at all in the future. Whether or not the unit is designed as a MUST RUN will depend on whether the generator is (a) on line and bid into the market or be included in the dispatch plan, and (b) the prevailing system

Organization	Yes or No	Question 3 Comment
		<p>conditions such as flow pattern, potential constraints, etc. A generator may be designated as a MUST RUN one day but not the others. Similar argument applies to a generator bidding in the ancillary service markets, or be dispatched to provide reserve or AGC control capability. In our view, generators’ physical characteristics and their response to changes on the BES are important considerations for them to be included in the BES. These characteristics affect the assessment and actual performance of the BES in the following key areas:</p> <ul style="list-style-type: none"> <li>o Voltage and frequency ride through capability</li> <li>o Voltage control (AVR, etc.)</li> <li>o Underfrequency trip setting</li> <li>o Protection relay setting coordination</li> <li>o Data submission for modeling; verification of capability and model</li> </ul> <p>We therefore suggest that the entire P.4 be removed as the information it asks for has nothing to do with a generator’s physical characteristics or material impact on BES reliability. Having a threshold by MVA suffices to determine if a generator needs to be included as a BES facility, whose characteristics, expected performance and data provision are important to achieve target BES performance and hence should be governed by reliability standards.</p>
<p><b>Response:</b> The form has been modified to request only reliability related functions are included.</p> <p><b>Q2.</b> Is the <del>generator or generator facility</del> <u>generation resource</u> used to provide <u>reliability--related</u> Ancillary Services?</p> <p><b>Q3.</b> Is the <del>generator</del> <u>generation resource</u> designated as a must run unit <u>for reliability</u>?</p>		
<p>Tri-State Generation and Transmission Assn., Inc. Energy Mangement</p>		<p>Again Yes/No is conflicting in the question. Information requested in#4 is subjective and too vague.</p>
<p>TSGT G&amp;T</p>		<p>Again Yes/No is conflicting in the question. Information requested in #4 is subjective and too vague.</p>
<p><b>Response:</b> The SDT has attempted to build in maximum flexibility within the form while still providing the review panel information that will be needed in evaluating a request. No change made.</p>		

Organization	Yes or No	Question 3 Comment
Hydro One Networks Inc.	Yes	See comments in Q1.
<b>Response:</b> Please see response to Q1.		
Long Island Power Authority	Yes	Need to define the term "must run unit"
PacifiCorp	Yes	PacifiCorp suggests modifying Question 3 as follows: "Is the generator designated as a must run unit by the Balancing Authority?"
<b>Response:</b> The form has been modified to request only reliability related functions are included.		
<b>Q3.</b> Is the <del>generator</del> <u>generator generation resource</u> designated as a must run unit <u>for reliability</u> ?		
Electricity Consumers Resource Council (ELCON)	Yes	Our "Yes" response is conditioned on the comments to Questions 1 and 2 above.
<b>Response:</b> Please see responses to Q1 and Q2.		
Bonneville Power Administration	Yes	Regarding #1 on page 4: BPA Believes seasonality may need to be considered when comparing the generator with the most severe single contingency.
<b>Response:</b> Seasonality issues can be explained in the written response areas of the application form or additional documentation can be provided as needed. No change made.		
WECC Staff	Yes	The requested information in the checklist is appropriate. However; the exceptions process as drafted, with no objective criteria defining how to assess the submittals, leaves it to each region to develop their own criteria to evaluate the responses to the checklist included in the submittals, leading to inconsistency between Regional Entities.
<b>Response:</b> The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many		

Organization	Yes or No	Question 3 Comment
		<p>hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. If the SDT could have come up with the simple answer, it would have been supplied within the bright-line. The SDT would also like to point out to the commenters that it directly solicited assistance in this matter in the first posting of the criteria and received very little in the form of substantive comments.</p> <p>There are so many individual variables that will apply to specific cases that there is no way to cover everything up front. There are always going to be extenuating circumstances that will influence decisions on individual cases. One could take this statement to say that the regional discretion hasn't been removed from the process as dictated in the Order. However, the SDT disagrees with this position. The exception request form has to be taken in concert with the changes to the ERO Rules of Procedure and looked at as a single package. When one looks at the rules being formulated for the exception process, it becomes clear that the role of the Regional Entity has been drastically reduced in the proposed revision. The role of the Regional Entity is now one of reviewing the submittal for completion and making a recommendation to the ERO Panel, not to make the final determination. The Regional Entity plays no role in actually approving or rejecting the submittal. It simply acts as an intermediary. One can counter that this places the Regional Entity in a position to effectively block a submittal by being arbitrary as to what information needs to be supplied. In addition, the SDT believes that the visibility of the process would belie such an action by the Regional Entity and also believes that one has to have faith in the integrity of the Regional Entity in such a process. Moreover, Appendix 5C of the proposed NERC Rules of Procedure, Sections 5.1.5, 5.3, and 5.2.4, provide an added level of protection requiring an independent Technical Review Panel assessment where a Regional Entity decides to reject or disapprove an exception request. This panel's findings become part of the exception request record submitted to NERC. Appendix 5C of the proposed NERC Rules of Procedure, Section 7.0, provides NERC the option to remand the request to the Regional Entity with the mandate to process the exception if it finds the Regional Entity erred in rejecting or disapproving the exception request. On the other side of this equation, one could make an argument that the Regional Entity has no basis for what constitutes an acceptable submittal. Commenters point out that the explicit types of studies to be provided and how to interpret the information aren't shown in the request process. The SDT again points to the variations that will abound in the requests as negating any hard and fast rules in this regard. However, one is not dealing with amateurs here. This is not something that hasn't been handled before by either party and there is a great deal of professional experience involved on both the submitter's and the Regional Entity's side of this equation. Having viewed the request details, the SDT believes that both sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to travel upward to the ERO Panel for adjudication.</p> <p>Now, the commenters could point to lack of direction being supplied to the ERO Panel as to specific guidelines for them to follow in making their decision. The SDT re-iterates the problem with providing such hard and fast rules. There are just too many variables to take into account. Providing concrete guidelines is going to tie the hands of the ERO Panel and inevitably result in bad decisions</p>

Organization	Yes or No	Question 3 Comment
		<p>being made. The SDT also refers the commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.1 where the basic premise on evaluating an exception request must be based on whether the Elements are necessary for the reliable operation of the interconnected transmission system. Further, reliable operation is defined in the Rules of Procedure as operating the elements of the bulk power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cyber security incident, or unanticipated failure of system elements. The SDT firmly believes that the technical prowess of the ERO Panel, the visibility of the process, and the experience gained by having this same panel review multiple requests will result in an equitable, transparent, and consistent approach to the problem. The SDT would also point out that there are options for a submitting entity to pursue that are outlined in the proposed ERO Rules of Procedure changes if they feel that an improper decision has been made on their submittal.</p> <p>Some commenters have asked whether a single ‘yes’ or ‘no’ response to an item on the exception request form will mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.2 of the proposed Rules of Procedure that states “No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved.”</p> <p>The SDT would like to point out several changes made to the specific items in the form that were made in response to industry comments. The SDT believes that these clarifications will make the process tighter and easier to follow and improve the quality of the submittals.</p> <p>Finally, the SDT would point to the draft SAR for Phase II of this project that calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. Given the complexity of the technical aspects of this problem and the filing deadline that the SDT is working under for Phase I of this project, the SDT believes that it has developed a fair and equitable method of approaching this difficult problem. The SDT asks the commenter to consider all of these facts in making your decision and casting your ballot and hopes that these changes will result in a favorable outcome.</p>
<p>Kootenai Electric Cooperative Snohomish County PUD Blachly-Lane Electric</p>	<p>Yes</p>	<p>KEC agrees that the items listed on page 4 of the Detailed Information to Support an Exception Request capture the information that generally would be necessary to make a reasoned determination concerning the BES status of a generation facility. KEC suggests three refinements to the questions: (1) Question 2 should be modified</p>

Organization	Yes or No	Question 3 Comment
<p>Cooperative</p> <p>Central Electric Cooperative (CEC)</p> <p>Clearwater Power Company (CPC)</p> <p>Consumer's Power Inc. (CPI)</p> <p>Douglas Electric Cooperative (DEC)</p> <p>Fall River Electric Cooperative (FALL)</p> <p>Lane Electric Cooperative (LEC)</p> <p>Lincoln Electric Cooperative (Lincoln)</p> <p>Northern Lights Inc. (NLI)</p> <p>Okanogan County Electric Cooperative (OCEC)</p> <p>Pacific Northwest Generating Cooperative (PNGC)</p> <p>Raft River Rural Electric Cooperative (RAFT)</p> <p>Umatilla Electric Cooperative</p> <p>West Oregon Electric Cooperative (WOEC)</p> <p>Coos-Curry Electric</p>		<p>by adding “necessary for the operation of the interconnected bulk transmission system” to the end of the question, so that it reads: “Is the generator or the generator facility used to provide Ancillary Services necessary for the operation of the interconnected bulk transmission system?” The italicized language is necessary to distinguish between a generator that provides, for example, reactive power or regulating reserves that support operation of the interconnected bulk grid, and, for example, a behind-the-meter generator that provides back-up generation to a specific industrial facility. The former may be necessary for the reliable operation of the interconnected bulk transmission system, but the latter is not.</p> <p>(2) The current draft of the BES Definition contains Exclusions for radials and for Local Networks. To be consistent with these aspects of the revised BES definition, KEC suggests modifying question 5 by adding “radial, or Local Network” to the question, so that it would read: “Does the generator use the BES, a radial system, or a Local Network to deliver its actual or scheduled output, or a portion of its actual or scheduled output, to Load?”</p> <p>(3) For reasons similar to those explained in our response to Question 2, a general “catch-all” question should be added that will prompt an entity submitting an Exception Request for a generator to submit any information it believes is relevant to the Exception that is not captured in the previous questions. We suggest the following language: Is there additional information not covered in questions 1 through 5 that supports the Exception Request? If yes, please provide the information and explain why it is relevant to the Exception Request. This will allow an entity seeking an Exception for a generator to identify any unusual circumstances or non-standard information that might support its Exception Request. An entity seeking such an Exception should have the opportunity to present any information it believes is relevant.</p>

City of Redding	Yes	
Tacoma Power	Yes	Tacoma Power supports the information requested on page 4.
BGE	Yes	No comment.
Michigan Public Power Agency	Yes	
<p><b>Response: Thank you for your support. The SDT did make some clarifying changes due to comments received.</b></p> <p><b>Q2.</b> Is the <del>generator or generator facility</del> <u>generation resource</u> used to provide <del>reliability--related</del> Ancillary Services?</p> <p><b>Q3.</b> Is the <del>generator</del> <u>generation resource</u> designated as a must run unit <u>for reliability</u>?</p>		

4. Do you have concerns about an entity’s ability to obtain the data they would need to file the ‘Detailed Information to Support an Exception Request’? If so, please be specific with your concerns so that the SDT can fully understand the problem.

**Summary Consideration:** Based on the comments received, the SDT believes that entities will be able to obtain the requisite information necessary to submit a request. However, should an entity have difficulty, they will need to obtain the assistance of their Regional Entity to secure the data. If the entity still can’t obtain the needed data, then the SDT fully expects that entity’s Regional Entity to work with them to come up with a plan that will allow that entity to fill out the request form in a manner that will be acceptable to the Regional Entity so that processing of the request can continue. The SDT recognizes that there will be costs associated with the request. The SDT feels that an entity may have to conduct a cost and benefit analysis in order to determine the value of pursuing a request.

No significant changes were made to the request form as a result of comments received to this question. There were suggestions to use some terms more consistently, and this suggestion was adopted. The SDT had used, “facility” and “element” to mean the same things, and has now adopted the word, “Element” throughout the revised document. Similarly the team changed the word, “application” to “request” for greater clarity.

Tacoma Power	No	Tacoma Power supports the expectation that entities will be able to supply the information requested.
<b>Response:</b> Thank you for your support.		
American Electric Power	No	As stated in the response to question #3, the question “How does an outage of the generator impact the over-all reliability of the BES” may be subjective and dependent on contingencies at any given time. It would be dependent on what state the BES would be in the area the generator is located. More detail would be needed in describing the study required to have consistent results.
<b>Response:</b> See response to Q3.		
Georgia System Operations Corporation	No	<p>Throughout the document, because it will be part of a larger Exception Request Form, it should, when possible, use terms consistent with the rest of that form (e.g., “Request” rather than “application”).</p> <p>Similarly, defined terms (even if only defined in the context of the Request Form in which these Principles will be used) such as “Exception,” “Request,” “Element” or “Facility” should be capitalized; if the use of lower case is intended to convey a different meaning than what is defined, another term should be used to avoid confusion.</p> <p>The Definition and Request Form generally use the term “Element,” so it is unclear why this document should so consistently use “facility.” For consistency, “Element(s)” or possibly “Element(s) or Facility” should be used.</p>
<b>Response:</b> The SDT has made changes to the Request Form based upon your comments, changing the word, “facility” to “Element” and “application” to “request” for consistency throughout the document.		
Independent Electricity System Operator	No	We anticipate that entities will be granted access to the required historical operations records and modeling data after signing of non-disclosure agreements with the

Organization	Yes or No	Question 4 Comment
		providers of the information.
<p><b>Response:</b> The SDT concurs that it may be necessary for entities to execute such agreements.</p>		
Northeast Power Coordinating Council	No	According to the Applicability section, the TPL Reliability Standards are only applicable to the Planning Coordinator (PC) and the Transmission Planner (TP). Was it the BES SDT’s assumption that Applicants would have the PC or TP run studies for them, or that all Applicants would gain access to those models and run the models themselves? (Ref. TPL-002-1b, Applicability: Planning Authority, and Transmission Planner.)
Pepco Holdings Inc	No	Not all TOs have the capability to perform the power flow and stability analysis on their own, necessary to meet the exception request. It may be burdensome for the TO to hire a consultant or to have their affiliated TPL perform the rigorous study/analysis as contained in the TPL standards. Additional details should be provided as to what part of the TPL standards apply. Should the Affiliated TPL be required to perform TOs studies for exception requests? If so should that be stated in a related standard as a requirement?
Southern Company Generation	Yes	An IPP with no Transmission Planning department may find it very difficult to perform an interconnection wide base case as required in the general instructions.
Bonneville Power Administration	Yes	BPA believes the studies discussed in pages 2-4 would likely need to be completed and the required information supplied by the Transmission Planner/Operator of the Balancing Authority Area since many of the assumptions regarding performance of the BES to delivery under a variety of operating conditions is known only to the TP and TOP of the system.
Consolidated Edison Co. of NY, Inc.	Yes	According to the Applicability section, the TPL Reliability Standards are only applicable to the Planning Coordinator (PC) and the Transmission Planner (TP). Was it the BES SDT’s assumption that Applicants would have the PC or TP run studies for them, or that all Applicants would somehow gain access to those models and run the models

Organization	Yes or No	Question 4 Comment
		<p>themselves? (Ref. TPL-002-1, Applicability: Planning Coordinator, and Transmission Planner.)</p>
<p><b>Response:</b> The Request Form includes language indicating that studies need to be consistent with the methodologies described in the TPL standards, not that the studies need to be the actual Planning Coordinator or Transmission Planner studies. The SDT feels that it is up to the Registered Entity to work out the details for studies needed for a request.</p>		
<p>Orange and Rockland Utilities, Inc.</p>	<p>No</p>	<p>However, please clarify “facility” and include “N-1” for power-flow studying.</p>
<p><b>Response:</b> The SDT has modified the document to consistently use the term, “Element” rather than facility throughout the document. The SDT believes that solely relying upon a single case study, i.e., N-1; would be inappropriate for the purposes of making a decision under this definition. Entities will need to consider the use of the Elements in a variety of cases to determine whether or not the Elements would be BES or not.</p>		
<p>WECC Staff</p>	<p>Yes</p>	<p>Entities would have a difficult time deciding what data to obtain. Getting the data for their own specific facilities should be relatively simple for the majority of entities. However, it is possible smaller entities may have a higher burden putting together the appropriate information for inclusion in a study case that they currently may not do. In addition, because the instructions state that a case will be “suitably complete and detailed,” WECC believes there is insufficient guidance as to what amount and degree of detail in the data is sufficient for the submittal process. Without thresholds it is difficult to determine whether the entities will have the ability to obtain necessary data to file for an exception. At this time, WECC views the instructions as insufficient for these reasons.</p>
<p><b>Response:</b> The SDT understands the concerns raised by the commenter in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. <p>Holland Board of Public Works Michigan Public Power Agency</p>	Yes	<p>On Page 4 Question 1, information on the host Balancing Authority's most severe single contingency may not be publically available and therefore difficult or impossible for a smaller entity to obtain. Even if the data is available, it may not be meaningful in a larger Balancing Authority area such as within MISO where the most severe contingency may be geographically and electrically remote. A more readily available and meaningful measure would be a comparison of the generator's capability as a percent of the peak load for the local Balancing Authority or sub-Balancing Authority, as applicable.</p>
<p><b>Response:</b> The SDT believes that an entity can use any data or information available to it in order to make its request, especially if other information is not available. Note that the SDT modified the form to clarify that entities may submit additional information</p>		

Organization	Yes or No	Question 4 Comment
(beyond the information listed on the form as “required”) to support their request for an exception.		
Duke Energy	Yes	What is the process for obtaining data from a 3rd party that is either unregistered or unwilling to supply the data?
<b>Response:</b> The SDT is not aware of any instance where an unregistered entity would have vital information relevant to a request. For an organization unwilling to share, the SDT expects that entities may need to execute confidentiality or other agreements in order to obtain the use of the necessary information and data.		
ACES Power Marketing Standards Collaborators	Yes	Some generation owners may not be able to obtain their BA’s most severe single Contingency. Many generator owners will not have access to the data necessary to demonstrate the reliability impact to the BES. This is particularly true for transmission dependent utilities.
City of St. George	Yes	The access to the required data would be potentially be a concern especially for smaller entities. Small entities will typically have to outsource the required studies to consultants and obtaining the data may be difficult for the consultants. The entities most likely to obtain exemptions (smaller & lower impact entities) are the ones that probably will have the most difficulty in obtaining the data. Generally larger utilities “upstream” from the smaller ones are hesitant to give information to other entities. Depending on the study requirements and criteria for application, this could be a very costly process.
Dominion	Yes	It has been Dominion’s experience that CEII or Code/Standards of Conduct rules may restrict generation entities (GO/GOP) from obtaining some of the information necessary to perform the analysis needed to file the “Detailed Information to Support an Exception Request”. Dominion is also aware that, in some cases, generation entities do not have the technical expertise (transmission planning, power flow and or stability analysis background) to perform such analysis.
Electricity Consumers	Yes	It may be necessary that the exception request form explicitly address this potential

Organization	Yes or No	Question 4 Comment
Resource Council (ELCON)		problem by allowing the entity seeking an exception to state that for reasons beyond its control it failed to acquire the necessary data, base case or supporting document to enable completion of the filing.
ReliabilityFirst	Yes	In some cases, models and even knowledge of the system configurations, operating protocols and procedures may not be well known by all the entities. System adjustments, load levels, topologies, maintenance and outage schedules, which happen daily, will or may be unknown to many entities, including the Regional Entities who may submit a request to include facilities. For cross regional boundaries, the problem becomes even larger. That coupled with generation unit owners/operators not permitted to know transmission information (i.e. Questions 4 and 5); this will put them at a huge disadvantage to participate in the exception request process.
Southwest Power Pool Standards Review Team	Yes	SCADA line flow data might be hard to capture for the last two years. Specifically the line flows may not be available.
Tri-State Generation and Transmission Assn., Inc. Energy Management	Yes	It may be hard for a GO to get the information requested in #1 or #4.
TSGT G&T	Yes	It may be hard for a GO to get the information requested in #1 or #4.
<p><b>Response:</b> Based on the comments received, the SDT believes that entities will be able to obtain the requisite information necessary to submit a request. However, should an entity have difficulty, it will need to obtain the assistance of its Regional Entity to secure the data. If the entity still can't obtain the needed data, then the SDT fully expects that entity's Regional Entity to work with them to come up with a plan that will allow that entity to fill out the request form in a manner that will be acceptable to the Regional Entity so that processing of the request can continue. The SDT expects that entities may need to execute confidentiality type or other agreements in order to obtain the use of the necessary information and data.</p>		
Farmington Electric Utility System	Yes	See response to question 2

Organization	Yes or No	Question 4 Comment
<b>Response:</b> Please see response to Q2.		
Consumers Energy	Yes	
City of Redding Electric Utility	Yes	
<b>Response:</b> Without any specific comment, the SDT is unable to respond.		

5. **Are there other specific characteristics that you feel would be important for presenting a case and which are generic enough that they belong in the request? If so, please identify them here and provide suggested language that could be added to the document.**

**Summary Consideration:** Based on the responses to this question, the SDT offers the following for summary consideration.

Regarding the FERC seven factor test, an entity requesting an exception can always submit data related to that test for the Regional Entity and ERO to evaluate.

In response to the suggestions for additional inclusion in the technical criteria document, there are no restrictions on what data can be submitted in an exception request. An entity requesting an exception can always submit data it believes will be beneficial to its exception request for the Regional Entity and ERO to evaluate.

Finally, if an entity that is submitting an exception request cannot gain access to certain information that is listed in the technical criteria document, it should work with its Regional Entity to come up with substitute data that is acceptable. The submitting entity should state in its exception request submittal that it is unable to access certain data from other parties and explain the reasons why that is the case.

Organization	Yes or No	Question 5 Comment
Northeast Power Coordinating Council	Yes	<p>There is no guidance provided as to how the information asked for in this form will be evaluated, and what the decision making process will entail. As such, a reference document should be developed and provide some guidance how to evaluate applications.</p> <p>Suggest that the BES SDT adopt the FERC Seven Factor test.</p>

**Response:** The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. If the SDT could have come up with the simple answer, it would have been supplied within the bright-line. The SDT would also like to point out to the commenters that it directly solicited assistance in this matter in the first posting of the criteria and received very little in the form of substantive comments.

There are so many individual variables that will apply to specific cases that there is no way to cover everything up front. There are

Organization	Yes or No	Question 5 Comment
		<p>always going to be extenuating circumstances that will influence decisions on individual cases. One could take this statement to say that the regional discretion hasn't been removed from the process as dictated in the Order. However, the SDT disagrees with this position. The exception request form has to be taken in concert with the changes to the ERO Rules of Procedure and looked at as a single package. When one looks at the rules being formulated for the exception process, it becomes clear that the role of the Regional Entity has been drastically reduced in the proposed revision. The role of the Regional Entity is now one of reviewing the submittal for completion and making a recommendation to the ERO Panel, not to make the final determination. The Regional Entity plays no role in actually approving or rejecting the submittal. It simply acts as an intermediary. One can counter that this places the Regional Entity in a position to effectively block a submittal by being arbitrary as to what information needs to be supplied. In addition, the SDT believes that the visibility of the process would belie such an action by the Regional Entity and also believes that one has to have faith in the integrity of the Regional Entity in such a process. Moreover, Appendix 5C of the proposed NERC Rules of Procedure, Sections 5.1.5, 5.3, and 5.2.4, provide an added level of protection requiring an independent Technical Review Panel assessment where a Regional Entity decides to reject or disapprove an exception request. This panel's findings become part of the exception request record submitted to NERC. Appendix 5C of the proposed NERC Rules of Procedure, Section 7.0, provides NERC the option to remand the request to the Regional Entity with the mandate to process the exception if it finds the Regional Entity erred in rejecting or disapproving the exception request. On the other side of this equation, one could make an argument that the Regional Entity has no basis for what constitutes an acceptable submittal. Commenters point out that the explicit types of studies to be provided and how to interpret the information aren't shown in the request process. The SDT again points to the variations that will abound in the requests as negating any hard and fast rules in this regard. However, one is not dealing with amateurs here. This is not something that hasn't been handled before by either party and there is a great deal of professional experience involved on both the submitter's and the Regional Entity's side of this equation. Having viewed the request details, the SDT believes that both sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to travel upward to the ERO Panel for adjudication.</p> <p>Now, the commenters could point to lack of direction being supplied to the ERO Panel as to specific guidelines for them to follow in making their decision. The SDT re-iterates the problem with providing such hard and fast rules. There are just too many variables to take into account. Providing concrete guidelines is going to tie the hands of the ERO Panel and inevitably result in bad decisions being made. The SDT also refers the commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.1 where the basic premise on evaluating an exception request must be based on whether the Elements are necessary for the reliable operation of the interconnected transmission system. Further, reliable operation is defined in the Rules of Procedure as operating the elements of the bulk power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cyber security incident, or unanticipated failure of system elements. The SDT firmly believes that the technical prowess of the ERO Panel, the visibility of the process, and the experience</p>

Organization	Yes or No	Question 5 Comment
		<p>gained by having this same panel review multiple requests will result in an equitable, transparent, and consistent approach to the problem. The SDT would also point out that there are options for a submitting entity to pursue that are outlined in the proposed ERO Rules of Procedure changes if they feel that an improper decision has been made on their submittal.</p> <p>Some commenters have asked whether a single ‘yes’ or ‘no’ response to an item on the exception request form will mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.2 of the proposed Rules of Procedure that states “No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved.” The SDT would like to point out several changes made to the specific items in the form that were made in response to industry comments. The SDT believes that these clarifications will make the process tighter and easier to follow and improve the quality of the submittals.</p> <p>Finally, the SDT would point to the draft SAR for Phase II of this project that calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. Given the complexity of the technical aspects of this problem and the filing deadline that the SDT is working under for Phase I of this project, the SDT believes that it has developed a fair and equitable method of approaching this difficult problem. The SDT asks the commenter to consider all of these facts in making your decision and casting your ballot and hopes that these changes will result in a favorable outcome.</p> <p>Regarding the FERC seven factor test, an entity requesting an exception can always submit data related to that test for the Regional Entity and ERO to evaluate.</p>
Hydro One Networks Inc.	Yes	<p>The general approach, information, data, and assessments proposed seem to be reasonable. However, guidance is not provided as to how this information may be evaluated in the decision making process. As such, a reference document should be developed and provide guidance how applications will be assessed. For example”1) Does the element(s)?</p> <ul style="list-style-type: none"> <li>o Would have qualified under one of the exclusions or inclusions but have marginally different threshold as prescribed in the definition;</li> <li>o transfer bulk power within (intra) or between (inter) two Balancing Authority Areas;</li> <li>o monitor facilities included in an Interconnection Reliability Operating Limit (IROL);</li> <li>o are not considered necessary for the operation of interconnected transmission</li> </ul>

Organization	Yes or No	Question 5 Comment
		<p>system under normal conditions, contingency or prolonged outage conditions.2) Are System Element(s) located in close electrical proximity to Load? o Electrical proximity may be a measurement of system impedance between load centers within the system seeking exception. o Other physical characteristics.3) Are System Elements treated as primarily radial in character? o Smaller deviation from the exclusion E1. o This can be demonstrated by the way the connections to the BES are operated (e.g., the local area is not operated as part of the BES with disconnection procedures when events occur in the local area to separate it.) o This can also be demonstrated by the way resources in the local area are treated in operations, for example, they are not included in a regional dispatch or secured by an ISO/RTO. o Power flows into the system, but rarely flows out. i. This can be demonstrated through transactional records or load flow analysis where it is shown that flow out does not occur or occurs only under a very limited set of conditions and for a limited quantity of energy. a. The limited set of conditions must clearly state the conditions where power flows out, for example, only under specified contingency events. b. Transactional records provided must be for the same time specified in the Exception Rules of Procedure for performing periodic exception self-certifications (presently two years). c. Power entering the system is not recognized or regularly transported on to some other system. (This can be demonstrated by operational procedures that restrict use of delivered power to that system, e.g., the absence of a wheeling agreement or an agreement that generally restricts wheeling under normal) d. The System Element(s) have a very small Distribution Factor on any other BES Element(s). o System Elements are not necessary for the operation of interconnected transmission under normal, contingency or prolonged outage conditions.</p>
WECC Staff	Yes	<p>In order to make a determination of BES status of an element, there should be a listing of effects of the outage on certain facilities, frequencies, voltages, transmission elements, or other information that should be included in the submittal by the entity. Without further specification of requirements for presenting a case it is likely that the Regional Entity will receive inconsistent submittals of data. Leaving open the question of what constitutes a sufficient presentation of a case would likely lead to a wide</p>

Organization	Yes or No	Question 5 Comment
		spectrum of submittals with respect to the amount of data and level of detail in the data.
<p><b>Response:</b> The technical criteria document currently includes a request for information related to an outage of an element on the BES.</p> <p>The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. Consolidated Edison Co. of NY, Inc.	Yes	We strongly recommend that the BES SDT adopt the FERC Seven Factor test for local distribution.

Organization	Yes or No	Question 5 Comment
<p><b>Response:</b> There are no restrictions on what data can be submitted in an exception request. Regarding the FERC seven factor test, an entity requesting an exception can always submit data related to that test for the Regional Entity and ERO to evaluate.</p>		
<p>American Electric Power</p>	<p>No</p>	<p>As stated in the response to question #3, it is unclear how the process will work with the interaction among the various NERC Functions. For instance, an exception request from generation might require collaboration among other functional entities, i.e. GOP, TOP, and RC.</p> <p>The existence of a must run unit means that unit has a material impact on any configuration of the BES and as such would need a serious waiver to not be considered a BES facility. As such, a must run unit would not receive an exception. As a result, should question #3 be removed?</p> <p>Criteria for applying for an exception should be outlined before filling out the form.</p>
<p><b>Response:</b> If an entity that is submitting an exception request cannot gain access to certain information that is listed in the technical criteria document, it should work with its Regional Entity to come up with substitute data that is acceptable. The submitting entity should state in its exception request submittal that it is unable to access certain data from other parties and explain the reasons why that is the case.</p> <p>As stated in the proposed ERO Rules of Procedure, ““No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved.”.</p> <p>Please see the proposed ERO Rules of Procedure for details on filling out a form.</p>		
<p>Farmington Electric Utility System</p>	<p>Yes</p>	<p>The SDT should consider additional limits on Generation. For example, if a generation prime mover (turbine) has a maximum output of 35 MW but is coupled to a generator with a rating in excess of 75 MVA. The generator output is limited by the turbine - thus the rating of the turbine should be a taken into consideration rather than the generator rating.</p>
<p>Hydro-Quebec TransEnergie</p>	<p>Yes</p>	<p>The general characteristics of the Interconnection (such as frequency or voltage variation), as they may guide the decision for exclusion of specific elements.</p>

Organization	Yes or No	Question 5 Comment
<p><b>Response:</b> Regarding the suggestions for inclusion in the technical criteria document, there are no restrictions on what data can be submitted in an exception request. An entity requesting an exception can always submit data it believes will be beneficial to its exception request for the RE and NERC to evaluate. No change made.</p>		
<p>Indeck Energy Services</p>	<p>Yes</p>	<p>As acknowledged in the response to Question 12 comments on the previous BES definition, the BES definition is expansive compared to the definition of the BPS in the FPA Section 215. The inclusion of the limited Exclusions is an attempt to remedy the situation. However, the Exclusions need to include a fifth one that if, based on studies or other assessments, it can be shown that any transmission or generator element otherwise identified as part of the BES is not important to the reliability of the BPS, then that element should be excluded from the mandatory standards program. There has never been a study to show that elements, such as a 20 MW wind farm, 60 MW merchant generator (which operates infrequently in the depressed market) in a large BA (eg NYISO) or a radial transmission line connecting a small generator are important to the reliability of the BPS. They are covered by the mandatory standards program through the registration criteria. The BES Definition is the opportunity to permit an entity to demonstrate that an element is unimportant to reliability of the BPS. The SDT has identified a small subset of elements that it is willing to exclude. By their very nature, these exclusions dim the bright line that is the stated goal of this project. However, the SDT’s foresight seems limited in its selections. Analytical studies are used to evaluate contingencies that could lead to the Big Three (cascading outages, instability or voltage collapse). Such a study showing that a transmission or generation element is bounded by the N-1 or N-2 contingency would exclude it from the BES definition. For example, in a BA with a NERC definition Reportable Disturbance of approximately 400 MW (eg NYISO), a 20 MW wind farm, 60 MW merchant generator or numerous other smaller facilities would be bounded by larger contingencies. It would take more than six 60 MW merchant generators with close location and common mode failure to even be a Reportable Disturbance, much less become the N-1 contingency for the Big Three. Exclusion E5 should be “E5 - Any facility that can be demonstrated to the Regional Entity by analytical study or other</p>

Organization	Yes or No	Question 5 Comment
		assessment to be unimportant to the reliability of the BPS (with periodic reports by the Regional Entity to NERC of any such assessments).”
<p><b>Response:</b> The SDT acknowledges and appreciates the comments and recommendations associated with modifications to the technical aspects (i.e., the bright-line and component thresholds) of the BES definition. However, the SDT has responsibilities associated with being responsive to the directives established in Orders No. 743 &amp; 743-A, particularly in regards to the filing deadline of January 25, 2012, and this has not afforded the SDT with sufficient time for the development of strong technical justifications that would warrant a change from the current values that exist through the application of the definition today. These and similar issues have prompted the SDT to separate the project into phases which will enable the SDT to address the concerns of industry stakeholders and regulatory authorities. Therefore, the SDT will consider all recommendations for modifications to the technical aspects of the definition for inclusion in Phase 2 of Project 2010-17 Definition of the Bulk Electric System. This will allow the SDT, in conjunction with the NERC Technical Standing Committees, to develop analyses which will properly assess the threshold values and provide compelling justification for modifications to the existing values.</p>

6. Are you aware of any conflicts between the proposed approach and any regulatory function, rule order, tariff, rate schedule, legislative requirement or agreement, or jurisdictional issue? If so, please identify them here and provide suggested language changes that may clarify the issue.

**Summary Consideration:** The majority of commenters responded that they were not aware of any conflicts. However, some comments were supplied indicating concerns.

Three commenters expressed the need to address the function of an Element or system that is subject to an exception request to determine whether it is a “facilit[y] used in the local distribution of electric energy” and therefore excluded from the BES under Section 215(a)(1) of the Federal Power Act. Those commenters have been directed to question 2 for detailed responses on this issue.

Two commenters submitted concerns that the ERO does not have the authority to apply the BES definition in Canada. The SDT is attempting to craft a BES definition that can be applied within the ERO footprint. It is neither within the scope of the SDT nor is it appropriate for the SDT to provide a Canadian regulatory resolution within the definition. As such, the SDT agrees that the ERO will have to address these types of non-jurisdictional situations with relevant Regions through the exception procedure.

Two commenters expressed a concern that information necessary to perform an analysis may be restricted either by federal-/state Codes/Standards of Conduct and/or CEII prohibitions. Based on the comments received, the SDT believes that entities will be able to obtain the requisite information necessary to submit a request. However, should an entity have difficulty, it will need to obtain the assistance of its Regional Entity to secure the data. If the entity still can’t obtain the needed data, then the SDT fully expects that entity’s Regional Entity to work with them to come up with a plan that will allow that entity to fill out the request form in a manner that will be acceptable to the Regional Entity so that processing of the request can continue.

One comment stated that organized markets have a “must run” generator concept that has nothing to do with reliability. Thus, Q3 for generation facilities might be confused with market tariff provisions. To resolve this concern, the SDT has clarified Q3 for generation resources as follows:

3. Is the ~~generator~~ generation resource designated as a must run unit for reliability?

<b>Response:</b> Thank you for your response.		
Indeck Energy Services	Yes	<p>As acknowledged in the response to Question 12 comments on the previous BES definition, the BES definition is expansive compared to the definition of the BPS in the FPA Section 215. The inclusion of the limited Exclusions is an attempt to remedy the situation. However, the Exclusions need to include a fifth one that if, based on studies or other assessments, it can be shown that any transmission or generator element otherwise identified as part of the BES is not important to the reliability of the BPS, then that element should be excluded from the mandatory standards program. There has never been a study to show that elements, such as a 20 MW wind farm, 60 MW merchant generator (which operates infrequently in the depressed market) in a large BA (eg NYISO) or a radial transmission line connecting a small generator are important to the reliability of the BPS. They are covered by the mandatory standards program through the registration criteria. The BES Definition is the opportunity to permit an entity to demonstrate that an element is unimportant to reliability of the BPS. The SDT has identified a small subset of elements that it is willing to exclude. By their very nature, these exclusions dim the bright line that is the stated goal of this project. However, the SDT's foresight seems limited in its selections. Analytical studies are used to evaluate contingencies that could lead to the Big Three (cascading outages, instability or voltage collapse). Such a study showing that a transmission or generation element is bounded by the N-1 or N-2 contingency would exclude it from the BES definition. For example, in a BA with a NERC definition Reportable Disturbance of approximately 400 MW (eg NYISO), a 20 MW wind farm, 60 MW merchant generator or numerous other smaller facilities would be bounded by larger contingencies. It would take more than six 60 MW merchant generators with close</p>

Organization	Yes or No	Question 6 Comment
		location and common mode failure to even be a Reportable Disturbance, much less become the N-1 contingency for the Big Three. Exclusion E5 should be “E5 - Any facility that can be demonstrated to the Regional Entity by analytical study or other assessment to be unimportant to the reliability of the BPS (with periodic reports by the Regional Entity to NERC of any such assessments).”
<p><b>Response:</b> The SDT has already incorporated a note at the bottom of the definition stating that exceptions can be pursued through the exception process. The SDT feels that this note is sufficient to address the concerns raised herein. In addition, the SDT reminds the commenter that all threshold values will be examined in Phase II of this project. No change made.</p>		
City of Redding Electric Utility	Yes	
<p><b>Response:</b> Without a specific comment, the SDT is unable to respond.</p>		
Hydro-Quebec TransEnergie	Yes	<p>For HQT's system, the proposed BES definition combined with the exception procedure are presently incompatible or at least inconsistent with the regulatory framework applicable in Quebec. The proposed changes have not address this concern, neither the SDT's responses to our previous comments last May (Q.9).We reiterate that the definition and the exception procedure shall be determined by Quebec's regulator, the Régie de l'énergie du Québec, (Quebec Energy Board) which has the responsibility to ensure that electric power transmission in Quebec is carried out according to the reliability standards it adopts. Per se, it would be necessary that E1 and E3 grant exclusions with much higher level of generation. It would also be necessary to allow for several levels of application for the Reliability Standards, in accordance with the Régie de l'énergie du Québec approach: the Bulk Power System (BPS) as determined using an impact-based methodology, the Main Transmission System (MTS), and other parts of Regional System. Standards related to the protection system (PRC-004-1 and PRC-005-1) and those related to the design of the transmission system (TPL 001-0 to TPL-004-0) shall be applicable to the first level, but all other reliability standards shall be applied to the second level, the MTS. The MTS definition is somewhat different than the Bulk Electric System</p>

Organization	Yes or No	Question 6 Comment
		definition, and it includes elements that impact the reliability of the grid, supply-demand balance and interchanges. We argue that it would be necessary for NERC to address the regulatory issues outside of the present context of the SDT and ROP team.
Manitoba Hydro	Yes	Canadian Entities are not under FERC jurisdiction, so the revised BES Definition may not apply. A number of Canadian Entities have the BES defined within their provincial legislation. This may introduce differences and even contradictions between elements that are included in the BES according to provincial legislation and the NERC definition.
<p><b>Response:</b> The SDT is attempting to craft a BES definition that can be applied within the ERO footprint. It is neither within the scope of the SDT nor is it appropriate for the SDT to provide a Canadian regulatory resolution within the definition. As such, the SDT agrees that the ERO will have to address these types of non-jurisdictional situations with relevant Regions through the exception procedure.</p>		
Kootenai Electric Cooperative	Yes	As discussed in more detail in our response to Question 2, KEC believes it is necessary to address the function of an Element or system that is subject to an Exceptions Request to determine whether it is a “facilit[y] used in the local distribution of electric energy” and therefore excluded from the BES under Section 215(a)(1) of the Federal Power Act.
City of Austin dba Austin Energy	Yes	As discussed in more detail in our response to Question 2, AE believes it is necessary to address the function of an Element or system subject to an Exceptions Request to determine whether it is a “facilit[y] used in the local distribution of electric energy” and, therefore, excluded from the BES under Section 215(a)(1) of the Federal Power Act.
Snohomish County PUD	Yes	As discussed in more detail in our response to Question 2, SNPD believes it is necessary to address the function of an Element or system that is subject to an Exceptions Request to determine whether it is a “facilit[y] used in the local distribution of electric energy” and therefore excluded from the BES under Section 215(a)(1) of the Federal Power Act.

Organization	Yes or No	Question 6 Comment
<p><b>Response:</b> Please see response to Q2.</p>		
ReliabilityFirst	Yes	<p>Since the inception of the Open Access Transmission Tariff, transmission models and even knowledge of the systems, operating protocols and procedures may not be well known or known at all by all the entities. System adjustments, load levels, topologies, maintenance and outage schedules (i.e. market sensitive information), which happens daily is not permitted to be known by the generation side of the industry. An unknown at this point and without a common set of criteria to be used by the Regional Entities and NERC Staff and Panels, it will be difficult to make consistent determinations across the ERO Enterprise.</p>
Dominion	Yes	<p>Much of the information necessary to perform the analysis required is restricted either by federal and/or state Codes/Standards of Conduct and/or CEI prohibitions.</p>
<p><b>Response:</b> Please see response to Q4.</p>		
ACES Power Marketing Standards Collaborators	Yes	<p>Some organized markets have a must run concept that has nothing to do with reliability. Thus, Q3 for generation facilities might be confused with these tariff provisions.</p>
<p><b>Response:</b> To resolve this concern, the SDT has clarified question 3 for generation resources to read:  <b>3. Is the <del>generator-generation resource</del> designated as a must run unit <u>for reliability</u>?</b></p>		

7. **Are there any other concerns with the proposed approach for demonstrating BES Exceptions that haven't been covered in previous questions and comments (bearing in mind that the definition itself and the proposed Rules of Procedure changes are posted separately for comments)? Please be as specific as possible with your comments.**

**Summary Consideration:** Based on the responses to this question, the SDT offers the following for summary consideration.

The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. If the SDT could have come up with the simple answer, it would have been supplied within the bright-line. The SDT would also like to point out to the commenters that it directly solicited assistance in this matter in the first posting of the criteria and received very little in the form of substantive comments.

There are so many individual variables that will apply to specific cases that there is no way to cover everything up front. There are always going to be extenuating circumstances that will influence decisions on individual cases. One could take this statement to say that the regional discretion hasn't been removed from the process as dictated in the Order. However, the SDT disagrees with this position. The exception application form has to be taken in concert with the changes to the ERO Rules of Procedure and looked at as a single package. When one looks at the rules being formulated for the exception process, it becomes clear that the role of the Regional Entity has been drastically reduced in the proposed revision. The role of the Regional Entity is now one of reviewing the submittal for completion and making a recommendation to the ERO panel, not to make the final determination. The Regional Entity plays no role in actually approving or rejecting the submittal. It simply acts as an intermediary. One can counter that this places the Regional Entity in a position to effectively block a submittal by being arbitrary as to what information needs to be supplied. In addition, the SDT believes that the visibility of the process would belie such an action by the Regional Entity and also believes that one has to have faith in the integrity of the Regional Entity in such a process. Moreover, Appendix 5C of the proposed NERC Rules of Procedure, Sections 5.1.5, 5.3, and 5.2.4, provide an added level of protection requiring an independent Technical Review Panel assessment where a Regional Entity decides to reject or disapprove an exception request. This panel's findings become part of the exception request record submitted to NERC. Appendix 5C of the proposed NERC Rules of Procedure, Section 7.0, provides NERC the option to remand the application to the Regional Entity with the mandate to process the exception if it finds the Regional Entity erred in rejecting or disapproving the exception request. On the other side of this equation, one could make an argument that the Regional Entity has no basis for what constitutes an acceptable submittal. Commenters point out that the explicit types of studies to be provided and how to interpret the information aren't shown in the application process. The SDT again points to the variations that will abound in the applications as negating any hard and fast rules in this regard. However, one is not dealing with amateurs here. This is not something that hasn't been handled before by either party and there

is a great deal of professional experience involved on both the submitter’s and the Regional Entity’s side of this equation. Having viewed the application details, the SDT believes that both sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to travel upward to the ERO panel for adjudication.

In addition, the SDT would point to the SAR for Phase II of this project that calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. Given the complexity of the technical aspects of this problem and the filing deadline that the SDT is working under for Phase I of this project, the SDT believes that it has developed a fair and equitable method of approaching this difficult problem. The SDT asks the commenter to consider all of these facts in making your decision and casting your ballot and hopes that these changes will result in a favorable outcome.

NERC and the industry cannot wait until Phase 2 for the development of the exception process as it is an Order No. 743 directive that must be addressed by the FERC established deadline of January 25, 2012.

If an entity that is submitting an exception request cannot gain access to certain information that is listed in the technical criteria document, it should work with its Regional Entity to come up with substitute data that is acceptable. In addition, the submitting entity should state in its exception request submittal that it is unable to access certain data from other parties and explain the reasons why that is the case.

Organization	Yes or No	Question 7 Comment
LG&E and KU Energy	Yes	LG&E and KU Energy request clarification as to how the two year data requirement would apply to a new facility for which the owner/operator requests an exemption.
<b>Response:</b> The SDT recommends that a submitting entity work with its Regional Entity to determine how best to handle this type of a situation.		
Tacoma Power	Yes	Tacoma Power has a concern that the form may be too general in nature. The task before NERC and the industry is to promote consistency in the application of the BES definition. The form will require the regions to develop individual criteria for assessing an exception request and making a recommendation on the request. We recommend in Phase 2 that the SDT develop specific evaluation criteria for the regions to apply to

Organization	Yes or No	Question 7 Comment
		an exception request. Thank you for consideration of our comments.
<p>City of Redding City of Redding Electric Utility</p>	<p>Yes</p>	<p>Redding acknowledges there is an immediate need for a method where an entity can present evidence that their facilities are “not necessary for the Reliable Operation of the interconnected bulk power transmission system” as stated in the NERC Rules of Procedure Section 3.0. “BASIS FOR APPROVAL OF AN EXCEPTION.” Without a process to present the evidence then the RE and the ERO are under no mandate to review facilities in light of any criteria besides the BES definition as NERC clearly pointed out in the City of Holland case where Holland was forced to register by the RE (RFC). However, Redding is very concerned that under the proposed Exception process the final evaluation of an element or facility is left to the sole judgment of NERC. The concern is there is no method, criteria, measurement, or standard that NERC will use for the evaluation. It is also a concern that NERC has a predetermined definition of Distribution Facilities and will not evaluate networked Distribution Facilities fairly. NERC has already stated their predetermined position as to what they determine to be distribution and not distribution facilities in their “MOTION TO INTERVENE AND COMMENTS OF THE NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION” filed in the case of the City of Holland, Michigan (Docket No. RC11-5-000). On page 10 and 11 of this motion, under the section labeled “A. Holland’s 138 kV lines are transmission rather than local distribution facilities” NERC states “Distribution facilities generally are characterized as elements that are designed and can carry electric energy (Watts/MW) in one direction only at any given time from a single source point (distribution substation) to final load centers.” NERC has clearly stated that only radial facilities are considered distribution facilities and were unwilling to consider that network facilities over 100Kv could be classified as Distribution Facilities in this case. Holland’s claim of NERC over-reaching their authority appears to have credibility. In conclusion, Redding supports the proposed exception process as it stands on the grounds that it allows an entity the right to a process which NERC is currently not obligated to allow, it requires that NERC judge the facilities on the merit of “necessary for the Reliable Operation of the interconnected bulk power transmission system”, and it allows an appeals process that must judge if NERC evaluated facilities on the standard set forth. However,</p>

Organization	Yes or No	Question 7 Comment
		Redding’s vote is conditional on the completion of phase 2 where the term “necessary for the Reliable Operation of the interconnected bulk power transmission system” needs to be defined.
Independent Electricity System Operator	Yes	We believe that the SDT proposed approach for exception criteria is reasonable recognizing that one method/criteria cannot be applicable to everyone and every situation within the ERO foot print. However, we believe that there is huge gap and lack of any transparency on how the exception application will be evaluated and processed. We strongly suggest that SDT develop a reference or a guidance document as part of the RoP that should provide some guidance to Registered Entities, Regional Entities and the ERO on how an exception application should be processed. The absence of such guidance will pose a challenge for each entity including the ERO, and may result in discrepancies amongst Regional Entities. The process may be perceived by registered entities as being non-transparency.
City of St. George	Yes	Clear, concise criteria with consistent repeatable results are a must for a successful outcome of the project effort. The included questions are appropriate questions but the use of those questions and the ultimate outcome is unclear with the current version. The background information indicates that continent wide criteria are not feasible. It is understood that this is a very difficult task and will be difficult to achieve (especially in the time allotted). However, if the decisions are left up to a “panel” to decide the results will be inconsistent and will vary region by region, as well as differ over time. The process involved will be very time consuming (i.e. expensive) and will be difficult to control especially during the initial timeframe. History has demonstrated that review and approval processes that pass from the entity to the regions, then to NERC and then on to FERC backup very easily due to limited staff and resources. The drafting team may want to consider moving this topic to Phase 2 of the project. However, Phase 2 needs to have fairly quick time frame in order to provide the needed direction to the industry in a timely manner.

Organization	Yes or No	Question 7 Comment
PSEg Services Corp	Yes	An applicant should be able to clearly tell whether or not an exception request will likely be granted before it is submitted. It is nearly impossible to divine the whether a request will be granted from a set of data questions. The team is urged to state the exclusion criteria explicitly; data questions required to evaluate a request should directly reference each criterion. See Order 743, paragraph 115: “NERC should develop an exemption process that includes clear, objective, transparent, and uniformly applicable criteria for exemption of facilities that are not necessary for operating the grid.”
ISO New England Inc	Yes	Given all of these decisional inputs requested by the Exception Application there needs to be some guidance or clarification here regarding the criteria that will be used to render a yes or no decision other than simply filling out the Application and allowing the Rules of Procedure process to take place. The Application process for Exceptions (inclusions or exclusions) appears to be subjective and lacks the decisional technical criteria for the applicant to be confident of the outcome.
Manitoba Hydro	Yes	Manitoba Hydro strongly disagrees with the proposed ‘Detailed Information to Support an Exception Request’ document and associated exception process for the following reasons: -It is not clear what elements or situations beyond what is covered in the core definition and associated inclusions and exclusions that the drafting team is hoping to capture through the exception process. Further, it is unclear what the benefit to reliability would be by allowing an impact based exception process given that entities will be extremely unlikely to use the exception process to include elements in the BES. -The exception process will be extremely resource intensive, particularly in the absence of any Industry approved threshold criteria. The costs to properly administer and monitor the process to ensure that impact based modeling is done accurately and that it captures the frequent changes on a dynamic system will occupy a wealth of Industry, NERC and Regional Entity time to the detriment of reliability.-It is not reasonable for industry to approve the exception process without knowing what thresholds are required to demonstrate an element as being part of the

Organization	Yes or No	Question 7 Comment
		<p>BES or not. We are concerned that BES determinations would be subjective and would vary from case to case with the particular staff examining the request. BES elements should be established and agreed upon by Industry, not set by a NERC panel. We understand that the drafting team has made this change in the interests of time, but the impact of the BES definition is too broad for this project to be rushed. -The 2010-17 project goals to increase the clarity of the BES definition and establish a 'bright-line' are compromised by the exception process. Changes and alterations to the BES definition should be approved by Industry through the Standards Under Development Process. An interpretation request or SAR should be developed by an entity if they feel that the core definition and associated exceptions and inclusions should be modified. We ask that NERC requests that FERC re-examines the directive to develop an exception process given that the BES definition, which already includes a list of exceptions, is sufficient to standalone without an associated exception process.</p>
ReliabilityFirst	Yes	<p>FERC Order 743-A, paragraph 1, discusses that NERC should "...establish an exemption process and criteria for excluding facilities that are not necessary for operating the interconnected transmission network". It also directed in paragraph 4 that "Order No. 743 also directed the ERO to develop an exemption process that includes clear, objective, transparent and uniformly applicable criteria for exempting facilities that are not necessary for operating the interconnected transmission grid." The SDT proposed a set of questions titled "Detailed Information to Support an Exception Request" to assist in the exemption process but in our mind is not "exception criteria" as stated in the FERC Orders. ReliabilityFirst Staff believes that NERC should develop criteria for which facilities or Elements could be exempted from the core definition; an example being Local Networks as outlined in the current draft of the definition. ReliabilityFirst Staff believes the Local Network exclusion is not "bright line" and could be removed from the core definition and used as criteria for exclusion in the exemption process. Item b of the LN (E3) exclusion would need evidence to support the historical and future power flows. Historical data and future power flow study results would be needed to support this exception. Additionally, another example for exemption criterion for inclusion to the BES could be any 69 kV network facilities that</p>

Organization	Yes or No	Question 7 Comment
		provide a parallel path to the BES. Evidence such as one-line diagrams along with power flow studies would need to be provided through the exemption process for these types of facilities to be included in the BES. ReliabilityFirst Staff believes that any BES facilities should not be candidates for exemption based upon the arbitrary determination of a panel that considers the aspects stated in the document “Detailed Information to Support an Exception Request”. Without uniform criteria as stated in the FERC Orders, it will be difficult for the panels to make consistent determinations across the ERO Enterprise.
Hydro One Networks Inc.	Yes	As mentioned above, we strongly suggest and encourage that SDT to develop a reference or a guidance document that will provide guidance to Registered Entities, Regional Entities and the ERO on how an exception application should/would be processed.
Arizona Public Service Company	Yes	In accordance with WECC’s position paper issued on October 5, 2011, AZPS agrees with WECC in that the proposed Technical Principles for Demonstrating BES Exceptions Request does not provide the necessary clarity as to what applying entities must provide to support their request, nor does it provide any criteria for consistency among regions in their assessment of requests.
SRP	Yes	SRP agrees with WECC Staff comments.
WECC Staff	Yes	WECC is very concerned that there are no specific qualifications or requirements, either for the entities or for the Regional Entity, with respect to: o the determination of which studies need to be conducted; o the format of the study data that should be submitted; or o the key performance measures that should be evaluated. This vagueness will lead to inconsistency in studies run, data submitted, and measures of data evaluation. If this inconsistency occurs, it will result in a potentially subjective and discordant process on multiple levels for both the submitting entities and the Regional Entities. It may result in submitting entity having to run multiple studies in order to determine what will be acceptable proof, which is overly burdensome on both the

Organization	Yes or No	Question 7 Comment
		<p>submitting entity requesting the exception and the Regional Entity reviewing the request. It also makes the consistency that FERC has requested difficult to assess and achieve. If the goal of the exceptions process is to result in consistent determinations across the regions, then WECC recommends that to the extent possible, the process be objective, clear, and include detailed instructions. The development of such an objective and detailed process is a difficult task and will require additional time. WECC believes it is better to not have an exceptions process in the interim period than to have an inefficient and overly burdensome process in place. To allow adequate time to complete the task of developing a detailed and consistent process WECC recommends that the Detailed Information to Support BES Exceptions Request be included in Phase II of the BES definition project.</p>
<p><b>Response:</b> The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. If the SDT could have come up with the simple answer, it would have been supplied within the bright-line. The SDT would also like to point out to the commenters that it directly solicited assistance in this matter in the first posting of the criteria and received very little in the form of substantive comments.</p> <p>There are so many individual variables that will apply to specific cases that there is no way to cover everything up front. There are always going to be extenuating circumstances that will influence decisions on individual cases. One could take this statement to say that the regional discretion hasn't been removed from the process as dictated in the Order. However, the SDT disagrees with this position. The exception request form has to be taken in concert with the changes to the ERO Rules of Procedure and looked at as a single package. When one looks at the rules being formulated for the exception process, it becomes clear that the role of the Regional Entity has been drastically reduced in the proposed revision. The role of the Regional Entity is now one of reviewing the submittal for completion and making a recommendation to the ERO Panel, not to make the final determination. The Regional Entity plays no role in actually approving or rejecting the submittal. It simply acts as an intermediary. One can counter that this places the Regional Entity in a position to effectively block a submittal by being arbitrary as to what information needs to be supplied. In addition, the SDT believes that the visibility of the process would belie such an action by the Regional Entity and also believes that one has to have faith in the integrity of the Regional Entity in such a process. Moreover, Appendix 5C of the proposed NERC Rules of Procedure, Sections 5.1.5, 5.3, and 5.2.4, provide an added level of protection requiring an independent Technical Review Panel assessment where a Regional Entity decides to</p>		

Organization	Yes or No	Question 7 Comment
		<p>reject or disapprove an exception request. This panel’s findings become part of the exception request record submitted to NERC. Appendix 5C of the proposed NERC Rules of Procedure, Section 7.0, provides NERC the option to remand the request to the Regional Entity with the mandate to process the exception if it finds the Regional Entity erred in rejecting or disapproving the exception request. On the other side of this equation, one could make an argument that the Regional Entity has no basis for what constitutes an acceptable submittal. Commenters point out that the explicit types of studies to be provided and how to interpret the information aren’t shown in the request process. The SDT again points to the variations that will abound in the requests as negating any hard and fast rules in this regard. However, one is not dealing with amateurs here. This is not something that hasn’t been handled before by either party and there is a great deal of professional experience involved on both the submitter’s and the Regional Entity’s side of this equation. Having viewed the request details, the SDT believes that both sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to travel upward to the ERO Panel for adjudication.</p> <p>Now, the commenters could point to lack of direction being supplied to the ERO Panel as to specific guidelines for them to follow in making their decision. The SDT re-iterates the problem with providing such hard and fast rules. There are just too many variables to take into account. Providing concrete guidelines is going to tie the hands of the ERO Panel and inevitably result in bad decisions being made. The SDT also refers the commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.1 where the basic premise on evaluating an exception request must be based on whether the Elements are necessary for the reliable operation of the interconnected transmission system. Further, reliable operation is defined in the Rules of Procedure as operating the elements of the bulk power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cyber security incident, or unanticipated failure of system elements. The SDT firmly believes that the technical prowess of the ERO Panel, the visibility of the process, and the experience gained by having this same panel review multiple requests will result in an equitable, transparent, and consistent approach to the problem. The SDT would also point out that there are options for a submitting entity to pursue that are outlined in the proposed ERO Rules of Procedure changes if they feel that an improper decision has been made on their submittal.</p> <p>Some commenters have asked whether a single ‘yes’ or ‘no’ response to an item on the exception request form will mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.2 of the proposed Rules of Procedure that states “No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved.” The SDT would like to point out several changes made to the specific items in the form that were made in response to industry comments. The SDT believes that these clarifications will make the process tighter and easier to follow and improve the quality of the submittals.</p>

Organization	Yes or No	Question 7 Comment
<p>Finally, the SDT would point to the draft SAR for Phase II of this project that calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. Given the complexity of the technical aspects of this problem and the filing deadline that the SDT is working under for Phase I of this project, the SDT believes that it has developed a fair and equitable method of approaching this difficult problem. The SDT asks the commenter to consider all of these facts in making your decision and casting your ballot and hopes that these changes will result in a favorable outcome.</p> <p>In addition, NERC and the industry cannot wait until Phase 2 for the development of the exception process as it is an Order No. 743 directive that must be addressed by the FERC established deadline of January 25, 2012.</p>		
<p>Dominion</p>	<p>Yes</p>	<p>The Detailed Information to Support an Exception Request form has 2 sections; one for transmission facilities and another for generation facilities. Yet, the Project 2010-17 Definition of Bulk Electric System document uses other terms such as real and reactive power resources, dispersed power producing resources, static or dynamic devices, blackstart resources, radial systems, local networks (LN), and reactive power devices. Dominion suggests that the Detailed Information to Support an Exception Request form be revised to conform to the Project 2010-17 Definition of Bulk Electric System document through either use of some sort of ‘selection’ (checkbox, drop down, write in) or revision of transmission facilities and generation facilities to be more inclusive.</p>
<p><b>Response:</b> The SDT is only determining the content of the technical criteria document. NERC will be responsible for addressing the format and user features of the final technical criteria document.</p>		
<p>TSGT G&amp;T Tri-State Generation and Transmission Assn., Inc. Energy Mangement</p>	<p>Yes</p>	<p>TSGT believes that the proposed “Technical Principles for Demonstrating BES Exceptions Request” does not clearly define the basis for decisions to exclude or include, which will lead to inconsistent application by the Regions. We believe that the checklist items for transmission and generation facilities are appropriate questions that must be answered in considering all requests. However, without objective criteria defining how to assess the materials submitted, the current methodology leaves it to</p>

Organization	Yes or No	Question 7 Comment
		<p>each region to develop their own methodology and criteria for evaluating the submittals. We believe the lack of clarity regarding what studies must be submitted and what must be demonstrated by the studies submitted will be overly burdensome on the submitting entity and the Region, as multiple studies may be required for the two to agree that there is sufficient justification for an exemption request. We believe that additional work is necessary to develop clear, objective methods and criteria for identifying which facilities may be excluded from or should be included in the Bulk Electric System. Clear, objective methods and criteria will enable the submitter of requests to understand what is necessary for submitting an exception request and will provide for consistency among the regions in their initial assessment and recommendations to the ERO.</p>
<p><b>Response:</b> The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. If the SDT could have come up with the simple answer, it would have been supplied within the bright-line. The SDT would also like to point out to the commenters that it directly solicited assistance in this matter in the first posting of the criteria and received very little in the form of substantive comments.</p> <p>There are so many individual variables that will apply to specific cases that there is no way to cover everything up front. There are always going to be extenuating circumstances that will influence decisions on individual cases. One could take this statement to say that the regional discretion hasn't been removed from the process as dictated in the Order. However, the SDT disagrees with this position. The exception request form has to be taken in concert with the changes to the ERO Rules of Procedure and looked at as a single package. When one looks at the rules being formulated for the exception process, it becomes clear that the role of the Regional Entity has been drastically reduced in the proposed revision. The role of the Regional Entity is now one of reviewing the submittal for completion and making a recommendation to the ERO Panel, not to make the final determination. The Regional Entity plays no role in actually approving or rejecting the submittal. It simply acts as an intermediary. One can counter that this places the Regional Entity in a position to effectively block a submittal by being arbitrary as to what information needs to be supplied. In addition, the SDT believes that the visibility of the process would belie such an action by the Regional Entity and also believes that one has to have faith in the integrity of the Regional Entity in such a process. Moreover, Appendix 5C of the proposed NERC Rules of Procedure, Sections 5.1.5, 5.3, and 5.2.4, provide an added level of protection requiring an independent Technical Review Panel assessment where a Regional Entity decides to</p>		

Organization	Yes or No	Question 7 Comment
		<p>reject or disapprove an exception request. This panel’s findings become part of the exception request record submitted to NERC. Appendix 5C of the proposed NERC Rules of Procedure, Section 7.0, provides NERC the option to remand the request to the Regional Entity with the mandate to process the exception if it finds the Regional Entity erred in rejecting or disapproving the exception request. On the other side of this equation, one could make an argument that the Regional Entity has no basis for what constitutes an acceptable submittal. Commenters point out that the explicit types of studies to be provided and how to interpret the information aren’t shown in the request process. The SDT again points to the variations that will abound in the requests as negating any hard and fast rules in this regard. However, one is not dealing with amateurs here. This is not something that hasn’t been handled before by either party and there is a great deal of professional experience involved on both the submitter’s and the Regional Entity’s side of this equation. Having viewed the request details, the SDT believes that both sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to travel upward to the ERO Panel for adjudication.</p> <p>Now, the commenters could point to lack of direction being supplied to the ERO Panel as to specific guidelines for them to follow in making their decision. The SDT re-iterates the problem with providing such hard and fast rules. There are just too many variables to take into account. Providing concrete guidelines is going to tie the hands of the ERO Panel and inevitably result in bad decisions being made. The SDT also refers the commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.1 where the basic premise on evaluating an exception request must be based on whether the Elements are necessary for the reliable operation of the interconnected transmission system. Further, reliable operation is defined in the Rules of Procedure as operating the elements of the bulk power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cyber security incident, or unanticipated failure of system elements. The SDT firmly believes that the technical prowess of the ERO Panel, the visibility of the process, and the experience gained by having this same panel review multiple requests will result in an equitable, transparent, and consistent approach to the problem. The SDT would also point out that there are options for a submitting entity to pursue that are outlined in the proposed ERO Rules of Procedure changes if they feel that an improper decision has been made on their submittal.</p> <p>Some commenters have asked whether a single ‘yes’ or ‘no’ response to an item on the exception request form will mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.2 of the proposed Rules of Procedure that states “No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved.” The SDT would like to point out several changes made to the specific items in the form that were made in response to industry comments. The SDT believes that these clarifications will make the process tighter and easier to follow and improve the quality of the submittals.</p>

Organization	Yes or No	Question 7 Comment
<p>Finally, the SDT would point to the draft SAR for Phase II of this project that calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. Given the complexity of the technical aspects of this problem and the filing deadline that the SDT is working under for Phase I of this project, the SDT believes that it has developed a fair and equitable method of approaching this difficult problem. The SDT asks the commenter to consider all of these facts in making your decision and casting your ballot and hopes that these changes will result in a favorable outcome.</p>		
<p>NERC Staff Technical Review</p>	<p>Yes</p>	<p>At a minimum, we believe there are some facilities which should not be excluded from the BES under any circumstances and a list of such facilities should be documented, including facilities such as (1) Elements that are relied on in the determination of an Interconnection Reliability Operating Limit (IROL); (2) Blackstart resources and the designated blackstart Cranking Paths identified in the Transmission Operator’s restoration plan regardless of voltage, (3) Elements subject to Nuclear Plant Interface Requirements (NPIRs) as agreed to by a Nuclear Plant Generator Operator and a Transmission Entity defined in NUC-001, (4) Elements identified as required to comply with a NERC Reliability Standard by application of criteria defined within the standard (e.g., the test defined in PRC-023 to identify sub-200 kV Elements to which the standard is applicable), and (5) a generating unit that is designated as a must run unit to assure reliability of the BES.</p> <p>Also, to make the process of reviewing exception applications consistent and transparent some high level guidance should be developed as to how the information provided will be assessed by the Regional Entities and NERC. In addition to supporting the objectives of consistency and transparency, this also would provide benefit to entities submitting an exception application by allowing them to understand how the Required Information will be evaluated.</p>
<p><b>Response:</b> The SDT notes that all BES definition exception requests are considered unique and will be handled on a case-by-case basis. In addition, there is no prohibition on what facilities can be included in an exception request. To say that an Element(s) can be automatically excluded or included on a continent-wide basis is contrary to the SDT’s intent. While most of the items noted do reside on the exception request form, the SDT reminds the commenter that the proposed ERO Rules of Procedure state that “No single piece</p>		

Organization	Yes or No	Question 7 Comment
		<p>of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved.”</p> <p>The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. Organization	Yes or No	Question 7 Comment
Michigan Public Power Agency	Yes	<p>The following revisions should be made to the procedures: 1. The Technical Review Panel (TRP) provided for in Section 5.3 should not include any staff from the host Regional Entity.</p> <p>2. The Regional Entity should be required to include an attestation of a qualified individual or individuals to support the factual and technical bases for the decision. This is necessary for purposes of establishing a record in the event of an appeal. If a dispute is appealed, there must be someone at the Regional Entity level that serves as the witness supporting the Regional Entity decision. Currently, there is no accountability for the arguments and suppositions put forth by the Regional Entity; no individuals that stand behind the technical bases proffered in the Regional Entity’s written decision. Requiring a qualified individual to attest to the facts and technical arguments relied upon in arriving at the decision will ensure that someone at the Regional Entity level is prepared to take responsibility for reviewing a decision before it is issued, to stand behind the assertions and conclusions reached by the Regional Entity, and whom the Submitting Party may cross examine at hearing.</p> <p>3. A party seeking an exception should have the right to request a hearing and should not be limited to a paper process.</p> <p>4. The procedures should not permit the TRP or the Regional Entity to make a decision based upon information that is outside of the record placed before it. That is, the TRP and the Regional Entity may not, on their own, conduct an investigation or seek information independently from what has been presented to it. If the TRP or the Regional Entity requires additional information, it must be requested and provided transparently, and the Submitting Party must have an opportunity to comment upon or challenge that information before the TRP or the Regional Entity relies upon it in any way. This is not currently happening at the Regional Entity and NERC level - decisions have been made based upon documents and information that are not part of the record; the information is not shared with the Submitting Party (the party challenging registration) prior to (or after) a decision is made.</p>

Organization	Yes or No	Question 7 Comment
		<p>5. Section 5.2.2. should be revised as follows: “Upon Acceptance of the Exception Request, the Regional Entity and Submitting Party (and Owner, if different) shall confer to establish milestones in order to complete the substantive review of the Exception Request within six months after Acceptance of the Exception Request or within an alternative time period under Section 5.0. The Regional Entity and the Submitting Party (and Owner, if different) shall also discuss whether and to what extent a reduced compliance burden is appropriate during the review period. At the conclusion of the review period, the Regional Entity shall issue a notice (in accordance with Sections 5.2.3) stating its Recommendation that the Exception Request be approved or disapproved.”</p>
Holland Board of Public Works	Yes	<p>The following revisions should be made to the procedures: 1. The Technical Review Panel (TRP) provided for in Section 5.3 should not include any staff from the host Regional Entity.</p> <p>2. The Regional Entity should be required to include an attestation of a qualified individual or individuals to support the factual and technical bases for the decision. <p><b>Response:</b> Your comments are not focused on the technical criteria document and they have been forwarded to the BES ROP team for consideration in their separate process.</p>		
Central Hudson Gas & Electric Corporation	Yes	<p>The ‘Technical Principles for Demonstrating BES Exceptions’ process was intended to establish technical exception ‘criteria’ which would be used by the industry to understand what facilities would qualify for inclusions and exclusions from the BES. What has been produced, however, is essentially a listing of ‘electrical system indicators’, identified on the form, which may be material to making a decision regarding, ‘is it BES or not’. The thresholds (or acceptable values) for the indicators,</p>

Organization	Yes or No	Question 7 Comment
		<p>however, have not been determined. It is understood that in Phase II of the BES Definition development process, the SDT will attempt to address these issues but until that work has been completed, the industry will remain enmeshed in confusion and inefficient application of resources and funding. Without these criteria, it is very difficult to believe that this process can be transparent and consistent. Re: Question 4. (For Transmission Facilities)For the purposes of responding to this question, what constitutes the BES? It would seem that you must exclude the elements you are seeking exceptions for or else the exception request is rendered essentially worthless.</p>
<p><b>Response:</b> The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. If the SDT could have come up with the simple answer, it would have been supplied within the bright-line. The SDT would also like to point out to the commenters that it directly solicited assistance in this matter in the first posting of the criteria and received very little in the form of substantive comments.</p> <p>There are so many individual variables that will apply to specific cases that there is no way to cover everything up front. There are always going to be extenuating circumstances that will influence decisions on individual cases. One could take this statement to say that the regional discretion hasn't been removed from the process as dictated in the Order. However, the SDT disagrees with this position. The exception application form has to be taken in concert with the changes to the ERO Rules of Procedure and looked at as a single package. When one looks at the rules being formulated for the exception process, it becomes clear that the role of the Regional Entity has been drastically reduced in the proposed revision. The role of the Regional Entity is now one of reviewing the submittal for completion and making a recommendation to the ERO panel, not to make the final determination. The Regional Entity plays no role in actually approving or rejecting the submittal. It simply acts as an intermediary. One can counter that this places the Regional Entity in a position to effectively block a submittal by being arbitrary as to what information needs to be supplied. In addition, the SDT believes that the visibility of the process would belie such an action by the Regional Entity and also believes that one has to have faith in the integrity of the Regional Entity in such a process. Moreover, Appendix 5C of the proposed NERC Rules of Procedure, Sections 5.1.5, 5.3, and 5.2.4, provide an added level of protection requiring an independent Technical Review Panel assessment where a Regional Entity decides to reject or disapprove an exception request. This panel's findings become part of the exception request record submitted to NERC. Appendix 5C of the proposed NERC Rules of Procedure, Section 7.0, provides NERC the option to remand the application to the Regional Entity with the mandate to process the exception if it finds the Regional Entity erred in rejecting or disapproving the exception request.</p>		

Organization	Yes or No	Question 7 Comment
		<p>On the other side of this equation, one could make an argument that the Regional Entity has no basis for what constitutes an acceptable submittal. Commenters point out that the explicit types of studies to be provided and how to interpret the information aren't shown in the application process. The SDT again points to the variations that will abound in the applications as negating any hard and fast rules in this regard. However, one is not dealing with amateurs here. This is not something that hasn't been handled before by either party and there is a great deal of professional experience involved on both the submitter's and the Regional Entity's side of this equation. Having viewed the application details, the SDT believes that both sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to travel upward to the ERO panel for adjudication.</p> <p>Finally, the SDT would point to the SAR for Phase II of this project that calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. Given the complexity of the technical aspects of this problem and the filing deadline that the SDT is working under for Phase I of this project, the SDT believes that it has developed a fair and equitable method of approaching this difficult problem. The SDT asks the commenter to consider all of these facts in making your decision and casting your ballot and hopes that these changes will result in a favorable outcome.</p> <p>The SDT acknowledges and appreciates the comments and recommendations associated with modifications to the technical aspects (i.e., the bright-line and component thresholds) of the BES definition. However, the SDT has responsibilities associated with being responsive to the directives established in Orders No. 743 &amp; 743-A, particularly in regards to the filing deadline of January 25, 2012, and this has not afforded the SDT with sufficient time for the development of strong technical justifications that would warrant a change from the current values that exist through the application of the definition today. These and similar issues have prompted the SDT to separate the project into phases which will enable the SDT to address the concerns of industry stakeholders and regulatory authorities. Therefore, the SDT will consider all recommendations for modifications to the technical aspects of the definition for inclusion in Phase 2 of Project 2010-17 Definition of the Bulk Electric System. This will allow the SDT, in conjunction with the NERC Technical Standing Committees, to develop analyses which will properly assess the threshold values and provide compelling justification for modifications to the existing values.</p>
National Grid	Yes	We are assuming that "yes" answers on this checklist are not intended to result in automatic rejection of the application. We think the procedure would benefit from a general statement noting that all answers taken together will be considered to make clear that no single answer will necessarily be dispositive of the outcome.
<p><b>Response:</b> Some commenters have asked whether a single 'yes' or 'no' response to an item on the exception application form will</p>		

Organization	Yes or No	Question 7 Comment
<p>mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.2 of the proposed Rules of Procedure that states “No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved.”</p>		
<p>Indeck Energy Services</p>	<p>Yes</p>	<p>As acknowledged in the response to Question 12 comments on the previous BES definition, the BES definition is expansive compared to the definition of the BPS in the FPA Section 215. The inclusion of the limited Exclusions is an attempt to remedy the situation. However, the Exclusions need to include a fifth one that if, based on studies or other assessments, it can be shown that any transmission or generator element otherwise identified as part of the BES is not important to the reliability of the BPS, then that element should be excluded from the mandatory standards program. There has never been a study to show that elements, such as a 20 MW wind farm, 60 MW merchant generator (which operates infrequently in the depressed market) in a large BA (eg NYISO) or a radial transmission line connecting a small generator are important to the reliability of the BPS. They are covered by the mandatory standards program through the registration criteria. The BES Definition is the opportunity to permit an entity to demonstrate that an element is unimportant to reliability of the BPS. The SDT has identified a small subset of elements that it is willing to exclude. By their very nature, these exclusions dim the bright line that is the stated goal of this project. However, the SDT’s foresight seems limited in its selections. Analytical studies are used to evaluate contingencies that could lead to the Big Three (cascading outages, instability or voltage collapse). Such a study showing that a transmission or generation element is bounded by the N-1 or N-2 contingency would exclude it from the BES definition. For example, in a BA with a NERC definition Reportable Disturbance of approximately 400 MW (eg NYISO), a 20 MW wind farm, 60 MW merchant generator or numerous other smaller facilities would be bounded by larger contingencies. It would take more than six 60 MW merchant generators with close location and common mode failure to even be a Reportable Disturbance, much less become the N-1 contingency for the Big Three. Exclusion E5 should be “E5 - Any facility that can be demonstrated to the Regional Entity by analytical study or other</p>

Organization	Yes or No	Question 7 Comment
		assessment to be unimportant to the reliability of the BPS (with periodic reports by the Regional Entity to NERC of any such assessments).”
<p><b>Response:</b> The SDT acknowledges and appreciates the comments and recommendations associated with modifications to the technical aspects (i.e., the bright-line and component thresholds) of the BES definition. However, the SDT has responsibilities associated with being responsive to the directives established in Orders No. 743 &amp; 743-A, particularly in regards to the filing deadline of January 25, 2012, and this has not afforded the SDT with sufficient time for the development of strong technical justifications that would warrant a change from the current values that exist through the application of the definition today. These and similar issues have prompted the SDT to separate the project into phases which will enable the SDT to address the concerns of industry stakeholders and regulatory authorities. Therefore, the SDT will consider all recommendations for modifications to the technical aspects of the definition for inclusion in Phase 2 of Project 2010-17 Definition of the Bulk Electric System. This will allow the SDT, in conjunction with the NERC Technical Standing Committees, to develop analyses which will properly assess the threshold values and provide compelling justification for modifications to the existing values.</p>		
American Electric Power	No	AEP agrees with the overall approach demonstrated by the exception request form; however, its appropriateness will be largely dependent on the process eventually used for its implementation. AEP would like guidance on how moth-balled generation should be treated. Perhaps this could be added to the exception form as well.
<p><b>Response:</b> The SDT is not able to respond to specific requests related to potential future exception requests. Please use the BES definition and the exception request form, after its approval by the NERC Board of Trustees and FERC, for such a request. Also, please consider working with your Regional Entity to determine how moth-balled facilities should be treated.</p>		
Snohomish County PUD Blachly-Lane Electric Cooperative Central Electric Cooperative (CEC) Clearwater Power Company	No	As a general matter, SNPD believes the SDT has provided a reasonable check list that will work in most cases to elicit necessary information from the entity submitting an Exception Request. With the added language suggested in our answers to the previous questions, we believe the proposed form will serve its intended purpose of ensuring that decisions regarding Exception Requests are based upon consistent information and are consistent with the requirements of the Federal Power Act and the BES Definition as developed by the Standards Drafting Team. SNPD also supports the Standards Drafting Team’s determination to abandon its initial approach to

## Standard Development Timeline

---

*This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.*

### Development Steps Completed

1. SAR posted for comment 12/17/10 – 1/21/11
2. SC authorized moving the SAR forward to standard development 3/25/11
3. First posting of definition 4/28/11 – 5/27/11
4. First posting of criteria 5/11/11 – 6/10/11

### Description of Current Draft

This draft is the second posting of the revised definition of the Bulk Electric System (BES). It is for a 45-day formal comment and parallel voting period.

Anticipated Actions	Anticipated Date
45-day Formal Comment Period with Parallel Initial Ballot	8/26/11 – 10/10/11
Recirculation ballot	December 2011
BOT adoption	January 2011

## Project 2010-17 Definition of Bulk Electric System

---

### Effective Dates

This definition shall become effective on the first day of the second calendar quarter after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, the definition will go into effect on the first day of the second calendar quarter after Board of Trustees adoption. Compliance obligations for Elements included by the definition shall begin 24 months after the applicable effective date of the definition.

### Version History

Version	Date	Action	Change Tracking
1	TBD	Respond to FERC Order No. 743 to clarify the definition of the Bulk Electric System	N/A

### Definitions of Terms Used in Standard

*This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.*

**Bulk Electric System (BES):** Unless modified by the lists shown below, all Transmission Elements operated at 100 kV or higher and Real Power and Reactive Power resources connected at 100 kV or higher. This does not include facilities used in the local distribution of electric energy.

#### **Inclusions:**

- **I1** - Transformers with primary and secondary terminals operated at 100 kV or higher unless excluded under Exclusion E1 or E3.
- **I2** - Generating resource(s) (with gross individual or gross aggregate nameplate rating per the ERO Statement of Compliance Registry Criteria) including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100 kV or above.
- **I3** - Blackstart Resources identified in the Transmission Operator's restoration plan.
- **I4** - Dispersed power producing resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating) utilizing a system designed primarily for aggregating capacity, connected at a common point at a voltage of 100 kV or above.
- **I5** - Static or dynamic devices dedicated to supplying or absorbing Reactive Power that are connected at 100 kV or higher, or through a dedicated transformer with a high-side voltage of 100 kV or higher, or through a transformer that is designated in Inclusion I1.

#### **Exclusions:**

- **E1** - Radial systems: A group of contiguous transmission Elements that emanates from a single point of connection of 100 kV or higher and:
  - a) Only serves Load. Or,
  - b) Only includes generation resources, not identified in Inclusion I3, with an aggregate capacity less than or equal to 75 MVA (gross nameplate rating). Or,
  - c) Where the radial system serves Load and includes generation resources, not identified in Inclusion I3, with an aggregate capacity of non-retail generation less than or equal to 75 MVA (gross nameplate rating).Note – A normally open switching device between radial systems, as depicted on prints or one-line diagrams for example, does not affect this exclusion.
- **E2** - A generating unit or multiple generating units that serve all or part of retail customer Load with electric energy on the customer's side of the retail meter if: (i) the net capacity

## Project 2010-17 Definition of Bulk Electric System

---

provided to the BES does not exceed 75 MVA, and (ii) standby, back-up, and maintenance power services are provided to the generating unit or multiple generating units or to the retail Load by a Balancing Authority, or provided pursuant to a binding obligation with a Generator Owner or Generator Operator, or under terms approved by the applicable regulatory authority.

- **E3 - Local networks (LN):** A group of contiguous transmission Elements operated at or above 100 kV but less than 300 kV that distribute power to Load rather than transfer bulk power across the interconnected system. LN's emanate from multiple points of connection at 100 kV or higher to improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system. The LN is characterized by all of the following:
  - a) **Limits on connected generation:** The LN and its underlying Elements do not include generation resources identified in Inclusion I3 and do not have an aggregate capacity of non-retail generation greater than 75 MVA (gross nameplate rating) ;
  - b) **Power flows only into the LN:** The LN does not transfer energy originating outside the LN for delivery through the LN; and
  - c) **Not part of a Flowgate or transfer path:** The LN does not contain a monitored Facility of a permanent Flowgate in the Eastern Interconnection, a major transfer path within the Western Interconnection, or a comparable monitored Facility in the ERCOT or Quebec Interconnections, and is not a monitored Facility included in an Interconnection Reliability Operating Limit (IROL).
- **E4 – Reactive Power devices** owned and operated by the retail customer solely for its own use.

Note - Elements may be included or excluded on a case-by-case basis through the Rules of Procedure exception process.

## Standard Development Timeline

---

*This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.*

### Development Steps Completed

1. SAR posted for comment 12/17/10 – 1/21/11
2. SC authorized moving the SAR forward to standard development 3/25/11
3. First posting of definition 4/28/11 – 5/27/11
- 3.4. First posting of criteria 5/11/11 – 6/10/11

### Description of Current Draft

This draft is the ~~first~~second posting of the revised definition of the Bulk Electric System (BES). It is for a ~~30~~45-day formal comment and parallel voting period.

Anticipated Actions	Anticipated Date
<del>30-day Formal Comment Period</del>	<del>4/28/11</del>

Recirculation ballot	<del>12/9/11</del> <u>December 2011</u>
BOT adoption	<del>12/30/11</del> <u>January 2011</u>

## Project 2010-17 Definition of Bulk Electric System

---

### Effective Dates

This definition shall become effective on the first day of the ~~first~~second calendar quarter, ~~24 months~~ after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, ~~all requirements the definition will~~ go into effect on the first day of the ~~first~~second calendar quarter, ~~24 months~~ after Board of Trustees adoption. Compliance obligations for Elements included by the definition shall begin 24 months after the applicable effective date of the definition.

### Version History

Version	Date	Action	Change Tracking
1	TBD	Respond to FERC Order No. 743 to clarify the definition of the Bulk Electric System	N/A

### Definitions of Terms Used in Standard

*This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.*

**Bulk Electric System (BES):** ~~Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.~~

#### Inclusions:

- ~~I1 - Transformers, other than Generator Step-up (GSU) transformers, including Phase Angle Regulators, with two primary and secondary winding terminals operated at 100 kV or higher unless excluded under Exclusions E1 and/or E3.~~  
~~I2 - Individual generating units greater than 20 MVA (gross nameplate rating) including the generator terminals through the GSU which has a high side voltage of 100 kV or above.~~
- ~~I3 - Generating units resource(s) located at a single site with aggregate capacity greater than 75 MVA (with gross individual or gross aggregate nameplate rating) per the ERO Statement of Compliance Registry Criteria) including the generator terminals through the high-side of the step-up GSU transformer(s); connected through a common bus operated at a voltage of 100 kV or above.~~
- ~~I4 - Blackstart Resources and the designated blackstart Cranking Paths identified in the Transmission Operator's restoration plan regardless of voltage.~~
- ~~I5 - Dispersed power producing resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating) utilizing a system designed primarily for aggregating capacity collector system, connected through a common point of interconnection to a system Element at a voltage of 100 kV or above.~~
- ~~I5 - Static or dynamic devices dedicated to supplying or absorbing Reactive Power that are connected at 100 kV or higher, or through a dedicated transformer with a high-side voltage of 100 kV or higher, or through a transformer that is designated in Inclusion I1.~~

#### Exclusions:

- ~~E1 - Any radial systems: which is described as connected A group of contiguous transmission Elements that emanates from a single point of connection of 100 kV or higher from a single Transmission source originating with an automatic interruption device and:~~

- a) Only ~~servingserves~~ Load. ~~A normally open switching device between radial systems may operate in a 'make before break' fashion to allow for reliable system reconfiguration to maintain continuity of electrical service.~~  
Or,
- b) Only ~~includingincludes~~ generation resources, not identified in Inclusions ~~I2, I3, I4 and I5~~ with an aggregate capacity less than or equal to 75 MVA (gross nameplate rating). Or,
- c) ~~Is a combination of items (a.) and (b.) w~~Where the radial system serves Load and includes generation resources, not identified in Inclusions ~~I2, I3, I4 and I5~~ with an aggregate capacity of non-retail generation less than or equal to 75 MVA (gross nameplate rating).

Note – A normally open switching device between radial systems, as depicted on prints or one-line diagrams for example, does not affect this exclusion.

- **E2** - A generating unit or multiple generating units that serve all or part of retail customer Load with electric energy on the customer's side of the retail meter if: (i) the net capacity provided to the BES does not exceed ~~the criteria identified in Inclusions I2 or I3~~ 75 MVA, and (ii) standby, back-up, and maintenance power services are provided to the generating unit or multiple generating units or to the retail Load by a Balancing Authority, or provided pursuant to a binding obligation with a ~~Balancing Authority or another~~ Generator Owner ~~/ or~~ Generator Operator, or under terms approved by the applicable regulatory authority.
- **E3** - Local ~~Distribution N~~ networks (LDN): A Ggroups of contiguous transmission Elements operated at or above 100 kV but less than 300 kV that distribute power to Load rather than transfer bulk power across the ~~I~~interconnected ~~S~~system. LDN's emanate from multiple points of connection at 100 kV or higher~~are connected to the Bulk Electric System (BES) at more than one location solely~~ to improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system. The LDN is characterized by all of the following:
  - ~~Separable by automatic fault interrupting devices: Wherever connected to the BES, the LDN must be connected through automatic fault interrupting devices;~~
  - a) Limits on connected generation: ~~Neither t~~The LDN; ~~nor~~and its underlying Elements do not include generation resources identified in Inclusion I3 and do not have an aggregate capacity of non-retail generation greater than 75 MVA (gross nameplate rating) (in aggregate), includes more than 75 MVA generation;
  - b) Power flows only into the ~~Local Distribution Network~~LDN: ~~The generation within the LDN shall not exceed the electric Demand within the LDN~~ The LN does not transfer energy originating outside the LN for delivery through the LN; and

~~Not used to transfer bulk power: The LDN is not used to transfer energy originating outside the LDN for delivery through the LDN; and~~

c) ~~Not part of a Flowgate or Ttransfer Ppath:~~ The LDN does not contain a monitored Facility of a permanent ~~fFlowgate~~ in the Eastern Interconnection, a major transfer path within the Western Interconnection ~~as defined by the Regional Entity~~, or a comparable monitored Facility in the ERCOT or Quebec Interconnections, and is not a monitored Facility included in an Interconnection Reliability Operating Limit (IROL).

- E4 – Reactive Power devices owned and operated by the retail customer solely for its own use.

Note - Elements may be included or excluded on a case-by-case basis through the Rules of Procedure exception process.

## Implementation Plan for Project 2010-17: Definition of BES

### Prerequisite Approvals

There are no other Reliability Standards or Standard Authorization Requests (SARs), in progress or approved, that must be implemented before this project can be implemented. However, this definition relies heavily on the fact that an approved exception process exists in the NERC Rules of Procedure.

### Effective Dates

This definition shall become effective on the first day of the second calendar quarter after applicable regulatory approval. In those jurisdictions where no regulatory approval is required the definition shall go into effect on the first day of the second calendar quarter after Board of Trustees adoption.

Compliance obligations for Elements included by the definition shall begin 24 months after the applicable effective date of the definition.

The SDT realizes that Order 743 suggested a maximum of 18 months for implementation of a revised definition of the BES. The 24 month period cited here is based on the various rehearing requests filed by entities expected to be affected by the revised definition. Thus, the SDT believes that this is a more realistic timeframe in which to effect any changes.

The SDT believes that the timeframe shown is needed to:

- Effectively produce reasonable transition plans – As shown in Order 743, part of the overall process of revising the definition of BES is for the ERO and Regional Entities to develop transition plans on a region by region basis to accommodate any changes needed in those regions due to the revised definition. The transition plans will include any actions necessary for entities to achieve compliance on any issues brought about by the revised definition.
- Submit any necessary registration changes – While Order 743 states that a revised definition should provide clarity and not necessarily require major changes to registration; it is possible that the revised definition may cause some registration changes. Entities will need time to submit their changes and for those changes to work their way through the process.
- File for exceptions – The revised definition does not exist in a vacuum. There is a corresponding process for entities to request exceptions for specific equipment or configurations. This process will be defined in the NERC Rules of Procedure and will involve individual entities or the Regional Entities having to make a technical case to justify the exception. This process will take some time to complete and it would be expected that there will be an initial backlog of cases to process.
- Provide training – Entities will need to train their operators and personnel on changes to their operations brought about by the revised definition.

The existing definition of BES shall be retired at midnight of the day immediately prior to the effective date of the new definition of BES in the particular jurisdiction in which the new definition is becoming effective.

## Implementation Plan for Project 2010-17: Definition of BES

### Prerequisite Approvals

There are no other Reliability Standards or Standard Authorization Requests (SARs), in progress or approved, that must be implemented before this project can be implemented. However, this definition relies heavily on the fact that an approved exception process exists in the NERC Rules of Procedure.

### Revision to Sections of Approved Standards and Definitions

~~There is one new definition associated with this project.~~

~~**Bulk Electric System (BES):** All Transmission Elements operated at 100 kV or higher, Real Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below.~~

#### ~~Inclusions:~~

- ~~● I1—Transformers, other than Generator Step-up (GSU) transformers, including Phase Angle Regulators, with two windings of 100 kV or higher unless excluded under Exclusions E1 and E3.~~
- ~~● I2—Individual generating units greater than 20 MVA (gross nameplate rating) including the generator terminals through the GSU which has a high side voltage of 100 kV or above.~~
- ~~● I3—Multiple generating units located at a single site with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating) including the generator terminals through the GSUs, connected through a common bus operated at a voltage of 100 kV or above.~~
- ~~● I4—Blackstart Resources and the designated blackstart Cranking Paths identified in the Transmission Operator's restoration plan regardless of voltage.~~
- ~~● I5—Dispersed power producing resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating) utilizing a collector system through a common point of interconnection to a system Element at a voltage of 100 kV or above.~~

#### ~~Exclusions:~~

- ~~● E1—Any radial system which is described as connected from a single Transmission source originating with an automatic interruption device and:
  - ~~a) Only serving Load. A normally open switching device between radial systems may operate in a 'make before break' fashion to allow for reliable system reconfiguration to maintain continuity of electrical service. Or,~~
  - ~~b) Only including generation resources not identified in Inclusions I2, I3, I4 and I5.~~Or,  
~~Is a combination of items (a.) and (b.) where the radial system serves Load and includes generation resources not identified in Inclusions I2, I3, I4 and I5.~~~~
- ~~● E2—A generating unit or multiple generating units that serve all or part of retail Load with electric energy on the customer's side of the retail meter if: (i) the net capacity provided to the BES does not exceed the criteria identified in Inclusions I2 or I3, and (ii) standby, back-up, and maintenance power services are provided to the generating unit or multiple generating units or to the retail Load pursuant to a binding obligation with a Balancing Authority or another Generator Owner/Generator Operator, or under terms approved by the applicable regulatory authority.~~

- ~~• E3—Local Distribution Networks (LDN): Groups of Elements operated above 100 kV that distribute power to Load rather than transfer bulk power across the Interconnected System. LDN's are connected to the Bulk Electric System (BES) at more than one location solely to improve the level of service to retail customer Load. The LDN is characterized by all of the following:~~

~~Separable by automatic fault interrupting devices: Wherever connected to the BES, the LDN must be connected through automatic fault interrupting devices;~~

- ~~a) Limits on connected generation: Neither the LDN, nor its underlying Elements (in aggregate), includes more than 75 MVA generation;~~
- ~~b) Power flows only into the Local Distribution Network: The generation within the LDN shall not exceed the electric Demand within the LDN; Not used to transfer bulk power: The LDN is not used to transfer energy originating outside the LDN for delivery through the LDN; and~~
- ~~c) Not part of a Flowgate or Transfer Path: The LDN does not contain a monitored Facility of a permanent flowgate in the Eastern Interconnection, a major transfer path within the Western Interconnection as defined by the Regional Entity, or a comparable monitored Facility in the Quebec Interconnection, and is not a monitored Facility included in an Interconnection Reliability Operating Limit (IROL).~~

~~• Elements may be included or excluded on a case by case basis through the Rules of Procedure exception process.~~

### **Effective Dates**

~~The effective date is the date entities are expected to meet the performance identified.~~

This definition shall become effective on the first day of the ~~first~~second calendar quarter, ~~24 months~~ after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, ~~all requirements~~ the definition shall go into effect on the first day of the ~~first~~second calendar quarter, ~~24 months~~ after Board of Trustees adoption.

Compliance obligations for Elements included by the definition shall begin 24 months after the applicable effective date of the definition.

The SDT realizes that Order 743 suggested a maximum of 18 months for implementation of a revised definition of the BES. The 24 month period cited here is based on the various rehearing requests filed by entities expected to be affected by the revised definition. Thus, the SDT believes that this is a more realistic timeframe in which to effect any changes.

The SDT believes that the timeframe shown is needed to:

- Effectively produce reasonable transition plans – As shown in Order 743, part of the overall process of revising the definition of BES is for the ERO and Regional Entities to develop transition plans on a region by region basis to accommodate any changes needed in those regions due to the revised definition. The transition plans will include any actions necessary for entities to achieve compliance on any issues brought about by the revised definition.

- Submit any necessary registration changes – While Order 743 states that a revised definition should provide clarity and not necessarily require major changes to registration; it is possible that the revised definition may cause some registration changes. Entities will need time to submit their changes and for those changes to work their way through the process.
- File for exceptions – The revised definition does not exist in a vacuum. There is a corresponding process for entities to request exceptions for specific equipment or configurations. This process will be defined in the NERC Rules of Procedure and will involve individual entities or the Regional Entities having to make a technical case to justify the exception. This process will take some time to complete and it would be expected that there will be an initial backlog of cases to process.
- Provide training – Entities will need to train their operators and personnel on changes to their operations brought about by the revised definition.

The existing definition of BES shall be retired at midnight of the day immediately prior to ~~upon~~ the effective date of the new definition of BES in the particular jurisdiction in which the new definition is becoming effective.

## **Comment Form for 2<sup>nd</sup> Draft of Definition of BES (Project 2010-17)**

---

Please **DO NOT** use this form to submit comments on the 2<sup>nd</sup> draft of the Definition of the Bulk Electric System (Project 2010-17). Use the [electronic comment form](#) **only** to submit comments. Comments must be submitted by **October 10, 2011**.

If you have questions please contact Ed Dobrowolski at [ed.dobrowolski@nerc.net](mailto:ed.dobrowolski@nerc.net) or by telephone at 609-947-3673.

### **Background Information Definition of the BES (Project 2010-17)**

The SDT responded to the comments received for the first posting of the definition for this project by clarifying the core definition, inclusions, and exclusions to meet the concerns of the industry. The SDT has also utilized a variety of other inputs including work that was done by regional entities such as WECC, NPCC, RFC, and FRCC in coming up with the present definition. Another input was FERC Orders No. 743 and 743a which provided several specific directives on clarifying the existing definition. It should be noted that the revised definition does not address functional entity registration or standards requirements applicability. Those are separate issues.

The core definition represents a true bright-line; but, it is clear that by itself, it does not cover all of the known situations and configurations that are needed for a complete definition. Therefore, the SDT developed several specific inclusions and exclusions that will be added to the core definition to complete it. At the present time, the SDT has drafted five specific inclusions and four specific exclusions.

Inclusions represent those items that are included as part of the Bulk Electric System (BES) where they would not have been included as part of the simple core definition. The reasons that the SDT has added these items are as follows:

- I1 – Since transformers have windings operating at different voltages, it was felt that clarification was required so as to more explicitly identify which transformers were to be included in the BES. The SDT believes that the present draft provides this needed clarification.
- I2 – This inclusion represents a merger of the original Inclusion I2 and the original Inclusion I3 concerning generation thresholds.
- I3 – Blackstart units are considered vital to the overall operation of the BES. Consequently, the SDT has included Blackstart Resources. However, due to industry comments, the SDT has deleted the inclusion of Cranking Paths.
- I4 – This item was added in order to accommodate the effects of variable generation on the BES. The intent of this configuration is to include variable generation (e.g., wind and solar resources) with an aggregate rating greater than 75 MVA and was considered different enough from what was proposed in Inclusion I2 as to warrant a separate inclusion statement in order to provide greater clarity in this area.
- I5 – This is a new inclusion brought about by industry comments to clarify the inclusion of Reactive Power devices.

In addition to inclusions, in order to complete the picture, specific exclusions also need to be considered. The SDT has currently drafted four specific exclusions:

- E1 – This item was added to address the basic issue of radial systems. Radial exclusion was part of the existing definition and was supported moving forward in all of the regional work as well as Order No. 743 (and Order No. 743a). The SDT has

## **Comment Form for 2<sup>nd</sup> Draft of Definition of BES (Project 2010-17)**

---

clarified this exclusion in response to industry comments by deleting the automatic interruption device.

- E2 – This item was added to address the situation of behind-the-meter generation. The wording is basically extracted from the ERO Statement of Compliance Registry Criteria.
- E3 – Local networks were added to the exclusion list after considerable discussions among the SDT and various registered entities that have configurations meeting these conditions. The SDT believes that any network that simply supports distribution should be excluded from the BES. The SDT has clarified the language for the exclusion and added a 300 kV upper limit.
- E4 – The SDT has added an exclusion for Reactive Power devices used solely by retail customers for their own use as a result of comments received.

Several commenters objected to simply carrying through the generation and voltage thresholds from the ERO Statement of Compliance Registry Criteria as part of the revised definition. However, no respondents provided technical justifications for changing these values. Furthermore, the scope of this project deals mainly with responding to FERC Orders 743 and 743a which clearly stated that the intent of the order was to maintain the status quo and to only address those urgent issues identified in the order. Hence, the tight schedule that was provided in the order. After consulting with the NERC Board of Trustees and the NERC Standards Committee, the SDT has decided to forgo any attempt at changing generation or voltage thresholds at this time. There simply isn't enough time or resources to do those topics justice with the mandated schedule. Therefore, the focus of the SDT efforts will be to address the directives in Orders 743 and 743a. However, this does not mean that the issues will be dropped. Both the NERC Board of Trustees and the NERC Standards Committee have endorsed the idea that the Project 2010-17 SDT take a phased approach to this project with a new Standards Authorization Request (SAR) to address generation thresholds as well as several other issues that have arisen from SDT deliberations. Issues such as what is necessary for the reliable operation of the BES, whether the BES needs to be a contiguous, possible interconnection difference, who is a user of the BES, and correlation of the definition of BES and the ERO Statement of Compliance Registry Criteria will be addressed with this new SAR. The proposed SAR has been posted for information purposes only concurrent with the second posting of this project. A formal comment period will follow.

In parallel with the definition project, another team has been set up to develop a change to the NERC Rules of Procedure (RoP) to allow for entities to technically justify excluding Elements from the BES that might otherwise be included according to the proposed definition. This same process would be used by Registered Entities to justify including Elements in the BES that might otherwise be excluded according to the proposed definition. This RoP team will develop the process for seeking an exemption from the definition but the DBESSDT will develop the criteria necessary for applying for an exemption through the standards development process. The DBESSDT developed exception criteria is posted separately but simultaneously to the second posting of the definition.

## Comment Form for 2<sup>nd</sup> Draft of Definition of BES (Project 2010-17)

**You do not have to answer all questions. Enter All Comments in Simple Text Format.**

*Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.*

The SDT has asked one specific question for each specific aspect of the definition.

1. The SDT has made clarifying changes to the core definition in response to industry comments. Do you agree with these changes? If you do not support these changes or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments.

Yes:

No:

Comments:

2. The SDT has revised the specific inclusions to the core definition in response to industry comments. Do you agree with Inclusion I1 (transformers)? If you do not support this change or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments.

Yes:

No:

Comments:

3. The SDT has revised the specific inclusions to the core definition in response to industry comments. Do you agree with Inclusion I2 (generation) including the reference to the ERO Statement of Compliance Registry Criteria? If you do not support this change or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments.

Yes:

No:

Comments:

4. The SDT has revised the specific inclusions to the core definition in response to industry comments. Do you agree with Inclusion I3 (blackstart)? If you do not support this change or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments.

Yes:

No:

Comments:

## **Comment Form for 2<sup>nd</sup> Draft of Definition of BES (Project 2010-17)**

---

5. The SDT has revised the specific inclusions to the core definition in response to industry comments. Do you agree with Inclusion I4 (dispersed power)? If you do not support this change or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments.

Yes:

No:

Comments:

6. The SDT has added specific inclusions to the core definition in response to industry comments. Do you agree with Inclusion I5 (reactive resources)? If you do not support this change or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments.

Yes:

No:

Comments:

7. The SDT has revised the specific exclusions to the core definition in response to industry comments. Do you agree with Exclusion E1 (radial system)? If you do not support this change or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments.

Yes:

No:

Comments:

8. The SDT has revised the specific exclusions to the core definition in response to industry comments. Do you agree with Exclusion E2 (behind-the-meter generation)? If you do not support this change or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments.

Yes:

No:

Comments:

9. The SDT has revised the specific exclusions to the core definition in response to industry comments. Do you agree with Exclusion E3 (local network)? If you do not support this change or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments.

Yes:

No:

## Standard Authorization Request Form

Title of Proposed Standard: NERC Glossary of Terms - Phase 2: Revision of the Bulk Electric System definition.
Request Date:
SC Approval Date:

<b>SAR Requester Information</b>	<b>SAR Type</b> (Check a box for each one that applies.)	
Name: Project 2010-17 Definition of Bulk Electric System (BES) SDT	<input type="checkbox"/>	New Standard
Primary Contact: Peter Heidrich (Manager of Reliability Standards, FRCC) , Project 2010-17 Definition of Bulk Electric System (BES) SDT Chair	<input checked="" type="checkbox"/>	Revision to existing Standard
Telephone: (813) 207-7994 Fax: (813) 289-5646	<input type="checkbox"/>	Withdrawal of existing Standard
E-mail: pheidrich@frcc.com	<input type="checkbox"/>	Urgent Action

<p><b>Purpose</b> (Describe what the standard action will achieve in support of bulk power system reliability.)</p> <p>Research possible revisions to the definition of Bulk Electric System (BES) (Phase 2) to address the issues identified through Project 2010-17 Definition of Bulk Electric System (BES) (Phase 1). The definition encompasses all Elements necessary for the reliable operation of the interconnected transmission network. The definition development may include other improvements to the definition as deemed appropriate by the drafting team, with the consensus of stakeholders, consistent with establishing a high quality and technically sound definition of the Bulk Electric System (BES).</p>
<p><b>Industry Need</b> (Provide a justification for the development or revision of the standard, including an assessment of the reliability and market interface impacts of implementing or not implementing the standard action.)</p> <p>This project supports the ERO's obligation to identify the Elements necessary for the reliable operation of the interconnected transmission network to ensure that the ERO, the Regional Entities, and the industry have the ability to properly identify the applicable entities and Elements subject to the NERC Reliability Standards.</p>
<p><b>Brief Description</b> (Provide a paragraph that describes the scope of this standard action.)</p> <p>Research possible revisions to the definition of Bulk Electric System (BES) developed in Phase 1 of this</p>

project to provide a technically justifiable definition that identifies the appropriate electrical components necessary for the reliable operation of the interconnected transmission network. The definition development may include other improvements to the definition as deemed appropriate by the drafting team, with the consensus of stakeholders, consistent with establishing a high quality and technically sound definition of the Bulk Electric System (BES).

**Detailed Description** (Provide a description of the proposed project with sufficient details for the standard drafting team to execute the SAR.)

Research possible revisions to the definition of Bulk Electric System (BES) developed in Phase 1 of this project to provide a technically justifiable definition that identifies the appropriate electrical components necessary for the reliable operation of the interconnected transmission network. The definition development will include an analysis of the following issues, from a continent-wide and an interconnection-wide basis, which were identified by the drafting team during the development of Project 2010-17 Definition of the Bulk Electric System. Clarification of these issues will appropriately define which Elements are necessary for the reliable operation of the interconnected transmission network.

- Determine the reliability benefit of a contiguous BES
- Determine the appropriate 'points of demarcation' between Transmission, Generation, and Distribution
- Determine the appropriate threshold for Generation Resources which supports reliable operation of the Bulk Electric System (BES)
- Determine the scope and significance of the equipment which supports the reliable operation of the Bulk Electric System (BES)
- Clarify the relationship between the BES definition and the ERO Statement of Compliance Registry Criteria established in FERC Order 693

Phase 2 of the definition development may include other improvements to the definition as deemed appropriate by the drafting team, with the consensus of stakeholders, consistent with establishing a high quality and technically justifiable definition of the Bulk Electric System (BES).

Based on the potential revisions to the definition of the Bulk Electric System (BES) and an analysis of the application of, and the results from, the exception process, the drafting team will review and if necessary propose revisions to the 'Technical Principles' associated with the Rules of Procedure Exception Process to ensure consistency in the application of the definition and the exception process.

**Standards Authorization Request Form**

**Reliability Functions**

<b>The Standard will Apply to the Following Functions</b> <i>(Check box for each one that applies.)</i>		
<input checked="" type="checkbox"/>	Reliability Assurer	Monitors and evaluates the activities related to planning and operations, and coordinates activities of Responsible Entities to secure the reliability of the bulk power system within a Reliability Assurer Area and adjacent areas.
<input checked="" type="checkbox"/>	Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.
<input checked="" type="checkbox"/>	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports Interconnection frequency in real time.
<input type="checkbox"/>	Interchange Authority	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced interchange schedules between Balancing Authority Areas.
<input checked="" type="checkbox"/>	Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area.
<input checked="" type="checkbox"/>	Resource Planner	Develops a >one year plan for the resource adequacy of its specific loads within its portion of the Planning Coordinator's Area.
<input checked="" type="checkbox"/>	Transmission Owner	Owns and maintains transmission facilities.
<input checked="" type="checkbox"/>	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
<input checked="" type="checkbox"/>	Transmission Planner	Develops a >one year plan for the reliability of the interconnected Bulk Electric System within the Transmission Planner Area.
<input checked="" type="checkbox"/>	Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
<input checked="" type="checkbox"/>	Distribution Provider	Delivers electrical energy to the End-use customer.
<input checked="" type="checkbox"/>	Generator Owner	Owns and maintains generation facilities.
<input checked="" type="checkbox"/>	Generator Operator	Operates generation unit(s) to provide real and reactive power.
<input type="checkbox"/>	Purchasing-Selling Entity	Purchases or sells energy, capacity, and necessary reliability-related services as required.
<input checked="" type="checkbox"/>	Load-Serving Entity	Secures energy and transmission service (and reliability-related services) to serve the End-use Customer.

***Reliability and Market Interface Principles***

<b>Applicable Reliability Principles</b> <i>(Check box for all that apply.)</i>	
<input checked="" type="checkbox"/>	1. Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
<input checked="" type="checkbox"/>	2. The frequency and voltage of interconnected bulk power systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
<input checked="" type="checkbox"/>	3. Information necessary for the planning and operation of interconnected bulk power systems shall be made available to those entities responsible for planning and operating the systems reliably.
<input checked="" type="checkbox"/>	4. Plans for emergency operation and system restoration of interconnected bulk power systems shall be developed, coordinated, maintained and implemented.
<input checked="" type="checkbox"/>	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk power systems.
<input checked="" type="checkbox"/>	6. Personnel responsible for planning and operating interconnected bulk power systems shall be trained, qualified, and have the responsibility and authority to implement actions.
<input checked="" type="checkbox"/>	7. The security of the interconnected bulk power systems shall be assessed, monitored and maintained on a wide area basis.
<input checked="" type="checkbox"/>	8. Bulk power systems shall be protected from malicious physical or cyber attacks.
<b>Does the proposed Standard comply with all of the following Market Interface Principles?</b> <i>(Select 'yes' or 'no' from the drop-down box.)</i>	
1. A reliability standard shall not give any market participant an unfair competitive advantage. Yes	
2. A reliability standard shall neither mandate nor prohibit any specific market structure. Yes	
3. A reliability standard shall not preclude market solutions to achieving compliance with that standard. Yes	
4. A reliability standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes

Mr. Allen Mosher  
Chair, NERC Standards Committee

Re: Report Regarding the Status of the Bulk Electric System Definition Development Project

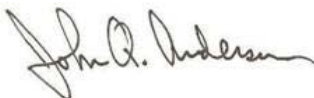

Dear Allen,

On behalf of the NERC Board of Trustees, I want to thank you and the drafting team for the early response relative to our inquiry on the status of the Bulk Electric System definition development project. The Standards Committee's report fulfills all of our expectations regarding the resolution that the Board approved at its August 4, 2011 meeting. It is gratifying to see that the industry has adopted a way forward that should enable NERC to meet the schedule set by the Federal Energy Regulatory Commission and we remain hopeful this highly important project will remain on track toward the January filing date.

The Trustees also recognize the industry has identified the generator threshold issue as one it believes important to defining the extent of the Bulk Electric System. It is also possible there will be future similar issues requiring deeper exploration. We believe the solution of separating out those elements requiring more thought and development time into separate phases is an appropriate solution. We support these additional efforts and look forward to future discussions related to them.

Should any additional issue arise that may impede the schedule, please work with the Board's Standards Oversight and Technology Committee to keep us informed and feel free to seek our guidance relative to proposed solutions.

Sincerely,

John Q. Anderson  
Chair

# Standards Committee

of the North American Electric Reliability Corporation

August 24, 2011

John Q. Anderson  
Chairman  
NERC Board of Trustees

Dear Chairman Anderson:

At the NERC Board of Trustees August 4, 2011 meeting, the Board approved the following Resolution on Definition of Bulk Electric System:

In furtherance of the Board's oversight of the standards development process and in anticipation of the Board's ultimate responsibility to determine whether the revised definition of "Bulk Electric System" that emerges from the standards development process should be approved and filed with the Federal Energy Regulatory Commission no later than January 25, 2012, as NERC's response to the directives in Order No. 743, the Board:

- (1) directs the Standards Committee and the Standard Drafting Team to consider the feedback heard at the August 4, 2011 board meeting regarding the development of the Bulk Electric System definition; and
- (2) further directs that the Standards Committee submit to the Board by September 9, 2011:
  - (a) the draft of the proposed Bulk Electric System definition as it exists on that date;
  - (b) the best justification that the Standard Drafting Team has prepared to support the change in generator threshold from 20 MVA to 75 MVA; and
  - (c) an options paper that addresses possible options for moving forward with the development of the proposed definition and responding to the Commission by the January 25, 2012 deadline; and
- (3) expects the Standards Drafting Team to continue its work on the Bulk Electric System definition.

The Drafting Team (DT) for Project 2010-17 Definition of the Bulk Electric System met the week of August 7, 2011 and determined that it was highly unlikely that the DT could develop an adequate technical justification to support revision of the single unit generator threshold criteria (20 to 75 MVA) in the time frame established by Order 743. The team revised its proposed definition and provided us with an update to its action plan that reflects adoption of the guidance provided by the Member Representatives Committee and Board of Trustees.

- Attachment A is a copy of the latest draft of the proposed definition of Bulk Electric System as of August 19, 2011. The revised definition is silent on generator threshold; there is no proposed change from 20 MVA to 75 MVA.
- Attachment B is a copy of the letter provided by the drafting team's chair, Peter Heidrich, on August 23, 2011 relative to the status of the project.
- Attachment C is a copy of the team's proposed action plan for moving this project forward to meet the applicable Commission directives by January 25, 2012. This includes splitting the

project into two phases, with phase 1 focused solely on meeting the Commission's relevant directives. Phase 2 will address other issues, including the generator threshold issue, raised by stakeholders or during drafting team deliberations.

It is our view that the drafting team's proposed course of action meets the intent of the Board's August 4 Resolution that the Standards Committee and the Standard Drafting Team consider the feedback heard at the August 4, 2011 Board meeting regarding the development of the Bulk Electric System definition and that the drafting team continue its work on the Bulk Electric System definition. The team expects to post its latest documents for a stakeholder comment period starting on August 25, 2011.

Sincerely yours,

Allen Mosher  
Chair, Standards Committee

## **Project 2010-17 Definition of Bulk Electric System**

---

### **Standard Development Timeline**

---

*This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.*

#### **Development Steps Completed**

1. SAR posted for comment 12/17/10 – 1/21/11
2. SC authorized moving the SAR forward to standard development 3/25/11
3. First posting of definition 4/28/11 – 5/27/11
4. First posting of criteria 5/11/11 – 6/10/11

#### **Description of Current Draft**

This draft is the second posting of the revised definition of the Bulk Electric System (BES). It is for a 45-day formal comment and parallel voting period.

<b>Anticipated Actions</b>	<b>Anticipated Date</b>
30-day Formal Comment Period	April 28, 2011
45-day Formal Comment Period with Parallel Initial Ballot	September 2011
Recirculation ballot	December 2011
BOT adoption	January 2011

## Project 2010-17 Definition of Bulk Electric System

---

### Effective Dates

This definition shall become effective on the first day of the second calendar quarter after applicable regulatory approval. In those jurisdictions where no regulatory approval is required, the definition will go into effect on the first day of the second calendar quarter after Board of Trustees adoption. Compliance obligations for Elements included by the definition shall begin 24 months after the applicable effective date of the definition.

### Version History

Version	Date	Action	Change Tracking
1	TBD	Respond to FERC Order No. 743 to clarify the definition of the Bulk Electric System	N/A

## Project 2010-17 Definition of Bulk Electric System

### Definitions of Terms Used in Standard

*This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.*

**Bulk Electric System (BES):** Unless modified by the lists shown below, all Transmission Elements operated at 100 kV or higher and Real Power and Reactive Power resources connected at 100 kV or higher. This does not include facilities used in the local distribution of electric energy.

#### **Inclusions:**

- **I1** - Transformers with primary and secondary terminals operated at 100 kV or higher unless excluded under Exclusion E1 or E3.
- **I2** - Generating resource(s) (with gross aggregate nameplate rating per the ERO Statement of Compliance Registry Criteria) including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100 kV or above.
- **I3** - Blackstart Resources identified in the Transmission Operator's restoration plan.
- **I4** - Dispersed power producing resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating) utilizing a system designed primarily for aggregating capacity, connected at a common point at a voltage of 100 kV or above.
- **I5** –Static or dynamic devices dedicated to supplying or absorbing Reactive Power that are connected at 100 kV or higher, or through a dedicated transformer with a high-side voltage of 100 kV or higher, or through a transformer that is designated in Inclusion I1.

#### **Exclusions:**

- **E1** - Radial systems: A group of contiguous transmission Elements that emanates from a single point of connection of 100 kV or higher and:
  - a) Only serves Load. Or,
  - b) Only includes generation resources, not identified in Inclusion I3, with an aggregate capacity less than or equal to 75 MVA (gross nameplate rating). Or,
  - c) Where the radial system serves Load and includes generation resources, not identified in Inclusion I3, with an aggregate capacity of non-retail generation less than or equal to 75 MVA (gross nameplate rating).Note – A normally open switching device between radial systems, as depicted on prints or one-line diagrams for example, does not affect this exclusion.

## **Project 2010-17 Definition of Bulk Electric System**

---

- **E2** - A generating unit or multiple generating units that serve all or part of retail customer Load with electric energy on the customer's side of the retail meter if: (i) the net capacity provided to the BES does not exceed 75 MVA, and (ii) standby, back-up, and maintenance power services are provided to the generating unit or multiple generating units or to the retail Load by a Balancing Authority, or provided pursuant to a binding obligation with a Generator Owner or Generator Operator, or under terms approved by the applicable regulatory authority.
- **E3** - Local networks (LN): A group of contiguous transmission Elements operated at or above 100 kV but less than 300 kV that distribute power to Load rather than transfer bulk power across the interconnected system. LN's emanate from multiple points of connection at 100 kV or higher to improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system. The LN is characterized by all of the following:
  - a) Limits on connected generation: The LN and its underlying Elements do not include generation resources identified in Inclusion I3 and do not have an aggregate capacity of non-retail generation greater than 75 MVA (gross nameplate rating) ;
  - b) Power flows only into the LN: The LN does not transfer energy originating outside the LN for delivery through the LN; and
  - c) Not part of a Flowgate or transfer path: The LN does not contain a monitored Facility of a permanent Flowgate in the Eastern Interconnection, a major transfer path within the Western Interconnection, or a comparable monitored Facility in the ERCOT or Quebec Interconnections, and is not a monitored Facility included in an Interconnection Reliability Operating Limit (IROL).
- **E4** – Reactive Power devices owned and operated by the retail customer solely for its own use.

Note - Elements may be included or excluded on a case-by-case basis through the Rules of Procedure exception process.

**RE: Project 2010-17 Definition of the Bulk Electric System - Action Plan**

Gentlemen;

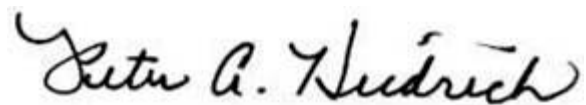

This letter provides the Standards Committee, the Board of Trustees and NERC staff with the Drafting Team's action plan for Project 2010-17 Definition of the Bulk Electric System (BES). The project is currently on schedule to complete the revision of the definition of the BES, the development of the associated Implementation Plan and all documents supporting the Rules of Procedure Exception Process by January 25, 2012, in response to the directives established by the Commission (FERC) in Order Nos. 743 and 743-A.

The drafting team submitted the following documents for quality review on Friday, August 19, 2011, in preparation for the next scheduled posting. The goal is to post the documents for stakeholder formal comment and initial ballot no later than September 2, 2011:

- Draft BES Definition
  - Responses to the initial posting of definition
  - Technical Justification for the Local Network exclusion (E3)
  - Second posting comment form for definition
- Draft Technical Principles for Demonstrating BES Exceptions (evidence document to support Rules of Procedure Process)
  - Responses to the initial posting of Technical Principles document
  - Second posting comment form for Technical Principles
- Draft Implementation Plan
- Table identifying how the team addressed applicable FERC directives
- Phase 2 SAR (to be posted for informational purposes only)

I have attached the latest action plan for successful completion of this project in phases which encompasses the MRC and BOT recommendations.

Sincerely,

A handwritten signature in black ink that reads "Peter A. Heidrich". The signature is written in a cursive style with a large initial 'P' and a long horizontal stroke at the end.

Peter A. Heidrich

Chair, Project 2010-17 Definition of the Bulk Electric System Drafting Team

cc: NERC Board of Trustees  
NERC Standards Committee

## August 23, 2011 Action Plan for Completion of Project 2010-17 – Definition of Bulk Electric System

The Standard Drafting Team (SDT) for Project 2010-17 Definition of the Bulk Electric System met the week of August 7, 2011 and determined that the feasibility of developing an adequate technical justification for the revision of the single unit generator threshold criteria (20 to 75 MVA) is highly unlikely in the time frame established by Order No. 743 (filing deadline of January 25, 2012). Therefore the SDT adopted the recommendations of the Member Representatives Committee (MRC) and the NERC Board of Trustees (BOT) and developed the following plan to meet the schedule for addressing the directives established by the Commission (FERC) in Order Nos. 743 and 743-A while also addressing concerns raised by SDT members and concerns received from stakeholders through the standard development process.

- The SDT revised the draft definition to eliminate any change in the generation thresholds. To accomplish this, the SDT has chosen to remain silent as to the actual values associated with the generator thresholds for units and referenced the ERO Statement of Compliance Registry Criteria for additional clarification. This will ensure that the current ‘status-quo’ application of the BES definition and the registration process will continue as it is today.
- The SDT developed a second Standard Authorization Request (SAR) for the project (Project 2010-17 Definition of the Bulk Electric System) to establish a phased approach where *phase 1* addresses the directives from Order Nos. 743 and 743-A and *phase 2* will address the concerns raised by SDT members and stakeholders through the Standard Development Process.
- The SDT finalized the revised draft BES definition and all associated documents for a 45-day concurrent posting (formal comment period and initial ballot) scheduled to begin no later than September 2, 2011. The SDT also prepared a revised version of the “*Technical Principles for Demonstrating BES Exceptions*<sup>1</sup>” for posting (formal comment period and initial ballot) in parallel with the posting of the BES definition.

---

<sup>1</sup> The “*Technical Principles for Demonstrating BES Exceptions*” was developed to supplement the Rules of Procedure Exception Process by providing guidance to the ERO, the Regional Entities and the industry on the detailed information and evidence necessary to support a BES Definition exception request.

# Local Network Exclusion

---

## Introduction

The purpose of this document is to provide the justification for the definitional exclusion of local networks (LN) from the definition of the Bulk Electric System (BES) as proposed in NERC Standards Development Project 2010-17. Presented herein are technical, logical, and practical considerations that provide such justification for exclusion of these facilities from the Bulk Electric System.

## Summary of Justification

The local network exclusion proposal is shown to be justified through the following facts:

1. In accordance with Commission Orders 743 and 743a on the matter of the revision of the Definition of the Bulk Electric System, the facilities used in the local distribution of electric energy are to be excluded;
2. The exclusion for local networks, as provided in the revised definition of the BES, ensures that a candidate for local network exclusion must satisfy all of the exclusion principles thus demonstrating that the candidate facilities are not performing a transmission function;
3. The limit on connected generation within the local network is consistent with the existing threshold above which a generating plant in aggregate becomes subject to owner and operator registration in the ERO Statement of Compliance Registry Criteria;
4. The voltage cap applied to the qualifications for a local network is established at 300 kV, which is consistent with the distinction being made between Extra High Voltage and High Voltage in the NERC Board of Trustees-approved Reliability Standard on transmission planning, TPL-001-2;
5. The power flow “shifts” that would occur on the elements of a local network are but a negligible fraction of that which distributes upon the BES elements for a given power transfer and is fully eclipsed by the Load in the local network; and
6. The interaction of the local network with the BES is similar in character to that of a radial facility.

## Description of Local Network

Local networks are defined in the draft BES Definition as:

*A group of contiguous transmission Elements operated at or above 100 kV but less than 300 kV that distribute power to Load rather than transfer bulk power across the interconnected system. LN's emanate from multiple points of connection at 100 kV or higher to improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system. The LN is characterized by all of the following:*

- a) *Limits on connected generation: The LN and its underlying Elements do not include generation resources identified in Inclusion I3 and do not have an aggregate capacity of non-retail generation greater than 75 MVA (gross nameplate rating) ;*
- b) *Power flows only into the LN: The LN does not transfer energy originating outside the LN for delivery through the LN; and*
- c) *Not part of a Flowgate or transfer path: The LN does not contain a monitored Facility of a permanent Flowgate in the Eastern Interconnection, a major transfer path within the Western Interconnection, or a comparable monitored Facility in the ERCOT or Quebec Interconnections, and is not a monitored Facility included in an Interconnection Reliability Operating Limit (IROL).*

Local networks are present to provide local electrical distribution service and are not planned, designed, nor operated to benefit or support the balance of the interconnected electrical transmission network. Their purpose is to provide local distribution service, not to provide transfer capacity for the interconnected electric transmission network. Their design and operation is such that at the point of connection with the interconnected electric transmission network, their effect on that network is similar to that of a radial facility, particularly in that flow always moves in a direction that is from the BES into the facility. Any distribution of parallel flows into the local network from the BES, as governed by the fundamentals of parallel electric circuits, is negligible, and, more importantly, is overcome by the Load served by the local network, thereby ensuring that the net actual power flow direction will always be into the local network at all interface points. The presence of a local network is not for the operability of the interconnected electric transmission network; neither will the local network's separation or retirement diminish the reliability of the interconnected electric transmission network.

## **Commission Determination on Exclusion of Local Distribution – Relation to Local Network**

In Order 743a, the Commission made it clear that facilities that are used in the local distribution of electric energy will be excluded from the Bulk Electric System. Such clarification was provided in both paragraphs 22 and 25 of the Order. The Commission agreed with certain commenters that facilities used in the local distribution of energy should be excluded from the revised Bulk Electric System definition.

In response to this facet of the Order, in developing the BES definition, the SDT has followed this guidance. Exclusion E3 was specifically designed to capture for exclusion those high voltage non-radial facilities being used for the local distribution of energy.

The exclusion characteristics in items a, b, and c above are further explained in the next section. These exclusion principles serve to ensure that facilities excluded under the local network exclusion (E3) are not necessary for the reliable operation of the interconnected electric transmission network and are instead used in the local distribution of energy.

## Exclusion Principles

Of key importance is that Exclusion E3 in the draft BES definition requires the facilities of a candidate network to meet all of the characteristics listed in the exclusion. The SDT adopted this approach to ensure that none of the characteristics typical of interconnected electric transmission networks, or necessary for the operation of the interconnected electric transmission system, would be permissible in those facilities that are qualified for Exclusion E3. In the discussion below, it is shown that these characteristics successfully prevent exclusion of facilities necessary for operating an interconnected electric transmission network, and allow only facilities that are not necessary for such operation to be excluded from the BES.

### A. First Exclusion Principle: Limits on Connected Generation

*Limits on connected generation: The LN and its underlying Elements do not include generation resources identified in Inclusion I3, and do not have an aggregate capacity of non-retail generation greater than 75 MVA (gross nameplate rating);*

This characteristic places restrictions on the type and size of generation resources that can be connected within the candidate facility. By placing this generation restriction on the local network, it is ensured that that the candidate facility will not under any circumstance act as a host to generation that exceeds the existing aggregate generation threshold in the ERO Statement of Compliance Registry Criteria (SCRC) and that the candidate facility will not contain Blackstart Resources. The SDT submits that this characteristic minimizes the contribution and influence the local network may have over the neighboring Elements of the BES by limiting both the magnitude and the function of the connected generation. The threshold of 75 MVA was chosen in a manner to provide consistency with the criteria applied in the ERO's SCRC regarding the registration for entities owning and operating generation plants in aggregate.

### B. Second Exclusion Principle: Power Flow and Function

*Power flows only into the LN: The LN does not transfer energy originating outside the LN for delivery through the LN;*

This characteristic ensures that the real power flow direction at all connection points to the BES is into the candidate local network, thereby ensuring that the candidate facilities behave in a manner that is radial in character. Further, the local network is restricted as to its use; i.e., it cannot be used for "wheel" transactions, or the transfer of energy originating outside the local network for delivery through the local network. By restricting the flow direction to be exclusively into the network at its connection points to the BES and precluding the network from providing transmission wheeling service, this exclusion characteristic further ensures that the local network is providing only a distribution service, and is not contributing to, nor is necessary for, the reliable operation of the interconnected electric transmission network. Regarding the location of the connection points to the BES, Exclusion E3 specifies that local networks "emanate from multiple points of connection at 100 kV or higher..." These points of emanation, where the local network begins and the BES ends, are established on a case-by-

case basis, but will necessarily be the points, below 300 kV, at which all of the qualifying exclusion principles are satisfied. As an example, see Appendix 1 to this document, which provides, among other things, a single line diagram depicting a local network and its interface with the BES.

*C. Third Exclusion Principle: Flowgates and Transfer Paths*

*Not part of a Flowgate or transfer path: The LN does not contain a monitored Facility of a permanent Flowgate in the Eastern Interconnection, a major transfer path within the Western Interconnection, or a comparable monitored Facility in the ERCOT or the Quebec Interconnections, and is not a monitored Facility included in an Interconnection Reliability Operating Limit (IROL).*

This characteristic further ensures that the candidate local network facilities do not contain nor comprise facilities of well-established flowgates and transfer paths throughout the Interconnections of North America. These transfer paths are customarily used to provide bulk power transfers within the Interconnections, and therefore, the function and purpose of any candidate facilities included in or among such paths extends beyond the distribution function. A number of interchange coordination Reliability Standards apply to these transfer paths and flowgates. The SDT feels that such facilities are necessary for the reliable operation of an interconnected electric transmission network and would not be excluded from the definition of the BES.

## **The Use of a 300 kV Cap is Appropriate for Local Network Exclusion**

The selection of a 300 kV cap for the applicability of an exclusion for a local network was based upon recent NERC Standards Development work in Project 2006-02 “Assess Transmission Future Needs and Develop Transmission Plans.” As conveyed in its work product, TPL-001-2, the Project 2006-02 SDT sets a voltage level of 300 kV to differentiate Extra High Voltage (EHV) facilities from High Voltage facilities acting as a threshold to distinguish between expected system performance criteria.<sup>1</sup> The Project 2010-17 SDT seeks to establish consistency in the limitations placed on the exclusion applicability for local network facilities, and has therefore adopted this 300 kV level to ensure that EHV facilities, which under the TPL-001-2 Standard are held to a higher standard of performance, are not subject to this exclusion.

## **There is Minimal Effect to Flow in the Local Network due to BES Power Transfer**

Similar to the character of a radial facility, and in order to qualify for exclusion from the BES under Exclusion E3.b, a local network must only have power flow into the network at all connection points to the BES. As demonstrated below, while this flow at the connection points is always into the local

---

<sup>1</sup> Per footnote #3 in TPL-001-2, “Bulk Electric System (BES) level references include extra-high voltage (EHV) Facilities defined as greater than 300 kV and high voltage (HV) Facilities defined as the 300 kV and lower voltage Systems. The designation of EHV and HV is used to distinguish between stated performance criteria allowances for interruption of Firm Transmission Service and Non-Consequential Load Loss.”

network, the magnitude of the flow at these connection points will exhibit very slight shifts as bulk power transactions are implemented on neighboring BES facilities. This occurs because local network facilities are electrically parallel to Elements comprising the BES, and hence, the local network will experience a small effect due to changes in power angle across the parallel network as BES dispatch and flow patterns change. However, such flow shift is shown to be minimal, and the resultant power flow at all BES interface points is dominated by the superimposed load flow serving the distribution Load connected within the local network. Again, Exclusion E3.b ensures that flow shall always be from the BES into the local network in order to qualify for exclusion.

In order to provide a realistic example of the electrical interaction between a typical local network and the BES, an electric system in the western United States was examined from a power transfer distribution factor (PTDF) perspective. In a PTDF analysis, the branch elements of an electrical network are examined on the basis of the percentage split of a given power flow as it propagates through the network. In the simplest example of two identical lines operated at the same voltage, arranged in parallel between a given sending bus and receiving bus, the total power transfer will divide equally among the two parallel line elements, and hence, each element would be found to have a 50% PTDF. In a more complicated network, the line elements will carry a portion of the total flow in a manner that is inversely proportional to their impedance; i.e., the lower the impedance of the network branch, the higher portion of the flow that will distribute along that branch.

The electric system in question is depicted in Appendix 1. The station name identifiers and the network topology (but not electrical connectivity) have been changed to respect the confidentiality of the information. In the represented system, a bulk power transfer was simulated, with a point of receipt (injection) at BES bus T9 and a point of delivery at the other end of the system at BES bus T10. With this simulated power transfer, power flow analysis tools were used to determine the distribution of this simulated transfer as it propagates across the various parallel branches of the network. As depicted in Appendix 1, the facilities that are presumed to be excluded via the local network exclusion (E3) are shown to carry negligible flow, with the largest PTDF at a mere 0.23% of the total transfer. Note that a PTDF analysis shows only the *incremental* shift in power flow and does not imply that this 0.23% actually flows in and then back out of the network. The power flow results demonstrate that the flow measured at the interface points of the BES continues to flow into the local network, and is essentially unchanged, as it is only shifted in magnitude by a mere 0.23% of the modeled transaction amount.

In addition to the PTDF analysis, another analysis of Line Outage Distribution Factors (LODF), examines the re-distribution of flow that occurs on parallel elements after a subject element is removed from service. For example, if a BES element is carrying 500 MW, and is taken out of service, LODF describes how that flow re-distributes among all parallel paths in a given network. LODF factors are measured in percent of the pre-outage flow on the outaged element. Conducting this analysis on the example network and modeling the worst case outage, which is the loss of the line element between BES buses T9 and T10, shows that the net shift in flow for the local network is 4.0% of the pre-outage flow, and the largest shift in flow on any of the individual local network elements is 2.7%. The flow direction at the interface points between the local network and the BES continues to be into the local network.

This degree of flow shift on the local network facilities is *de minimus*, and neither diminishes or improves the reliability of the parallel BES facilities. From both a PTDF and an LODF analysis perspective, the local network exhibits qualities equivalent to radial facilities in that the power flow emanates from the point of BES connection in one direction – the only difference being that in the case of the local network, in order to provide source reliability to the distribution Load, more than one connection is provided to the BES.

# Appendix 1

## Local Network Technical Justification

### Power Transfer Distribution Factor Analysis

This appendix provides Power Transfer Distribution Factor (PTDF) and Line Outage Distribution Factor (LODF) analyses and assessments using a relevant power flow case used in actual operating studies in the Western Interconnection to assess reliable Operating Transfer Capability on a rated path in the Western Electricity Coordinating Council ("WECC"). The electrical system representation is accurate; however, the bus names and topology have been graphically rearranged to address any Critical Energy Infrastructure Information ("CEII") concerns.

Although linear analyses, such as these, are relatively independent of actual power transfer levels, the modeled system conditions represented peak load demand and high power transfer conditions. The PTDF analyzes the injection of power from BES electrical bus T9 and delivering it to BES bus T10, which is consistent with the use of the BES transfer path. Based on the PTDF assessment, 92% of the power flow is transferred over the 500 kV line that directly connects BES buses T9 and T10. The remaining flow appears on the underlying 230 kV lines and adjacent 345 kV and 500 kV lines. The largest PTDF on any local network is 0.23 percent.

The LODF analysis considers the "worst-case" outage of the strongest (lowest impedance) transmission element, the line between BES buses T9 and T10. The LODF values that are computed represent the percentage of the pre-outage T9-T10 flow that re-distributes on each of the remaining branches. The analysis shows that the net shift in flow for the local network is 4.0% of the pre-outage flow, and the largest shift in flow on any of the individual local network elements is 2.7%. The 2.7% shift occurs on the local network branch between buses LN19 and LN28, and a 1.3% shift occurs on the branch between LN27 and LN33. The flow direction at the interface points between the local network and the BES continues to be into the local network.

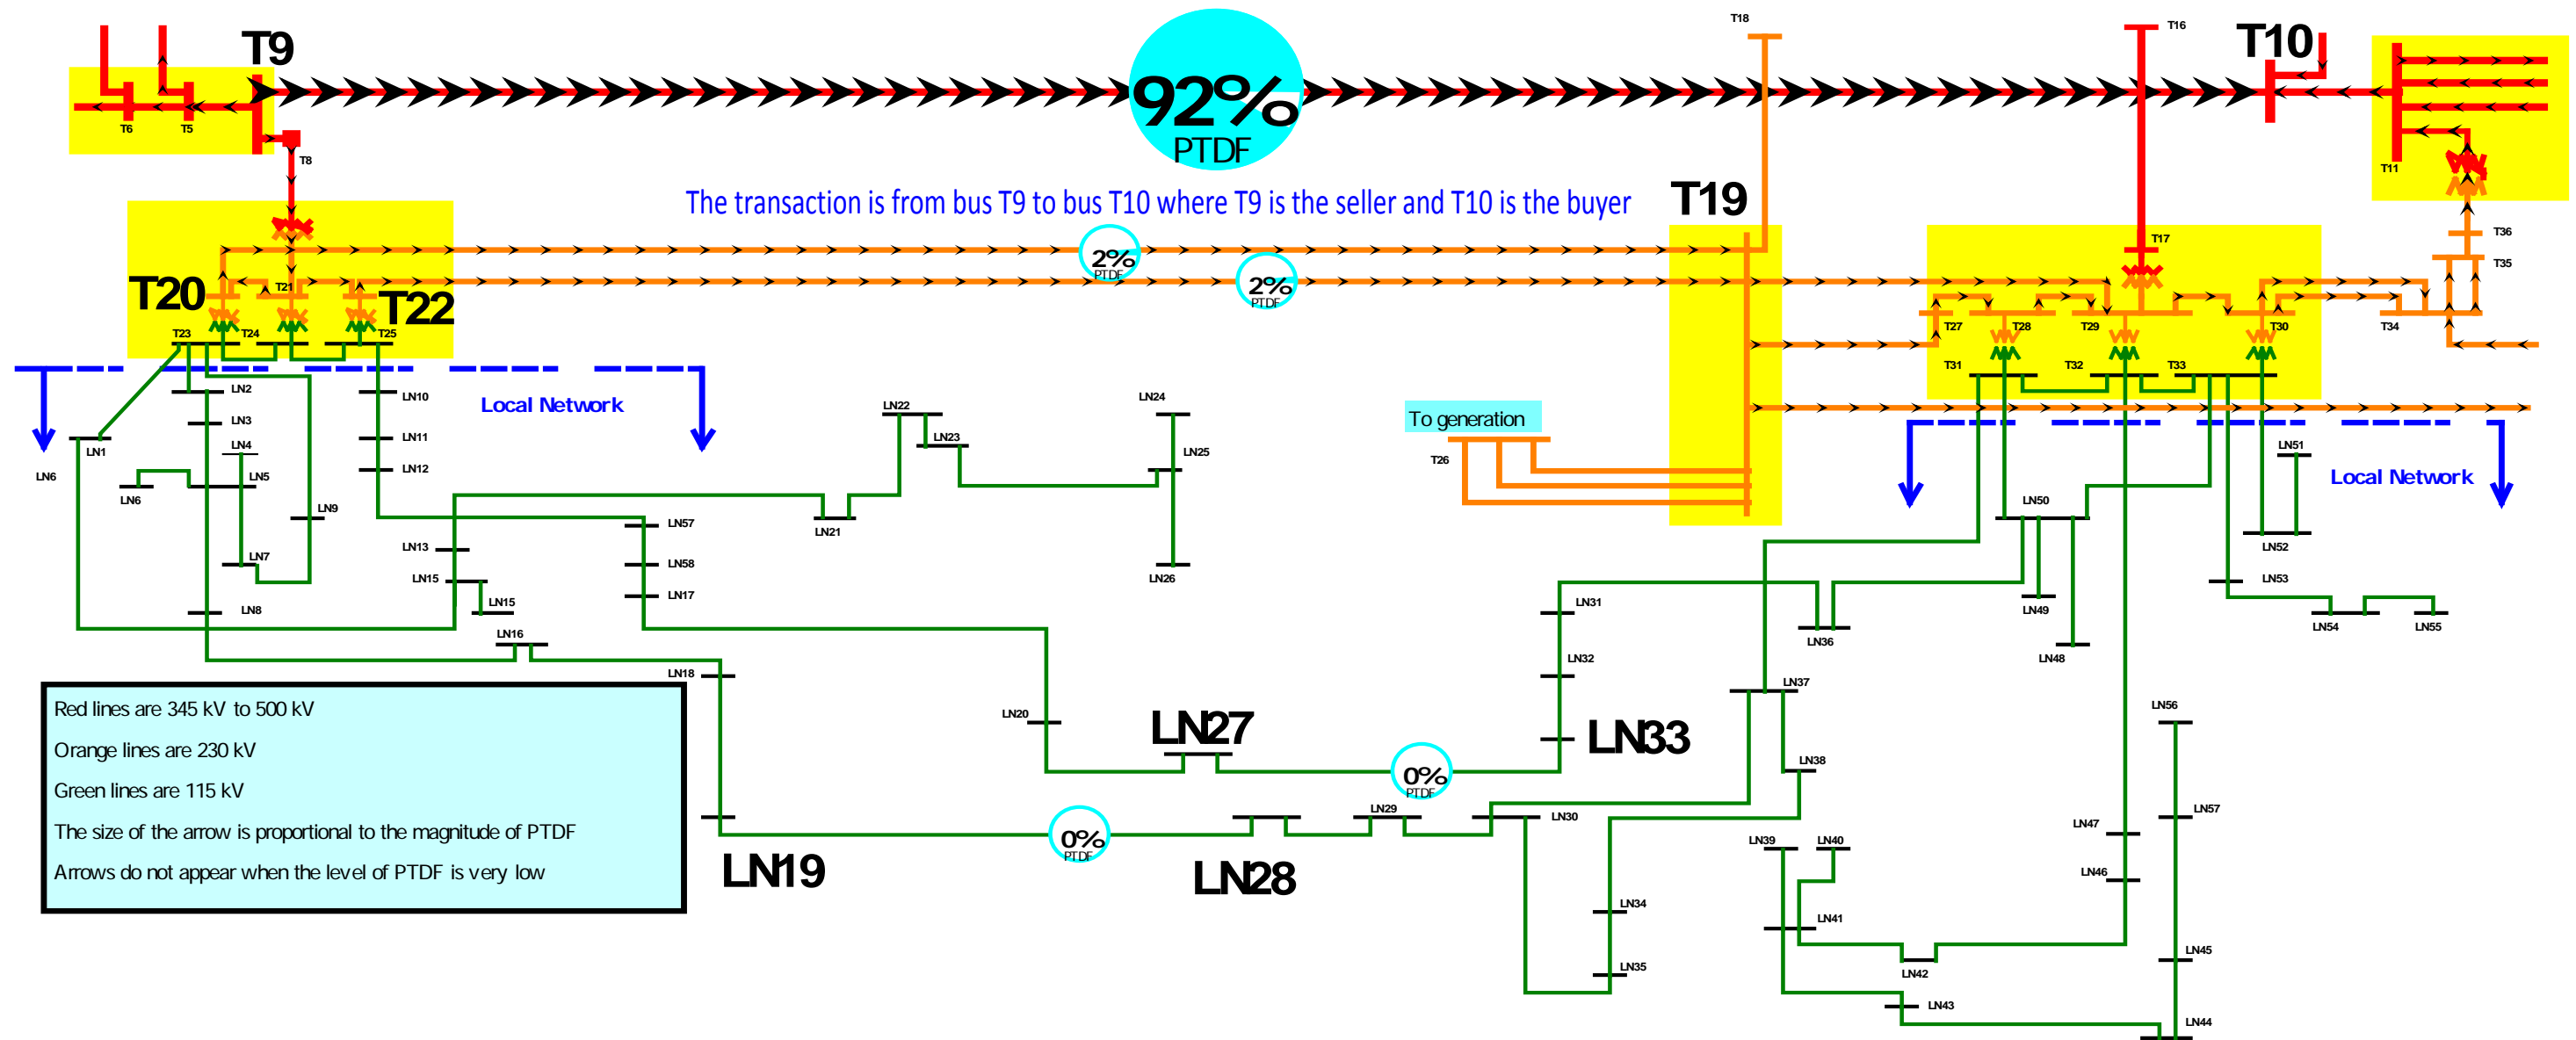

Below are three single line diagrams, which depict the 1) powerflow, 2) percentage distribution of flows for the PTDF analysis, and 3) the percent of flow distribution for the LODF analysis. In these diagrams, the local network elements are indicated by a green line color, and the local network station buses are indicated with an "LN" designation, for example, "LN23".

Following the single line diagrams are two tables: Table 1 - a tabulation of the PTDF values for the network, and Table 2 - depicting the LODF values for the T9-T10 line outage case.

# The Powerflow Single Line

# The Power Transfer Distribution Factors ("PTDF") Single Line

The Line Outage Distribution Factors ("LODF") Single Line identifying the revised PTDF values of the transmission line from T9 to T10 is opened

For the LODF assessment the transmission line from bus T9 to bus T10 is opened and the PTDF are recalculated (See the LODF table for additional details)

## Standards Announcement

### Project 2010-17 Definition of Bulk Electric System

Two Ballot Windows Now Open September 30 – October 10, 2011

Now available at: <https://standards.nerc.net/CurrentBallots.aspx>

Two ballots windows are now open for Project 2010-17 Definition of Bulk Electric System (BES). The first is for the definition of Bulk Electric System, and the second is for a draft application form titled *Detailed Information to Support an Exception Request* referenced in the Rules of Procedure Exception Process. Both ballots are open through **8 p.m. Eastern on Monday, October 10, 2011.**

The revised definition of Bulk Electric System, draft application form titled *Detailed Information to Support an Exception Request*, associated implementation plan and several informational documents have been posted on the project page at [http://www.nerc.com/filez/standards/Project2010-17\\_BES.html](http://www.nerc.com/filez/standards/Project2010-17_BES.html).

#### Instructions for Balloting Revisions

Members of each of the two ballot pools associated with this project may log in and submit their votes for both the definition and the *Detailed Information to Support an Exception Request* from the following page: <https://standards.nerc.net/CurrentBallots.aspx>.

#### Special Instructions for Submitting Comments With a Ballot

Comments submitted with ballots are extremely valuable to help the drafting team revise its work. In an effort to reduce the burden on stakeholders providing comments, the drafting team requests that all comments (both those submitted with a ballot and those submitted by stakeholders not balloting) be submitted through the electronic comment forms posted at:

<https://www.nerc.net/nercsurvey/Survey.aspx?s=e82643bb1de1434c9834c69757faa8d0>

<https://www.nerc.net/nercsurvey/Survey.aspx?s=9995ac42ce2644d9aebc87f58dd166ad>

This will ensure that stakeholders only provide a single set of comments, but have an opportunity to notify the drafting team if they have provided comments.

**When submitting a ballot with comments, submit the comments through the electronic form and then simply record a “Comments submitted” in the comments field of the ballot to indicate that comments were submitted.**

Please note that comments submitted during the formal comment period and the ballot use the same electronic form, and it is NOT necessary for ballot pool members to submit more than one set of comments (one during the comment period and a second with a ballot).

## Next Steps

The drafting team will consider all comments received, and decide whether to make additional revisions to the definition and *Detailed Information to Support an Exception Request*. The drafting team is working to meet the regulatory deadline in FERC Orders 743 and 743A (filing by January 25, 2012).

The Standards Committee and NERC Board of Trustees have recommended that the drafting team address issues such as generation thresholds in a second phase of this project. This approach will ensure that the drafting team has sufficient time to adequately consider and develop a sound technical basis for an approach, and will allow the drafting team to meet the regulatory deadline in FERC Orders 743 and 743A (filing by January 25, 2012). The drafting team has posted a **draft** Supplemental Standards Authorization Request (SAR) for information purposes only; the SAR will be posted for comment at a future time. Additional information about the project, including a [Fact Sheet](#) and additional informational documents, has been posted on the project webpage at [http://www.nerc.com/filez/standards/Project2010-17\\_BES.html](http://www.nerc.com/filez/standards/Project2010-17_BES.html).

## Project Background

On November 18, 2010 FERC issued [Order 743 \(amended by Order 743A\)](#) and directed NERC to revise the definition of Bulk Electric System so that the definition encompasses all Elements and Facilities necessary for the reliable operation and planning of the interconnected bulk power system. Additional specificity will reduce ambiguity and establish consistency across all Regions in distinguishing between BES and non-BES Elements and Facilities.

In addition, NERC was directed to develop a process for identifying any Elements or Facilities that should be excluded from the BES. NERC is working to address these directives with two activities – the definition of Bulk Electric System is being revised through the standard development process and a BES Definition Exception Process is being developed as proposed modifications to the Rules of Procedure. The proposed modifications have been posted for a comment period through October 27, 2011. The work of the BES Definition Exception Process has been publicly posted at: [http://www.nerc.com/filez/standards/Rules\\_of\\_Procedure-RF.html](http://www.nerc.com/filez/standards/Rules_of_Procedure-RF.html).

*For more information or assistance, please contact Monica Benson,  
Standards Process Administrator, at [monica.benson@nerc.net](mailto:monica.benson@nerc.net) or at 404-446-2560.*

## Standards Announcement

### Project 2010-17 BES Definition

Two Ballot Pool Windows Open August 26 – September 26, 2011

Two Formal Comment Periods Open August 26 – October 10, 2011

Two Ballot Windows Open September 30 – October 10, 2011

Available tomorrow at: <https://standards.nerc.net/BallotPool.aspx>

The Definition of Bulk Electric System Standard Drafting Team (DBES SDT) has posted a second draft of the Definition of Bulk Electric System (BES) and associated implementation plan for a formal 45-day comment period, through **8 p.m. Eastern on Monday, October 10, 2011**.

The Definition of Bulk Electric System Standard Drafting Team (DBES SDT) has also posted a draft application form titled *Detailed Information to Support an Exception Request* referenced in the Rules of Procedure Exception Process for a formal 45-day comment period, through **8 p.m. Eastern on Monday, October 10, 2011**. (Note that the information contained in this draft form includes revisions made to the *Technical Principles for Supporting BES Exceptions* that was posted for comment in May and June 2011.)

A separate team is working with NERC to draft a new Appendix 5C to NERC's Rules of Procedure to address the process for requesting BES exceptions. This team will be posting the Rules of Procedure changes for stakeholder comment in September. The comment period for the Rules of Procedure changes will overlap the comment period for the definition and application form, to provide an opportunity for stakeholders to review all three documents to understand how they will work together.

Clean and redline versions of the definition and associated implementation plan, along with a technical justification for the Local Network exclusion and a clean version of the application form titled *Detailed Information to Support an Exception Request* have been posted on the project page at: [http://www.nerc.com/filez/standards/Project2010-17\\_BES.html](http://www.nerc.com/filez/standards/Project2010-17_BES.html). The format of the application form titled *Detailed Information to Support an Exception Request* has changed substantially since the first posting, making a redline impractical, so none has been provided.

The Standards Committee and NERC Board of Trustees have recommended that the drafting team address issues such as generation thresholds in a second phase of this project. This approach will ensure that the drafting team has sufficient time to adequately consider and develop a sound technical basis for an approach, and will allow the drafting team to meet the regulatory deadline in FERC Orders 743 and 743a (filing by January 25, 2012). The drafting team has posted a **draft** Supplemental Standards Authorization Request (SAR) for information purposes only; the SAR will be posted for comment at a future time.

## Ballot Pools Forming

During the first 30 days of the comment period, two separate ballot pools will be formed: one for balloting the Definition of Bulk Electric System, and a second for balloting the application form titled *Detailed Information to Support an Exception Request*. The ballot pool windows will be open from **Friday, August 26 through 8 a.m. Eastern on Monday, September 26, 2011**.

During the final 10 days of the comment period, two separate initial ballots will be conducted, one for the Definition of the Bulk Electric System, and a second for the application form titled *Detailed Information to Support an Exception Request*. The ballot windows will begin on Friday, September 30th and end at 8 p.m. Eastern on Monday, October 10, 2011.

## Instructions for Joining Ballot Pools

Registered Ballot Body members must join each of the ballot pools to be eligible to vote in the upcoming ballots at the following page: <https://standards.nerc.net/BallotPool.aspx>

During the pre-ballot window, members of each ballot pool may communicate with one another by using their “ballot pool list server.” (Once the balloting begins, ballot pool members are prohibited from using the ballot pool list servers.) The list servers for this project are:

- Definition of BES ballot:  
[bp-2010-17\\_BES\\_Def\\_in@nerc.com](mailto:bp-2010-17_BES_Def_in@nerc.com)
- *Detailed Information to Support an Exception Request* form:  
[bp-2010-17\\_TechInfo\\_BES\\_in@nerc.com](mailto:bp-2010-17_TechInfo_BES_in@nerc.com)

## Instructions for Submitting Comments

Please use this [electronic comment form](#) to submit comments on the Definition of Bulk Electric System. Please use this separate [electronic comment form](#) to submit comments on the draft form application form titled *Detailed Information to Support an Exception Request*.

If you experience any difficulties in using either of these electronic forms, please contact Monica Benson at [monica.benson@nerc.net](mailto:monica.benson@nerc.net). An off-line, unofficial copy of each comment form is posted on the project page:

## Background

On November 18, 2010 FERC issued [Order 743 \(amended by Order 743A\)](#) and directed NERC to revise the definition of Bulk Electric System so that the definition encompasses all Elements and Facilities necessary for the reliable operation and planning of the interconnected bulk power system. Additional specificity will reduce ambiguity and establish consistency across all Regions in distinguishing between BES and non-BES Elements and Facilities.

In addition, NERC was directed to develop a process for identifying any Elements or Facilities that should be excluded from the BES. NERC is working to address these directives with two activities – the definition of Bulk Electric System (BES) is being revised through the standard development process and a BES Definition Exception Process is being developed as a proposed modification to the Rules of Procedure. The work of the BES Definition Exception Process has been publicly posted at: [http://www.nerc.com/filez/standards/Rules\\_of\\_Procedure-RF.html](http://www.nerc.com/filez/standards/Rules_of_Procedure-RF.html). The Rules of Procedure team expects to post the next draft of its proposed addition to the Rules of Procedure (Appendix 5C – BES Exception Process) in September.

# Standards Announcement

## Project 2010-17 Definition of Bulk Electric System Initial Ballot Results

[Now available](#)

### Ballot Results for Definition of Bulk Electric System

The two ballots windows for Project 2010-17 Definition of Bulk Electric System (BES): the first for the definition of Bulk Electric System and associated implementation plan, and the second for the draft application form titled Detailed Information to Support an Exception Request referenced in the Rules of Procedure Exception Process closed at 8 p.m. Eastern on Monday, October 10, 2011.

Voting statistics for each ballot are listed below, and the [Ballot Results](#) Web page provides a link to the detailed results.

BES Definition	Technical Criteria to Support a BES Exception Request
Quorum: 92.97%	Quorum: 89.53%
Approval: 71.68%	Approval: 64.03%

### Next Steps

The drafting team will consider all comments received, and decide whether to make additional revisions to the definition of Bulk Electric System, the associated implementation plan, and the application form titled *Detailed Information to Support an Exception Request* referenced in the Rules of Procedure Exception Process. The drafting team is working to meet the regulatory deadline established in FERC Orders 743 and 743A (filing by January 25, 2012).

The Standards Committee and NERC Board of Trustees have recommended that the drafting team address issues such as generation thresholds in a second phase of this project. This approach will ensure that the drafting team has sufficient time to adequately consider and develop a sound technical basis for an approach, and will allow the drafting team to meet the regulatory deadline in FERC Orders 743 and 743A (filing by January 25, 2012). The drafting team has posted a **draft** Supplemental Standards Authorization Request (SAR) for information purposes only; the SAR will be posted for comment at a future time. Additionally, the drafting team has posted a [Fact Sheet](#), which provides an up to date review of the project scope, project plan - phased approach, current status and upcoming events, on the [project webpage](#).

### Project Background

On November 18, 2010 FERC issued [Order 743 \(amended by Order 743A\)](#) and directed NERC to revise the definition of Bulk Electric System so that the definition encompasses all Elements and Facilities necessary for the reliable operation and planning of the interconnected bulk power system. Additional specificity will reduce ambiguity and establish consistency across all Regions in distinguishing between BES and non-BES Elements and Facilities.

In addition, NERC was directed to develop a process for identifying any Elements or Facilities that should be excluded from the BES. NERC is working to address these directives with two activities – the definition of Bulk Electric System is being revised through the standard development process and a BES Definition Exception Process is being developed as proposed modifications to the Rules of Procedure. The proposed modifications have been posted for a comment period through October 27, 2011. The work of the BES Definition Exception Process has been publicly posted at: [http://www.nerc.com/filez/standards/Rules\\_of\\_Procedure-RF.html](http://www.nerc.com/filez/standards/Rules_of_Procedure-RF.html).

### Standards Development Process

The [Standard Processes Manual](#) contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate. For more information or assistance, please contact Monica Benson at [monica.benson@nerc.net](mailto:monica.benson@nerc.net).

Yes
The SERC OC Standards Review Group agrees to the clarifying changes to the core definition in general; however, we maintain that 200kV and above is the correct bright line for the Bulk Electric System.
Yes
We agree in general with the revisions to the specific inclusions for transformers in I1; however, we believe the transformer voltage level should be 200kV or above.
Yes
We agree in general with the revisions to I2 for generation; however, we maintain that 200kV and above is the correct bright line for the Bulk Electric System.
No
We agree with the changes but believe clarity would be added by changing the word "identified" to "designated".
Yes
No
We feel that this inclusion should be limited to dynamic devices with an aggregate capacity greater than 75 MVA (gross aggregate nameplate rating) connected through a common point.
Yes
We suggest the wording "non-retail generation" should be clarified with an explanation of why it is used in this exclusion.
No

Clarification needs to be provided for what is meant by E2 (ii), regarding generation on the customer's side of the retail meter; otherwise we have trouble developing a position on this question.

No

We would agree with the exclusion if the wording of the exclusion includes the following phrase (in quotation marks) added at the end of E3 b): Power flows only into the LN: The LN does not transfer energy originating outside the LN for delivery through the LN "under normal operating conditions".

Yes

Yes

The definition of the BES is referenced in several existing standards and the Statement of Compliance Registry Criteria. The SERC OC standards Review Group is concerned how this revised definition will impact entity registration, i.e., how will the revised definition be integrated into the Compliance Registry Criteria. The implementation plan should include how the integration is going to occur. The Rules of Procedure exception process should be further defined or referenced in this definition. "The comments expressed herein represent a consensus of the views of the above named members of the SERC OC Standards Review Group only and should not be construed as the position of SERC Reliability Corporation, its board or its officers."

Individual

Doug Hohlbaugh

FirstEnergy Corp.

Yes

However, consider changing the last sentence to read "This does not include facilities operated at less than 100kV, unless modified below, which are used in the local sub-transmission and distribution of electric energy."

Yes

Yes

Yes

We agree with the team's conclusion to remove cranking paths from the BES definition since NERC (i.e. EOP standards) specifically address reliability matters associated with cranking paths. Although we believe item I3 (blackstart unit) is unnecessary as part of the BES Definition, we will not object to its inclusion. A blackstart unit is a facility necessary for BES restoration, but not necessarily required to be included within the BES Definition.

Yes

Yes

While we do not object to I5, we question its need based on item I2 and believe I2 also covers this item

Yes

No

We suggest striking item "ii"

Yes

Yes

Yes

FE supports the SDT's phased project approach which was well articulated in the NERC BES Definition Fact Sheet

Michigan Public Power Agency
Yes
The Michigan Public Power Agency (MPPA) believes the SDT continues to make substantial progress towards a clear and workable definition of the Bulk Electric System (“BES”) that markedly improves both the existing definition and the SDT’s previous proposal. MPPA therefore strongly supports the new definition, although our support is conditioned on: (1) A workable Exceptions process being developed in conjunction with the BES definition; and, (2) the SDT moving forward expeditiously on Phase II of the standards development process in accordance with the SAR recently put forward by the SDT, which would address a number of important technical issues that have been identified in the standards development process to date. MPPA strongly supports the following elements of the revised BES definition: (1) Clarification of how lists of Inclusions and Exclusions applies: The revised core definition moves the phrase “Unless modified by the lists shown below” to the beginning of the definition. This change makes clear that the Inclusions and Exclusions apply to all Elements that would otherwise be included in or excluded from the core definition (i.e., “all Transmission Elements operated at 100 kV or higher and Real Time and Reactive Power resources connected at 100 kV or higher”). (2) The exclusion for Local Distribution Facilities. As the starting point for the BES definition, MPPA supports use of the phrase “all Transmission Elements” and the qualifying sentence: “This does not include facilities used in the local distribution of electric energy.” This language helps ensure that FERC, NERC, and the Regional Entities (“REs”) will act within the jurisdictional constraints Congress placed in Section 215 of the Federal Power Act (“FPA”). In Section 215(a)(1), Congress unequivocally excluded “facilities used in the local distribution of electric energy” from the keystone “bulk-power system” definition. 16 U.S.C. § 824o(a)(1). Including the same language in the definition helps ensure that entities involved in enforcement of reliability standards will act within their statutory limits. In addition, as a practical matter, inclusion of the language will help focus both the industry and responsible agencies on the high-voltage interstate transmission system, where the reliability problems Congress intended to regulate – “instability, uncontrolled separation, [and] cascading failures,” 16 U.S.C. § 824o(a)(4) – will originate. At the same time, level-of-service issues arising in

local distribution systems will be left to the authority of state and local regulatory agencies and governing bodies, just as Congress intended. 16 U.S.C. § 824o(i)(2) (reserving to state and local authorities enforcement of standards for adequacy of service). MPPA also believes the use of the phrase "Transmission Elements" as the starting point for the base definition is desirable because both "Transmission" and "Elements" are already defined in the NERC Glossary of Terms Used, and the term "Transmission" makes clear that the BES includes only Elements used in Transmission and therefore excludes Elements used in local distribution of electric power. MPPA believes this was one of the many key elements addressed by FERC in Order No. 743 and reinforced by FERC Order No. 743A and has been missing from the previous definition as well as the original definition being used since Compliance efforts commenced in June, 2007 . Because of this lack of clarity MPPA has had numerous discussions with the region regarding all 17 of our member's connection to the TO/TOP in Michigan. Our discussions have resulted in defending 6 of our members specifically from the "Bright Line definition" path while having no tools in our tool box to substantiate our exclusion. When a small municipality with a peak load of 12.6 MW and no generation must be defended from a TO and/or TOP registration just because of its connection to it's TO/TOP the process requires needed adjustment for clarity. This was too small to even qualify as a DP under the Statement of Compliance Registry Criteria but must have to defend itself from a TO/TOP registration issue. (3) Appropriate Generator Thresholds. In the standards development process, it has become apparent that the thresholds for classifying generators as BES in the current NERC Statement of Compliance Registry Criteria ("SCRC") (20 MVA for individual generators, 75 MVA for multiple generators aggregated at a single site), which predate the adoption of FPA Section 215, were never the product of a careful analysis to determine whether generators of that size are necessary for operation of the interconnected bulk transmission system. Ideally, such an analysis would be conducted as part of the current standards development process. A member of MPPA has been involved in a registration issue and it has a 3rd party study conducted by a nation consulting firm showing for the MISO area, generation levels of 100 MVA and 300 MVA aggregate or above are below the standard calculation mathematical significant impact criteria for static and dynamic planning protocol. MPPA recognizes that, given the deadlines imposed by FERC in Order No. 743, it will not be possible for the SDT to conduct such an analysis within the time available. Accordingly, MPPA agrees with the approach taken by the SDT, which is to propose a Phase II of the standards development process that would address the generator threshold issue and several other technical issues that have arisen during the current process. As long as Phase II proceeds expeditiously, MPPA is prepared to support the BES definition as proposed by the SDT. While MPPA strongly supports the overall approach adopted by the SDT and much of the specific language incorporated into the second draft of the BES definition, we believe the second draft would benefit from further clarification or modification in a number of respects, most of which are detailed in our subsequent answers. Our support for the definition is not contingent upon these changes being adopted. Further, we believe a workable Exclusion Process is essential for a BES Definition that will meet the legal requirements of FPA Section 215, especially for systems operating in the Eastern Interconnection. That being said, we raise the issue here to emphasize the importance of the Exclusions for Local Networks and Radial Systems and the Exceptions process. These Exclusions and the Exceptions are essential for a definition that works in the Eastern Interconnection because the core definition will be over-inclusive in our region. As long as those Exclusions and the Exceptions Process are retained in a form substantially equivalent to those produced by the SDT at this juncture, MPPA will support the SDT's proposal. Finally, we suggest that the SDT address the circumstances when a facility is covered by both an Inclusion and an Exclusion. We note that some of the inclusions already contain language addressing this question. For example, Inclusion 1 indicates that transformers falling within the specified parameters are part of the BES ". . . unless excluded under Exclusions E1 or E3." Where it is not already included, similar language should be included in the other Inclusions and/or Exclusions to explain whether the SDT intends the Inclusions or the Exclusions to predominate in situations where facilities might be covered by both. We suggest clarifying language in our comments to I1 and I4 below.

Yes

MPPA supports the SDT's changes to the first Inclusion because it is more clear and simple than the initial approach. That being said, we suggest that an additional sentence of clarification would help avoid future controversy about the meaning of Inclusion 1. As MPPA understands it, the BES intends to include transformers only if both the primary and secondary terminals operate at 100 kV or above, which is why the definition uses the word "and" ("the primary and secondary terminals"). We support this approach since it would exclude transformers where the secondary terminals serve distribution

loads, and which therefore function as distribution rather than transmission facilities. MPPA believes the SDT's intent would be clarified by adding a sentence at the end of Inclusion 1 that reads: "Transformers with either primary or secondary terminals, or both, that operate at or below 100 kV are not part of the BES." This language will help ensure that there is no controversy over whether the SDT's use of the word "and" in the phrase "the primary and secondary terminals" was intentional. We also support the SDT's proposal to develop detailed guidance concerning the point of demarcation between BES and non-BES elements in the Phase II SAR. In this regard, we note that, while Inclusion 1 at least implicitly suggests that the dividing line between BES and non-BES Elements should be at the transformer where transmission-level voltages are stepped down to distribution-level voltages, we believe further clarification of this point of demarcation between the BES and non-BES Elements is necessary. There are many different configurations of transformers and other equipment that may lie at the juncture between the BES and non-BES systems. If the point of demarcation is designated at the transformer without further elaboration, many entities that own equipment on the high side of a transformer will be swept into the BES, and thereby exposed to inappropriately stringent regulations and undue costs. For example, distribution-only utilities commonly own the switches, bus and transformer protection devices on the high side of transformers where they take delivery from their transmission provider. Ownership of these protective devices and high-voltage bus on the high side of the transformer should not cause these entities to be classified as BES owners. MPPA has some members who have been forced to sell of such assets in the hopes of remove the necessity for a TO/TOP registration path in this region. We also support the incorporation of language ("... unless excluded under Exclusions E1 or E3") making it clear that transformers that are operated as an integral part of a Radial System or Local Network should not be considered BES facilities, regardless of their operating voltage. Further clarification might be achieved by using the phrase "... unless the transformer is operated as part of a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2."

Yes

MPPA supports the changes made in Inclusion 2 and believe that the definition in its current form adds clarity. In particular, we support the SDT's decision to collapse Inclusions 2 and 3 from the previous draft definition into a single Inclusion that addresses the treatment of generation for purposes of the BES definition. MPPA also supports the SDT's proposal for a Phase II of the BES Definition process that would examine the technical justification for these thresholds and that would establish new thresholds based on a careful technical analysis. It is our understanding that the generator threshold issue will be vetted through the complete standards development process. We agree with this approach because if the generator threshold is treated as merely an element of NERC's Rules of Procedure, it can be changed with considerably less due process and industry input than the Standards Development Process. Compare NERC Rules of Procedure § 1400 (providing for changes to Rules of Procedure upon approval of the NERC board and FERC) with NERC Standards Process Manual (Sept. 3, 2010) (providing for, e.g., posting of SDT proposals for comment, successive balloting, and super-majority approval requirements). See also Order No. 743-A, 134 FERC ¶ 61,210 at P 4 (2011) ("Order No. 743 directed the ERO to revise the definition of 'bulk electric system' through the NERC Standards Development Process" (emph. added)). Addressing all aspects of Phase II through the Standards Development Process will improve the content of the definition by bringing to bear industry expertise on all aspects of the definition and will ensure that, once firm guidelines are established, they can be relied upon by both industry and regulators without threat that they will be changed with little notice and little due process. MPPA also believes further clarification of the proposed language would be appropriate. The SDT proposes continued reliance upon the thresholds that are used in the NERC Statement of Compliance Registry Criteria for registration of Generation Owners and Generation Operators, which is currently 20 MVA for an individual generation unit and 75 MVA for multiple units on a single site. Conceptually, we are concerned about this approach because, as we understand it, the purpose of the Compliance Registry is to sweep in all generators that might be material to the reliable operation of the BES, and not to definitively determine whether a given generator is, in fact, material to the reliable operation of the BES. As the SCRC itself states, the SCRC is intended only to identify "candidates for registration." SCRC at p.3, § 1 (emph. added). Accordingly, we believe that the generator threshold determined in Phase II should be incorporated directly into the BES Definition rather than being incorporated by reference from the SCRC. We also believe that the specific language proposed by the SDT could be further clarified. The SDT proposes to include generation in the BES if the "Generation resource(s)" has a "nameplate rating per the ERO Statement of Compliance Registry." We understand this

language is intended to be a placeholder for the results of the technical analysis that would occur in Phase II but we believe simply stating that the threshold will be “per the ERO Statement of Compliance Registry” is ambiguous. Further, for the reasons noted above, we believe the threshold should be part of the BES Definition, and should not simply be a cross-reference to the SCRC (and, given the different purposes of the BES Definition and the SCRC, it is not clear that the same threshold should be used in both). We therefore propose that Inclusion 2 be rewritten to state: “Qualifying Individual Generation Resources or Qualifying Aggregate Resources connected at a voltage of 100 kV or above.” Two definitions would then be added to the note at the end of the definition to read as follows: For purposes of this BES Definition, Qualifying Individual Generation Resources means an individual generating unit that meets the materiality threshold to be included in this definition or, in the absence of such a materiality threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of such a resource as a Generation Owner under the ERO Statement of Compliance Registry Criteria. For purposes of this BES Definition, Qualifying Aggregate Generation Resources means any facility consisting of one or more generating units that are connected at a common bus that meets the materiality threshold to be included in this definition, or, in the absence of such a threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of multiple-unit generator as a Generation Owner under the ERO Statement of Compliance Registry Criteria.. The “materiality threshold” is intended to refer to the generator threshold developed in Phase II. We suggest using definitions in this fashion for several reasons. First, we believe the language we suggest more clearly states the intention of the SDT, which we understand is to classify generation units as part of the BES if they are necessary for operation of the BES, but to exclude smaller generating units because they are not material to the operation of the interconnected transmission grid. Second, we believe use of the defined terms better reflects the intention of the SDT to reserve the specific question about generator thresholds to the technical analysis that will occur in Phase II without having to revise the BES Definition at the end of that process. That is, the definitions are designed to allow the SDT to include revised thresholds in the definition at the conclusion of the Phase II process based upon the technical analysis planned for Phase II, and the revised thresholds will be automatically incorporated into the BES Definition if the language we suggest is used. The thresholds used in the SCRC would only be a fall-back, to be used only until Phase II is completed. Third, the definitions can be incorporated into other parts of the BES Definition, which will add consistency and clarity. As noted in our answers to several of the questions below, the specific 75 MVA threshold is retained in several of the Exclusions and Inclusions, and we believe the industry would be better served if the revised thresholds arrived at after technical analysis in Phase II are automatically incorporated into all relevant provisions of the BES Definition. There is no reason for the SDT to continue to rely on the 75 MVA threshold once the analysis planned for Phase II on the threshold issue is completed. Fourth, the phrase “or that meets the materiality threshold to be included in this definition” is intended to preserve the SDT’s flexibility to make a determination that generators below a specific threshold are not “necessary to” maintain the reliability of the interconnected transmission system, and to incorporate that finding as part of the definition itself, even if a different threshold is used in the SCRC to identify potential candidates for registration. Accordingly, our proposed language makes clear that a specific threshold in the definition controls over any threshold that might be included in the SCRC. For the reasons stated above, we believe it is highly desirable to include any material threshold in the BES Definition itself rather than relegating the threshold to the SCRC, which is merely a procedural rule rather than a full-fledged Reliability Standard. Finally, we agree with the SDT’s decision to examine the question of where the line between BES and non-BES Elements should be drawn more closely in Phase II under the rubric of “contiguous vs. non-contiguous BES,” and commend the work of the Project 2010-07 Standards Drafting Team and the GO-TO Team as a good starting point for the SDT’s analysis on this issue. We understand Inclusion 2 would classify generators exceeding specific thresholds as part of the BES, but would not necessarily require facilities interconnecting such generators to be part of the BES. As discussed more fully in our answer to Question 9, based on extensive technical analysis that has already been performed by the NERC Project 2010-07 Standards Drafting Team and its predecessor, the NERC “GO-TO Team,” regulating as part of the BES a dedicated interconnection facility connecting a BES generator to the interconnected bulk transmission grid will result in an unnecessary regulatory burden that produces considerable expense for the owner of the interconnection facility with little or no improvement in bulk system reliability. We also believe the clauses at the end of Inclusion 2 are somewhat confusing and that greater clarity would be achieved by changing “. . . including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of

100 kV or above" so that the Inclusion covers transformers with terminals "connected at a voltage of 100 kV or above, including the generator terminal(s) on the high side of the step-up transformer(s) if operated at a voltage of 100 kV or above." MPPA and its members believe it is essential that regional entities and NERC recognize that "facilities used in the local distribution of electric energy" are not included in the definition of BES, regardless of the gross individual or gross aggregate nameplate rating of generation resources. While the addition of the second sentence in the core definition makes this clarification, MPPA and its members believes it is necessary that regional entities and NERC recognize that neither this Inclusion nor any of the Inclusions may be used as a basis to compel registration and compliance in such instances, regardless of the size of the generators. The statutory exemption of facilities used in the local distribution of electric energy is not limited by generator number or capacity. NERC's definitions cannot impose limitations that are not set forth in the statute. For purposes of the exclusion of facilities that might otherwise meet the definition of BES, the thresholds for determining what generating resources constitute BES facilities should be modified from the current levels (gross individual nameplate capacity of 20 MVA or gross aggregate nameplate rating of 75 MVA). MPPA and its members would support modification of the thresholds to not less than 100 MVA (gross individual capacity) and 300 MVA (gross aggregate nameplate).

Yes

Yes

MPPA supports the revised language generally, but believes additional changes would make the language clearer. Specifically, we believe Inclusion 4 should not incorporate a hard 75 MVA generation threshold (i.e., "resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)"). Instead, we urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," which is discussed in more detail in our response to Question 3. This language, or some equivalent, will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. More generally, we are not certain what is accomplished by Inclusion 4 that is not already accomplished by Inclusion 2, which also addresses whether generation should be defined as BES. The SDT's stated concern is with variable generation units such as wind and solar plants. It is not clear to us why this concern is not fully addressed in Inclusion 2, which addresses multiple generation units connected at a common bus, the configuration of most variable generation plants with multiple units. We are also concerned that the language, as proposed, could have unintended consequences and improperly classify local distribution systems as BES in certain circumstances. This is because multiple distributed generation units could render a local distribution system a "collector system" and the entire system the equivalent of an aggregated generation unit, causing the local distribution system to be improperly denied status as a LN. If many different distributed generation units are connected to a local distribution system, it is very unlikely that more than a few of those units would fail simultaneously, and it is therefore unlikely that multiple generation units would produce a measureable impact on the interconnected bulk transmission system, especially if the units individually do not otherwise exceed the materiality threshold to be established by the SDT in Phase II. Further, we are concerned that, if small distributed generation units become the industry norm, Inclusion 4 could unintentionally sweep in local distribution systems, especially where local policies favor the growth of small solar or other renewable generation systems for public policy reasons. Finally, we suggest that the SDT add the phrase ". . . unless the dispersed power producing resources operate within a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2." This language, which parallels the language included at the end of Inclusion I1, would make clear that dispersed small-scale generators scattered throughout a Radial System or Local Network serving retail load would not convert the Radial System or Local Network into a BES system, even if the aggregate capacity of those small generators exceeds the relevant threshold.

No

MPPA has several concerns about the new language in Inclusion 5. First, because Reactive Power devices produce power, they are "power producing resources" and we therefore believe Inclusion 5 is duplicative of Inclusion 4, which addresses "power producing devices." Second, there is no capacity threshold specified in Inclusion 5 for Reactive Power devices that would be considered part of the BES. This is inconsistent with the approach taken in the balance of the definition, where thresholds are specified for generators and other types of power producing devices. Finally, MPPA believes the

appropriate threshold for inclusion or exclusion of Reactive Power devices from the BES should be subject to the same technical analysis that will cover generators in the Phase II process. Without such analysis either: 1) no threshold except for those connected at 100kV, or: 2) of .95 power factor of a 20 MVA generator, or 6 MVAR and use the fact that most Facility Connection Requirements require a power factor in the range of between 0.85 – 0.9 lagging to 0.9 – 0.95 leading for a generator. Hence, a 20 MVA generator (the smallest to meet the registry criteria) will need to absorb a minimum of 6 MVAR and use that as the technical justification.

Yes

MPPA and its members continue to support the radial system exclusion, which is necessary as a legal matter, because, for example, FERC in Orders No. 743 and 743-A has required that the existing radial exemption in the NERC Statement of Compliance Registry Criteria be maintained. As a practical matter, radial systems are used for service to retail loads, usually in remote or rural areas, and not for the transmission of bulk power. Hence, operation of the radials has little or nothing to do with the reliable operation of the interconnected bulk transmission network. But we believe that further clarification is necessary. First, the deletion of “originating with an automatic interruption device” is a step in the right direction. However, “emanates from a single point of connection” could be too narrowly interpreted (i.e., multiple buses within a single substation could be viewed as multiple points of connection). MPPA and its members proposes the following modification: “emanates from a single substation connected to the BES at 100 kV or higher ...”. Entities whose only connection emanates from a single substation and otherwise meet the BES definition should not be denied exclusion under E1 solely because they connect to multiple buses within a single substation. Additionally, adoption of “E3- Local Networks” renders specious any argument that clams that connecting to multiple buses within a single substation makes a material difference for reliability purposes since local networks would have multiple connections anyway. Additionally, it is not clear why it is necessary to include the note at the end of the revised definition. (“A normally open switching device between radial systems, as depicted on prints or one-line diagrams for example, does not affect this exclusion.”) This raises questions as to what “normally open” means, and whether the only evidence demonstrating what “normally open” means will be prints or one-line diagrams. Further, it is not entirely clear what is meant by the language “does not affect this exclusion”. If the note remains, it should be modified to read something like, “a normally open switching device between radial systems does not prevent application of this exclusion.” Finally, the generation threshold limit in E1(b) and E1(c) should be revised as discussed in response to Q1. Specifically, the proposed threshold of 75 MVA for this exclusion should be raised to not less than 300 MVA in both E1(b) and E1 (c).

Yes

MPPA and its members support the revised language. The language provides clarity regarding the BES status of customer-owned cogeneration facilities. However, MPPA and its members urge the SDT to remove the reference to the 75 MVA threshold and replace it with the defined term “Qualifying Aggregate Generation Resources” or some equivalent language for the reasons stated in our responses to Questions 3, 5, and 7. In addition, we are concerned that Exclusion 2 will place local distribution utilities in a difficult position because, under Exclusion 1 or Exclusion 3 as drafted, they could lose their status as a Radial System or a Local Network through the actions of a customer constructing behind-the-meter generation. With respect to Radial Systems, the appearance of behind-the-meter generators could cause the Radial System to exceed the thresholds specified in subparagraphs (b) and (c) of Exclusion 1 through no fault of the Radial System owner. Similar, a Local Network could lose its status because behind-the-meter generation could be of sufficient size that power moves into the interconnected grid in certain hours or under certain contingencies, rather than moving purely onto the Local Network, as required in subparagraph (b) of Exclusion 3. The Exclusions for Radial Systems and Local Networks should be made consistent with the Exclusion for behind-the-meter generation. There is no technical reason to believe the power flowing from a behind-the-meter customer-owned generator will have less impact on the bulk system than an equivalent-sized generator owned by a utility operating a Radial System or LN.

Yes

MPPA and its members strongly supports the categorical exclusion of Local Networks (“LNs”) from the BES. We believe the exclusion is necessary to ensure that the BES definition complies with the statutory requirement, discussed in our response to Question 1, to exclude all facilities used in the local distribution of electric power. LNs are, of course, probably the most common form of local distribution facility. Further, the conversion of radial systems to local distribution networks should be

encouraged because networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. If the BES definition were to provide an exclusion for radials without providing a similar exclusion for LNs, however, it would discourage networking local distribution systems because of the significantly increased regulatory burdens faced by the local distribution utility if it elected to network its radial facilities. By placing radial systems and LNs on the same regulatory footing, the proposed definition will ensure that decisions about whether to network radial systems are made on the basis of costs and benefits to the retail customers served by those radials, and not on the basis of disparate regulatory treatment. Consumers will ultimately benefit from the path chosen by the SDT. MPPA and its members also support specific refinements made to the LN exclusion by the SDT in the current draft of the BES definition. In particular, MPPA supports the clarification of the purposes of a LN. The current draft states that LNs connect at multiple points to “improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system.” Snohomish supports this change in language because it reflects the fundamental purposes of a LN and emphasizes one of the key distinctions between LNs and bulk transmission facilities, namely, that LNs are designed primarily to serve local retail load while bulk transmission facilities are designed primarily to move bulk power from a bulk source (generally either the point of interconnection of a wholesale generator or a the point of interconnection with another bulk transmission system) to one or more wholesale purchasers. MPPA believes further improvement of the language could be achieved with additional modifications and clarifications. With respect to the core language of Exclusion 3, we believe the language making a “group of contiguous transmission Elements operated at or above 100 kV” the starting point for identifying a LN would be improved by deleting the term “transmission” from this phrase. This is so because LNs are not used for transmission and the use of the term “transmission Elements” is therefore both confusing and unnecessary. There would be no room for argument about what the SDT intended by including the word “transmission” if the word is deleted and the Exclusion applies to any “group of Elements operated at 100 kV or above” that meets the remaining requirement of the Exclusion. Further, any definitional value that is added by using the term “transmission Elements” is accomplished by using that term in the core definition, and there is no reason to carry the term through in the Exclusions. MPPA also believes that subparagraphs (a) and (b) are redundant in the sense that whatever protection is offered by the generation limit in subparagraph (a) is duplicated by the limit in subparagraph (b) requiring no flow out of the LN. We believe the SDT can eliminate subparagraph (a) of Exclusion 3 and simply rely on subparagraph (b) because if power only flows into the LN even if it interconnects more than 75 MVA of generation, the interconnected generation interconnected will have no significant interaction with the interconnected bulk transmission system. It will only interact with the LN. And, with the advent of distributed generation, it is easy to foresee a situation in which a large number of very small distributed generators are interconnected into a LDN, so that the aggregate capacity of these generators exceeds 75 MVA. However, because the generators are small and dispersed and, under the criterion in subparagraph (b), would be wholly absorbed within the LN rather than transmitting power onto the interconnected grid, those generators would not have a material impact on the grid. We also suggest that subparagraph (b) of Exclusion 3 could be more clearly drafted. Subparagraph (b), as part of the requirement that power flow into a LN rather than out of it, includes this description: “The LN does not transfer energy originating outside the LN for delivery through the LN.” We understand this language is intended to distinguish a LN from a link in the transmission system – power on a transmission link passes through the transmission link to a load located elsewhere, while power in a LN enters the LN and is consumed by retail load within the LN. While we agree with the concept proposed by the SDT, we believe the language would be clearer if it read: “The LN does not transfer energy originating outside the LN for delivery through the LN to loads located outside the LN.” We believe the italicized language is necessary to distinguish between a transmission system, where power that originates outside a system is delivered through the system and passes through the system to a sink located somewhere outside the system, from a LN, in which power originating outside the LN passes through the LN and is delivered to retail load within the LN. To put it another way, the italicized language helps distinguish a transmission system from an LN, in which the LN “transfers energy originating outside the LN for delivery through the LN to loads located within the LN.” We also believe the language of subparagraph (a) of Exclusion 3 could be improved. Subparagraph (d) would make LNs part of the BES if they interconnect “non-retail generation greater than 75 MVA (gross nameplate rating).” For the reasons stated in our responses to Questions 3, 5 and 7, we urge the SDT to replace the reference to a hard 75 MVA threshold with the defined term “Qualifying Aggregate Generation Resources” or some equivalent. We are also uncertain what is

meant by the use of the term "non-retail generation" in subparagraph (a). From context, we believe the SDT considers "non-retail generation" to mean generation that is used by retail customers located within a LN rather than being exported and sold on wholesale markets outside the LN. We therefore suggest that the SDT replace the phrase "non-retail generation" with the phrase "generation sold in wholesale markets and transmitted outside the LN." Similarly, we are unsure what is meant by the phrase "the LN and its underlying Elements." We believe the phrase "and its underlying Elements" could simply be deleted from the definition without loss of meaning. In the alternative, the SDT might consider using the phrase "the LN, including all Elements located on the distribution side of any Automatic Fault Interrupting Devices (or other points of demarcation) separating the LN from the bulk interstate transmission system." We believe this phrase more accurately reflects the SDT's intent, which appears to be that generation exceeding 75 MVA in aggregate capacity interconnected anywhere within the LN disqualifies that LN from being excluded from the BES under Exclusion 3. Finally, MPPA believes that both subparagraphs (a) and (b) of Exclusion 3 could be safely eliminated as long as subparagraph (c) is retained. Subparagraph (c) makes a LN part of the BES if it is classified as a Flow Gate or Transfer Path. Flow Gates and Transfer Paths are, by definition, the key facilities that allow reliable transmission of bulk electric power on the interconnected grid. If a LN has not been identified as either a Flow Gate or a Transfer Path, it is unlikely the LN is necessary for the reliable transmission of electricity on the interconnected bulk system. Apart from these specific improvements that we believe could be achieved by modifying the language of Exclusion 3, we believe the SDT may need to re-examine certain assumptions that appear to underlie the current draft. Specifically, subparagraph (a) suggests that if BES generation is embedded within a LN, the LN itself must also be BES. But two NERC bodies have already addressed similar questions and concluded there is no technical basis for such concerns. NERC's Standards Drafting Team for Project 2010-07 and its predecessor, the "GO-TO Task Force" were formed to address how the dedicated interconnection facilities linking a BES generator to high-voltage transmission facilities should be treated under the NERC standards. The GO-TO Team concluded that by complying with a handful of reliability standards, primarily related to vegetation management, reliable operation of the bulk interconnected system could be protected without unduly burdening the owners of such interconnection systems. Therefore, there is no reason, according to the GO-TO Team, that dedicated high-voltage interconnection facilities must be treated as "Transmission" and classified as part of the BES in order to make reliability standards effective. See Final Report from the NERC Ad Hoc Group for Generator Requirements at the Transmission Interface (Nov. 16, 2009) (paper written by the GO-TO Task Force). Similarly, the Project 2010-07 Team observed that interconnection facilities "are most often not part of the integrated bulk power system, and as such should not be subject to the same level of standards applicable to Transmission Owners and Transmission Operators who own and operate transmission Facilities and Elements that are part of the integrated bulk power system." White Paper Proposal for Information Comment, NERC Project 2010-07: Generator Requirements at the Transmission Interface, at 3 (March 2011). Requiring Generation Owners and Operators to comply with the same standards as BES Transmission Owners and Operators "would do little, if anything, to improve the reliability of the Bulk Electric System," especially "when compared to the operation of the equipment that actually produces electricity – the generation equipment itself." Id. We believe that interconnection of BES generators within a LN is analogous and that, based on the findings of the Project 2010-07 and GO-TO Teams, automatically classifying a LN as "BES" simply because a large generator is embedded in the LN will result in substantial overregulation and unnecessary expense with little gain for bulk system reliability. If anything, generation interconnected through a LN is less likely to produce material impacts on the interconnected bulk transmission system than the equivalent generator interconnected through a single dedicated line because an LN is interconnected to the bulk system at several points, so that if one interconnection goes down, power can still flow from the BES generator to the bulk system on other interconnection points. Where a dedicated interconnection facility is involved, by contrast, if the interconnection line fails, the generator is unavailable to the interconnected bulk system. Similarly, we suggest that the SDT re-examine the assumptions underlying subparagraph (b), which seems to suggest that a local distribution system cannot be classified as a Local Network if power flows out of that system at any time, even if the amount is de minimis, the outward flow is only for a few hours a year, or the outward flow occurs only in an extreme contingency. Accordingly, we suggest that the initial clause of subparagraph (b) be revised to read: "Except in unusual circumstances, power flows only into the LN."

Yes

Yes, MPPA and its members support the revised language because retail reactive devices are used to

address local customer or retail voltage issues, rather than voltage issues on the interconnected bulk grid, and such local devices should therefore be excluded from the BES definition.

No

MPPA and its members extends its thanks to the SDT and to the many industry entities that have actively participating in the Standards Development Process. MPPA strongly supports the current draft and believes, with certain refinements discussed in our comments, that the definition will serve the industry and reliability regulators well for many years to come. In addition, as noted earlier, MPPA is encouraged that the 20/75 MVA generation thresholds referred to in the NERC Statement of Compliance Registry Criteria, which have been relied upon by the SDT largely as a matter of necessity, will be reviewed and a technical assessment will be performed to identify the appropriate generation unit and plant size threshold to ensure a reliable North America. Finally, we understand that the Rules of Procedure Team will continue to move forward with developing an Exceptions Process that will complement the BES Definition and ensure that, to the extent the BES Definition is over-inclusive, facilities that should not be classified as BES will be excluded from the BES. Because the Exceptions Process is integral to a workable BES Definition, we support the current process for moving forward with the Exceptions Process and the BES Definition on parallel paths. We note that MPPA and its members specifically supports the changes made by the SDT in the "Effective Date" provision of the BES Definition, which shortens the effective date of the new definition to the beginning of the first calendar quarter after regulatory approval (as opposed to the first calendar quarter twenty-four months after regulatory approval), with a 24-month transition period. MPPA supports this conclusion because it will allow entities seeking deregistration under the terms of the new BES definition to obtain the benefits of the new definition without an unreasonable wait, while allowing any entities that may be newly-classified as BES owners or operators sufficient time to come into compliance with newly-applicable Reliability Standards. MPPA and its members also supports the 24-month transition period for the reasons laid out by the SDT.

Yes

We generally support the changes made.

Yes

We support the language as drafted.

No

Reliance upon the Registry Criteria falls back to the 20MVA threshold. We believe this threshold is very low and unnecessarily draws in small entities for which there is no impact to the BES. We understand the barriers and the volume of technical evidence required for any change and we therefore have no alternative language to suggest.

Yes

We support the inclusion as drafted.

No

As drafted, it appears to draw in all generation resources that sum to 75 MVA or higher. We question then if there is value of categorizing every wind turbine on a >75MVA wind farm as a BES asset and, what would be the unintended consequences. Perhaps language delineating the point of aggregation as the demarcation point of a BES asset would better serve.

Yes

We have no comments.

No
This seems very confusing, but should be clear and easy enough for anyone to pickup, read, understand, apply and arrive at the same conclusion. The term local distribution needs to be either defined or have some guidance provided on what it is intended to cover. A suggestion for defining distribution would be that radials and local networks makeup distribution facilities. Radials usually terminate at distribution or customer substations and local networks are primarily used for distribution also. The Commission granted NERC the ability to define distribution in Order 743-A, paragraphs 67-71. It is not clear if the BES is meant to be a contiguous system or not from the language in the revised definition. ReliabilityFirst Staff believes that the BES should be contiguous, and therefore, any facilities needed to connect real and reactive resources to the BES need to be included. To maintain reliability, the BES cannot have pockets of generation that are not connected to the BES via BES facilities. ReliabilityFirst Staff believes that without including the paths from BES generators in the BES, the reliable operation of the system could be jeopardized if the paths are unavailable due to non-compliance to Reliability Standards. For example, wind farm collector systems at voltages operated at less than 100 kV should be included in the BES for the above reason.
Yes
Yes
No
Blackstart Resource is a defined NERC term, but as outlined in the definition, it could be read to include the transmission assets that also make up the resource as part of the TOP plan. Is that the intent? ReliabilityFirst Staff also feels that without including the Cranking Paths, the reliable operation of the system could be jeopardized if a restoration is required and the Cranking Paths are unavailable due to non-compliance to Reliability Standards.
No
The term "Dispersed Power Producing Resource" is not a defined term and needs further clarification. However, I4 is not needed and is already included in I2. I4 does not add any additional facilities that are not already included in I2. How are "dispersed power producing resources" different from "generating resources" described in I2? If the intent of I4 is to include wind generators but exclude wind farm collector systems in the BES, ReliabilityFirst Staff disagrees. To maintain reliability, the BES cannot have pockets of generation that are not connected to the BES via BES facilities. ReliabilityFirst Staff believes that without including the paths from BES generators in the BES, the reliable operation of the system could be jeopardized if the paths are unavailable due to non-compliance to Reliability Standards. For example, wind farm collector systems at voltages operated at less than 100 kV should be included in the BES for the above reason. I4 could be deleted.
Yes
No
The term radial must be specifically defined in this application. ReliabilityFirst Staff believes this to mean a true radial in the sense that an adverse impact by the radial facilities does NOT affect or impact BES facilities. In the first sentence the word "Element" is capitalized but "transmission" is not, we believe both terms should be capitalized. The phrase "single point of connection" should have guidance so that everyone reading this definition reads the single point of interconnection the same. Some have read this phrase to be a single substation, while others have read this phrase to be one and only one line or supply (i.e. interconnection point), which is it? The "Note" we disagree with. In any and all cases if there is any operation or use of the BES, the facilities should be included. By the wording of this exclusion, one cannot determine if taps (sections of line from a BES transmission line

to a single substation) are intended to be included in the BES or not. More specifically, where does the radial facility begin and the BES end? This determination was clearer in the previous version of the definition with the use of the language "...originating with an automatic interruption device...".

No

It is not clear why "ii" is needed. If the net generation exceeds 75 MVA, then it is included in the BES whether or not there are ancillary services provided for that generation. Would customer owned generation less than a net of 75 MVA but greater than 20 MVA be included in the BES if item ii was not met?

No

ReliabilityFirst Staff proposes to use the LN exclusion as part of the definition of what elements make up the facilities used in the local "distribution" of electric energy and could be included in the Exception Process as a criterion for exclusion.

Yes

Yes

This definition needs to be clear and easy enough for anyone to pickup, read, understand, apply and arrive at the same conclusion on whether the facility or element is included or excluded. This definition leaves room for continued debate and interpretation. To help make this definition clearer, ReliabilityFirst Staff has provided a redline version of the core definition under a separate cover (file titled "Bulk Electric System definition by RFC Staff 10-4-2011").

David Taylor

NERC

No

The sentence, "This does not include facilities used in the local distribution of electricity," is a commentary or statement of objective rather than a definition of what facilities comprise the BES. Including such information that does not define the facilities to be included or excluded will be a source of confusion in applying the definition. The BES definition as proposed by the SDT may in fact include such facilities and as stated in paragraph 37 of Order 743: "Determining where the line between "transmission" and "local distribution" lies, which includes an inquiry into which lower voltage "transmission" facilities are necessary to operate the interconnected transmission system, should be part of the exemption process the ERO develops." If the drafting team believes that Exclusions E1 through E4 in the definition are sufficient to not include any facilities used in the local distribution of electricity then those exclusions, and not the aforementioned sentence in the "core definition," define the facilities that are not included (i.e., the sentence is unnecessary).

Yes

Yes

The drafting team's proposed approach for Inclusion I2 (generation), including the reference to the ERO Statement of Compliance Registry Criteria, is generally acceptable given the scope of this project and the breaking of the project into two phases. Thresholds for generator MVA rating and interconnection voltage should be considered in the second phase of this project.

No

The cranking path(s) identified in the Transmission Operator's restoration plan should be included in the BES definition.

Yes

Yes

No

While we appreciate the improvement in the text for Exclusion E1, but we continue to believe that E1 should require (i) the normally open switch must not be used to make a parallel connection if the normally switch is operated at 100 kV or higher and (ii) an automatic interrupting device that is part

of the BES must be provided at the point of interconnection between the radial system and the BES.
Yes
No
While we appreciate the improvement in the text of Exclusion E3, but we continue to believe that E3 should require automatic interrupting devices that are part of the BES must be provided at the points of interconnection between the Local Network and the BES.

OPG continues to question the need for the changes required (and costs imposed) as a result of this new definition. This is particularly true in the NPCC region where an impact based methodology is being used to determine the set of BES elements. A very clear 100kV bright line, as proposed in this draft, will dramatically increase the list of generation elements that must meet reliability standards, without a corresponding increase in wide-area reliability. OPG recommends that the work planned for phase II, technical justification of the generation and voltage thresholds, should be completed before implementing the new definition of BES.
Yes
No
OPG does not agree that the question of the 20 MVA (single) versus 75 MVA (aggregate) threshold should be deferred until a subsequent phase of the standard development process ("Phase II"). This question should be resolved now. In general, key elements of the development process should not be parsed out into multiple phases, in hopes that "Standard Development Fatigue" will eliminate critics of the approach. Further, selecting the generator terminals as the boundary for BES within the generating station means that the Isolated Phase Bus (IPB), which connects the generator terminals to the Low Voltage (LV) terminals of the generator step-up (GSU) transformer, is now included as a BES element. The IPB is operated at low voltage, no more than 22kV, so including it as a BES element is going beyond the FERC order 743 and 743a. OPG strongly recommends that the BES boundary be moved to the LV terminals of the GSU transformer.
No
To assure availability of the generation blackstart resources identified in the Transmission Operator's Power System Restoration Plan the generators are tested according to the requirements of reliability standard EOP-009. Blackstart resources are only required post LOBES (Loss of Bulk Electric System) and in many cases do not contribute to the reliability of the BES under normal operating conditions. OPG recommends that this inclusion be removed from the new definition of BES.
Yes
No
OPG recommends that the wording of this inclusion be made clear that the BES boundary extends to the Low Voltage terminals of the transformer, used in the interface connection, and does not include the static or dynamic reactive power source itself unless it is directly connected to the BES.
No
Non-retail generation needs to be properly defined in the text of the exclusion.
Yes
No

Non-retail generation needs to be properly defined in the text of the exclusion.
Yes
Yes
Further to comments submitted in Question #1, OPG disagrees in general with proceeding to implement a 100 kV brightline definition in the absence of a properly quantified cost/benefit analysis. Entities are being asked to incur a high cost for no demonstrated benefit in wide-area reliability.

More specific description is needed for the equipment intended to be included in I1. For example, is it intended to include autotransformers, PARs, primary, secondary, tertiary windings, etc.? There will be difficulty applying the definition to facilities without this detail. Suggest rewording to: All transformers (including auto-transformers, voltage regulators, and phase angle regulators and all windings) with primary and secondary terminals operated at or above 100kV, and generator step-up (GSU) transformers with one terminal operated at or above 100KV, unless excluded by E1 or E3.
No
In deference to direction given to the Drafting Team, Inclusion I2 should remove the reference to the Statement of Compliance Registry Criteria. The current language induces circular arguments without a true governing document. The definition should drive what appears in the registration criteria. I2 should be revised to read: "Generating resources with a gross nameplate rating of 20MVA or greater, or generating plant/facility connected at a common bus, with an aggregate nameplate rating of 75MVA or greater and is directly connected to a BES Element." This is consistent with the proposed I2 and the current Compliance Registry Criteria. Ultimately the definition should be the governing document and provide the details of what generation should be included. It is understood that Phase 2 of this project will address this.
No
Eliminating I3 should be considered based on the availability and performance expectations of black start resources being ensured by existing standards, and unless they meet the BES definition under the I2 inclusion they do not have any reliability impact on BES operation. If I3 is retained, suggest rewording Inclusion I3 to read as follows: Black start resources material to and designated as part of the Transmission Operator's restoration plan.
No
Suggest the term "common point" needs clarification and/or definition (is risk of single mode failure intended, i.e. where all the resources could be lost for a single event?). Suggest the following wording: "connected at a common point through a dedicated step-up transformer with a high-side voltage of 100 KV or above." Dispersed power producing sources such as wind and solar should not be included as BES elements because of the variable and intermittent nature of these resources. If these dispersed power producing resources had dedicated energy storage facilities only then that could make them BES elements. Generally the collector systems for these resources (from the bulk transmission system reliability perspective) do not differ from distribution systems which are excluded from the BES.
No
Technical studies need to be conducted to confirm reactive resource impacts on the reliability of the BES. The inclusion of reactive resources is a significant expansion of the current BES definition and therefore requires technical justification for inclusion. Inclusion I5 as written is confusing with a reference to Inclusion I1 in the definition. Suggest removing references to reactive resources from Phase 1 until technical justification can be demonstrated (as part of Phase 2).
No
E1 can be simplified by not dividing in three subsets of a, b and c. The end result is that a Radial system is excluded if it does not have more than 75 MVA aggregate non-retail generation. There

seems to be an error with reference to I3. Black start unit paths are not designated as BES and were taken out in this version under I3 so E1 and E3 should not reference I3. This contradicts the radial or LN exclusion from I3. Suggest deleting the reference to I3 in E1 and E3 because this reference is in contradiction to I3. I3 does not require a path to be BES, but it implied that a radial cannot be excluded if there is a black start unit on the radial. Further clarification is needed to the language in the Note referring to the "Normally Open switch". The E1 reference Note should be re-worded to state "Radial systems shall be assessed with all normally open switching devices in their open positions." Explanatory figures should be included to illustrate the system configurations addressed. Black start unit paths must be considered in the construction of E1. In E1c, what is meant by "non-retail"?

No

Why are references to Balancing Authority, Generator Owner, and Generator Operator included in E2 which is part of the BES definition? The wording of Exclusion E2 should be consistent with the Statement of Compliance Registry Criteria in Section III.c.4.

No

What is the technical justification for 300kv and higher? Local Network is capitalized (network not capitalized at the beginning of E3) throughout E3, yet it is not defined in the NERC Glossary. The installed generation limit in a Local Network should be addressed in Phase 2. Any studies supporting E3 should be made available.

No

Consider using other wording to replace "retail". The statement "owned or operated by the retail customer" is confusing and arguably inaccurate and should be revised. Refer to comments related to reactive resources for Question 6 regarding Inclusion I5. Retail and non-retail generation should be defined.

Yes

Technical bases have not been provided for the proposed definition of the BES. Additionally, the cost impacts have not been assessed and weighed against the potential benefits of this proposal. There is confusion arising from the construction and interactions of the Inclusion, and Exclusion sections. System diagrams, put in a separate guidance document, would help in understanding. The situation of using Exceptions to understand Exclusions must be avoided. Suggest consider incorporating Inclusions directly, and leave the Exclusions as is format wise. The Implementation period discusses a 24 month timeframe( the Order suggests 18) from when the standard becomes effective to begin Compliance obligations. If construction is required to become compliant or meet performance requirements with standards, or CIP Version 5 standards increase the amount of BES assets this will be insufficient when considering budgeting, designing, siting requirements, and permitting. Concern exists over the paradigm that the definition should "mirror" the NERC Compliance Registry Criteria regarding who is registered. Some RSC members believe the definition should drive any changes to the registry criteria and not the criteria perpetuating the thresholds in the definition. However, there is a need to confirm that Phase 2 of this project will address this. The Inclusions and Exclusions listed need clarifications and perhaps diagrams and accompanying guidelines to clarify and explain the intent.

Under the proposed definition, clause E3.b. stipulates that 'power only flows into the Local Network (LN): The LN does not transfer energy originating outside the LN for delivery through the LN.' Clearly, this is a bright line. The Local Network Exclusion document, however, describes that 'power flow "shifts" of 'negligible fraction' are acceptable. Further, the document acknowledges that parallel flows through the LN, 'as governed by the fundamentals of parallel circuits' will occur. Finally, the document goes on to exhibit that flows through the LN, however minimal, will result from both power transfer distribution factor (PTDF) and line outage distribution factor (LODF) analysis. If this is the case, what bright line criterion should be applied for this Exclusion Principal if no maximum PTDF and/or LODF are specified?
Yes
Yes
Due to the movement to a phased BES definition development process and assuming the definition is approved as proposed, there is an urgent need for NERC to provide clear guidance to Registered Entities regarding how to proceed with facilities and address changes to the NERC Compliance Registry registration obligations brought in/on by the application of the new definition. The problem stems from a likely scenario whereby the affected Registered Entities may be faced with an Implementation Plan and an Exception Request Procedure which must be completed prior to the completion of the Phase II definition development process. If that is the case, many Registered Entities will be confronted with either (1) spending large amounts of human and financial resources, not yet acquired, to address facilities/procedures necessary to address possible new compliance obligations only to find their efforts rendered unnecessary by the results produced in Phase II or, (2) waiting until the results of Phase II are provided and risking being found non-compliant and subject to substantial penalties in the future. Neither option can be viewed as a desirable, or for that matter, an acceptable position to be placed in.

City of Anaheim
No
The City of Anaheim recommends either changing the E1 (b) language back to that of the previous BES definition draft, i.e. 75 MVA or above connected at 100 kV or above, or limit the amount of generation allowed within a Radial Element or Local Network to 300 MVA or less, which is the amount of uncontrolled load loss that constitutes a reportable "disturbance" pursuant to EOP-004 and DOE Form OE-417. If DOE and NERC do not consider a 300 MW uncontrolled loss of load a reportable event, then why would the potential loss of a 75 MVA of non-critical generator connected at 69 kV make a Radial Element or Local Network critical to the reliability of the BES? The current ERO Statement of Compliance Criteria does not require GO/GOP registration for generation connected below 100 kV as long as it's not critical to the reliability of the BES, i.e. black start, etc., even if the amount of generation is greater than 75 MVA. There is good reason for this because the mere loss of 75 MVA generator would not affect the reliability of a system as big as the Western Interconnection, at all, and a fault at say 69 kV would have sufficient impedance not to affect the BES from an electrical perspective.
Yes

Deborah J Chance
Chevron U.S.A. Inc.
Yes
Yes. Very good progress was made in the process. The initial overly broad language was inadvertently including parties that are not necessary to meet the NERC and FERC goals. The current language has clarified some of the ambiguities.
Yes
No
It is not logical to allow an aggregate of 75 MVA at a single site for multiple generators while maintaining 20 MVA for a single generator. Further, if a party exceeds export of 75 MVA to meet an emergency condition on the grid, it should not be a triggering event for BES definition. Parties should be concerned with keeping the grid operational rather than the adverse effect of exceeding 75 MVA.
Yes
Yes
Yes
Yes
This is very important exclusion for an entity operating in remote areas of the country that provides distribution service to third parties where utilities are unable or unwilling to serve. While the distribution is at a low voltage, the power was initially received by the operating entity at a high voltage.
Yes
This is a very important exclusion for Combined Heat and Power facilities that utilize large amounts of steam and power, and secure and/or provide their own operating reserves.
Yes
This provision complements E1 in defining the difference between distribution and transmission

Individual
Alice Ireland
Xcel Energy
In general, Xcel Energy supports the changes to the core definition of Bulk Electric System. Some additional clarification may be required as suggested below under the individual Inclusions or Exclusions.

No
Xcel Energy believes that this inclusion is still a little vague and could use some clarification. For instance, if a wind farm has an aggregated capacity greater than 75 MVA (and therefore meets Inclusion 14) exactly what facilities are included as part of the BES, every turbine, all distribution transformers and cables, etc. If all equipment is included, what level of detail is required of this BES facility for modeling purposes, and who is responsible for modeling this system. Or, is the intent to only include the facilities at the common point of connection, whereby the facility could be modeled as 1 large facility?
No
Xcel Energy believes that some more definition is required to clarify the intent of the note under Exclusion E1 related to normal open switching device. A direct statement would remove any ambiguity, such as "a normally open switch in a system that could be interconnected or experience loop flows will be considered (BES/non BES)".

Inclusion 5 should be changed to be consistent with the core definition and to clarify Reactive Power devices. Under I5, the additional phrase "or through a dedicated transformer with a high side voltage of 100 kV or higher," appears to conflict with the core definition's phrase "and Real Power and Reactive Power resources connected at 100 kV or higher". For example, if you have a device connected to a 69Kv system which is used solely for an end-user's load, but the 69kv system is transformed up to a 115kV system, such device could be included as BES or you would have to define what is meant by "dedicated. If Reactive Power is meant to agree with the definition under NERC's Glossary of Terms, there should be consistency and less verbiage. MWDSC also agrees with WECC's comment that there should be some minimum threshold for Reactive Power devices similar to that identified for generating resources in Inclusion 2. MWDSC recommends that Inclusion 5 be changed as follows: I5 - "Reactive Power devices dedicated to support the BES that are connected at 100kV or higher, or through a transformer that is designated in Inclusion I1."
Yes
Yes
Yes

No
Exclusion 4 appears to limit the devices just to retail customers. However, any end-user load, including wholesale or retail, should be included. NERC's Glossary of Terms uses the phrase "end-use customer", not retail customers to describe loads. MWDC recommends that Exclusion 4 be changed as follows: E4 - Reactive Power devices owned and operated by an end-use customer solely for its own use.

Yes
Yes
No
Need to add the exception for exclusions under E1 or E3, and also reword to exclude devices connected to a transformer winding less than 100 kV unless that is the only connection to that winding. Suggested rewording of I5 : "Unless excluded under Exclusions E1 or E3, static or dynamic devices dedicated to supplying or absorbing Reactive Power that are connected at 100 kV or higher, or through a dedicated transformer with a high-side voltage or 100 kV or higher, or through a transformer winding less than 100 kV that is designated in Inclusion I1 if the winding does not have any circuits or load connected to it." This would eliminate having to include a capacitor connected to the 69 kV winding of a three winding BES transformer such as 230/138/69 kV if that winding had other connections such as 69 kV circuits. The voltage threshold of 100 kV and above should capture devices connected to 100 kV or higher windings of transformers designated in Inclusion I1.

David Proebstel
Clallam County PUD No.1
Yes
The Public Utility District No. 1 of Clallam County ("CLPD") believes the SDT continues to make substantial progress towards a clear and workable definition of the Bulk Electric System ("BES") that markedly improves both the existing definition and the SDT's previous proposal. CLPD therefore strongly supports the new definition, although our support is conditioned on: (1) a workable

Exceptions process being developed in conjunction with the BES definition; and, (2) the SDT moving forward expeditiously on Phase II of the standards development process in accordance with the SAR recently put forward by the SDT, which would address a number of important technical issues that have been identified in the standards development process to date. CLPD strongly supports the following elements of the revised BES definition: (1) Clarification of how lists of Inclusions and Exclusions applies: The revised core definition moves the phrase "Unless modified by the lists shown below" to the beginning of the definition. This change makes clear that the Inclusions and Exclusions apply to all Elements that would otherwise be included in or excluded from the core definition (i.e., "all Transmission Elements operated at 100 kV or higher and Real Time and Reactive Power resources connected at 100 kV or higher") and eliminates a latent ambiguity in the first draft of the definition, discussed further in our comments on the first draft. (2) The exclusion for Local Distribution Facilities. As the starting point for the BES definition, CLPD supports use of the phrase "all Transmission Elements" and the qualifying sentence: "This does not include facilities used in the local distribution of electric energy." This language helps ensure that FERC, NERC, and the Regional Entities ("REs") will act within the jurisdictional constraints Congress placed in Section 215 of the Federal Power Act ("FPA"). In Section 215(a)(1), Congress unequivocally excluded "facilities used in the local distribution of electric energy" from the keystone "bulk-power system" definition. 16 U.S.C. § 824o(a)(1). Including the same language in the definition helps ensure that entities involved in enforcement of reliability standards will act within their statutory limits. In addition, as a practical matter, inclusion of the language will help focus both the industry and responsible agencies on the high-voltage interstate transmission system, where the reliability problems Congress intended to regulate – "instability, uncontrolled separation, [and] cascading failures," 16 U.S.C. § 824o(a)(4) – will originate. At the same time, level-of-service issues arising in local distribution systems will be left to the authority of state and local regulatory agencies and governing bodies, just as Congress intended. 16 U.S.C. § 824o(i)(2) (reserving to state and local authorities enforcement of standards for adequacy of service). For similar reasons, Clallam believes use of the phrase "Transmission Elements" as the starting point for the base definition is desirable because both "Transmission" and "Elements" are already defined in the NERC Glossary of Terms Used, and the term "Transmission" makes clear that the BES includes only Elements used in Transmission and therefore excludes Elements used in local distribution of electric power. (3) Appropriate Generator Thresholds. In the standards development process, it has become apparent that the thresholds for classifying generators as BES in the current NERC Statement of Compliance Registry Criteria ("SCRC") (20 MVA for individual generators, 75 MVA for multiple generators aggregated at a single site), which predate the adoption of FPA Section 215, were never the product of a careful analysis to determine whether generators of that size are necessary for operation of the interconnected bulk transmission system. Ideally, such an analysis would be conducted as part of the current standards development process. Clallam recognizes that, given the deadlines imposed by FERC in Order No. 743, it will not be possible for the SDT to conduct such an analysis within the time available. Accordingly, Clallam agrees with the approach taken by the SDT, which is to propose a Phase II of the standards development process that would address the generator threshold issue and several other technical issues that have arisen during the current process. As long as Phase II proceeds expeditiously, Clallam is prepared to support the BES definition as proposed by the SDT. While Clallam strongly supports the overall approach adopted by the SDT and much of the specific language incorporated into the second draft of the BES definition, we believe the second draft would benefit from further clarification or modification in a number of respects, most of which are detailed in our subsequent answers. Our support for the definition is not contingent upon these changes being adopted. Further, we believe a workable Exclusion Process is essential for a BES Definition that will meet the legal requirements of FPA Section 215, especially for systems operating in the Western Interconnection. As detailed in our II proceeds expeditiously, Clallam is prepared to support the BES definition as proposed by the SDT. While Clallam strongly supports the overall approach adopted by the SDT and much of the specific language incorporated into the second draft of the BES definition, we believe the second draft would benefit from further clarification or modification in a number of respects, most of which are detailed in our subsequent answers. Our support for the definition is not contingent upon these changes being adopted. Further, we believe a workable Exclusion Process is essential for a BES Definition that will meet the legal requirements of FPA Section 215, especially for systems operating in the Western Interconnection. As detailed in our previous comments, Clallam believes a 200-kV threshold would be more appropriate for WECC than a 100-kV threshold. In addition, a 200-kV threshold for the West is backed by solid technical analysis conducted by the WECC Bulk Electric System Definition Task Force, and repeated claims that there is no

technical analysis to support this view is therefore incorrect. That being said, we raise the issue here to emphasize the importance of the Exclusions for Local Networks and Radial Systems and the Exceptions process. These Exclusions and the Exceptions are essential for a definition that works in the Western Interconnection because the core definition will be over-inclusive in our region. As long as those Exclusions and the Exceptions Process are retained in a form substantially equivalent to those produced by the SDT at this juncture, Clallam will support the SDT's proposal and will not further pursue its claims regarding the 200-kV threshold.

Yes

We support the SDT's changes to the first Inclusion because it is more clear and simple than the initial approach. That being said, we suggest that an additional sentence of clarification would help avoid future controversy about the meaning of Inclusion 1. As we understand it, the BES intends to include transformers only if both the primary and secondary terminals operate at 100 kV or above, which is why the definition uses the word "and" ("the primary and secondary terminals"). We support this approach since it would exclude transformers where the secondary terminals serve distribution loads, and which therefore function as distribution rather than transmission facilities. We believe the SDT's intent would be clarified by adding a sentence at the end of Inclusion 1 that reads: "Transformers with either primary or secondary terminals, or both, that operate at or below 100 kV are not part of the BES." This language will help ensure that there is no controversy over whether the SDT's use of the word "and" in the phrase "the primary and secondary terminals" was intentional. We also support the SDT's proposal to develop detailed guidance concerning the point of demarcation between BES and non-BES elements in the Phase II SAR. In this regard, we note that, while Inclusion 1 at least implicitly suggests that the dividing line between BES and non-BES Elements should be at the transformer where transmission-level voltages are stepped down to distribution-level voltages, we believe further clarification of this point of demarcation between the BES and non-BES Elements is necessary. Many different configurations of transformers and other equipment that may lie at the juncture between the BES and non-BES systems. If the point of demarcation is designated at the transformer without further elaboration, many entities that own equipment on the high side of a transformer will be swept into the BES, and thereby exposed to inappropriately stringent regulations and undue costs. For example, distribution-only utilities commonly own the switches, bus and transformer protection devices on the high side of transformers where they take delivery from their transmission provider. Ownership of these protective devices and high-voltage bus on the high side of the transformer should not cause these entities to be classified as BES owners. As the Phase II process moves forward, we commend to the SDT the extensive work performed on the point of demarcation question by the WECC BESDTF. We also support the incorporation of language (" . . . unless excluded under Exclusions E1 or E3") making it clear that transformers that are operated as an integral part of a Radial System or Local Network should not be considered BES facilities, regardless of their operating voltage. Further clarification might be achieved by using the phrase ". . . unless the transformer is operated as part of a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2."

Yes

CLPD supports the changes made in Inclusion 2 and believe that the definition in its current form adds clarity. In particular, we support the SDT's decision to collapse Inclusions 2 and 3 from the previous draft definition into a single Inclusion that addresses the treatment of generation for purposes of the BES definition. We also support that aspect of the SDT's proposal for a Phase II of the BES Definition process that would examine the technical justification for these thresholds and that would establish new thresholds based on a careful technical analysis. It is our understanding that the generator threshold issue will be vetted through the complete standards development process. We agree with this approach because if the generator threshold is treated as merely an element of NERC's Rules of Procedure, it can be changed with considerably less due process and industry input than the Standards Development Process. Compare NERC Rules of Procedure § 1400 (providing for changes to Rules of Procedure upon approval of the NERC board and FERC) with NERC Standards Process Manual (Sept. 3, 2010) (providing for, e.g., posting of SDT proposals for comment, successive balloting, and super-majority approval requirements). See also Order No. 743-A, 134 FERC ¶ 61,210 at P 4 (2011) ("Order No. 743 directed the ERO to revise the definition of 'bulk electric system' through the NERC Standards Development Process" (emph. added)). Addressing all aspects of Phase II through the Standards Development Process will improve the content of the definition by bringing to bear industry expertise on all aspects of the definition and will ensure that, once firm guidelines are established,

they can be relied upon by both industry and regulators without threat that they will be changed with little notice and little due process. CLPD believes further clarification of the proposed language would be appropriate. The SDT proposes continued reliance upon the thresholds that are used in the NERC Statement of Compliance Registry Criteria for registration of Generation Owners and Generation Operators, which is currently 20 MVA for an individual generation unit and 75 MVA for multiple units on a single site. as we understand it, the purpose of the Compliance Registry is to sweep in all generators that might be material to the reliable operation of the BES, and not to definitively determine whether a given generator is, in fact, material to the reliable operation of the BES. As the SCRC itself states, the SCRC is intended only to identify "candidates for registration." SCRC at p.3, § 1 (emph. added). Accordingly, we believe that the generator threshold determined in Phase II should be incorporated directly into the BES Definition rather than being incorporated by reference from the SCRC. We also believe that the specific language proposed by the SDT could be further clarified. The SDT proposes that generation be included in the BES if the "Generation resource(s)" has a "nameplate rating per the ERO Statement of Compliance Registry." We understand this language is intended to be a placeholder for the results of the technical analysis that would occur in Phase II but we believe simply stating that the threshold will be "per the ERO Statement of Compliance Registry" is ambiguous. Further, for the reasons noted above, we believe the threshold should be part of the BES Definition, and should not simply be a cross-reference to the SCRC (and, given the different purposes of the BES Definition and the SCRC, it is not clear that the same threshold should be used in both). We therefore propose that Inclusion 2 be rewritten to state: "Qualifying Individual Generation Resources or Qualifying Aggregate Resources connected at a voltage of 100 kV or above." Two definitions would then be added to the note at the end of the definition to read as follows: For purposes of this BES Definition, Qualifying Individual Generation Resources means an individual generating unit that meets the materiality threshold to be included in this definition or, in the absence of such a materiality threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of such a resource as a Generation Owner under the ERO Statement of Compliance Registry Criteria. For purposes of this BES Definition, Qualifying Aggregate Generation Resources means any facility consisting of one or more generating units that are connected at a common bus that meets the materiality threshold to be included in this definition, or, in the absence of such a threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of multiple-unit generator as a Generation Owner under the ERO Statement of Compliance Registry Criteria. The "materiality threshold" is intended to refer to the generator threshold developed in Phase II. We suggest using definitions in this fashion for several reasons. First, we believe the language we suggest more clearly states the intention of the SDT, which we understand is to classify generation units as part of the BES if they are necessary for operation of the BES, but to exclude smaller generating units because they are not material to the operation of the interconnected transmission grid. Second, we believe use of the defined terms better reflects the intention of the SDT to reserve the specific question about generator thresholds to the technical analysis that will occur in Phase II without having to revise the BES Definition at the end of that process. That is, the definitions are designed to allow the SDT to include revised thresholds in the definition at the conclusion of the Phase II process based upon the technical analysis planned for Phase II, and the revised thresholds will be automatically incorporated into the BES Definition if the language we suggest is used. The thresholds used in the SCRC would only be a fall-back, to be used only until Phase II is completed. Third, the definitions can be incorporated into other parts of the BES Definition, which will add consistency and clarity. As noted in our answers to several of the questions below, the specific 75 MVA threshold is retained in several of the Exclusions and Inclusions, and we believe the industry would be better served if the revised thresholds arrived at after technical analysis in Phase II are automatically incorporated into all relevant provisions of the BES Definition. There is no reason for the SDT to continue to rely on the 75 MVA threshold once the analysis planned for Phase II on the threshold issue is completed. Fourth, the phrase "or that meets the materiality threshold to be included in this definition" is intended to preserve the SDT's flexibility to make a determination that generators below a specific threshold are not "necessary to" maintain the reliability of the interconnected transmission system, and to incorporate that finding as part of the definition itself, even if a different threshold is used in the SCRC to identify potential candidates for registration. Accordingly, our proposed language makes clear that a specific threshold in the definition controls over any threshold that might be included in the SCRC. For the reasons stated above, we believe it is highly desirable to include any material threshold in the BES Definition itself rather than relegating the threshold to the SCRC, which is merely a procedural rule rather than a full-fledged Reliability

Standard. Finally, we agree with the SDT's decision to examine the question of where the line between BES and non-BES Elements should be drawn more closely in Phase II under the rubric of "contiguous vs. non-contiguous BES," and commend the work of the Project 2010-07 Standards Drafting Team and the GO-TO Team as a good starting point for the SDT's analysis on this issue. We understand Inclusion 2 would classify generators exceeding specific thresholds as part of the BES, but would not necessarily require facilities interconnecting such generators to be part of the BES. As discussed more fully in our answer to Question 9, based on extensive technical analysis that has already been performed by the NERC Project 2010-07 Standards Drafting Team and its predecessor, the NERC "GO-TO Team," regulating as part of the BES a dedicated interconnection facility connecting a BES generator to the interconnected bulk transmission grid will result in an unnecessary regulatory burden that produces considerable expense for the owner of the interconnection facility with little or no improvement in bulk system reliability. We also believe the clauses at the end of Inclusion 2 are somewhat confusing and that greater clarity would be achieved by changing ". . . including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100 kV or above" so that the Inclusion covers transformers with terminals "connected at a voltage of 100 kV or above, including the generator terminal(s) on the high side of the step-up transformer(s) if operated at a voltage of 100 kV or above."

Yes

CLPD supports the removal of the Cranking Path language in I3. As noted in our response to Question 9, there is no reason to classify as BES the facilities interconnecting a BES generator to the bulk interstate system. A Cranking Path is simply a specific type of such an interconnection facility.

Yes

CLPD supports the revised language generally, but believes additional changes would make the language clearer. Specifically, we believe Inclusion 4 should not incorporate a hard 75 MVA generation threshold (i.e., "resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)"). Instead, we urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," which is discussed in more detail in our response to Question 3. This language, or some equivalent, will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. More generally, we are not certain what is accomplished by Inclusion 4 that is not already accomplished by Inclusion 2, which also addresses whether generation should be defined as BES. The SDT's stated concern is with variable generation units such as wind and solar plants. It is not clear to us why this concern is not fully addressed in Inclusion 2, which addresses multiple generation units connected at a common bus, the configuration of most variable generation plants with multiple units. We are also concerned that the language, as proposed, could have unintended consequences and improperly classify local distribution systems as BES in certain circumstances. This is because multiple distributed generation units could render a local distribution system a "collector system" and the entire system the equivalent of an aggregated generation unit, causing the local distribution system to be improperly denied status as a LN. If many different distributed generation units are connected to a local distribution system, it is very unlikely that more than a few of those units would fail simultaneously, and it is therefore unlikely that multiple generation units would produce a measureable impact on the interconnected bulk transmission system, especially if the units individually do not otherwise exceed the materiality threshold to be established by the SDT in Phase II. Further, we are concerned that, if small distributed generation units become the industry norm, Inclusion 4 could unintentionally sweep in local distribution systems, especially where local policies favor the growth of small solar or other renewable generation systems for public policy reasons. Finally, we suggest that the SDT add the phrase ". . . unless the dispersed power producing resources operate within a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2." This language, which parallels the language included at the end of Inclusion I1, would make clear that dispersed small-scale generators scattered throughout a Radial System or Local Network serving retail load would not convert the Radial System or Local Network into a BES system, even if the aggregate capacity of those small generators exceeds the relevant threshold.

No

CLPD has several concerns about the new language in Inclusion 5. First, because Reactive Power devices produce power, they are "power producing resources" and we therefore believe Inclusion 5 is duplicative of Inclusion 4, which addresses "power producing devices." Second, there is no capacity

threshold specified in Inclusion 5 for Reactive Power devices that would be considered part of the BES. This is inconsistent with the approach taken in the balance of the definition, where thresholds are specified for generators and other types of power producing devices. Finally, CLPD believes the appropriate threshold for inclusion or exclusion of Reactive Power devices from the BES should be subject to the same technical analysis that will cover generators in the Phase II process.

Yes

CLPD continues to support the radial system exclusion, which is necessary as a legal matter, because, for example, FERC in Orders No. 743 and 743-A has required that the existing radial exemption in the NERC Statement of Compliance Registry Criteria be maintained. As a practical matter, radial systems are used for service to retail loads, usually in remote or rural areas, and not for the transmission of bulk power. Hence, operation of the radials has little or nothing to do with the reliable operation of the interconnected bulk transmission network. We also support the inclusion of the note discussing normally open switches because this language provides needed clarity for a common radial system configuration. We also agree with the substantive thrust of this language, which is that a radial system should not be considered part of the BES if it is interconnected at a single point, even if there is an alternative point of delivery that is normally open. While we support the Exclusion for Radial Systems, we believe several clarifications and refinements are necessary. (1) The term "transmission Elements" in the initial paragraph should be changed to "Elements." Radial systems are not transmission systems and including the word "transmission" in the Radial System exclusion is therefore unnecessary and confusing. (2) Subparagraph (b) of Exclusion 1 refers to "generation resources . . . with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)". We urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," discussed in more detail in our response to Question 3. This language, or some equivalent, will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. (3) Subparagraph (b) also seems to assume that if a Radial System contains a generator exceeding the 75 MVA threshold, the Radial System itself must be included in the BES because it links the generator to the interconnected bulk transmission system. As discussed more fully in our response to Question 9, below, NERC's Project 2010-17 Standards Drafting Team and GO-TO Task Force have both concluded that this assumption is unwarranted. (4) The "Note" as drafted by the SDT indicates that "a normally open switching device between radial systems" will not serve to disqualify the Radial from exclusion under Exclusion 1. As noted above, CLPD strongly supports the note conceptually. However, we believe this language should be included in a separate subparagraph (d), rather than a note, because treatment as a "note" suggests it is less important than other portions of the Exclusion. We also suggest the language be changed to read: (d) Normally-open switching devices between radial elements as depicted and properly identified on system one-line diagrams does not affect this exclusion. This will make clear that a radial with more than one normally-open switch connecting it to another radial is still a radial. From the perspective of the BES Definition, the key question is whether switches operating between Radials are normally open, not whether there is more than one normally-open switch.

Yes

CLPD supports the revised language. The language provides clarity regarding the BES status of customer-owned cogeneration facilities. However, CLPD urges the SDT to remove the reference to the 75 MVA threshold and replace it with the defined term "Qualifying Aggregate Generation Resources" or some equivalent language for the reasons stated in our responses to Questions 3, 5, and 7. In addition, we are concerned that Exclusion 2 will place local distribution utilities in a difficult position because, under Exclusion 1 or Exclusion 3 as drafted, they could lose their status as a Radial System or a Local Network through the actions of a customer constructing behind-the-meter generation. With respect to Radial Systems, the appearance of behind-the-meter generators could cause the Radial System to exceed the thresholds specified in subparagraphs (b) and (c) of Exclusion 1 through no fault of the Radial System owner. Similar, a Local Network could lose its status because behind-the-meter generation could be of sufficient size that power moves into the interconnected grid in certain hours or under certain contingencies, rather than moving purely onto the Local Network, as required in subparagraph (b) of Exclusion 3. The Exclusions for Radial Systems and Local Networks should be made consistent with the Exclusion for behind-the-meter generation. There is no technical reason to believe the power flowing from a behind-the-meter customer-owned generator will have less impact on the bulk system than an equivalent-sized generator owned by a utility operating a Radial System

or LN.

Yes

CLPD strongly supports the categorical exclusion of Local Networks (“LNs”) from the BES. We believe the exclusion is necessary to ensure that the BES definition complies with the statutory requirement, discussed in our response to Question 1, to exclude all facilities used in the local distribution of electric power. LNs are, of course, probably the most common form of local distribution facility. Further, the conversion of radial systems to local distribution networks should be encouraged because networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. If the BES definition were to provide an exclusion for radials without providing a similar exclusion for LNs, however, it would discourage networking local distribution systems because of the significantly increased regulatory burdens faced by the local distribution utility if it elected to network its radial facilities. By placing radial systems and LNs on the same regulatory footing, the proposed definition will ensure that decisions about whether to network radial systems are made on the basis of costs and benefits to the retail customers served by those radials, and not on the basis of disparate regulatory treatment. Consumers will ultimately benefit from the path chosen by the SDT. CLPD also supports specific refinements made to the LN exclusion by the SDT in the current draft of the BES definition. In particular, CLPD supports the clarification of the purposes of a LN. The current draft states that LNs connect at multiple points to “improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system.” Clallam supports this change in language because it reflects the fundamental purposes of a LN and emphasizes one of the key distinctions between LNs and bulk transmission facilities, namely, that LNs are designed primarily to serve local retail load while bulk transmission facilities are designed primarily to move bulk power from a bulk source (generally either the point of interconnection of a wholesale generator or a the point of interconnection with another bulk transmission system) to one or more wholesale purchasers. CLPD believes further improvement of the language could be achieved with additional modifications and clarifications. With respect to the core language of Exclusion 3, we believe the language making a “group of contiguous transmission Elements operated at or above 100 kV” the starting point for identifying a LN would be improved by deleting the term “transmission” from this phrase. This is so because LNs are not used for transmission and the use of the term “transmission Elements” is therefore both confusing and unnecessary. There would be no room for argument about what the SDT intended by including the word “transmission” if the word is deleted and the Exclusion applies to any “group of Elements operated at 100 kV or above” that meets the remaining requirement of the Exclusion. Further, any definitional value that is added by using the term “transmission Elements” is accomplished by using that term in the core definition, and there is no reason to carry the term through in the Exclusions. CLPD also believes that subparagraphs (a) and (b) are redundant in the sense that whatever protection is offered by the generation limit in subparagraph (a) is duplicated by the limit in subparagraph (b) requiring no flow out of the LN. We believe the SDT can eliminate subparagraph (a) of Exclusion 3 and simply rely on subparagraph (b) because if power only flows into the LN even if it interconnects more than 75 MVA of generation, the interconnected generation interconnected will have no significant interaction with the interconnected bulk transmission system. It will only interact with the LN. And, with the advent of distributed generation, it is easy to foresee a situation in which a large number of very small distributed generators are interconnected into a LDN, so that the aggregate capacity of these generators exceeds 75 MVA. However, because the generators are small and dispersed and, under the criterion in subparagraph (b), would be wholly absorbed within the LN rather than transmitting power onto the interconnected grid, those generators would not have a material impact on the grid. We also suggest that subparagraph (b) of Exclusion 3 could be more clearly drafted. Subparagraph (b), as part of the requirement that power flow into a LN rather than out of it, includes this description: “The LN does not transfer energy originating outside the LN for delivery through the LN.” We understand this language is intended to distinguish a LN from a link in the transmission system – power on a transmission link passes through the transmission link to a load located elsewhere, while power in a LN enters the LN and is consumed by retail load within the LN. While we agree with the concept proposed by the SDT, we believe the language would be clearer if it read: “The LN does not transfer energy originating outside the LN for delivery through the LN to loads located outside the LN.” We believe the italicized language is necessary to distinguish between a transmission system, where power that originates outside a system is delivered through the system and passes through the system to a sink located somewhere outside the system, from a LN, in which power originating outside the LN passes through the LN and is delivered to retail load within the LN. To put it another

way, the italicized language helps distinguish a transmission system from an LN, in which the LN "transfers energy originating outside the LN for delivery through the LN to loads located within the LN." We also believe the language of subparagraph (a) of Exclusion 3 could be improved. Subparagraph (d) would make LNs part of the BES if they interconnect "non-retail generation greater than 75 MVA (gross nameplate rating)." For the reasons stated in our responses to Questions 3, 5 and 7, we urge the SDT to replace the reference to a hard 75 MVA threshold with the defined term "Qualifying Aggregate Generation Resources" or some equivalent. We are also uncertain what is meant by the use of the term "non-retail generation" in subparagraph (a). From context, we believe the SDT considers "non-retail generation" to be the equivalent of generation that is located behind the retail meter, usually but not always owned by the customer and used to serve the customer's own load. We therefore suggest that the SDT replace the term "non-retail generation" with "generation located behind the retail customer's meter." Similarly, we are unsure what is meant by the phrase "the LN and its underlying Elements." We believe the phrase "and its underlying Elements" could simply be deleted from the definition without loss of meaning. In the alternative, the SDT might consider using the phrase "the LN, including all Elements located on the distribution side of any Automatic Fault Interrupting Devices (or other points of demarcation) separating the LN from the bulk interstate transmission system." We believe this phrase more accurately reflects the SDT's intent, which appears to be that generation exceeding 75 MVA in aggregate capacity interconnected anywhere within the LN disqualifies that LN from being excluded from the BES under Exclusion 3. Finally, CLPD believes that both subparagraphs (a) and (b) of Exclusion 3 could be safely eliminated as long as subparagraph (c) is retained. Subparagraph (c) makes a LN part of the BES if it is classified as a Flow Gate or Transfer Path. Flow Gates and Transfer Paths are, by definition, the key facilities that allow reliable transmission of bulk electric power on the interconnected grid. If a LN has not been identified as either a Flow Gate or a Transfer Path, it is unlikely the LN is necessary for the reliable transmission of electricity on the interconnected bulk system. Apart from these specific improvements that we believe could be achieved by modifying the language of Exclusion 3, we believe the SDT may need to re-examine certain assumptions that appear to underlie the current draft. Specifically, subparagraph (a) suggests that if BES generation is embedded within a LN, the LN itself must also be BES. But two NERC bodies have already addressed similar questions and concluded there is no technical basis for such concerns. NERC's Standards Drafting Team for Project 2010-07 and its predecessor, the "GO-TO Task Force" were formed to address how the dedicated interconnection facilities linking a BES generator to high-voltage transmission facilities should be treated under the NERC standards. The GO-TO Team concluded that by complying with a handful of reliability standards, primarily related to vegetation management, reliable operation of the bulk interconnected system could be protected without unduly burdening the owners of such interconnection systems. Therefore, there is no reason, according to the GO-TO Team, that dedicated high-voltage interconnection facilities must be treated as "Transmission" and classified as part of the BES in order to make reliability standards effective. See Final Report from the NERC Ad Hoc Group for Generator Requirements at the Transmission Interface (Nov. 16, 2009) (paper written by the GO-TO Task Force). Similarly, the Project 2010-07 Team observed that interconnection facilities "are most often not part of the integrated bulk power system, and as such should not be subject to the same level of standards applicable to Transmission Owners and Transmission Operators who own and operate transmission Facilities and Elements that are part of the integrated bulk power system." White Paper Proposal for Information Comment, NERC Project 2010-07: Generator Requirements at the Transmission Interface, at 3 (March 2011). Requiring Generation Owners and Operators to comply with the same standards as BES Transmission Owners and Operators "would do little, if anything, to improve the reliability of the Bulk Electric System," especially "when compared to the operation of the equipment that actually produces electricity – the generation equipment itself." Id. We believe that interconnection of BES generators within a LN is analogous and that, based on the findings of the Project 2010-07 and GO-TO Teams, automatically classifying a LN as "BES" simply because a large generator is embedded in the LN will result in substantial overregulation and unnecessary expense with little gain for bulk system reliability. If anything, generation interconnected through a LN is less likely to produce material impacts on the interconnected bulk transmission system than the equivalent generator interconnected through a single dedicated line because an LN is interconnected to the bulk system at several points, so that if one interconnection goes down, power can still flow from the BES generator to the bulk system on other interconnection points. Where a dedicated interconnection facility is involved, by contrast, if the interconnection line fails, the generator is unavailable to the interconnected bulk system. Similarly, we suggest that the SDT re-examine the

assumptions underlying subparagraph (b), which seems to suggest that a local distribution system cannot be classified as a Local Network if power flows out of that system at any time, even if the amount is de minimis, the outward flow is only for a few hours a year, or the outward flow occurs only in an extreme contingency. Accordingly, we suggest that the initial clause of subparagraph (b) be revised to read: "Except in unusual circumstances, power flows only into the LN."

Yes

Yes, CLPD supports the revised language because retail reactive devices are used to address local customer or retail voltage issues, rather than voltage issues on the interconnected bulk grid, and such local devices should therefore be excluded from the BES definition.

No

CLPD extends its thanks to the SDT and to the many industry entities that have actively participating in the Standards Development Process. CLPD strongly supports the current draft and believes, with certain refinements discussed in our comments, that the definition will serve the industry and reliability regulators well for many years to come. In addition, as noted earlier, CLPD is encouraged that the 20/75 MVA generation thresholds referred to in the NERC Statement of Compliance Registry Criteria, which have been relied upon by the SDT largely as a matter of necessity, will be reviewed and a technical assessment will be performed to identify the appropriate generation unit and plant size threshold to ensure a reliable North America. Finally, we understand that the Rules of Procedure Team will continue to move forward with developing an Exceptions Process that will complement the BES Definition and ensure that, to the extent the BES Definition is over-inclusive, facilities that should not be classified as BES will be excluded from the BES. Because the Exceptions Process is integral to a workable BES Definition, we support the current process for moving forward with the Exceptions Process and the BES Definition on parallel paths. We note that CLPD specifically supports the changes made by the SDT in the "Effective Date" provision of the BES Definition, which shortens the effective date of the new definition to the beginning of the first calendar quarter after regulatory approval (as opposed to the first calendar quarter twenty-four months after regulatory approval), with a 24-month transition period. CLPD supports this conclusion because it will allow entities seeking deregistration under the terms of the new BES definition to obtain the benefits of the new definition without an unreasonable wait, while allowing any entities that may be newly-classified as BES owners or operators sufficient time to come into compliance with newly-applicable Reliability Standards. CLPD also supports the 24-month transition period for the reasons laid out by the SDT.

NV Energy

Yes

The core definition is simpler than the prior version. We support the addition of the last sentence regarding the exclusion of facilities used in the local distribution of electric energy.

Yes

The changes made to I1 (Transformers) appropriately resolves several of the industry concerns about three-winding transformers as well as an inadvertent use of the word "and" rather than "or".

No

While we do not agree with making specific reference and linkage to the generator thresholds of the SCRC, it is understood that a timely justification of any alternative threshold was not possible. It is of paramount importance that the subject of generation thresholds be addressed in subsequent development of this Definition. We are of the opinion that generation ought to be considered as a "user" of the BES, not necessarily a part of the BES, similar in concept to the way Load uses the BES. Using this concept, the BES would be restricted to the "wires" type facilities. Standards would nevertheless be applicable to generators that use the BES, so no gap in reliability would exist.

Yes

Yes

Yes

The SDT has appropriately captured the necessary inclusion of high voltage transmission reactive

resources.
Yes
There may be an opportunity to consolidate the sub-items of E1 into a single inclusion statement in order to simplify this exclusion designation. We propose the following replacement option: "E1 - Radial systems: A group of contiguous transmission Elements that emanates from a single point of connection of 100 kV or higher and serves any combination of load and/or generation, provided that the generation resources are not identified in Inclusion I3 and do not have an aggregate capacity of non-retail generation greater than 75 MVA (gross nameplate rating)."

Ian Grant
Tennessee Valley Authority
Yes
TVA agrees to the clarifying changes to the core definition in general; however, we maintain that 200kV and above is the correct bright line for the Bulk Electric System, and requests that the Phase 2 for the project use 200kV and above or develop a transmission voltage and/or an MVA threshold that is technically based.
Yes
TVA agrees in general with the revisions to the specific inclusions for transformers in I1; however, we believe the low side transformer voltage level should be 200kV or above, and requests that the Phase 2 for the project use 200kV and above or develop a transmission voltage and/or an MVA threshold that is technically based.
Yes
TVA agrees in general with the revisions to I2 for generation; however, we maintain that 200kV and above is the correct bright line for generation connected to the Bulk Electric System, and requests that the Phase 2 for the project use 200kV and above or develop a transmission voltage and/or an MVA threshold that is technically based.
No
TVA agrees with the changes but believe clarity would be added by changing the word "identified" to "designated".
Yes
No
TVA feels that this inclusion should be limited to dynamic devices with an aggregate capacity greater than 75 MVAR (gross aggregate nameplate rating) connected through a common point at a voltage of 200kV or above, and requests that the Phase 2 for the project use 75 MVAR connected at 200kV or above or develop a transmission voltage and/or an MVAR threshold that is technically based.
Yes
TVA suggests the wording "non-retail generation" should be clarified with an explanation of why it is used in this exclusion.
No
Clarification needs to be provided for what is meant by E2 (ii), regarding generation on the customer's side of the retail meter; otherwise we have trouble developing a position on this question.
No
TVA would agree with the exclusion if the wording of the exclusion includes the following phrase (in

italics) added at the end of E3 b): "Power flows only into the LN: The LN does not transfer energy originating outside the LN for delivery through the LN under normal operating conditions; and"
Yes
Yes
The definition of the BES is referenced in several existing standards and the Statement of Compliance Registry Criteria. TVA is concerned with this revised definition's impact on entity registrations, i.e., how will the revised definition be integrated into the Compliance Registry Criteria. The implementation plan should include how the integration is going to occur. The 24 month period for new facilities that are to become BES elements as a result of this definition is very important to successful implementation of the definition. An period shorter that 24 months would be very problematic for the industry.

Reference to NERC Statement of Compliance Registry Criteria (SCRC) needs to be eliminated from the BES Definition. This circularity must be eliminated. Proposed revised language is: "12 - Generating resource(s) with a gross individual nameplate rating greater than 20 MVA or with a gross aggregate nameplate rating greater than 75 MVA including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100 kV or above."

Springfield Utility Board
Yes
SUB particularly agrees with the addition of, "This does not include facilities used in the local distribution of electric energy." to the BES draft definition.
Yes
SUB supports and appreciates the change in language from, "unless excluded under Exclusions E1 and E3" to "Exclusion E1 or E3". This makes it clear that Radial System or Local Network transformers should not be considered BES facilities, regardless of operating voltage.
No SUB comment as this is not currently applicable to SUB's operations.
No SUB comment as this is not currently applicable to SUB's operations.
No SUB comment as this is not currently applicable to SUB's operations.
Yes
SUB agrees in general, but does not agree that ALL reactive resources should be automatically included in the BES Definition. For example, is a local network (100 kV or above), which is otherwise excluded, but has a reactive device used for power factor correction (100 kV or above), still excluded? There are a significant number of reactive resources that are used to serve systems that provide service primarily to load, with either no or a minimal amount of generation. If this section is included, the Exclusion language needs to be modified to exclude those reactive resources from the BES that are radial serving only load or local networks that serve load (with less than 75MVA of generation). SUB does not agree with the language referring to only those "retail customer" reactive power devices for Exclusion E.4. This is too narrow and does not accurately reflect the use of reactive power devices installed by registered entities when retail customers do not "fix" their reactive power issues on their own. SUB recommends that the language in I5 and E4 be consistent, and that "retail customer" should include Registered Entities as well as end users. This present language is overly broad and, absent modifications to the BES definition, will generate a significant amount of paperwork. SUB suggests the following language change: I5 –Static or dynamic devices dedicated to supplying or absorbing Reactive Power that: a)are connected at 100 kV or higher and are not part of a radial system or area network that are excluded from the BES, or; b)are connected through a dedicated transformer with a high-side voltage of 100 kV or higher and are not part of a radial system or area network that are excluded from the BES, or; c)are connected through a transformer that is designated in Inclusion I1 and are not part of a radial system or area network that are excluded from the BES .
Yes
SUB supports a radial system exclusion.
No SUB comments as this is not currently applicable to SUB's operations.
Yes
SUB strongly supports the exclusion of Local Networks from the BES. SUB particularly agrees with the addition of, "LN's emanate from multiple points of connection at 100 kV or higher to improve the level of service to customer Load and not to accommodate bulk power transfer across the interconnected system." language to the draft E3 Exclusion, as well as the LN characterization being more clearly defined. SUB is concerned that the E3 Exclusion does not specify that these power flows would be "under normal operating conditions" and specify if all power flow is considered. SUB recommends that unscheduled power flow should not be considered, but that it is applicable only to scheduled power flow. While SUB supports the exclusion of LNs from the BES, we believe there is additional work that needs to be done regarding the Local Network Exclusion Technical Justification. Without specific parameters, determining inclusions and exclusions will be left to the discretion of too many. This will create ambiguity and inconsistency of application.
Yes
Reactive power devices used to serve radial networks or Local Networks are often owned and operated by the registered entity (not the "retail customer") to address Area Network – wide reactive power issues. This language should read: "E4. Reactive power devices that are within a radial system excluded under E1 or within a local network excluded under E3" If the current draft language is left as it is, there will likely be a lot of unnecessary paperwork to exclude reactive power devices within radial system or local networks from the BES through the exclusion process. SUB suggests that the language in the E4 Exclusion be consistent with that in the I5 Inclusion.

Yes
When submitting BES Definition comments, SUB would suggest a “not-applicable”, “no-impact” or “abstain” option in addition to “yes” or “no”. In some cases, the draft language has no impact on an entity’s system, yet that entity’s selection of “yes” or “no” may imply agreement or disagreement rather than expressing lack of applicability. This could skew the perception of agreement or disagreement, and create a potential issue for those who are directly impacted by the changes.
Individual
Kerry Wiedrich
Mission Valley Power
Yes
Mission Valley Power - We agree with the changes. We must point out that the overall flow, or how one proceeds through the inclusions and exclusions is not clear. Can an item that meets an inclusion be subsequently excluded? If so, this needs to be explicitly stated. So far, we only have the flow chart produced by the ROP team that indicates otherwise ( <a href="http://www.nerc.com/docs/standards/sar/20110428_BES_Flowcharts.pdf">http://www.nerc.com/docs/standards/sar/20110428_BES_Flowcharts.pdf</a> ). This was made evident by the question at the 9/28 webinar regarding an I5 capacitor on an E3 local network. The questioner thought the capacitor was BES per I5, but the answer was that it was excluded per E3. We can find no support for the answer given. The listing of specific exclusions within I1 (exception proves the rule) argues for questioner’s stance that the capacitor is BES as written. Also, if included items could subsequently be excluded, they would be no different from any other item that met the voltage threshold of 100kV. There would be no need for any of the inclusions if all possible outputs from the inclusion tests go to the same exclusion test inputs. We strongly support the addition of the language regarding local distribution facilities, as it matches congressional intent to leave the regulation of these facilities to state and local authorities.
Yes
Mission Valley Power - Comments: Mission Valley Power strongly agrees with this inclusion as written. It is consistent with the recent PRC-004 and PRC-005 interpretation and the NERC definition of Transmission. We believe the recent changes to this inclusion add clarity.
No
Mission Valley Power - Referencing the Criteria which in turn references the BES definition creates a circular definition. Mission Valley Power encourages the adoption of specific thresholds that are technically justified. We also note that the Criteria and its revisions do not go through the standards development process, so that thresholds may change with little warning and without triggering an implementation plan for facilities that may be swept into the BES as a result.
Yes
Mission Valley Power - We agree with the removal of the voltage language, since the inclusions and exclusions apply only to equipment over 100 kV.
Yes
Mission Valley Power agrees both with the inclusion and with the revised language. The revised language removes the need to provide a separate definition for “Collector System”.
No
Mission Valley Power - While we agree that reactive devices of sizable capacity connected at 100 kV or higher are needed for BES reliability, Mission Valley Power fails to see why this inclusion is needed as they are already captured by the 100 kV threshold. We would propose instead to eliminate this inclusion and substitute an exclusion for smaller capacity devices. If the SDT really believes an inclusion for reactive devices is needed, we suggest the SDT provide a technically justified capacity limit within the inclusion. In addition we suggest also including the phrase “...unless excluded under Exclusion E1, E2 or E4” similar to that in I1. Please see the answer to Q1 above Q10 below.
No
Mission Valley Power notes that a new term has been introduced, “non-retail generation,” with no definition provided. The answer to the question on this during the 9/28 webinar indicated that non-retail generation was behind the retail customer’s meter. We can see no reason why the net-metered PV systems should count toward the aggregate limit (exceeding the limit means no exclusion) while a non-blackstart thermal plant doesn’t (the radial system is excluded if any amount of load is present).

We have also heard the SDT meant just the opposite of what was stated in the webinar. We ask that a reasonable definition for non-retail be provided within the BES definition document. We strongly agree that radial systems should be excluded and that the presence of normally open switching devices between radial systems should not cause them to be considered non-radial. Such a result would cause the removal of these devices to the detriment of the local level of service. We note that the singular "A normally open switching device" is used and suggest that an allowance be made for the possibility of multiple devices. "Normally open switching devices..."

Yes

No

Mission Valley Power - : We strongly agree that local networks should be excluded, since they act much like the radial systems excluded in E1 while providing a higher level of service to customers. These networks should not be discouraged in the name of reliability. We again object to the introduction of the new confusing term "non-retail generation" with no definition provided.

No

Mission Valley Power - : We strongly agree that local networks should be excluded, since they act much like the radial systems excluded in E1 while providing a higher level of service to customers. These networks should not be discouraged in the name of reliability. We again object to the introduction of the new confusing term "non-retail generation" with no definition provided.

Yes

Mission Valley Power - In order to help meet the fast approaching target date, Mission Valley Power will be voting affirmative in this ballot, with the hope these comments will be addressed in Phase II. If the ballot should fail, please address these comments in this phase. Thanks to the team for their good work.

Puget Sound Energy

Yes

This draft of the definition is very much improved. We appreciate the work of the Standard Development Team and its efforts to increase the clarity of this important definition. For additional clarity, the first paragraph should read "Unless specifically excluded under the list of exclusions below or included or excluded through the Procedure for Requesting and Receiving an Exception from the Application of the NERC Definition of Bulk Electric System, all Transmission Elements operated at 100 kV or higher and Real Power and Reactive Power resources connected at 100 kV or higher, including those Transmission Elements described in the list of inclusions below." The sentence "This does not include facilities used in the local distribution of electric energy." should be removed from the first paragraph. Because this issue is specifically addressed in exclusions E1 and E3, the inclusion of this general sentence here is unnecessary and could even be ambiguous (raising the question of whether additional Transmission Elements might be excluded even if not described in E1 or E2).

Yes

Inclusion I1 references primary and secondary terminals of transformers, while Inclusions I2 and I5 reference the high-side of transformers. The SDT should consider using consistent terminology throughout the definition for this concept.

Yes

The term "per" should be replaced by "greater than the levels specified for a Generator Owner/Operator in". For a definition of this importance, the term "per" is too vague.

Yes

Yes

Yes

Yes

The language addressing generation resources in sections b and c of E1 could be more clear (an example of clearer language is section a of E3). At the least, the language in these two sections should be revised to read "... includes generation resources that are not identified in Inclusion I3 and that do not have an aggregate capacity exceeding 75 MVA ...".

• Please clarify the phrase "facilities used in local distribution" as used in the 'core' BES Definition. What is the purpose of this phrase in the BES Definition? How does the SDT propose that an entity demonstrate that a facility is used in local distribution? • Does this phrase "facilities used in local distribution" establish a jurisdictional boundary which takes precedence over all other parts of the BES Definition and Designations? • If this phrase does not take precedence over the remainder of the BES Definition and Designations, i.e., perhaps only over some parts BES Definition and Designations, or over none of the BES Definition and Designations, then what was the drafting teams understanding of and intent with regard to "facilities used in local distribution?" • What are Entities supposed to do with respect to "facilities used in local distribution" identified by State and Provincial regulators? • How has NERC assured that the posted BES Definition and Designations meet the intent of the Commission to establish an exemption process that avoids identifying "facilities used in local distribution" as part of the BES (¶37 and ¶39 below)? Recommendations: If "facilities used in local distribution" are to be excluded on jurisdictional grounds, then • The last sentence in the Core definition should be revised as follows: "This does not include facilities used in the local distribution of electric energy, as identified by a jurisdictional governmental authority." • We strongly recommend that the BES SDT adopt the FERC Seven Factor test as a proven basis for establishing the boundary between jurisdictional Transmission and non-jurisdictional "facilities used in local distribution." Supporting Discussion: In FERC Order 743-A the Commission stated 69. We agree ... that the Seven Factor Test could be relevant and possibly is a logical starting point for determining which facilities are local distribution for reliability purposes" By adopting this FERC Seven Factor test, the BES SDT will have fulfilled its obligation to respond to these FERC mandates relating to "local distribution" as stated in FERC Order 743: "Determining where the line between 'transmission' and 'local distribution' lies," (¶37), "To the extent that any individual line would be considered to be local distribution, that line would not be considered part of the bulk electric system" (¶39), to establish "[A] means to track and review facilities that are classified as local distribution to ensure accuracy and consistent application of the definition" (¶119). Supporting References: FERC Order 743 observed some believe that "the Commission's [and by extension NERC's] proposal exceeds its jurisdiction by encompassing local distribution facilities that are not necessary for operating the interconnected transmission network." [FERC Order 743, ¶27.] In this regard FERC Order 743 states: At ¶37, Congress specifically exempted "facilities used in the local distribution of electric energy" from the definition. ... Determining where the line between "transmission" and "local distribution" lies, which includes an inquiry into which lower voltage "transmission" facilities are necessary to operate the interconnected transmission system, should be part of the exemption process the ERO develops. And at ¶39, To the extent that any individual line would be considered to be local distribution, that line would not be considered part of the bulk electric system. And at ¶119, ... [W]e believe that it would be beneficial for the ERO in maintaining a list of exempted facilities, to consider including a means to track and review facilities that are classified as local distribution to ensure accuracy and consistent application of the definition. Similarly, the ERO could track exemptions for radial facilities. [Emphasis added] Note that in ¶119 the Commission clearly distinguishes between "radial facilities" and "local distribution" just as it

differentiates between jurisdictional radials and non-jurisdictional local distribution facilities in footnote 82: 82 As discussed further below, the Commission uses the term "exclusion" herein when discussing facilities expressly excluded by the statute (i.e., local distribution) and the term "exemption" when referring to the exemption process NERC will develop for use with facilities other than local distribution that may be exempted from compliance with the mandatory Reliability Standards for other reasons. FERC Order 743-A suggests: 69. We agree with Consumers Energy, Portland General and others that the Seven Factor Test could be relevant and possibly is a logical starting point for determining which facilities are local distribution for reliability purposes ..."

No

We suggest using wording from the Statement of Compliance Registry Criteria: Any generator regardless of size which is material to ... [Ref: Statement of Compliance Registry Criteria, III.c.3-Blackstart] Define "material to" as a generator listed as a necessary part of the TOP-defined minimum system to restore the BES. This term "material to" should exclude Blackstart-capable generators not necessary for BES restoration or only used for local distribution system restoration. Wording Recommendation: Following the words "identified in" add the words "and material to" so that the new Inclusion reads: 13 - Blackstart Resources identified in and material to the Transmission Operator's restoration plan.

No

Normally, static and dynamic devices supply Reactive Power (VARs) to or absorb VARs from the surrounding system. By their nature, VARs do not travel far, e.g., miles. So, VARs by their nature only produce local impacts. Please explain the meaning of the phrase "dedicated to supplying or absorbing Reactive Power," with emphasis on explaining why the term "dedicated" was employed? How does an Entity determine if a particular static or dynamic device is "dedicated" to the BES? What Guidance documents can the BES SDT provide describing "dedicated" static and dynamic devices?

Yes

Please define the term "non-retail generation."

Yes

Con Edison shares the concerns raised by the State of New York Department of Public Service (NYPSC) in its September 12, 2011 letter to NERC Chairman Anderson. The NYPSC expressed concern that the proposed BES Definition "would impose significant costs, costs that New York ratepayers will be expected to bear, with little or no increase in reliability benefits." The BES definition is being revised without an assessment of costs or benefits. The SDT is encouraged to work with NERC Staff to perform such an assessment prior to providing the revised BES definition to the NERC Board. Regional Entities share this concern with cost effectiveness. In NPCC, the Board of Directors directed NPCC Staff to develop a methodology to assess the cost and benefit of Standards. This NPCC Cost Effectiveness Analysis Procedure (CEAP) establishes a process to address those concerns. The CEAP introduces two assessments of the estimated industry-wide costs of requirements into that Standard's development process. The procedure adds supporting information and background for the NPCC stakeholders, ballot body and the NPCC Board of Directors. Moreover, during a 2010 FERC technical conference the Commission recognized that "reliability does not come without cost." As a result, significant interest was expressed in development of a process to identify the costs for draft reliability Standards and the ability of the proposed standards to achieve the reliability objective(s) sought in a cost effective manner. We understand that it is a NERC priority to define adequate level of reliability and use it as the basis for determining the cost effectiveness of a proposed rule. While this has not yet been finalized, NERC could use this proposed standard as a test case for determining the relationship between costs and benefits.

Tillamook PUD
Yes
We strongly support the addition of the language regarding local distribution facilities, as it matches congressional intent to leave the regulation of these facilities to state and local authorities.
Yes
Tillamook PUD strongly agrees with this inclusion as written. It is consistent with the recent PRC-004 and PRC-005 interpretation and the NERC definition of Transmission. We believe the recent changes to this inclusion add clarity.
No
Referencing the Criteria which in turn references the BES definition creates a circular definition. Tillamook PUD encourages the adoption of specific thresholds that are technically justified. We also note that the Criteria and its revisions do not go through the standards development process, so that thresholds may change with little warning and without triggering an implementation plan for facilities that may be swept into the BES as a result.
Yes
Tillamook PUD agrees with the removal of the voltage language since the inclusions and exclusions only apply to equipment over 100 kV.
Yes
Tillamook PUD agrees both with the inclusion and with the revised language. The revised language removes the need to provide a separate definition for "Collector System".
No
While we agree that reactive devices of sizable capacity connected at 100 kV or higher are needed for BES reliability, Tillamook PUD fails to see why this inclusion is needed as they are already captured by the 100 kV threshold. We would propose instead to eliminate this inclusion and substitute an exclusion for smaller capacity devices. If the SDT really believes an inclusion for reactive devices is needed, we suggest the SDT provide a technically justified capacity limit within the inclusion. In addition we suggest also including the phrase "...unless excluded under Exclusion E1, E2 or E4" similar to that in I1.
No
Tillamook PUD notes that a new term has been introduced, "non-retail generation," with no definition provided. The answer to the question on this during the 9/28 webinar indicated that non-retail generation was behind the retail customer's meter. We can see no reason why the net-metered PV systems should count toward the aggregate limit (exceeding the limit means no exclusion) while a non-blackstart thermal plant doesn't (the radial system is excluded if any amount of load is present). We have also heard the SDT meant just the opposite of what was stated in the webinar. We ask that a reasonable definition for non-retail be provided within the BES definition document. We strongly agree that radial systems should be excluded and that the presence of normally open switching devices between radial systems should not cause them to be considered non-radial. Such a result would cause the removal of these devices to the detriment of the local level of service. We note that the singular "A normally open switching device" is used and suggest that an allowance be made for the possibility of multiple devices. "Normally open switching devices..."
Yes
No
We strongly agree that local networks should be excluded, since they act much like the radial systems excluded in E1 while providing a higher level of service to customers. These networks should not be discouraged in the name of reliability. We again object to the introduction of the new confusing term "non-retail generation" with no definition provided.
No
Any device that might be excluded under E4 has already been included per I5. Unless I5 is removed, or rewritten as suggested above; this exclusion will exclude nothing.
Yes
If Tillamook PUD had signed up to ballot in time, we would be voting yes with the hope that these

comments would be addressed in Phase II. If the ballot fails, please address these comments in this phase.

Yes

No

AEP is a proponent of cross-referencing related documents to avoid elements from becoming out of sync, however, rather than having the BES Definition document reference the ERO Statement of Compliance Registry Criteria, perhaps it should be the other way around. This definition document undergoes a more thorough industry development and review process. The ERO Statement of Compliance Registry Criteria does not get specific in regards to device types. The BES Definition document is a more appropriate place to designate inclusion criteria.

Yes

No

We believe more clarity is needed as to where exactly the "common point" is, for example in the case of a wind farm. This first common point could be interpreted as the output voltage of the wind generator, would be less than the 100kv threshold and thereby could (unintentionally?) exclude the facility as a whole. If this was unintentional, we recommend rewording I4 in a manner similar to I2.

No

I5 only specifies voltage limits, and makes no mention of reactive limits. We suggest that the drafting team consider adding reactive capacity to these criteria as well.

No

AEP supports the concept of the exclusion of radial systems, however further clarification is needed regarding whether or not the source equipment is included as part of the radial system (for example, ring bus or breaker and a half bus configurations). Regarding the following text: "Note – A normally open switching device between radial systems, as depicted on prints or one-line diagrams for example, does not affect this exclusion." We interpret this as not including two radial lines which could be tied together through a normally open switch, are we correct? Additional clarity may be needed regarding this note.

No

It appears an entity with less than 75 MVA would not have been included as part of the earlier inclusions. Is it necessary to note this threshold once again in the exclusion section? Might it be possible to add some of the "behind the meter load" to the inclusion section to reduce the amount of both the inclusions and exclusions? Doing so would likely provide more clarity to the standard.

Yes

No

Does this refer to distribution level or reactive power resources? If so, it would appear these are not included as part of I5. Or instead, does this refer to customer equipment at BES voltages? If it is the latter, we recommend E4 be reworded to state "Reactive Power devices that meet the Inclusion criteria of I5 that are owned and operated by the retail customer solely for its own use..."

Yes

There needs to be some clarification regarding the default status of an asset, as well as the order and priority of the inclusion and exclusion classifications within the definition. First, prior to any evaluation by virtue of the definition, is an asset by default excluded from the BES, or rather, it is included? In addition, once the definition is used to evaluate an asset which has both inclusion attributes and exclusion attributes, which of the two classifications has greater weight? For example, if an asset is first included by the BES definition inclusion criteria can it then be excluded by BES definition

exclusion criteria? Or instead, if an asset is first excluded by BES definition exclusion criteria can it then be included by the BES definition inclusion criteria? AEP's recommendation is that an asset, by default, not be considered part of the BES. Next, the asset would be evaluated by the inclusion criteria as specified within the definition. Next, any asset explicitly included by the inclusion criteria is then evaluated using the exclusion criteria. Once the entity has made their determination based on the definition, exception requests could then be made to include or exclude assets as appropriate. We believe our interpretation is what is implied by the draft definition, however, this needs to be explicitly communicated within the definition itself.

Individual

Joe Petaski

Manitoba Hydro

Yes

Manitoba Hydro agrees in general with the changes made to the core definition but the sentence 'This does not include facilities used in the local distribution of electric energy' should be removed as it is covered under Exclusion E3 and reduces the clarity of the core definition.

Yes

Yes

No

Inclusion I3 should specifically state that only the Blackstart Resources specified through EOP-005-2 R1.4 are included in the BES since "Transmission Operator restoration plan" is not a NERC defined term. Suggested wording: "I3 - Blackstart Resources identified through EOP-005-2 R1.4"

Yes

Manitoba Hydro agrees with I4 but it does create a discrepancy between the BES Definition and the Registration Criteria Document. The Registration Criteria document should be updated and I2 and I4 should be combined into a single Inclusion.

Yes

Yes

Manitoba Hydro agrees with E1 but the wording of the note regarding 'normally open switching devices' is unclear. In the Industry Webinar on September 28th, the Drafting Team made it clear that the note means that if an element can be connected to the BES from multiple points but under normal operating conditions it is only connected to the BES at a single point by means of normally open switches, then the element is still excluded from the BES provided it meets either the E1 a, b, or c criteria. The team also noted that the discretion to operate the normally open switching devices in the best interests of reliability rests with the operating entity. Suggested wording: "Note: The ability to connect a group of contiguous transmission Elements from multiple connection points of 100kV or higher through normally open switching devices does not negate this Exclusion. " As well, part c) of E1 should be changed to "c) Only serves Load and includes..."

Yes

Manitoba Hydro agrees with E2 but suggests that the phrase 'A generating unit or multiple generating units' be replaced with 'Generating resource(s)' for clarity and consistency.

No

Manitoba Hydro agrees with the Local Network Exclusion but disagrees with the drafting team's removal of the requirement to have protective devices protecting the BES from the LN. We suggest that the following requirement is re-inserted into E3 to meet the LN Exclusion: "a) Wherever connected to the BES, the LN must be connected with a Protection System."

Individual
John A. Gray
The Dow Chemical Company
Yes
The Dow Chemical Company ("Dow) is an international chemical and plastics manufacturing firm and a leader in science and technology, providing chemical, plastic, and agricultural products and services to many essential consumer markets throughout the world. Dow and certain of its worldwide affiliates and subsidiaries, including Union Carbide Corporation, own and operate electrical facilities at a

number of industrial sites within the U.S., principally, in Texas and Louisiana. The electrical facilities at these various industrial sites are configured similarly and perform similar functions. In most cases, a tie line or lines connect the industrial site to the electric transmission grid. Power is delivered from the electric transmission grid to the industrial site through the tie line(s). Lines “behind-the-meter” within the industrial site then deliver power to individual manufacturing plants within the site. Additionally, cogeneration facilities, some of which are well over 75 MW in size, are located at a number of industrial sites owned by Dow and its subsidiaries. These cogeneration facilities generate power that is distributed within the industrial site and used for manufacturing plant operations. In some instances, excess power not required for plant operations is delivered back into the electric transmission grid through the tie line(s) connecting the industrial site to the grid. While the tie lines and some of the internal lines at these industrial sites operate at 100kV or higher, they do not perform anything that resembles a transmission function. Rather than transmit power long distances from generation to load centers, the tie lines and internal lines perform primarily an end user distribution function consisting of the distribution of power brought in from the grid or generated internally to different plants within each industrial site. In some cases, the facilities also perform an interconnection function to the extent they enable power from cogeneration facilities to be delivered into the grid. The voltage of the tie lines and internal lines at these industrial sites is dictated by the load and basic configuration of each site. Higher voltage lines are used when necessary to meet applicable load requirements or to reduce line losses. That does not mean that such lines perform a transmission function. At some sites, Dow is registered as a Generation Owner and Generation Operator. At other sites, the applicable Regional Entity has found that such registration is not required because of the relatively small amount of power supplied to the grid from the applicable cogeneration resources, even though those cogeneration resources have an aggregate capacity greater than 75 MVA (gross aggregate nameplate rating). Tie lines (to the grid) and internal lines at an industrial site that operate at 100kV or higher should be excluded from the BES definition if, due to the relatively small amount of power supplied to the grid from the generation resources at the site, the owner of those generation resources is not required to be registered as a Generation Owner and the operator of those generation resources is not required to be registered as a Generation Operator. At sites where the owner of the generation resources is registered as a Generation Owner and the operator of those generation resources is registered as a Generation Operator, the internal lines (between the generation resources and the manufacturing plants) that operate at 100kV or higher should be excluded from the BES definition, because they are distribution and not transmission facilities. The lines interconnecting the generation resources at such sites to the transmission grid should be included in the BES definition, but the owner and operator of such interconnection lines should not be registered as a Transmission Owner or Transmission Operator. In no instance has a Regional Entity determined that Dow or any subsidiary should be registered as a Transmission Owner or Transmission Operator. Instead, such interconnection lines should be considered as part of the generation resource and Generation Owners and Generation Operators should be subject to reliability standards specifically developed for such interconnection lines. Dow is strongly opposed to any BES definition that would result in either the tie lines or the internal lines at industrial sites being subject to the mandatory reliability standards applicable to Transmission Owners and Transmission Operators. Complying with reliability standards would cause Dow and its subsidiaries to incur substantial compliance costs and create potential exposure to penalties in the future for noncompliance. Perhaps such costs and exposure could be justified if subjecting these facilities to compliance with reliability standards resulted in a material increase in reliability of the BES, but there is no reason to believe that will be the case. In fact, the opposite might be true. The tie lines and internal lines at industrial sites owned by Dow and its subsidiaries have been operated for decades as end user distribution and interconnection facilities, and practices and procedures have developed over the years that have enabled such operations to achieve a high degree of reliability for such sites. Requiring these facilities to now operate in a different manner as transmission facilities may well result in a degradation of the reliability of the manufacturing plants located at such sites. For example, outages would have to be coordinated with the RTO, which may not be interested in coordinating such outages with scheduled manufacturing plant outages. In light of these considerations, Dow agrees with the proposed revisions to the core definition, particularly the proposal to include a sentence expressly excluding facilities used in the local distribution of electric energy, provided it is understood that end user-owned delivery facilities located “behind-the-meter” are, regardless of voltage level, presumptively outside the scope of this definition.

Yes

No
Comments: Dow agrees with the proposed revisions to Inclusion I2, particularly the proposal to expressly reference the ERO Statement of Compliance Registry Criteria, but the following phrase should be added at the end "unless excluded under Exclusion E2".
Yes
No
It is not clear how "Dispersed power producing resources" differ from "Generating Resource (s)" in I2. Inclusion I4 should clarify this. We suggest that the phrase "Variable Energy Resources" be used instead of "Dispersed power producing resources". Variable Energy Resources should be defined as "Resources producing electricity using wind or solar energy." The following phrase should be added at the end "unless excluded under Exclusion E2".
No
The phrase "or through a dedicated transformer with a high-side voltage of 100 kV or higher" is inconsistent with I1 and would bring Reactive Power Equipment that is lower than 100Kv into the BES definition. This phrase should be deleted. The following phrase should be added at the end "unless excluded under Exclusion E4".
Yes
Dow generally agrees with the proposed revisions to Exclusion E1, but believes that several additional clarifying revisions should be made. First, the phrase "a single point of connection" in the introductory sentence should be revised to read "a single point of connection (including multiple connections to the same ring bus or different buses where the energy normally flows in the same direction)". This revision is intended to ensure that radial systems include arrangements involving multiple parallel lines that are designed to operate as a single radial system, but that nevertheless connect at the grid ring bus or different buses on the grid for reliability. Second, for this same reason, an additional (i.e., second) note should be added to the end of Exclusion E1 that reads as follows: "Note, a normally closed switching device that enables multiple lines emanating from the same grid ring bus or different grid buses to operate as a single radial system does not affect this exclusion." Third, in "c)," the phrase "with an aggregate capacity of non-retail generation less than or equal to 75 MVA (gross nameplate rating)" is confusing and potentially inconsistent to the extent that "non-retail generation" may be different from "gross nameplate rating." The apparent intent of the clause is to exclude radial systems that serve both load and generation, provided the generation capacity made available to the transmission grid does not exceed 75 MVA. Dow would recommend that the phrase be revised to read "where the net capacity provided to the transmission grid does not exceed 75 MVA." This revision would provide greater clarity and is consistent with the language used in Exclusion E2.
Yes
Dow generally agrees with the proposed revisions to Exclusion E2, but believes that a clarifying revision should be made. Substitute "transmission grid" for "BES" in the phrase "provided to the BES" to insure that the measurement is to the grid.
Yes
Dow is uncertain whether end user-owned, behind-the-meter delivery facilities of the sort it has described above would fall within the scope of the core BES definition proposed by NERC. To date, none of the Regional Entities has suggested that Dow should register as a Transmission Owner or Transmission Operator with respect to any of these Dow-owned delivery facilities. If a literal application of the proposed BES Definition would, because of their voltage level or for any other reason, include such facilities, then Dow has an interest in assuring that the E3 exclusion for "local network" facilities is structured to embrace them. To that end, Dow would propose, first, the elimination of the 300 Kv cap for these facilities. Dow has systems that operate above 300 Kv due solely to the capacity of the lines to supply power over the distance required at our large manufacturing sites. Second, for the same reasons discussed above (in response to question #7), the phrase "do not have an aggregate capacity of non-retail generation greater than 75 MVA (gross nameplate rating)" in "a)" should be changed to "the net capacity provided to the transmission grid does not exceed 75 MVA." Third, the introductory phrase in "b)" -- "Power flows only into the LN" -- is inconsistent with the recognition in "a)" (as amended pursuant to Dow's above suggestion) that

power may flow out of an LN and into the transmission grid if there is generation connected to the LN and the 75 MVA limit is observed. Dow recommends either deleting the introductory clause or correcting it to read "Power is not transferred through the LN."

No

The term "solely" should be replaced by the term "primarily". All devices to control Reactive power behind-the-meter arguably provide some benefit to the transmission grid.

No

Group

Jonathan Hayes

Southwest Power Pool

No

The last sentence of the core states that no distribution facilities will be included, but some of these facilities could be included due to blackstart resources. We don't disagree with the idea of removing distribution facilities, but would like to see some clarification or qualifier.

Yes

Yes

Yes

No

We believe that the removal of the wording "single site" in I2 would remove the need to cover dispersed power producing resources in I4. What is the reason for keeping I4 in this version? Also we understand that 75MVA is held in I4 because of no direct link to the registry criteria, but feel that this number could change in phase two of the project which would create unnecessary work in the future.

No

We understand that this inclusion is used to capture those devices other than generation resources, but the language leads us to believe that it could include all generators used to supply or absorb reactive power. We would suggest that I5 be changed to read " -Static or dynamic devices specifically used for supplying or absorbing Reactive Power that are connected at 100 kV or higher, or through a dedicated transformer with a high-side voltage of 100 kV or higher, or through a transformer that is designated in Inclusion I1.

No

Why was the defined term for "T"ransmission dropped in this version of the definition? This should be kept in this version of the definition as well.

No

This number could change in phase two of the project which would create unnecessary work in the future.

Yes

No

This particular Exclusion doesn't address the qualifier as to the impact to the BES. We request that it emulate the language provided for E2 (behind the meter gen) and classified for this specific exclusion.

Yes

A reference needs to be made to the ROP changes which also provide a mechanism whereby Elements may be excluded/included in the BES. Without that reference the proposed definition does not completely include all means for exceptions/inclusions. We would suggest the definition be expanded to say "...modified by the list shown below or as provided by Appendix 5C of the NERC Rules of Procedure. We submitted this in the original posting and the response received was that it was inadvertently left out and that it would be placed back in. We don't see the reference in this draft of the definition.

Individual
Rick Hansen
City of St. George
Yes
The core definition is acceptable as long as the concerns for inclusion and exclusion are addressed as outlined in the other comments.
Yes
No
The basis for the Compliance Registry Criteria generation levels for inclusion seems to be arbitrary with little or no justification. As currently proposed, a small 20 MVA generator must comply with same requirements as large units of several hundred MVA of generation capacity. Phase 2 of the BES project may help address the issue but in the meantime many facilities must comply with numerous standards with little or no benefit to the reliability of the actual BES. No timeline for Phase 2 is indicated. Finding a bright line number for the generation levels on a per unit or overall plant basis will be a difficult task, but the present MVA levels of the Registration Criteria are very low for automatic inclusion. The compliance requirements of an entity should match the impact to the system.
Yes
No
This language follows the 75 MVA plant requirements from the Registration Criteria. See comments to question 3 (for I2) above. Additional detail is needed to clarify exactly at what point in the dispersed system the BES starts and what is not BES.
No
A reasonable minimum value for inclusion should be added. As presently written all static or dynamic devices would be included in the BES regardless of size.
No
Radial systems should be excluded as generally outlined in E1, however the generation levels (of 75 MVA) are too restrictive. The primary criteria should be, does power flow into the radial system? If there is always flow into the radial system, generation levels should not prevent exclusion from the BES.
No
Same basic comments and concerns as question #7.
No
The exclusion of Local Networks should be provided, however the generation level limits are too restrictive. As long as the power flow is into the system the generation level of the local network shouldn't matter as long as it is being used to serve local load. E3a should be deleted from the definition, or at least some higher level of allowed generation should be included. Another possibility would be a ratio of local load to local generation. Areas with local generation serving local load will have similar characteristics or affects to the BES system as were used in the Local Network justification paper (Appendix 1) included with the documents. If some reasonable level of local generation was added to the example system it is unlikely that the affects to the BES flows would change from what was presented in the example.
Yes
Yes
The small utility exclusion issues discussed in the first draft of the documents are not included (draft 1 proposed E4) nor addressed in the draft 2 documentation. Under the present definition many small utilities with local generation to serve its own local load will be required to register for additional functions, or at a minimum go through a long, expensive, time consuming process to get an individual exclusion from the BES. The topics that have been postponed to Phase 2 of the project are critical to and will have a direct impact to many utilities. Phase 2 needs to have specific shorter than normal

timelines established, similar to what Phase 1 has had. The present definition and standards in general makes little or no consideration for the actual impact of an entity or facility on the bulk system. As such small utilities with a few miles of 115 kV or 138 kV lines and some generation are required to meet the same requirements as large utilities with 100's or 1,000's of miles of 345 kV or 500 kV lines and that operate very large generation plants of several hundred MVA of capacity. All utilities support reliability improvement, but the requirements and associated costs need to match their actual impact to the overall system.

Frank Gaffney

Florida Municipal Power Agency

Yes

FMPA appreciates the SDT's work on this project. For the most part, FMPA supports what it believes to be the intent of the proposed language. The proposed specific exclusion of facilities used in the local distribution of electric energy is appropriate and consistent with Section 215 of the Federal Power Act. However, we have suggestions to better carry out what we believe to be the SDT's intent. The first sentence can be read as: "... all ... Real Power and Reactive Power resources connected at 100 kV or higher", which is surely not what the SDT intends. The basic problem is that Inclusions I2 and I4 do not modify the first sentence, e.g., from a set theory perspective, the set described by the first sentence includes the sets described in inclusions I2 and I4; hence, I2 and I4 do not modify the first sentence. From a literal reading, this would cause any size generator connected at 100 kV to be included, which is surely not the intent of the SDT. For similar reasons, the core definition and Inclusion I5 now has the effect of including all generators connected at 100 kV since a generator is a "dynamic device ... supplying or absorbing Reactive Power". The word "dedicated" in I5 is not sufficient in FMPA's mind to unambiguously exclude generators from this statement. FMPA suggests the following wording to address these issues: "Transmission Elements (not including elements used in the local distribution of electric energy) and Real Power and Reactive Power resources as described in the list below, unless excluded by Exclusion or Exception: a. Transmission Elements other than transformers and reactive resources operated at 100 kV or higher. b. Transformers with primary and secondary terminals operated at 100 kV or higher. c. Generating resource(s) (with gross individual or gross aggregate nameplate rating per the ERO Statement of Compliance Registry Criteria) including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100 kV or above. d. Blackstart Resources identified in the Transmission Operator's restoration plan. e. Dispersed power producing resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating) utilizing a system designed primarily for aggregating capacity, connected at a common point at a voltage of 100 kV or above, but not including generation on the retail side of the retail meter. f. Non-generator static or dynamic devices dedicated to supplying or absorbing more than 6 MVAR of Reactive Power that are connected at 100 kV or higher, or through a dedicated transformer with a high-side voltage of 100 kV or higher, or through a transformer that is designated in bullet 2 above."

Yes

Please see comments to Question 1

Yes

Please see comments to Question 1

Yes

Please see comments to Question 1

Yes

We recommend clarifying that the dispersed power resources covered by this inclusion do not include generators on the retail side of the retail meter. Specifically, we recommend that the Inclusion read: "Dispersed power producing resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating) utilizing a system designed primarily for aggregating capacity, connected at a common point at a voltage of 100kV or above, but not including generation on the retail side of the retail meter."

To help clarify and to avoid inclusion of de minimis reactive resources, we propose a size threshold of 6 MVAR consistent with the smallest size generator included in the BES at a 0.95 power factor, which is a common leading power factor used in Facility Connection Requirements for generators. In other

words, 6 MVAR is consistent with typically the least amount of MVAR required to be absorbed by the smallest generator meeting the registry criteria.

Yes

FMPA supports the exclusion of radial systems from the BES Definition. Such systems are generally not “necessary for operating an interconnected electric transmission network,” the standard in Orders 743 and 743-A. We have several suggestions to clarify the proposed language for this Exclusion. Proposed Exclusion E1 refers to “[a] group of contiguous transmission Elements that emanates from a single point of connection of 100 kV or higher.” We appreciate the SDT’s clarification of the point of connection requirement, but the term “a single point of connection” should be further defined (more clearly than just by voltage), and should be generic enough to encompass the various bus configurations. It is not the case, for example, that each individual breaker position in a ring bus is a separate point of connection for this purpose; in that situation, a bus at one voltage level at one substation should be considered “a single point of connection.” Some examples of configurations that should be considered a single point of connection for this purpose are at [https://www.frc.com/Standards/StandardDocs/BES/BESAppendixA\\_V4\\_clean.pdf](https://www.frc.com/Standards/StandardDocs/BES/BESAppendixA_V4_clean.pdf), Examples 1-6. Although the core definition (appropriately) refers to “Transmission Elements” (with a capital “T”), proposed Exclusion E1 refers to “transmission Elements” (with a lowercase “t”). To avoid confusion, either “Transmission” should be capitalized in both locations, or the word “transmission” should simply be deleted from Exclusion E1, leaving a “group of contiguous Elements.” We understand that the lack of capitalization may have been a deliberate choice by the SDT in an attempt to avoid confusion that SDT members believe exists in the Glossary definition. If the Glossary definition of Transmission is unclear—which FMPA does not necessarily believe is the case—the answer is not to simply abandon the Glossary definition in favor of an entirely undefined term; it is to submit a SAR to improve the Glossary definition. Exclusion E1(c) refers to “an aggregate capacity of non-retail generation less than or equal to 75 MVA.” “Non-retail generation” is potentially ambiguous, because it could be read as distinguishing between generation that will be sold at wholesale and generation that is used by the retail provider to meet retail load. On the understanding that the intent is in fact to describe generation behind the end-user meter, sometimes referred to as “behind-the-second-meter generation,” we suggest the following revision: “an aggregate generation capacity less than or equal to 75 MVA, not including generation on the retail customer’s side of the retail meter.” Exclusion E1 concludes with a “Note”: “A normally open switching device between radial systems, as depicted on prints or one-line diagrams for example, does not affect this exclusion.” The Note should not specify the types of evidence required to prove a normally open switch, and the phrase “as depicted on prints or one-line diagrams” should be deleted. This phrase is equivalent to a “Measure” in a standard and should not be embedded in the equivalent of a “Requirement.” Since the phrase only gives an “example,” it does not in fact add anything to the Note, but may lead to confusion over what sort of evidence is required.

Yes

Yes

: FMPA supports the exclusion of Local Networks from the BES. Such systems are generally not “necessary for operating an interconnected electric transmission network,” the standard in Orders 743 and 743-A. However, we have several suggestions to clarify the proposed language for this Exclusion. Exclusion E3(c) states: “Power flows only into the LN: The LN does not transfer energy originating outside the LN for delivery through the LN.” This statement is unclear because the two parts mean different things. FMPA proposes rewriting this sentence to state: “Power flows only into the LN, that is, at each individual connection at 100 kV or higher, the pre-contingency flow of power is from outside the LN into the LN for all hours of the previous 2 years” to help clarify the intent. Two years is suggested because it is the time period set out in the draft exception application form for which an applicant should state whether power flows through an Element to the BES. FMPA’ comments in response to Question 7 above regarding “points of connection at 100kV or higher” and “non-retail generation” are applicable to Exclusion E3 as well. The term “bulk power,” which occurs twice in Exclusion E3, is vague and could be read incorrectly as a reference to the statutorily-defined “bulk-power system,” which is not, we think, the SDT’s intent. The word “bulk” should be deleted, so that the Exclusion simply refers to transferring “power” across the interconnected system. FMPA raised this concern in response to the last posting of the BES Definition. In response, the SDT removed some instances of “bulk power” but left the remaining two, stating that “the SDT believes it provides

conceptual value to the exclusion principle." The SDT does not state what conceptual value the term is intended to provide; on the assumption that it relates to a distinction between transferring power from local generation to serve local load, and transferring power over longer distances, FMPA suggests, as an alternative to simply deleting the word "bulk," that the Exclusion be revised to refer to "transfers of power from non-LN generation to non-LN load."

Massachusetts Department of Public Utilities

No

The Massachusetts Department of Public Utilities ("MA DPU") appreciates the opportunity to provide comments on the second draft definition of the Bulk Electric System ("BES"). Massachusetts is the largest state by population and load in New England. It comprises 46% of both the region's population and electricity consumption. Generating plants located in Massachusetts represent 42% of New England's capacity and our capitol city, Boston, is the largest load center in the region. Some of the revisions since the last posting of the draft BES definition have improved the proposed language. However, the MA DPU has a number of concerns regarding both the substance of the definition and the process for developing this standard: 1) Phased Approach. While well-intentioned, separating the BES definition project into two separate phases is problematic from both a procedural and substantive perspective. While we recognize that the filing due date is rapidly approaching, the BES definition cannot be considered in a vacuum, divorced from the concerns raised by a number of parties in response to past postings of the BES definition. The issues NERC has identified for consideration during the proposed "Phase 2" are inseparable from the development of the BES definition (e.g., generation thresholds, technical justification for the 100 kV threshold) and should be squarely addressed before a definition is adopted and ratepayers incur costs related to compliance with mandates that may or may not be revised through the second phase of the project. The importance of considering concerns before adopting a definition is heightened by the proposed two-year implementation requirement. This short implementation period almost guarantees that entities will commit resources shortly after adoption of the definition to ensure compliance within the mandated period. In other words, ratepayers will bear costs related to compliance irrespective of any change resulting from the Phase 2 process or the exception process. Expediency, while understandable given the filing deadline, must be balanced against the risk that a multi-phased approach could lead to significant consumer costs without attendant meaningful reliability benefits. 2) Cost-Benefit Analysis. A cost impact analysis should be performed as part of developing any reliability standard. However, the development of the BES definition has failed to consider the cost impacts of the definition (and its inclusions and exclusions) and has not weighed these impacts against identified benefits that the definition would achieve. The MA DPU supported the May 21, 2011 comments from the New England States Committee on Electricity ("NESCOE") on the last posting of the BES definition. In these comments, NESCOE stated that "any new costs a revised definition imposes – which fall ultimately on consumers – should provide meaningful reliability benefits." A cost-benefit analysis should be integral to the development of a BES definition and, indeed, any reliability standard. This analysis should include a probabilistic risk assessment examining the likelihood of an event and the costs and risks resulting from such event, which should be weighed against the costs of complying with the proposed reliability measures. 3) Technical Justification. In addition to performing a cost-benefit analysis, a technical basis must be provided to justify a proposed reliability standard. However, the proposed BES definition does not provide a technical justification for the 100 kV threshold, the threshold for generation resources, or other elements of the definition. As stated above, while well-intentioned and understandable, deferring this technical justification to a later and separate phase of the project is a flawed and potentially costly approach. Providing a technical justification for a reliability standard is a core function of standards development and should be addressed at the forefront of the process rather than relegated to a separate phase largely undertaken after a standard is filed. In Order 743, the Federal Energy Regulatory Commission ("FERC" or "the Commission") directed NERC to revise the BES definition. Revision to Electric Reliability Organization Definition of Bulk Electric System, Order No. 743A, 134 FERC ¶ 61,210 (Mar. 17, 2011) at P 8, citing to Revision to Electric Reliability

Organization Definition of Bulk Electric System, Order No. 743, 133 FERC ¶ 61,150 (2010). The Commission stated that one way NERC could address the technical and policy concerns FERC had identified would be to institute a “bright-line threshold that includes all facilities operated at or above 100 kV except defined radial facilities, and establish an exemption process and criteria for excluding facilities [NERC] determines are not necessary for operating the interconnected transmission network.” Id. at P 8. However, the Commission made clear in Order 743 that NERC may propose an alternative proposal and that the 100 kV threshold is an “initial line of demarcation” to be refined through exclusions and exemptions. Id. at PP 8, 40. Accordingly, unless and until NERC provides a technical justification for its approach, the Standard should use the 100 kV threshold concept in a way that is consistent with the Commission’s guidance. Specifically, the two criteria that bound the BES definition are (1) the statutory exclusion of facilities used in local distribution, and (2) the requirement that the facilities included be “necessary for reliable operation” of the interconnected transmission system. A definition that recognizes these limits, coupled with an efficient and transparent exception process, would appear to meet the Commission’s expectations. For these reasons, absent a technical justification for imposing a 100 kV threshold, the MA DPU supports the revised core definition offered by NESCOE in comments filed on this 2nd Draft: “All Transmission Elements operated at 100 kV or higher and Real Power and Reactive Power resources connected at 100 kV or higher that are necessary for the reliable operation of the interconnected transmission network, including but not limited to the facilities listed below as Inclusions, and excluding (1) facilities that are used in the local distribution of electric energy, and (2) the facilities and systems listed below as Exclusions. Other Elements may be included or excluded on a case-by-case basis through the Rules of Procedure exception process.” The definition of the BES is critical to NERC’s role as ERO and will have a significant impact on system reliability and cost to consumers. While FERC had concerns that the existing definitions for the bulk power system were under-inclusive, the proposed Standard, as drafted, risks erring in the opposite direction and appears inconsistent with the Commission’s guidance in this area.

No

The MA DPU supports the revised Inclusion I1 language that treats Exclusions E1 and E3 as alternative exclusions, either of which may qualify as an exclusion. However, specificity is needed regarding what equipment is included in I1 (e.g., autotransformers, PARs, primary, secondary, tertiary windings).

No

Failing to establish a known MVA rating at this stage is problematic. The BES definition cannot be considered in a vacuum, and adjusting or establishing thresholds such as MVA ratings will create regulatory uncertainty and may result in additional costs and unnecessary system upgrades. Additionally, Inclusion I2 should remove the reference to the Statement of Compliance Registry Criteria. The definition should be the governing document regarding generation that is included in the BES.

No

The inclusion should be revised to specify that only those blackstart units that are “material to” the BES are included in the definition.

No

The aggregate 75 MVA of connected generation does not appear to be adequately supported by technical analysis and appears, on its face, as too low. Among our concerns is that such a low level will have a potential adverse impact on the development of renewable generation resources. In addition, the inclusion needs to be clarified in order that entities have clear guidance on what is meant by “common point of interconnection.”

No

The inclusion of all devices that supply reactive power to the BES is unnecessary and will result in unjustified costs to the ratepayer. Static devices (fixed capacitors) should remain excluded from the BES as they are dispatched by operations personnel, and if one fixed capacitor bank fails, the operator can replace its impact by switching in another fixed bank. This represents routine operation of the system. On the other hand, dynamic devices may be important to maintaining voltage stability of the system. These installations typically are rated to supply or absorb 75 MVA or more to or from the BES. Therefore, the MA DPU suggests that dynamic reactive power devices rated at 75 MVA or more could be included in the BES. Further, revised inclusion I5 is a new inclusion that lacks definition

(and appears to be redundant with the general BES definition). NERC should provide technical justification for the additional language under Inclusion I5.
Yes
The aggregate 75 MVA of connected generation appears too low and would benefit from additional technical justification.
Yes
While the MA DPU generally supports Exclusion E2, no information has been provided by NERC demonstrating that the 75 MVA rating is based on any sound technical analysis.
Yes
The MA DPU generally supports this exclusion but believes it is too narrow. As noted in the response to question 7, Exclusion E3 should likely allow a higher level of aggregate generation MVA on a Local Network. In addition, local networks should not necessarily be ineligible for Exclusion E3 simply because an amount of power may transfer out of the network at times. NERC's draft technical network exclusions document should be amended such that local networks would be permitted to qualify for network exclusions under E3 if power flowing out of the network is minimal and would not likely adversely impact the BES.
Yes
While we are generally supportive of this exclusion, the term "retail" needs to be clarified (i.e., are retail customers of all sizes intended to be excluded?).

Blachly-Lane Electric Cooperative (BLEC)
Yes
The Blachly-Lane Electric Cooperative (BLEC) believes the SDT continues to make substantial progress towards a clear and workable definition of the Bulk Electric System ("BES") that markedly improves both the existing definition and the SDT's previous proposal. BLEC therefore supports the new definition, although our support is conditioned on: (1) a workable Exceptions process being

developed in conjunction with the BES definition; and, (2) the SDT moving forward expeditiously on Phase II of the standards development process in accordance with the SAR recently put forward by the SDT, which would address a number of important technical issues that have been identified in the standards development process to date. BLEC strongly supports the following elements of the revised BES definition: (1) Clarification of how lists of Inclusions and Exclusions applies: The revised core definition moves the phrase "Unless modified by the lists shown below" to the beginning of the definition. This change makes clear that the Inclusions and Exclusions apply to all Elements that would otherwise be included in or excluded from the core definition (i.e., "all Transmission Elements operated at 100kV or higher and Real Time and Reactive Power resources connected at 100kV or higher") and eliminates a latent ambiguity in the first draft of the definition, discussed further in our comments on the first draft. (2) The exclusion for "facilities used in the local distribution of electric energy." As the starting point for the BES definition, BLEC supports the use of the phrase "all Transmission Elements" and the qualifying sentence: "This does not include facilities used in the local distribution of electric energy." This language helps ensure that FERC, NERC, and the Regional Entities ("REs") will act within the jurisdictional constraints Congress placed in Section 215 of the Federal Power Act ("FPA"). In Section 215(a)(1), Congress unequivocally excluded "facilities used in the local distribution of electric energy" from the keystone "bulk-power system" definition. 16 U.S.C. § 824o(a)(1). Including the same language in the definition helps ensure that entities involved in enforcement of reliability standards will act within their statutory limits. In addition, as a practical matter, inclusion of the language will help focus both the industry and responsible agencies on the high-voltage interstate transmission system, where the reliability problems Congress intended to regulate – "instability, uncontrolled separation, [and] cascading failures," 16 U.S.C. § 824o(a)(4) – will originate. At the same time, level-of-service issues arising in local distribution systems will be left to the authority of state and local regulatory agencies and governing bodies, just as Congress intended. 16 U.S.C. § 824o(i)(2) (reserving to state and local authorities enforcement of standards for adequacy of service). BLEC thanks the SDT for the excellent work to include this sentence. For similar reasons, BLEC believes the use of the phrase "Transmission Elements" as the starting point for the base definition is desirable because both "Transmission" and "Elements" are already defined in the NERC Glossary of Terms Used in NERC Reliability Standards, and the term "Transmission" makes clear that the BES includes only Elements used in Transmission and therefore excludes Elements used in local distribution of electric power. (3) Appropriate Generator Thresholds. In the standards development process, it has become apparent that the thresholds for classifying generators as BES in the current NERC Statement of Compliance Registry Criteria ("SCRC") (20 MVA for individual generators, 75 MVA for multiple generators aggregated at a single site), which predate the adoption of FPA Section 215, were never the product of a careful analysis to determine whether generators of that size are necessary for operation of the interconnected bulk transmission system. Ideally, such an analysis would be conducted as part of the current standards development process. BLEC recognizes that, given the deadlines imposed by FERC in Order No. 743, it will not be possible for the SDT to conduct such an analysis within the time available. Accordingly, BLEC agrees with the approach taken by the SDT, which is to propose a Phase II of the standards development process that would address the generator threshold issue and several other technical issues that have arisen during the current process. As long as Phase II proceeds expeditiously, BLEC is prepared to support the BES definition as proposed by the SDT. While BLEC supports the overall approach adopted by the SDT and much of the specific language incorporated into the second draft of the BES definition, we believe the second draft would benefit from further clarification or modification in a number of respects, most of which are detailed in our subsequent answers. Further, we believe a workable Exclusion Process is essential for a BES Definition that will meet the legal requirements of FPA Section 215, especially for systems operating in the Western Interconnection. As detailed in our previous comments, BLEC believes a 200kV threshold would be more appropriate for WECC than a 100kV threshold. In addition, a 200kV threshold for the West is backed by solid technical analysis conducted by the WECC Bulk Electric System Definition Task Force, and repeated claims that there is no technical analysis to support this view are therefore incorrect. That said, we raise the issue here to emphasize the importance of the Exclusions for Local Networks and Radial Systems and the Exceptions process. These Exclusions and the Exceptions are essential for a definition that works in the Western Interconnection because the core definition will be over-inclusive in our region. As long as those Exclusions and the Exceptions Process are retained in a form substantially equivalent to those produced by the SDT at this juncture, BLEC will support the SDT's proposal.

Yes

We support the SDT's changes to the first Inclusion because it is more clear and simple than the initial approach. That being said, we suggest that an additional sentence of clarification would help avoid future controversy about the meaning of Inclusion 1. As we understand it, the BES intends to include transformers only if both the primary and secondary terminals operate at 100kV or above, which is why the definition uses the word "and" ("the primary and secondary terminals"). We support this approach since it would exclude transformers where the secondary terminals serve distribution loads, and which therefore function as distribution rather than transmission facilities. We believe the SDT's intent would be clarified by adding a sentence at the end of Inclusion 1 that reads: "Transformers with either primary or secondary terminals, or both, that operate at or below 100kV are not part of the BES." This language will help ensure that there is no controversy over whether the SDT's use of the word "and" in the phrase "the primary and secondary terminals" was intentional. We also support the SDT's proposal to develop detailed guidance concerning the point of demarcation between BES and non-BES elements in the Phase II SAR. In this regard, we note that, while Inclusion 1 at least implicitly suggests that the dividing line between BES and non-BES Elements should be at the transformer where transmission-level voltages are stepped down to distribution-level voltages, we believe further clarification of this point of demarcation between the BES and non-BES Elements is necessary. Many different configurations of transformers and other equipment that may lie at the juncture between the BES and non-BES systems. If the point of demarcation is designated at the transformer without further elaboration, many entities that own equipment on the high side of a transformer will be swept into the BES, and thereby exposed to inappropriately stringent regulations and undue costs. For example, distribution-only utilities commonly own the switches, bus, and transformer protection devices on the high side of transformers where they take delivery from their transmission provider. Ownership of these protective devices and high-voltage bus on the high side of the transformer should not cause these entities to be classified as BES owners. As the Phase II process moves forward, we commend to the SDT the extensive work performed on the point of demarcation question by the WECC BESDTF. We also support the incorporation of language (" . . . unless excluded under Exclusions E1 or E3") making it clear that transformers that are operated as an integral part of a Radial System or Local Network should not be considered BES facilities, regardless of their operating voltage. Further clarification might be achieved by using the phrase ". . . unless the transformer is operated as part of a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2."

Yes

BLEC supports the changes made in Inclusion 2 and believes that the definition in its current form adds clarity. In particular, we support the SDT's decision to collapse Inclusions 2 and 3 from the previous draft definition into a single Inclusion that addresses the treatment of generation for purposes of the BES definition. We also support the SDT's proposal for a Phase II of the BES Definition process that would examine the technical justification for these thresholds and that would establish new thresholds based on a careful technical analysis. It is our understanding that the generator threshold issue will be vetted through the complete standards development process. We agree with this approach because if the generator threshold is treated as merely an element of NERC's Rules of Procedure, it can be changed with considerably less process and industry input than the Standards Development Process. Compare NERC Rules of Procedure § 1400 (providing for changes to Rules of Procedure upon approval of the NERC board and FERC) with NERC Standards Process Manual (Sept. 3, 2010) (providing for, e.g., posting of SDT proposals for comment, successive balloting, and super-majority approval requirements). See also Order No. 743-A, 134 FERC ¶ 61,210 at P 4 (2011) ("Order No. 743 directed the ERO to revise the definition of 'bulk electric system' through the NERC Standards Development Process" (emph. added)). Addressing all aspects of Phase II through the Standards Development Process will improve the content of the definition by bringing to bear industry expertise on all aspects of the definition and will ensure that, once firm guidelines are established, they can be relied upon by both industry and regulators without threat that they will be changed with little notice and little process. BLEC believes further clarification of the proposed language would be appropriate. The SDT proposes continued reliance upon the thresholds that are used in the NERC Statement of Compliance Registry Criteria for registration of Generation Owners and Generation Operators, which is currently 20 MVA for an individual generation unit and 75 MVA for multiple units on a single site. Conceptually, we are concerned about this approach because, as we understand it, the purpose of the Compliance Registry is to sweep in all generators that might be material to the reliable operation of the BES, and not to definitively determine whether a given generator is, in fact, material to the reliable operation of the BES. As the SCRC itself states, the SCRC

is intended only to identify "candidates for registration." SCRC at p.3, § 1 (emph. added). Accordingly, we believe that the generator threshold determined in Phase II should be incorporated directly into the BES Definition rather than being incorporated by reference from the SCRC. We also believe that the specific language proposed by the SDT could be further clarified. The SDT proposes that generation be included in the BES if the "Generation resource(s)" has a "nameplate rating per the ERO Statement of Compliance Registry." We understand this language is intended to be a placeholder for the results of the technical analysis that would occur in Phase II but we believe simply stating that the threshold will be "per the ERO Statement of Compliance Registry" is ambiguous. Further, for the reasons noted above, we believe the threshold should be part of the BES Definition, and should not simply be a cross-reference to the SCRC (and, given the different purposes of the BES Definition and the SCRC, it is not clear that the same threshold should be used in both). We therefore propose that Inclusion 2 be rewritten to state: "Qualifying Individual Generation Resources or Qualifying Aggregate Resources connected at a voltage of 100kV or above." Two definitions would then be added to the note at the end of the definition to read as follows: For purposes of this BES Definition, Qualifying Individual Generation Resources means an individual generating unit that meets the materiality threshold to be included in this definition or, in the absence of such a materiality threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of such a resource as a Generation Owner under the ERO Statement of Compliance Registry Criteria. For purposes of this BES Definition, Qualifying Aggregate Generation Resources means any facility consisting of one or more generating units that are connected at a common bus that meets the materiality threshold to be included in this definition, or, in the absence of such a threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of multiple-unit generator as a Generation Owner under the ERO Statement of Compliance Registry Criteria.. The "materiality threshold" is intended to refer to the generator threshold developed in Phase II. We suggest using definitions in this fashion for several reasons. First, we believe the language we suggest more clearly states the intention of the SDT, which we understand is to classify generation units as part of the BES if they are necessary for operation of the BES, but to exclude smaller generating units because they are not material to the operation of the interconnected transmission grid. Second, we believe use of the defined terms better reflects the intention of the SDT to reserve the specific question about generator thresholds to the technical analysis that will occur in Phase II without having to revise the BES Definition at the end of that process. That is, the definitions are designed to allow the SDT to include revised thresholds in the definition at the conclusion of the Phase II process based upon the technical analysis planned for Phase II, and the revised thresholds will be automatically incorporated into the BES Definition if the language we suggest is used. The thresholds used in the SCRC would only be a fall-back, to be used only until Phase II is completed. Third, the definitions can be incorporated into other parts of the BES Definition, which will add consistency and clarity. As noted in our answers to several of the questions below, the specific 75 MVA threshold is retained in several of the Exclusions and Inclusions, and we believe the industry would be better served if the revised thresholds arrived at after technical analysis in Phase II are automatically incorporated into all relevant provisions of the BES Definition. There is no reason for the SDT to continue to rely on the 75 MVA threshold once the analysis planned for Phase II on the threshold issue is completed. Fourth, the phrase "or that meets the materiality threshold to be included in this definition" is intended to preserve the SDT's flexibility to make a determination that generators below a specific threshold are not "necessary to" maintain the reliability of the interconnected transmission system, and to incorporate that finding as part of the definition itself, even if a different threshold is used in the SCRC to identify potential candidates for registration. Accordingly, our proposed language makes clear that a specific threshold in the definition controls over any threshold that might be included in the SCRC. For the reasons stated above, we believe it is highly desirable to include any material threshold in the BES Definition itself rather than relegating the threshold to the SCRC, which is merely a procedural rule rather than a full-fledged Reliability Standard. Finally, we agree with the SDT's decision to examine the question of where the line between BES and non-BES Elements should be drawn more closely in Phase II under the rubric of "contiguous vs. non-contiguous BES," and commend the work of the Project 2010-07 Standards Drafting Team and the GO-TO Team as a good starting point for the SDT's analysis on this issue. We understand Inclusion 2 would classify generators exceeding specific thresholds as part of the BES, but would not necessarily require facilities interconnecting such generators to be part of the BES. As discussed more fully in our answer to Question 9, based on extensive technical analysis that has already been performed by the NERC Project 2010-07 Standards Drafting Team and its predecessor, the NERC "GO-TO Team," regulating

as part of the BES a dedicated interconnection facility connecting a BES generator to the interconnected bulk transmission grid will result in an unnecessary regulatory burden that produces considerable expense for the owner of the interconnection facility with little or no improvement in bulk system reliability. We also believe the clauses at the end of Inclusion 2 are somewhat confusing and that greater clarity would be achieved by changing “. . . including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100kV or above” so that the Inclusion covers transformers with terminals “connected at a voltage of 100kV or above, including the generator terminal(s) on the high side of the step-up transformer(s) if operated at a voltage of 100kV or above.”

Yes

BLEC supports the removal of the Cranking Path language in I3. As noted in our response to Question 9, there is no reason to classify as BES the facilities interconnecting a BES generator to the bulk interstate system. A Cranking Path is simply a specific type of such an interconnection facility.

Yes

BLEC supports the revised language generally, but believes additional changes would make the language clearer. Specifically, we believe Inclusion 4 should not incorporate a hard 75 MVA generation threshold (i.e. “resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)”). Instead, we urge the SDT to replace this language with the defined term “Qualifying Aggregate Generation Resources,” which we discuss in more detail in our response to Question 3. This language will preserve the SDT’s ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. More generally, we are not certain what is accomplished by Inclusion 4 that is not already accomplished by Inclusion 2, which also addresses whether generation should be defined as BES. The SDT’s stated concern is with variable generation units such as wind and solar plants. It is not clear to us why this concern is not fully addressed in Inclusion 2, which addresses multiple generation units connected at a common bus, the configuration of most variable generation plants with multiple units. We are also concerned that the language, as proposed, could have unintended consequences and improperly classify local distribution systems as BES in certain circumstances. This is because multiple distributed generation units could render a local distribution system a “collector system” and the entire system the equivalent of an aggregated generation unit, causing the local distribution system to be improperly denied status as a Local Network. If many different distributed generation units are connected to a local distribution system, it is very unlikely that more than a few of those units would fail simultaneously, and it is therefore unlikely that multiple generation units would produce a measureable impact on the interconnected bulk transmission system, especially if the units individually do not otherwise exceed the materiality threshold to be established by the SDT in Phase II. Further, we are concerned that, if small distributed generation units become the industry norm, Inclusion 4 could unintentionally sweep in local distribution systems, especially where local policies favor the growth of small solar or other renewable generation systems for public policy reasons. Finally, we suggest that the SDT add the phrase “. . . unless the dispersed power producing resources operate within a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2.” This language, which parallels the language included at the end of Inclusion I1, would make clear that dispersed small-scale generators scattered throughout a Radial System or Local Network serving retail load would not convert the Radial System or Local Network into a BES system, even if the aggregate capacity of those small generators exceeds the relevant threshold.

No

BLEC has several concerns about the new language in Inclusion 5. First, because Reactive Power devices produce power, they are “power producing resources” and we therefore believe Inclusion 5 is duplicative of Inclusion 4, which addresses “power producing devices.” Second, there is no capacity threshold specified in Inclusion 5 for Reactive Power devices that would be considered part of the BES. This is inconsistent with the approach taken in the balance of the definition, where thresholds are specified for generators and other types of power producing devices. Third, BLEC believes the appropriate threshold for inclusion or exclusion of Reactive Power devices from the BES should be subject to the same technical analysis that will cover generators in the Phase II process. Finally, BLEC believes this issue should be addressed in Phase 2 since there is not technical justification or analysis done to determine the thresholds. BLEC strongly believes that there should be technical justification for thresholds for this issue and all other issues.

Yes

BLEC continues to strongly support the radial system exclusion, which is necessary as a legal matter, because, among other reasons, FERC in Orders No. 743 and 743-A has required that the existing radial exemption in the NERC Statement of Compliance Registry Criteria be maintained. As a practical matter, radial systems are used for service to retail loads, usually in remote or rural areas, and not for the transmission of bulk power. Hence, operation of the radials has little or nothing to do with the reliable operation of the interconnected bulk transmission network. We also support the inclusion of the note discussing normally open switches because this language provides needed clarity for a common radial system configuration. We also agree with the substantive thrust of this language, which is that a radial system should not be considered part of the BES if it is interconnected at a single point, even if there is an alternative point of delivery that is normally open. While we support the Exclusion for Radial Systems, we believe several clarifications and refinements are necessary. (1) The term "transmission Elements" in the initial paragraph should be changed to "Elements." Radial systems are not transmission systems and including the word "transmission" in the Radial System exclusion is therefore unnecessary and confusing. (2) Subparagraph (b) of Exclusion 1 refers to "generation resources . . . with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)". We urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," discussed in more detail in our response to Question 3. This language will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. (3) Subparagraph (b) also seems to assume that if a Radial System contains a generator exceeding the 75 MVA threshold, the Radial System itself must be included in the BES because it links the generator to the interconnected bulk transmission system. As discussed more fully in our response to Question 9, below, NERC's Project 2010-17 Standards Drafting Team and GO-TO Task Force have both concluded that this assumption is unwarranted. (4) The "Note" as drafted by the SDT indicates that "a normally open switching device between radial systems" will not serve to disqualify the Radial from exclusion under Exclusion 1. As discussed above, BLEC strongly supports the note conceptually. However, we believe this language should be included in a separate subparagraph (d), rather than a note, because treatment as a "note" suggests it is less important than other portions of the Exclusion. We also suggest the language be changed to read: (d) Normally-open switching devices between radial elements as depicted and identified on system one-line diagrams does not affect this exclusion. This will make clear that a radial with more than one normally-open switch connecting it to another radial is still a radial. From the perspective of the BES Definition, the key question is whether switches operating between Radials are normally open, not whether there is more than one normally-open switch.

BLEC supports the revised language. The language provides clarity regarding the BES status of customer-owned cogeneration facilities. However, BLEC urges the SDT to remove the reference to the 75 MVA threshold and replace it with the defined term "Qualifying Aggregate Generation Resources" or some equivalent language for the reasons stated in our responses to Questions 3, 5, and 7. In addition, we are concerned that Exclusion 2 will place local distribution utilities in a difficult position because, under Exclusion 1 or Exclusion 3 as drafted, they could lose their status as a Radial System or a Local Network through the actions of a customer constructing behind-the-meter generation. With respect to Radial Systems, the appearance of behind-the-meter generators could cause the Radial System to exceed the thresholds specified in subparagraphs (b) and (c) of Exclusion 1 through no fault of the Radial System owner. Similar, a Local Network could lose its status because behind-the-meter generation could be of sufficient size that power moves into the interconnected grid in certain hours or under certain contingencies, rather than moving purely onto the Local Network, as required in subparagraph (b) of Exclusion 3. The Exclusions for Radial Systems and Local Networks should be made consistent with the Exclusion for behind-the-meter generation. There is no technical reason to believe the power flowing from a behind-the-meter customer-owned generator will have less impact on the bulk system than an equivalent-sized generator owned by a utility operating a Radial System or LN.

Yes

BLEC strongly supports the exclusion of Local Networks ("LNs") from the BES. The conversion of radial systems to local networks should be encouraged because networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. If the BES definition were to provide an exclusion for radials without providing a similar exclusion for LNs,

however, it would discourage networking local distribution systems because of the significantly increased regulatory burdens faced by the local distribution utility if it elected to network its radial facilities. By placing radial systems and LNs on the same regulatory footing, the proposed definition will ensure that decisions about whether to network radial systems are made on the basis of costs and benefits to the retail customers served by those radials, and not on the basis of disparate regulatory treatment. Consumers would ultimately benefit. BLEC also supports specific refinements made to the LN exclusion by the SDT in the current draft of the BES definition. In particular, BLEC supports the clarification of the purposes of a LN. The current draft states that LNs connect at multiple points to “improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system.” BLEC supports this change in language because it reflects the fundamental purposes of a LN and emphasizes one of the key distinctions between LNs and bulk transmission facilities, namely, that LNs are designed primarily to serve local retail load while bulk transmission facilities are designed primarily to move bulk power from a bulk source (generally either the point of interconnection of a wholesale generator or a the point of interconnection with another bulk transmission system) to one or more wholesale purchasers. BLEC believes further improvement of the language could be achieved with additional modifications and clarifications. With respect to the core language of Exclusion 3, we believe the language making a “group of contiguous transmission Elements operated at or above 100kV” the starting point for identifying a LN would be improved by deleting the term “transmission” from this phrase. This is so because LNs are not used for transmission and the use of the term “transmission Elements” is therefore both confusing and unnecessary. There would be no room for argument about what the SDT intended by including the word “transmission” if the word is deleted and the Exclusion applies to any “group of Elements operated at 100kV or above” that meets the remaining requirement of the Exclusion. Further, any definitional value that is added by using the term “transmission Elements” is accomplished by using that term in the core definition, and there is no reason to carry the term through in the Exclusions. BLEC also believes that subparagraphs (a) and (b) are redundant, because whatever protection is offered by the generation limit in subparagraph (a) is duplicated by the limit in subparagraph (b) requiring no flow out of the LN. We believe the SDT can eliminate subparagraph (a) of Exclusion 3 and simply rely on subparagraph (b) because if power only flows into the LN even if it interconnects more than 75 MVA of generation, the interconnected generation interconnected will have no significant interaction with the interconnected bulk transmission system. It will only interact with the LN. And, with the advent of distributed generation, it is easy to foresee a situation in which a large number of very small distributed generators are interconnected into a LN, so that the aggregate capacity of these generators exceeds 75 MVA. However, because the generators are small and dispersed and, under the criterion in subparagraph (b), would be wholly absorbed within the LN rather than transmitting power onto the interconnected grid, those generators would not have a material impact on the grid. We also suggest that subparagraph (b) of Exclusion 3 could be more clearly drafted. Subparagraph (b), as part of the requirement that power flow into a LN rather than out of it, includes this description: “The LN does not transfer energy originating outside the LN for delivery through the LN.” We understand this language is intended to distinguish a LN from a link in the transmission system – power on a transmission link passes through the transmission link to a load located elsewhere, while power in a LN enters the LN and is consumed by retail load within the LN. While we agree with the concept proposed by the SDT, we believe the language would be clearer if it read: “The LN does not transfer energy originating outside the LN for delivery through the LN to loads located outside the LN.” We believe the italicized language is necessary to distinguish between a transmission system, where power that originates outside a system is delivered through the system and passes through the system to a sink located somewhere outside the system, from a LN, in which power originating outside the LN passes through the LN and is delivered to retail load within the LN. To put it another way, the italicized language helps distinguish a transmission system from an LN, in which the LN “transfers energy originating outside the LN for delivery through the LN to loads located within the LN.” We also believe the language of subparagraph (a) of Exclusion 3 could be improved. Subparagraph (d) would make LNs part of the BES if they interconnect “non-retail generation greater than 75 MVA (gross nameplate rating).” For the reasons stated in our responses to Questions 3, 5 and 7, we urge the SDT to replace the reference to a hard 75 MVA threshold with the defined term “Qualifying Aggregate Generation Resources” or some equivalent. We are also uncertain what is meant by the use of the term “non-retail generation” in subparagraph (a). From context, we believe the SDT considers “non-retail generation” to be the equivalent of generation that is located behind the retail meter, usually but not always owned by the customer and used to serve the customer’s own

load. We therefore suggest that the SDT replace the term “non-retail generation” with “generation located behind the retail customer’s meter.” Similarly, we are unsure what is meant by the phrase “the LN and its underlying Elements.” We believe the phrase “and its underlying Elements” could simply be deleted from the definition without loss of meaning. In the alternative, the SDT might consider using the phrase “the LN, including all Elements located on the distribution side of any Automatic Fault Interrupting Devices (or other points of demarcation) separating the LN from the bulk interstate transmission system.” We believe this phrase more accurately reflects the SDT’s intent, which appears to be that generation exceeding 75 MVA in aggregate capacity interconnected anywhere within the LN disqualifies that LN from being excluded from the BES under Exclusion 3. BLEC also believes that both subparagraphs (a) and (b) of Exclusion 3 could be safely eliminated as long as subparagraph (c) is retained. Subparagraph (c) makes a LN part of the BES if it is classified as a Flow Gate or Transfer Path. Flow Gates and Transfer Paths are, by definition, the key facilities that allow reliable transmission of bulk electric power on the interconnected grid. If a LN has not been identified as either a Flow Gate or a Transfer Path, it is unlikely the LN is necessary for the reliable transmission of electricity on the interconnected bulk system. Apart from these specific improvements that we believe could be achieved by modifying the language of Exclusion 3, we believe the SDT may need to re-examine certain assumptions that appear to underlie the current draft. Specifically, subparagraph (a) suggests that if BES generation is embedded within a LN, the LN itself must also be BES. But two NERC bodies have already addressed similar questions and concluded there is no technical basis for such concerns. NERC’s Standards Drafting Team for Project 2010-07 and its predecessor, the “GO-TO Task Force” were formed to address how the dedicated interconnection facilities linking a BES generator to high-voltage transmission facilities should be treated under the NERC standards. The GO-TO Team concluded that by complying with a handful of reliability standards, primarily related to vegetation management, reliable operation of the bulk interconnected system could be protected without unduly burdening the owners of such interconnection systems. Therefore, there is no reason, according to the GO-TO Team, that dedicated high-voltage interconnection facilities must be treated as “Transmission” and classified as part of the BES in order to make reliability standards effective. See Final Report from the NERC Ad Hoc Group for Generator Requirements at the Transmission Interface (Nov. 16, 2009) (paper written by the GO-TO Task Force). Similarly, the Project 2010-07 Team observed that interconnection facilities “are most often not part of the integrated bulk power system, and as such should not be subject to the same level of standards applicable to Transmission Owners and Transmission Operators who own and operate transmission Facilities and Elements that are part of the integrated bulk power system.” White Paper Proposal for Information Comment, NERC Project 2010-07: Generator Requirements at the Transmission Interface, at 3 (March 2011). Requiring Generation Owners and Operators to comply with the same standards as BES Transmission Owners and Operators “would do little, if anything, to improve the reliability of the Bulk Electric System,” especially “when compared to the operation of the equipment that actually produces electricity – the generation equipment itself.” Id. We believe that interconnection of BES generators within a LN is analogous and that, based on the findings of the Project 2010-07 and GO-TO Teams, automatically classifying a LN as “BES” simply because a large generator is embedded in the LN will result in substantial overregulation and unnecessary expense with little gain for bulk system reliability. If anything, generation interconnected through a LN is less likely to produce material impacts on the interconnected bulk transmission system than the equivalent generator interconnected through a single dedicated line because an LN is interconnected to the bulk system at several points, so that if one interconnection goes down, power can still flow from the BES generator to the bulk system on other interconnection points. Where a dedicated interconnection facility is involved, by contrast, if the interconnection line fails, the generator is unavailable to the interconnected bulk system. Similarly, we suggest that the SDT re-examine the assumptions underlying subparagraph (b), which seems to suggest that a local distribution system cannot be classified as a Local Network if power flows out of that system at any time, even if the amount is de minimis, the outward flow is only for a few hours, a year, or the outward flow occurs only in an extreme contingency. Accordingly, we suggest that the initial clause of subparagraph (b) be revised to read: “Except in unusual circumstances, power flows only into the LN.” Finally, we note that the LN exclusion must not operate in any way as a substitution for the statutory prohibition on including “facilities used in the local distribution of electric energy” in the BES. Therefore, even with the LN exclusion, the SDT must retain this statutory language in the core definition of the BES, as discussed in our answer to Question One. If a certain piece of equipment is a “facility used in the local distribution of electric energy,” then it is not part of the BES in the first instance, and so consideration

of the LN Exclusion, or of any other Exclusion, any Inclusion, or any Exception, would be both unnecessary and uncalled for.

Yes

BLEC supports the revised language because retail reactive devices are used to address local customer or retail voltage issues, rather than voltage issues on the interconnected bulk grid, and such local devices should therefore be excluded from the BES definition.

No

BLEC extends its thanks to the SDT and to the many industry entities that have actively participating in the Standards Development Process. BLEC supports the current draft and believes, with certain refinements discussed in our comments, that the definition will serve the industry and reliability regulators well for many years to come. In addition, as noted earlier, BLEC is encouraged that the 20/75 MVA generation thresholds referred to in the NERC Statement of Compliance Registry Criteria, which have been relied upon by the SDT largely as a matter of necessity, will be reviewed and a technical assessment will be performed to identify the appropriate generation unit and plant size threshold to ensure a reliable North America. Finally, we understand that the Rules of Procedure Team will continue to move forward with developing an Exceptions Process that will complement the BES Definition and ensure that, to the extent the BES Definition is over-inclusive, facilities that should not be classified as BES will be excluded from the BES. Because the Exceptions Process is integral to a workable BES Definition, we support the current process for moving forward with the Exceptions Process and the BES Definition on parallel paths. We note that BLEC specifically supports the changes made by the SDT in the "Effective Date" provision of the BES Definition, which shortens the effective date of the new definition to the beginning of the first calendar quarter after regulatory approval (as opposed to the first calendar quarter twenty-four months after regulatory approval), with a 24-month transition period. BLEC supports this conclusion because it will allow entities seeking deregistration under the terms of the new BES definition to obtain the benefits of the new definition without an unreasonable wait, while allowing any entities that may be newly-classified as BES owners or operators sufficient time to come into compliance with newly-applicable Reliability Standards. BLEC also supports the 24-month transition period for the reasons laid out by the SDT.

WECC

Yes

Yes

Yes

Yes

WECC agrees with the inclusion of the blackstart units, but does not agree with the deletion of the cranking path from the I3. The cranking path should be included in the definition since the NERC standards EOP-005 and CIP-002 R1.2.4 require documenting the cranking path. The revised CIP-002-4 Standard identifies the cranking path as a critical asset in Attachment 1 (1.5).

Yes

WECC seeks further clarification on Inclusion 4. Several comments were submitted in the last round of comments whether each individual wind turbine in a wind farm, will be included in the BES. WECC believes the language change to I4 by the SDT did not address this issue. The current language in I4 could be interpreted as each individual turbine (example 1MW) would be part of the BES. WECC believes that I4 is not intended to include each individual wind turbine in a wind farm as a BES element but rather to include the point at which the aggregation becomes large enough to meet the aggregate capacity threshold of 75 MVA. WECC recommends the SDT modify the language in I4 to clarify this issue.

Yes

WECC believes I5 should be modified to identify a minimum Reactive Power threshold for static or dynamic devices similar to the threshold identified for generating resources in I2. As worded, any size

device dedicated to supplying or absorbing Reactive Power that is connected at 100 kV or higher, no matter how small, would be included in the BES.
Yes
The use of the word "affect" in the note may cause problems with interpretation by users. WECC suggests replacing the term "affect" with "alter".
Yes
E2 is inconsistent with Section III.c. of the NERC Statement of Compliance Registry Criteria and is in conflict with I2. As written, E2 uses a net capacity threshold of 75MVA, which does not distinguish between a single generating unit and multiple generating units. The threshold in the NERC Statement of Compliance Registry Criteria for a single generating unit is 20MVA. As a result, E2 would appear to exclude generators from 20MVA to 75MVA that serve any amount of retail load behind the meter. WECC recommends replacing "(i) the net capacity provided to the BES does not exceed 75 MVA" with "(i) the net capacity provided to the BES does not exceed the individual or gross nameplate ratings provided in the NERC Statement of Compliance Registry Criteria." WECC's recommended change makes E2 consistent with I2 and the SDT's plan to address generator thresholds in Phase II.
Yes
Yes
Yes
Following are additional comments not covered in previous questions: • Under the section "Effective Dates": There may be confusion with the statement "Compliance Obligations for Elements included by definition shall begin 24 months after the applicable effective date of the definition." The phrase "included by definition" can be interpreted broadly. • WECC notes that a generation threshold of 75MVA is specified in Exclusions E1, E2, and E3. WECC believes that generation thresholds for Exclusions should be addressed in Phase II when generation thresholds for Inclusions are being considered.

Coos-Curry Electric Cooperative (CCEC)
Yes
The Coos-Curry Electric Cooperative (CCEC ) believes the SDT continues to make substantial progress towards a clear and workable definition of the Bulk Electric System ("BES") that markedly improves both the existing definition and the SDT's previous proposal. CCEC therefore supports the new definition, although our support is conditioned on: (1) a workable Exceptions process being developed in conjunction with the BES definition; and, (2) the SDT moving forward expeditiously on Phase II of the standards development process in accordance with the SAR recently put forward by the SDT, which would address a number of important technical issues that have been identified in the standards development process to date. CCEC strongly supports the following elements of the revised BES definition: (1) Clarification of how lists of Inclusions and Exclusions applies: The revised core definition moves the phrase "Unless modified by the lists shown below" to the beginning of the definition. This change makes clear that the Inclusions and Exclusions apply to all Elements that would otherwise be included in or excluded from the core definition (i.e., "all Transmission Elements operated at 100kV or higher and Real Time and Reactive Power resources connected at 100kV or higher") and eliminates a latent ambiguity in the first draft of the definition, discussed further in our comments on the first draft. (2) The exclusion for "facilities used in the local distribution of electric energy." As the starting point for the BES definition, CCEC supports the use of the phrase "all Transmission Elements" and the qualifying sentence: "This does not include facilities used in the local distribution of electric energy." This language helps ensure that FERC, NERC, and the Regional Entities ("REs") will act within the jurisdictional constraints Congress placed in Section 215 of the Federal Power Act ("FPA"). In Section 215(a)(1), Congress unequivocally excluded "facilities used in the local distribution of electric energy" from the keystone "bulk-power system" definition. 16 U.S.C. § 824o(a)(1). Including the same language in the definition helps ensure that entities involved in enforcement of reliability standards will act within their statutory limits. In addition, as a practical matter, inclusion of the language will help focus both the industry and responsible agencies on the

high-voltage interstate transmission system, where the reliability problems Congress intended to regulate – “instability, uncontrolled separation, [and] cascading failures,” 16 U.S.C. § 824o(a)(4) – will originate. At the same time, level-of-service issues arising in local distribution systems will be left to the authority of state and local regulatory agencies and governing bodies, just as Congress intended. 16 U.S.C. § 824o(i)(2) (reserving to state and local authorities enforcement of standards for adequacy of service). CCEC thanks the SDT for the excellent work to include this sentence. For similar reasons, CCEC believes the use of the phrase “Transmission Elements” as the starting point for the base definition is desirable because both “Transmission” and “Elements” are already defined in the NERC Glossary of Terms Used in NERC Reliability Standards, and the term “Transmission” makes clear that the BES includes only Elements used in Transmission and therefore excludes Elements used in local distribution of electric power. (3) Appropriate Generator Thresholds. In the standards development process, it has become apparent that the thresholds for classifying generators as BES in the current NERC Statement of Compliance Registry Criteria (“SCRC”) (20 MVA for individual generators, 75 MVA for multiple generators aggregated at a single site), which predate the adoption of FPA Section 215, were never the product of a careful analysis to determine whether generators of that size are necessary for operation of the interconnected bulk transmission system. Ideally, such an analysis would be conducted as part of the current standards development process. CCEC recognizes that, given the deadlines imposed by FERC in Order No. 743, it will not be possible for the SDT to conduct such an analysis within the time available. Accordingly, CCEC agrees with the approach taken by the SDT, which is to propose a Phase II of the standards development process that would address the generator threshold issue and several other technical issues that have arisen during the current process. As long as Phase II proceeds expeditiously, CCEC is prepared to support the BES definition as proposed by the SDT. While CCEC supports the overall approach adopted by the SDT and much of the specific language incorporated into the second draft of the BES definition, we believe the second draft would benefit from further clarification or modification in a number of respects, most of which are detailed in our subsequent answers. Further, we believe a workable Exclusion Process is essential for a BES Definition that will meet the legal requirements of FPA Section 215, especially for systems operating in the Western Interconnection. As detailed in our previous comments, CCEC believes a 200kV threshold would be more appropriate for WECC than a 100kV threshold. In addition, a 200kV threshold for the West is backed by solid technical analysis conducted by the WECC Bulk Electric System Definition Task Force, and repeated claims that there is no technical analysis to support this view are therefore incorrect. That said, we raise the issue here to emphasize the importance of the Exclusions for Local Networks and Radial Systems and the Exceptions process. These Exclusions and the Exceptions are essential for a definition that works in the Western Interconnection because the core definition will be over-inclusive in our region. As long as those Exclusions and the Exceptions Process are retained in a form substantially equivalent to those produced by the SDT at this juncture, CCEC will support the SDT’s proposal.

Yes

We support the SDT’s changes to the first Inclusion because it is more clear and simple than the initial approach. That being said, we suggest that an additional sentence of clarification would help avoid future controversy about the meaning of Inclusion 1. As we understand it, the BES intends to include transformers only if both the primary and secondary terminals operate at 100kV or above, which is why the definition uses the word “and” (“the primary and secondary terminals”). We support this approach since it would exclude transformers where the secondary terminals serve distribution loads, and which therefore function as distribution rather than transmission facilities. We believe the SDT’s intent would be clarified by adding a sentence at the end of Inclusion 1 that reads: “Transformers with either primary or secondary terminals, or both, that operate at or below 100kV are not part of the BES.” This language will help ensure that there is no controversy over whether the SDT’s use of the word “and” in the phrase “the primary and secondary terminals” was intentional. We also support the SDT’s proposal to develop detailed guidance concerning the point of demarcation between BES and non-BES elements in the Phase II SAR. In this regard, we note that, while Inclusion 1 at least implicitly suggests that the dividing line between BES and non-BES Elements should be at the transformer where transmission-level voltages are stepped down to distribution-level voltages, we believe further clarification of this point of demarcation between the BES and non-BES Elements is necessary. Many different configurations of transformers and other equipment that may lie at the juncture between the BES and non-BES systems. If the point of demarcation is designated at the transformer without further elaboration, many entities that own equipment on the high side of a transformer will be swept into the BES, and thereby exposed to inappropriately stringent regulations

and undue costs. For example, distribution-only utilities commonly own the switches, bus, and transformer protection devices on the high side of transformers where they take delivery from their transmission provider. Ownership of these protective devices and high-voltage bus on the high side of the transformer should not cause these entities to be classified as BES owners. As the Phase II process moves forward, we commend to the SDT the extensive work performed on the point of demarcation question by the WECC BESDTF. We also support the incorporation of language (“ . . . unless excluded under Exclusions E1 or E3”) making it clear that transformers that are operated as an integral part of a Radial System or Local Network should not be considered BES facilities, regardless of their operating voltage. Further clarification might be achieved by using the phrase “. . . unless the transformer is operated as part of a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2.”

Yes

CCEC supports the changes made in Inclusion 2 and believes that the definition in its current form adds clarity. In particular, we support the SDT’s decision to collapse Inclusions 2 and 3 from the previous draft definition into a single Inclusion that addresses the treatment of generation for purposes of the BES definition. We also support the SDT’s proposal for a Phase II of the BES Definition process that would examine the technical justification for these thresholds and that would establish new thresholds based on a careful technical analysis. It is our understanding that the generator threshold issue will be vetted through the complete standards development process. We agree with this approach because if the generator threshold is treated as merely an element of NERC’s Rules of Procedure, it can be changed with considerably less process and industry input than the Standards Development Process. Compare NERC Rules of Procedure § 1400 (providing for changes to Rules of Procedure upon approval of the NERC board and FERC) with NERC Standards Process Manual (Sept. 3, 2010) (providing for, e.g., posting of SDT proposals for comment, successive balloting, and super-majority approval requirements). See also Order No. 743-A, 134 FERC ¶ 61,210 at P 4 (2011) (“Order No. 743 directed the ERO to revise the definition of ‘bulk electric system’ through the NERC Standards Development Process” (emph. added)). Addressing all aspects of Phase II through the Standards Development Process will improve the content of the definition by bringing to bear industry expertise on all aspects of the definition and will ensure that, once firm guidelines are established, they can be relied upon by both industry and regulators without threat that they will be changed with little notice and little process. CCEC believes further clarification of the proposed language would be appropriate. The SDT proposes continued reliance upon the thresholds that are used in the NERC Statement of Compliance Registry Criteria for registration of Generation Owners and Generation Operators, which is currently 20 MVA for an individual generation unit and 75 MVA for multiple units on a single site. Conceptually, we are concerned about this approach because, as we understand it, the purpose of the Compliance Registry is to sweep in all generators that might be material to the reliable operation of the BES, and not to definitively determine whether a given generator is, in fact, material to the reliable operation of the BES. As the SCRC itself states, the SCRC is intended only to identify “candidates for registration.” SCRC at p.3, § 1 (emph. added). Accordingly, we believe that the generator threshold determined in Phase II should be incorporated directly into the BES Definition rather than being incorporated by reference from the SCRC. We also believe that the specific language proposed by the SDT could be further clarified. The SDT proposes that generation be included in the BES if the “Generation resource(s)” has a “nameplate rating per the ERO Statement of Compliance Registry.” We understand this language is intended to be a placeholder for the results of the technical analysis that would occur in Phase II but we believe simply stating that the threshold will be “per the ERO Statement of Compliance Registry” is ambiguous. Further, for the reasons noted above, we believe the threshold should be part of the BES Definition, and should not simply be a cross-reference to the SCRC (and, given the different purposes of the BES Definition and the SCRC, it is not clear that the same threshold should be used in both). We therefore propose that Inclusion 2 be rewritten to state: “Qualifying Individual Generation Resources or Qualifying Aggregate Resources connected at a voltage of 100kV or above.” Two definitions would then be added to the note at the end of the definition to read as follows: For purposes of this BES Definition, Qualifying Individual Generation Resources means an individual generating unit that meets the materiality threshold to be included in this definition or, in the absence of such a materiality threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of such a resource as a Generation Owner under the ERO Statement of Compliance Registry Criteria. For purposes of this BES Definition, Qualifying Aggregate Generation Resources means any facility consisting of one or more generating units that are connected at a common bus that meets the

materiality threshold to be included in this definition, or, in the absence of such a threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of multiple-unit generator as a Generation Owner under the ERO Statement of Compliance Registry Criteria. The "materiality threshold" is intended to refer to the generator threshold developed in Phase II. We suggest using definitions in this fashion for several reasons. First, we believe the language we suggest more clearly states the intention of the SDT, which we understand is to classify generation units as part of the BES if they are necessary for operation of the BES, but to exclude smaller generating units because they are not material to the operation of the interconnected transmission grid. Second, we believe use of the defined terms better reflects the intention of the SDT to reserve the specific question about generator thresholds to the technical analysis that will occur in Phase II without having to revise the BES Definition at the end of that process. That is, the definitions are designed to allow the SDT to include revised thresholds in the definition at the conclusion of the Phase II process based upon the technical analysis planned for Phase II, and the revised thresholds will be automatically incorporated into the BES Definition if the language we suggest is used. The thresholds used in the SCRC would only be a fall-back, to be used only until Phase II is completed. Third, the definitions can be incorporated into other parts of the BES Definition, which will add consistency and clarity. As noted in our answers to several of the questions below, the specific 75 MVA threshold is retained in several of the Exclusions and Inclusions, and we believe the industry would be better served if the revised thresholds arrived at after technical analysis in Phase II are automatically incorporated into all relevant provisions of the BES Definition. There is no reason for the SDT to continue to rely on the 75 MVA threshold once the analysis planned for Phase II on the threshold issue is completed. Fourth, the phrase "or that meets the materiality threshold to be included in this definition" is intended to preserve the SDT's flexibility to make a determination that generators below a specific threshold are not "necessary to" maintain the reliability of the interconnected transmission system, and to incorporate that finding as part of the definition itself, even if a different threshold is used in the SCRC to identify potential candidates for registration. Accordingly, our proposed language makes clear that a specific threshold in the definition controls over any threshold that might be included in the SCRC. For the reasons stated above, we believe it is highly desirable to include any material threshold in the BES Definition itself rather than relegating the threshold to the SCRC, which is merely a procedural rule rather than a full-fledged Reliability Standard. Finally, we agree with the SDT's decision to examine the question of where the line between BES and non-BES Elements should be drawn more closely in Phase II under the rubric of "contiguous vs. non-contiguous BES," and commend the work of the Project 2010-07 Standards Drafting Team and the GO-TO Team as a good starting point for the SDT's analysis on this issue. We understand Inclusion 2 would classify generators exceeding specific thresholds as part of the BES, but would not necessarily require facilities interconnecting such generators to be part of the BES. As discussed more fully in our answer to Question 9, based on extensive technical analysis that has already been performed by the NERC Project 2010-07 Standards Drafting Team and its predecessor, the NERC "GO-TO Team," regulating as part of the BES a dedicated interconnection facility connecting a BES generator to the interconnected bulk transmission grid will result in an unnecessary regulatory burden that produces considerable expense for the owner of the interconnection facility with little or no improvement in bulk system reliability. We also believe the clauses at the end of Inclusion 2 are somewhat confusing and that greater clarity would be achieved by changing ". . . including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100kV or above" so that the Inclusion covers transformers with terminals "connected at a voltage of 100kV or above, including the generator terminal(s) on the high side of the step-up transformer(s) if operated at a voltage of 100kV or above."

Yes

CCEC supports the removal of the Cranking Path language in I3. As noted in our response to Question 9, there is no reason to classify as BES the facilities interconnecting a BES generator to the bulk interstate system. A Cranking Path is simply a specific type of such an interconnection facility.

Yes

CCEC supports the revised language generally, but believes additional changes would make the language clearer. Specifically, we believe Inclusion 4 should not incorporate a hard 75 MVA generation threshold (i.e., "resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)"). Instead, we urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," which we discuss in more detail in our response to

Question 3. This language will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. More generally, we are not certain what is accomplished by Inclusion 4 that is not already accomplished by Inclusion 2, which also addresses whether generation should be defined as BES. The SDT's stated concern is with variable generation units such as wind and solar plants. It is not clear to us why this concern is not fully addressed in Inclusion 2, which addresses multiple generation units connected at a common bus, the configuration of most variable generation plants with multiple units. We are also concerned that the language, as proposed, could have unintended consequences and improperly classify local distribution systems as BES in certain circumstances. This is because multiple distributed generation units could render a local distribution system a "collector system" and the entire system the equivalent of an aggregated generation unit, causing the local distribution system to be improperly denied status as a Local Network. If many different distributed generation units are connected to a local distribution system, it is very unlikely that more than a few of those units would fail simultaneously, and it is therefore unlikely that multiple generation units would produce a measureable impact on the interconnected bulk transmission system, especially if the units individually do not otherwise exceed the materiality threshold to be established by the SDT in Phase II. Further, we are concerned that, if small distributed generation units become the industry norm, Inclusion 4 could unintentionally sweep in local distribution systems, especially where local policies favor the growth of small solar or other renewable generation systems for public policy reasons. Finally, we suggest that the SDT add the phrase ". . . unless the dispersed power producing resources operate within a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2." This language, which parallels the language included at the end of Inclusion I1, would make clear that dispersed small-scale generators scattered throughout a Radial System or Local Network serving retail load would not convert the Radial System or Local Network into a BES system, even if the aggregate capacity of those small generators exceeds the relevant threshold.

No

CCEC has several concerns about the new language in Inclusion 5. First, because Reactive Power devices produce power, they are "power producing resources" and we therefore believe Inclusion 5 is duplicative of Inclusion 4, which addresses "power producing devices." Second, there is no capacity threshold specified in Inclusion 5 for Reactive Power devices that would be considered part of the BES. This is inconsistent with the approach taken in the balance of the definition, where thresholds are specified for generators and other types of power producing devices. Third, CCEC believes the appropriate threshold for inclusion or exclusion of Reactive Power devices from the BES should be subject to the same technical analysis that will cover generators in the Phase II process. Finally, CCEC believes this issue should be addressed in Phase 2 since there is not technical justification or analysis done to determine the thresholds. CCEC strongly believes that there should be technical justification for thresholds for this issue and all other issues.

Yes

CCEC continues to strongly support the radial system exclusion, which is necessary as a legal matter, because, among other reasons, FERC in Orders No. 743 and 743-A has required that the existing radial exemption in the NERC Statement of Compliance Registry Criteria be maintained. As a practical matter, radial systems are used for service to retail loads, usually in remote or rural areas, and not for the transmission of bulk power. Hence, operation of the radials has little or nothing to do with the reliable operation of the interconnected bulk transmission network. We also support the inclusion of the note discussing normally open switches because this language provides needed clarity for a common radial system configuration. We also agree with the substantive thrust of this language, which is that a radial system should not be considered part of the BES if it is interconnected at a single point, even if there is an alternative point of delivery that is normally open. While we support the Exclusion for Radial Systems, we believe several clarifications and refinements are necessary. (1) The term "transmission Elements" in the initial paragraph should be changed to "Elements." Radial systems are not transmission systems and including the word "transmission" in the Radial System exclusion is therefore unnecessary and confusing. (2) Subparagraph (b) of Exclusion 1 refers to "generation resources . . . with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)". We urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," discussed in more detail in our response to Question 3. This language will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II

included in the BES Definition by operation rather than requiring further revision of the Definition. (3) Subparagraph (b) also seems to assume that if a Radial System contains a generator exceeding the 75 MVA threshold, the Radial System itself must be included in the BES because it links the generator to the interconnected bulk transmission system. As discussed more fully in our response to Question 9, below, NERC's Project 2010-17 Standards Drafting Team and GO-TO Task Force have both concluded that this assumption is unwarranted. (4) The "Note" as drafted by the SDT indicates that "a normally open switching device between radial systems" will not serve to disqualify the Radial from exclusion under Exclusion 1. As discussed above, CCEC strongly supports the note conceptually. However, we believe this language should be included in a separate subparagraph (d), rather than a note, because treatment as a "note" suggests it is less important than other portions of the Exclusion. We also suggest the language be changed to read: (d) Normally-open switching devices between radial elements as depicted and identified on system one-line diagrams does not affect this exclusion. This will make clear that a radial with more than one normally-open switch connecting it to another radial is still a radial. From the perspective of the BES Definition, the key question is whether switches operating between Radials are normally open, not whether there is more than one normally-open switch.

Yes

CCEC supports the revised language. The language provides clarity regarding the BES status of customer-owned cogeneration facilities. However, CCEC urges the SDT to remove the reference to the 75 MVA threshold and replace it with the defined term "Qualifying Aggregate Generation Resources" or some equivalent language for the reasons stated in our responses to Questions 3, 5, and 7. In addition, we are concerned that Exclusion 2 will place local distribution utilities in a difficult position because, under Exclusion 1 or Exclusion 3 as drafted, they could lose their status as a Radial System or a Local Network through the actions of a customer constructing behind-the-meter generation. With respect to Radial Systems, the appearance of behind-the-meter generators could cause the Radial System to exceed the thresholds specified in subparagraphs (b) and (c) of Exclusion 1 through no fault of the Radial System owner. Similar, a Local Network could lose its status because behind-the-meter generation could be of sufficient size that power moves into the interconnected grid in certain hours or under certain contingencies, rather than moving purely onto the Local Network, as required in subparagraph (b) of Exclusion 3. The Exclusions for Radial Systems and Local Networks should be made consistent with the Exclusion for behind-the-meter generation. There is no technical reason to believe the power flowing from a behind-the-meter customer-owned generator will have less impact on the bulk system than an equivalent-sized generator owned by a utility operating a Radial System or LN.

Yes

CCEC strongly supports the exclusion of Local Networks ("LNs") from the BES. The conversion of radial systems to local networks should be encouraged because networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. If the BES definition were to provide an exclusion for radials without providing a similar exclusion for LNs, however, it would discourage networking local distribution systems because of the significantly increased regulatory burdens faced by the local distribution utility if it elected to network its radial facilities. By placing radial systems and LNs on the same regulatory footing, the proposed definition will ensure that decisions about whether to network radial systems are made on the basis of costs and benefits to the retail customers served by those radials, and not on the basis of disparate regulatory treatment. Consumers would ultimately benefit. CCEC also supports specific refinements made to the LN exclusion by the SDT in the current draft of the BES definition. In particular, CCEC supports the clarification of the purposes of a LN. The current draft states that LNs connect at multiple points to "improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system." CCEC supports this change in language because it reflects the fundamental purposes of a LN and emphasizes one of the key distinctions between LNs and bulk transmission facilities, namely, that LNs are designed primarily to serve local retail load while bulk transmission facilities are designed primarily to move bulk power from a bulk source (generally either the point of interconnection of a wholesale generator or a the point of interconnection with another bulk transmission system) to one or more wholesale purchasers. CCEC believes further improvement of the language could be achieved with additional modifications and clarifications. With respect to the core language of Exclusion 3, we believe the language making a "group of contiguous transmission Elements operated at or above 100kV" the starting point for identifying a LN would be improved by

deleting the term "transmission" from this phrase. This is so because LNs are not used for transmission and the use of the term "transmission Elements" is therefore both confusing and unnecessary. There would be no room for argument about what the SDT intended by including the word "transmission" if the word is deleted and the Exclusion applies to any "group of Elements operated at 100kV or above" that meets the remaining requirement of the Exclusion. Further, any definitional value that is added by using the term "transmission Elements" is accomplished by using that term in the core definition, and there is no reason to carry the term through in the Exclusions. CCEC also believes that subparagraphs (a) and (b) are redundant, because whatever protection is offered by the generation limit in subparagraph (a) is duplicated by the limit in subparagraph (b) requiring no flow out of the LN. We believe the SDT can eliminate subparagraph (a) of Exclusion 3 and simply rely on subparagraph (b) because if power only flows into the LN even if it interconnects more than 75 MVA of generation, the interconnected generation interconnected will have no significant interaction with the interconnected bulk transmission system. It will only interact with the LN. And, with the advent of distributed generation, it is easy to foresee a situation in which a large number of very small distributed generators are interconnected into a LN, so that the aggregate capacity of these generators exceeds 75 MVA. However, because the generators are small and dispersed and, under the criterion in subparagraph (b), would be wholly absorbed within the LN rather than transmitting power onto the interconnected grid, those generators would not have a material impact on the grid. We also suggest that subparagraph (b) of Exclusion 3 could be more clearly drafted. Subparagraph (b), as part of the requirement that power flow into a LN rather than out of it, includes this description: "The LN does not transfer energy originating outside the LN for delivery through the LN." We understand this language is intended to distinguish a LN from a link in the transmission system – power on a transmission link passes through the transmission link to a load located elsewhere, while power in a LN enters the LN and is consumed by retail load within the LN. While we agree with the concept proposed by the SDT, we believe the language would be clearer if it read: "The LN does not transfer energy originating outside the LN for delivery through the LN to loads located outside the LN." We believe the italicized language is necessary to distinguish between a transmission system, where power that originates outside a system is delivered through the system and passes through the system to a sink located somewhere outside the system, from a LN, in which power originating outside the LN passes through the LN and is delivered to retail load within the LN. To put it another way, the italicized language helps distinguish a transmission system from an LN, in which the LN "transfers energy originating outside the LN for delivery through the LN to loads located within the LN." We also believe the language of subparagraph (a) of Exclusion 3 could be improved. Subparagraph (d) would make LNs part of the BES if they interconnect "non-retail generation greater than 75 MVA (gross nameplate rating)." For the reasons stated in our responses to Questions 3, 5 and 7, we urge the SDT to replace the reference to a hard 75 MVA threshold with the defined term "Qualifying Aggregate Generation Resources" or some equivalent. We are also uncertain what is meant by the use of the term "non-retail generation" in subparagraph (a). From context, we believe the SDT considers "non-retail generation" to be the equivalent of generation that is located behind the retail meter, usually but not always owned by the customer and used to serve the customer's own load. We therefore suggest that the SDT replace the term "non-retail generation" with "generation located behind the retail customer's meter." Similarly, we are unsure what is meant by the phrase "the LN and its underlying Elements." We believe the phrase "and its underlying Elements" could simply be deleted from the definition without loss of meaning. In the alternative, the SDT might consider using the phrase "the LN, including all Elements located on the distribution side of any Automatic Fault Interrupting Devices (or other points of demarcation) separating the LN from the bulk interstate transmission system." We believe this phrase more accurately reflects the SDT's intent, which appears to be that generation exceeding 75 MVA in aggregate capacity interconnected anywhere within the LN disqualifies that LN from being excluded from the BES under Exclusion 3. CCEC also believes that both subparagraphs (a) and (b) of Exclusion 3 could be safely eliminated as long as subparagraph (c) is retained. Subparagraph (c) makes a LN part of the BES if it is classified as a Flow Gate or Transfer Path. Flow Gates and Transfer Paths are, by definition, the key facilities that allow reliable transmission of bulk electric power on the interconnected grid. If a LN has not been identified as either a Flow Gate or a Transfer Path, it is unlikely the LN is necessary for the reliable transmission of electricity on the interconnected bulk system. Apart from these specific improvements that we believe could be achieved by modifying the language of Exclusion 3, we believe the SDT may need to re-examine certain assumptions that appear to underlie the current draft. Specifically, subparagraph (a) suggests that if BES generation is embedded within a LN, the LN itself must also be

BES. But two NERC bodies have already addressed similar questions and concluded there is no technical basis for such concerns. NERC's Standards Drafting Team for Project 2010-07 and its predecessor, the "GO-TO Task Force" were formed to address how the dedicated interconnection facilities linking a BES generator to high-voltage transmission facilities should be treated under the NERC standards. The GO-TO Team concluded that by complying with a handful of reliability standards, primarily related to vegetation management, reliable operation of the bulk interconnected system could be protected without unduly burdening the owners of such interconnection systems. Therefore, there is no reason, according to the GO-TO Team, that dedicated high-voltage interconnection facilities must be treated as "Transmission" and classified as part of the BES in order to make reliability standards effective. See Final Report from the NERC Ad Hoc Group for Generator Requirements at the Transmission Interface (Nov. 16, 2009) (paper written by the GO-TO Task Force). Similarly, the Project 2010-07 Team observed that interconnection facilities "are most often not part of the integrated bulk power system, and as such should not be subject to the same level of standards applicable to Transmission Owners and Transmission Operators who own and operate transmission Facilities and Elements that are part of the integrated bulk power system." White Paper Proposal for Information Comment, NERC Project 2010-07: Generator Requirements at the Transmission Interface, at 3 (March 2011). Requiring Generation Owners and Operators to comply with the same standards as BES Transmission Owners and Operators "would do little, if anything, to improve the reliability of the Bulk Electric System," especially "when compared to the operation of the equipment that actually produces electricity – the generation equipment itself." Id. We believe that interconnection of BES generators within a LN is analogous and that, based on the findings of the Project 2010-07 and GO-TO Teams, automatically classifying a LN as "BES" simply because a large generator is embedded in the LN will result in substantial overregulation and unnecessary expense with little gain for bulk system reliability. If anything, generation interconnected through a LN is less likely to produce material impacts on the interconnected bulk transmission system than the equivalent generator interconnected through a single dedicated line because an LN is interconnected to the bulk system at several points, so that if one interconnection goes down, power can still flow from the BES generator to the bulk system on other interconnection points. Where a dedicated interconnection facility is involved, by contrast, if the interconnection line fails, the generator is unavailable to the interconnected bulk system. Similarly, we suggest that the SDT re-examine the assumptions underlying subparagraph (b), which seems to suggest that a local distribution system cannot be classified as a Local Network if power flows out of that system at any time, even if the amount is de minimis, the outward flow is only for a few hours, a year, or the outward flow occurs only in an extreme contingency. Accordingly, we suggest that the initial clause of subparagraph (b) be revised to read: "Except in unusual circumstances, power flows only into the LN." Finally, we note that the LN exclusion must not operate in any way as a substitution for the statutory prohibition on including "facilities used in the local distribution of electric energy" in the BES. Therefore, even with the LN exclusion, the SDT must retain this statutory language in the core definition of the BES, as discussed in our answer to Question One. If a certain piece of equipment is a "facility used in the local distribution of electric energy," then it is not part of the BES in the first instance, and so consideration of the LN Exclusion, or of any other Exclusion, any Inclusion, or any Exception, would be both unnecessary and uncalled for.

Yes

CCEC supports the revised language because retail reactive devices are used to address local customer or retail voltage issues, rather than voltage issues on the interconnected bulk grid, and such local devices should therefore be excluded from the BES definition.

No

CCEC extends its thanks to the SDT and to the many industry entities that have actively participating in the Standards Development Process. CCEC supports the current draft and believes, with certain refinements discussed in our comments, that the definition will serve the industry and reliability regulators well for many years to come. In addition, as noted earlier, CCEC is encouraged that the 20/75 MVA generation thresholds referred to in the NERC Statement of Compliance Registry Criteria, which have been relied upon by the SDT largely as a matter of necessity, will be reviewed and a technical assessment will be performed to identify the appropriate generation unit and plant size threshold to ensure a reliable North America. Finally, we understand that the Rules of Procedure Team will continue to move forward with developing an Exceptions Process that will complement the BES Definition and ensure that, to the extent the BES Definition is over-inclusive, facilities that should not

be classified as BES will be excluded from the BES. Because the Exceptions Process is integral to a workable BES Definition, we support the current process for moving forward with the Exceptions Process and the BES Definition on parallel paths. We note that CCEC specifically supports the changes made by the SDT in the "Effective Date" provision of the BES Definition, which shortens the effective date of the new definition to the beginning of the first calendar quarter after regulatory approval (as opposed to the first calendar quarter twenty-four months after regulatory approval), with a 24-month transition period. CCEC supports this conclusion because it will allow entities seeking deregistration under the terms of the new BES definition to obtain the benefits of the new definition without an unreasonable wait, while allowing any entities that may be newly-classified as BES owners or operators sufficient time to come into compliance with newly-applicable Reliability Standards. CCEC also supports the 24-month transition period for the reasons laid out by the SDT.

Kathleen Goodman

ISO New England Inc

Yes

The second sentence is unclear with respect to its intent. If it's intended to cover the exclusion described in E3, the sentence is not needed. If it's intended to mean something else, it is unclear as to what is intended and likely should be deleted.

No

I1 needs to be clarified such that it is clear on whether this includes autotransformers, phase angle regulators, and devices which have a tertiary winding. Using the tertiary winding as an example, it is not clear whether the tertiary winding itself is considered BES, especially if it is serving a radial system as described in E1.

Yes

No

The SDT has interpreted the FERC Directive to revise the BES definition in a manner that goes beyond the mandate of ensuring that the definition encompasses all facilities necessary for operating an interconnected electric transmission network. The SDT states that operation is interpreted as being under both normal and emergency conditions. However, loss of all electric power is the end state condition when all normal and emergency remediating actions have failed to prevent a collapse of the grid. System restoration involves the use of blackstart generators that are not resources necessary for operating the electrical grid but rather a means to recover following (not part of the emergency itself) an extreme emergency. The SDT should simply refer to the current Compliance Registry, which, for now, appears to adequately deal with the issue of how to treat Blackstart resources. I3 states "Blackstart Resources identified in the Transmission Operator's restoration plan". This is contrary to the preferred language that is part of the approved ERO Statement of Compliance Registry, III.C.3 that states, "Any generator, regardless of size, that is a blackstart unit material to (emphasis added) and designated as part of a transmission operator entity's restoration plan". This language is necessary to distinguish between those Blackstart Resources that are depended upon to restore the BES following an emergency ("Key Facilities") as compared to those Blackstart Resources that are used to restore power to customer load. Additionally, discussions with others during the preparation of comments have revealed that some interpret this requirement to include the GSU. We do not interpret this in this manner, but this should be clarified to avoid confusion.

No

I4 is unclear as to whether or not the collector system (or system designed primarily for aggregating capacity) itself is BES or just the resource. "Utilizing a system designed primarily for aggregating capacity" needs to be more clearly defined to account for multiple systems that may exist out of one common point. A suggestion would be to modify the end of the sentence to say "connected at any common point." I4 will allow for significant amounts of dispersed power producing resources to be excluded from the BES. This includes wind resources which are increasing in numbers and having a significant impact on system operations. It does not seem appropriate that having ten 70 MVA (total of 700 MVA) installations each with their own connection to a 115 kV bus should fall outside of the BES. As currently written, they would fall outside of the inclusion if they do not utilize the same collector system. It is unclear whether or not supplemental equipment associated with the dispersed

power producing resources is included in the BES. As an example, many wind resources are being interconnected utilizing supplemental dynamic and static reactive devices which are crucial to the operation of these resources. The dynamic devices are often controlling themselves and static reactive devices, which may or may not be connected above 100 kV. Leaving these devices out of the BES definition seems to be a potential gap.

Yes

No

The term "single point" is not clear. A better explanation is necessary. For example, the same bus in a bus/branch model should suffice as a "single point". There should not be a requirement to be at the same node as found in a nodal model. The term "a group of contiguous transmission elements" is ambiguous and needs to be clarified. The "Non-retail" qualifier in E1.c) should be deleted. It adds confusion to the exclusion and is not defined.

No

Exclusion E2 is confusing as written and seems counter intuitive. As an example, a 400 MW generator which is behind the meter with a 400 MW load could be excluded. This generator could have a significant impact on the performance of the system and yet it is excluded. As a simple example, loss of the 400 MW generator would require that the 400 MW load be supplied from the system, possibly leading to low voltages and thermal overloads. Additionally, a machine of this size could adversely impact the dynamic response of the system, leading to damping concerns or unit instability. If E2 is to be retained, it is not clear under what load conditions should the load at the facility be measured. Load levels, and resulting net flows to the system, can be significantly different between seasons, time of day, and the status of end user equipment at large industrial/manufacturing sites. The term "Retail Customer Load" needs to be defined. The Balancing Authority should not be included as an entity providing this service. In general the Statement of Compliance Registry has provided the preferred language to use here (Page 9, [Exclusions: second paragraph).

No

E3 could result in many large load pockets being excluded from the BES definition and should be deleted. Assuming that it is retained, we offer the following additional comments. The term "a group of contiguous transmission elements" is ambiguous and needs to be clarified. Please clarify in the exclusion if the flows into the LN as described in E3.b) are pre-contingency flows only. Please clarify the system conditions (time of year, peak or off-peak) that should be considered in determining of flow is only into the LN. The "Non-retail" qualifier in E3.a) should be deleted.

No

The term "retail customer" is unclear and will lead to confusion. This exclusion should be removed as there are many instances where a generator may be using the reactive power device to meet other interconnection requirements and the reactive device should be held to the same BES requirements as the generator.

Yes

There are a number of possible scenarios where an element falls under both an inclusion and exclusion. The definition is unclear as to whether or not this would have the element be BES or not. During the webinar an example was given about a static shunt device meeting the requirements of I5, but is part of a radial network. The response during the webinar was that this would be excluded. If this is correct, it means that an exclusion takes precedence over an inclusion. Is this always the case? This needs to be clarified and stated somewhere in this document. To be consistent with regard to the terms "Operated at 100 kV" and "Connected at 100 kV", we suggest that reference to generators should state, "Connected at a transmission element operated at 100 kV". This will avoid confusion in cases where a generator is connected to a transmission element rated at 100 kV but operated at a lower voltage.

Dave Markham

Central Electric Cooperative (CEC)

Yes

The Central Electric Cooperative (CEC) believes the SDT continues to make substantial progress

towards a clear and workable definition of the Bulk Electric System ("BES") that markedly improves both the existing definition and the SDT's previous proposal. CEC therefore supports the new definition, although our support is conditioned on: (1) a workable Exceptions process being developed in conjunction with the BES definition; and, (2) the SDT moving forward expeditiously on Phase II of the standards development process in accordance with the SAR recently put forward by the SDT, which would address a number of important technical issues that have been identified in the standards development process to date. CEC strongly supports the following elements of the revised BES definition: (1) Clarification of how lists of Inclusions and Exclusions applies: The revised core definition moves the phrase "Unless modified by the lists shown below" to the beginning of the definition. This change makes clear that the Inclusions and Exclusions apply to all Elements that would otherwise be included in or excluded from the core definition (i.e., "all Transmission Elements operated at 100kV or higher and Real Time and Reactive Power resources connected at 100kV or higher") and eliminates a latent ambiguity in the first draft of the definition, discussed further in our comments on the first draft. (2) The exclusion for "facilities used in the local distribution of electric energy." As the starting point for the BES definition, CEC supports the use of the phrase "all Transmission Elements" and the qualifying sentence: "This does not include facilities used in the local distribution of electric energy." This language helps ensure that FERC, NERC, and the Regional Entities ("REs") will act within the jurisdictional constraints Congress placed in Section 215 of the Federal Power Act ("FPA"). In Section 215(a)(1), Congress unequivocally excluded "facilities used in the local distribution of electric energy" from the keystone "bulk-power system" definition. 16 U.S.C. § 824o(a)(1). Including the same language in the definition helps ensure that entities involved in enforcement of reliability standards will act within their statutory limits. In addition, as a practical matter, inclusion of the language will help focus both the industry and responsible agencies on the high-voltage interstate transmission system, where the reliability problems Congress intended to regulate – "instability, uncontrolled separation, [and] cascading failures," 16 U.S.C. § 824o(a)(4) – will originate. At the same time, level-of-service issues arising in local distribution systems will be left to the authority of state and local regulatory agencies and governing bodies, just as Congress intended. 16 U.S.C. § 824o(i)(2) (reserving to state and local authorities enforcement of standards for adequacy of service). CEC thanks the SDT for the excellent work to include this sentence. For similar reasons, CEC believes the use of the phrase "Transmission Elements" as the starting point for the base definition is desirable because both "Transmission" and "Elements" are already defined in the NERC Glossary of Terms Used in NERC Reliability Standards, and the term "Transmission" makes clear that the BES includes only Elements used in Transmission and therefore excludes Elements used in local distribution of electric power. (3) Appropriate Generator Thresholds. In the standards development process, it has become apparent that the thresholds for classifying generators as BES in the current NERC Statement of Compliance Registry Criteria ("SCRC") (20 MVA for individual generators, 75 MVA for multiple generators aggregated at a single site), which predate the adoption of FPA Section 215, were never the product of a careful analysis to determine whether generators of that size are necessary for operation of the interconnected bulk transmission system. Ideally, such an analysis would be conducted as part of the current standards development process. CEC recognizes that, given the deadlines imposed by FERC in Order No. 743, it will not be possible for the SDT to conduct such an analysis within the time available. Accordingly, CEC agrees with the approach taken by the SDT, which is to propose a Phase II of the standards development process that would address the generator threshold issue and several other technical issues that have arisen during the current process. As long as Phase II proceeds expeditiously, CEC is prepared to support the BES definition as proposed by the SDT. While CEC supports the overall approach adopted by the SDT and much of the specific language incorporated into the second draft of the BES definition, we believe the second draft would benefit from further clarification or modification in a number of respects, most of which are detailed in our subsequent answers. Further, we believe a workable Exclusion Process is essential for a BES Definition that will meet the legal requirements of FPA Section 215, especially for systems operating in the Western Interconnection. As detailed in our previous comments, CEC believes a 200kV threshold would be more appropriate for WECC than a 100kV threshold. In addition, a 200kV threshold for the West is backed by solid technical analysis conducted by the WECC Bulk Electric System Definition Task Force, and repeated claims that there is no technical analysis to support this view are therefore incorrect. That said, we raise the issue here to emphasize the importance of the Exclusions for Local Networks and Radial Systems and the Exceptions process. These Exclusions and the Exceptions are essential for a definition that works in the Western Interconnection because the core definition will be over-inclusive in our region. As long as those Exclusions and the Exceptions

Process are retained in a form substantially equivalent to those produced by the SDT at this juncture, CEC will support the SDT's proposal.

Yes

We support the SDT's changes to the first Inclusion because it is more clear and simple than the initial approach. That being said, we suggest that an additional sentence of clarification would help avoid future controversy about the meaning of Inclusion 1. As we understand it, the BES intends to include transformers only if both the primary and secondary terminals operate at 100kV or above, which is why the definition uses the word "and" ("the primary and secondary terminals"). We support this approach since it would exclude transformers where the secondary terminals serve distribution loads, and which therefore function as distribution rather than transmission facilities. We believe the SDT's intent would be clarified by adding a sentence at the end of Inclusion 1 that reads: "Transformers with either primary or secondary terminals, or both, that operate at or below 100kV are not part of the BES." This language will help ensure that there is no controversy over whether the SDT's use of the word "and" in the phrase "the primary and secondary terminals" was intentional. We also support the SDT's proposal to develop detailed guidance concerning the point of demarcation between BES and non-BES elements in the Phase II SAR. In this regard, we note that, while Inclusion 1 at least implicitly suggests that the dividing line between BES and non-BES Elements should be at the transformer where transmission-level voltages are stepped down to distribution-level voltages, we believe further clarification of this point of demarcation between the BES and non-BES Elements is necessary. Many different configurations of transformers and other equipment that may lie at the juncture between the BES and non-BES systems. If the point of demarcation is designated at the transformer without further elaboration, many entities that own equipment on the high side of a transformer will be swept into the BES, and thereby exposed to inappropriately stringent regulations and undue costs. For example, distribution-only utilities commonly own the switches, bus, and transformer protection devices on the high side of transformers where they take delivery from their transmission provider. Ownership of these protective devices and high-voltage bus on the high side of the transformer should not cause these entities to be classified as BES owners. As the Phase II process moves forward, we commend to the SDT the extensive work performed on the point of demarcation question by the WECC BESDTF. We also support the incorporation of language (" . . . unless excluded under Exclusions E1 or E3") making it clear that transformers that are operated as an integral part of a Radial System or Local Network should not be considered BES facilities, regardless of their operating voltage. Further clarification might be achieved by using the phrase ". . . unless the transformer is operated as part of a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2."

Yes

CEC supports the changes made in Inclusion 2 and believes that the definition in its current form adds clarity. In particular, we support the SDT's decision to collapse Inclusions 2 and 3 from the previous draft definition into a single Inclusion that addresses the treatment of generation for purposes of the BES definition. We also support the SDT's proposal for a Phase II of the BES Definition process that would examine the technical justification for these thresholds and that would establish new thresholds based on a careful technical analysis. It is our understanding that the generator threshold issue will be vetted through the complete standards development process. We agree with this approach because if the generator threshold is treated as merely an element of NERC's Rules of Procedure, it can be changed with considerably less process and industry input than the Standards Development Process. Compare NERC Rules of Procedure § 1400 (providing for changes to Rules of Procedure upon approval of the NERC board and FERC) with NERC Standards Process Manual (Sept. 3, 2010) (providing for, e.g., posting of SDT proposals for comment, successive balloting, and super-majority approval requirements). See also Order No. 743-A, 134 FERC ¶ 61,210 at P 4 (2011) ("Order No. 743 directed the ERO to revise the definition of 'bulk electric system' through the NERC Standards Development Process" (emph. added)). Addressing all aspects of Phase II through the Standards Development Process will improve the content of the definition by bringing to bear industry expertise on all aspects of the definition and will ensure that, once firm guidelines are established, they can be relied upon by both industry and regulators without threat that they will be changed with little notice and little process. CEC believes further clarification of the proposed language would be appropriate. The SDT proposes continued reliance upon the thresholds that are used in the NERC Statement of Compliance Registry Criteria for registration of Generation Owners and Generation Operators, which is currently 20 MVA for an individual generation unit and 75 MVA for multiple units on a single site.

Conceptually, we are concerned about this approach because, as we understand it, the purpose of the Compliance Registry is to sweep in all generators that might be material to the reliable operation of the BES, and not to definitively determine whether a given generator is, in fact, material to the reliable operation of the BES. As the SCRC itself states, the SCRC is intended only to identify "candidates for registration." SCRC at p.3, § 1 (emph. added). Accordingly, we believe that the generator threshold determined in Phase II should be incorporated directly into the BES Definition rather than being incorporated by reference from the SCRC. We also believe that the specific language proposed by the SDT could be further clarified. The SDT proposes that generation be included in the BES if the "Generation resource(s)" has a "nameplate rating per the ERO Statement of Compliance Registry." We understand this language is intended to be a placeholder for the results of the technical analysis that would occur in Phase II but we believe simply stating that the threshold will be "per the ERO Statement of Compliance Registry" is ambiguous. Further, for the reasons noted above, we believe the threshold should be part of the BES Definition, and should not simply be a cross-reference to the SCRC (and, given the different purposes of the BES Definition and the SCRC, it is not clear that the same threshold should be used in both). We therefore propose that Inclusion 2 be rewritten to state: "Qualifying Individual Generation Resources or Qualifying Aggregate Resources connected at a voltage of 100kV or above." Two definitions would then be added to the note at the end of the definition to read as follows: For purposes of this BES Definition, Qualifying Individual Generation Resources means an individual generating unit that meets the materiality threshold to be included in this definition or, in the absence of such a materiality threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of such a resource as a Generation Owner under the ERO Statement of Compliance Registry Criteria. For purposes of this BES Definition, Qualifying Aggregate Generation Resources means any facility consisting of one or more generating units that are connected at a common bus that meets the materiality threshold to be included in this definition, or, in the absence of such a threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of multiple-unit generator as a Generation Owner under the ERO Statement of Compliance Registry Criteria.. The "materiality threshold" is intended to refer to the generator threshold developed in Phase II. We suggest using definitions in this fashion for several reasons. First, we believe the language we suggest more clearly states the intention of the SDT, which we understand is to classify generation units as part of the BES if they are necessary for operation of the BES, but to exclude smaller generating units because they are not material to the operation of the interconnected transmission grid. Second, we believe use of the defined terms better reflects the intention of the SDT to reserve the specific question about generator thresholds to the technical analysis that will occur in Phase II without having to revise the BES Definition at the end of that process. That is, the definitions are designed to allow the SDT to include revised thresholds in the definition at the conclusion of the Phase II process based upon the technical analysis planned for Phase II, and the revised thresholds will be automatically incorporated into the BES Definition if the language we suggest is used. The thresholds used in the SCRC would only be a fall-back, to be used only until Phase II is completed. Third, the definitions can be incorporated into other parts of the BES Definition, which will add consistency and clarity. As noted in our answers to several of the questions below, the specific 75 MVA threshold is retained in several of the Exclusions and Inclusions, and we believe the industry would be better served if the revised thresholds arrived at after technical analysis in Phase II are automatically incorporated into all relevant provisions of the BES Definition. There is no reason for the SDT to continue to rely on the 75 MVA threshold once the analysis planned for Phase II on the threshold issue is completed. Fourth, the phrase "or that meets the materiality threshold to be included in this definition" is intended to preserve the SDT's flexibility to make a determination that generators below a specific threshold are not "necessary to" maintain the reliability of the interconnected transmission system, and to incorporate that finding as part of the definition itself, even if a different threshold is used in the SCRC to identify potential candidates for registration. Accordingly, our proposed language makes clear that a specific threshold in the definition controls over any threshold that might be included in the SCRC. For the reasons stated above, we believe it is highly desirable to include any material threshold in the BES Definition itself rather than relegating the threshold to the SCRC, which is merely a procedural rule rather than a full-fledged Reliability Standard. Finally, we agree with the SDT's decision to examine the question of where the line between BES and non-BES Elements should be drawn more closely in Phase II under the rubric of "contiguous vs. non-contiguous BES," and commend the work of the Project 2010-07 Standards Drafting Team and the GO-TO Team as a good starting point for the SDT's analysis on this issue. We understand Inclusion 2 would classify generators exceeding specific

thresholds as part of the BES, but would not necessarily require facilities interconnecting such generators to be part of the BES. As discussed more fully in our answer to Question 9, based on extensive technical analysis that has already been performed by the NERC Project 2010-07 Standards Drafting Team and its predecessor, the NERC "GO-TO Team," regulating as part of the BES a dedicated interconnection facility connecting a BES generator to the interconnected bulk transmission grid will result in an unnecessary regulatory burden that produces considerable expense for the owner of the interconnection facility with little or no improvement in bulk system reliability. We also believe the clauses at the end of Inclusion 2 are somewhat confusing and that greater clarity would be achieved by changing ". . . including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100kV or above" so that the Inclusion covers transformers with terminals "connected at a voltage of 100kV or above, including the generator terminal(s) on the high side of the step-up transformer(s) if operated at a voltage of 100kV or above."

Yes

CEC supports the removal of the Cranking Path language in I3. As noted in our response to Question 9, there is no reason to classify as BES the facilities interconnecting a BES generator to the bulk interstate system. A Cranking Path is simply a specific type of such an interconnection facility.

Yes

CEC supports the revised language generally, but believes additional changes would make the language clearer. Specifically, we believe Inclusion 4 should not incorporate a hard 75 MVA generation threshold (i.e., "resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)"). Instead, we urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," which we discuss in more detail in our response to Question 3. This language will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. More generally, we are not certain what is accomplished by Inclusion 4 that is not already accomplished by Inclusion 2, which also addresses whether generation should be defined as BES. The SDT's stated concern is with variable generation units such as wind and solar plants. It is not clear to us why this concern is not fully addressed in Inclusion 2, which addresses multiple generation units connected at a common bus, the configuration of most variable generation plants with multiple units. We are also concerned that the language, as proposed, could have unintended consequences and improperly classify local distribution systems as BES in certain circumstances. This is because multiple distributed generation units could render a local distribution system a "collector system" and the entire system the equivalent of an aggregated generation unit, causing the local distribution system to be improperly denied status as a Local Network. If many different distributed generation units are connected to a local distribution system, it is very unlikely that more than a few of those units would fail simultaneously, and it is therefore unlikely that multiple generation units would produce a measureable impact on the interconnected bulk transmission system, especially if the units individually do not otherwise exceed the materiality threshold to be established by the SDT in Phase II. Further, we are concerned that, if small distributed generation units become the industry norm, Inclusion 4 could unintentionally sweep in local distribution systems, especially where local policies favor the growth of small solar or other renewable generation systems for public policy reasons. Finally, we suggest that the SDT add the phrase ". . . unless the dispersed power producing resources operate within a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2." This language, which parallels the language included at the end of Inclusion I1, would make clear that dispersed small-scale generators scattered throughout a Radial System or Local Network serving retail load would not convert the Radial System or Local Network into a BES system, even if the aggregate capacity of those small generators exceeds the relevant threshold.

No

CEC has several concerns about the new language in Inclusion 5. First, because Reactive Power devices produce power, they are "power producing resources" and we therefore believe Inclusion 5 is duplicative of Inclusion 4, which addresses "power producing devices." Second, there is no capacity threshold specified in Inclusion 5 for Reactive Power devices that would be considered part of the BES. This is inconsistent with the approach taken in the balance of the definition, where thresholds are specified for generators and other types of power producing devices. Third, CEC believes the appropriate threshold for inclusion or exclusion of Reactive Power devices from the BES should be subject to the same technical analysis that will cover generators in the Phase II process. Finally, CEC

believes this issue should be addressed in Phase 2 since there is not technical justification or analysis done to determine the thresholds. CEC strongly believes that there should be technical justification for thresholds for this issue and all other issues.

Yes

CEC continues to strongly support the radial system exclusion, which is necessary as a legal matter, because, among other reasons, FERC in Orders No. 743 and 743-A has required that the existing radial exemption in the NERC Statement of Compliance Registry Criteria be maintained. As a practical matter, radial systems are used for service to retail loads, usually in remote or rural areas, and not for the transmission of bulk power. Hence, operation of the radials has little or nothing to do with the reliable operation of the interconnected bulk transmission network. We also support the inclusion of the note discussing normally open switches because this language provides needed clarity for a common radial system configuration. We also agree with the substantive thrust of this language, which is that a radial system should not be considered part of the BES if it is interconnected at a single point, even if there is an alternative point of delivery that is normally open. While we support the Exclusion for Radial Systems, we believe several clarifications and refinements are necessary. (1) The term "transmission Elements" in the initial paragraph should be changed to "Elements." Radial systems are not transmission systems and including the word "transmission" in the Radial System exclusion is therefore unnecessary and confusing. (2) Subparagraph (b) of Exclusion 1 refers to "generation resources . . . with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)". We urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," discussed in more detail in our response to Question 3. This language will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. (3) Subparagraph (b) also seems to assume that if a Radial System contains a generator exceeding the 75 MVA threshold, the Radial System itself must be included in the BES because it links the generator to the interconnected bulk transmission system. As discussed more fully in our response to Question 9, below, NERC's Project 2010-17 Standards Drafting Team and GO-TO Task Force have both concluded that this assumption is unwarranted. (4) The "Note" as drafted by the SDT indicates that "a normally open switching device between radial systems" will not serve to disqualify the Radial from exclusion under Exclusion 1. As discussed above, CEC strongly supports the note conceptually. However, we believe this language should be included in a separate subparagraph (d), rather than a note, because treatment as a "note" suggests it is less important than other portions of the Exclusion. We also suggest the language be changed to read: (d) Normally-open switching devices between radial elements as depicted and identified on system one-line diagrams does not affect this exclusion. This will make clear that a radial with more than one normally-open switch connecting it to another radial is still a radial. From the perspective of the BES Definition, the key question is whether switches operating between Radials are normally open, not whether there is more than one normally-open switch.

Yes

CEC supports the revised language. The language provides clarity regarding the BES status of customer-owned cogeneration facilities. However, CEC urges the SDT to remove the reference to the 75 MVA threshold and replace it with the defined term "Qualifying Aggregate Generation Resources" or some equivalent language for the reasons stated in our responses to Questions 3, 5, and 7. In addition, we are concerned that Exclusion 2 will place local distribution utilities in a difficult position because, under Exclusion 1 or Exclusion 3 as drafted, they could lose their status as a Radial System or a Local Network through the actions of a customer constructing behind-the-meter generation. With respect to Radial Systems, the appearance of behind-the-meter generators could cause the Radial System to exceed the thresholds specified in subparagraphs (b) and (c) of Exclusion 1 through no fault of the Radial System owner. Similar, a Local Network could lose its status because behind-the-meter generation could be of sufficient size that power moves into the interconnected grid in certain hours or under certain contingencies, rather than moving purely onto the Local Network, as required in subparagraph (b) of Exclusion 3. The Exclusions for Radial Systems and Local Networks should be made consistent with the Exclusion for behind-the-meter generation. There is no technical reason to believe the power flowing from a behind-the-meter customer-owned generator will have less impact on the bulk system than an equivalent-sized generator owned by a utility operating a Radial System or LN.

Yes

CEC strongly supports the exclusion of Local Networks (“LNs”) from the BES. The conversion of radial systems to local networks should be encouraged because networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. If the BES definition were to provide an exclusion for radials without providing a similar exclusion for LNs, however, it would discourage networking local distribution systems because of the significantly increased regulatory burdens faced by the local distribution utility if it elected to network its radial facilities. By placing radial systems and LNs on the same regulatory footing, the proposed definition will ensure that decisions about whether to network radial systems are made on the basis of costs and benefits to the retail customers served by those radials, and not on the basis of disparate regulatory treatment. Consumers would ultimately benefit. CEC also supports specific refinements made to the LN exclusion by the SDT in the current draft of the BES definition. In particular, CEC supports the clarification of the purposes of a LN. The current draft states that LNs connect at multiple points to “improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system.” CEC supports this change in language because it reflects the fundamental purposes of a LN and emphasizes one of the key distinctions between LNs and bulk transmission facilities, namely, that LNs are designed primarily to serve local retail load while bulk transmission facilities are designed primarily to move bulk power from a bulk source (generally either the point of interconnection of a wholesale generator or a the point of interconnection with another bulk transmission system) to one or more wholesale purchasers. CEC believes further improvement of the language could be achieved with additional modifications and clarifications. With respect to the core language of Exclusion 3, we believe the language making a “group of contiguous transmission Elements operated at or above 100kV” the starting point for identifying a LN would be improved by deleting the term “transmission” from this phrase. This is so because LNs are not used for transmission and the use of the term “transmission Elements” is therefore both confusing and unnecessary. There would be no room for argument about what the SDT intended by including the word “transmission” if the word is deleted and the Exclusion applies to any “group of Elements operated at 100kV or above” that meets the remaining requirement of the Exclusion. Further, any definitional value that is added by using the term “transmission Elements” is accomplished by using that term in the core definition, and there is no reason to carry the term through in the Exclusions. CEC also believes that subparagraphs (a) and (b) are redundant, because whatever protection is offered by the generation limit in subparagraph (a) is duplicated by the limit in subparagraph (b) requiring no flow out of the LN. We believe the SDT can eliminate subparagraph (a) of Exclusion 3 and simply rely on subparagraph (b) because if power only flows into the LN even if it interconnects more than 75 MVA of generation, the interconnected generation interconnected will have no significant interaction with the interconnected bulk transmission system. It will only interact with the LN. And, with the advent of distributed generation, it is easy to foresee a situation in which a large number of very small distributed generators are interconnected into a LN, so that the aggregate capacity of these generators exceeds 75 MVA. However, because the generators are small and dispersed and, under the criterion in subparagraph (b), would be wholly absorbed within the LN rather than transmitting power onto the interconnected grid, those generators would not have a material impact on the grid. We also suggest that subparagraph (b) of Exclusion 3 could be more clearly drafted. Subparagraph (b), as part of the requirement that power flow into a LN rather than out of it, includes this description: “The LN does not transfer energy originating outside the LN for delivery through the LN.” We understand this language is intended to distinguish a LN from a link in the transmission system – power on a transmission link passes through the transmission link to a load located elsewhere, while power in a LN enters the LN and is consumed by retail load within the LN. While we agree with the concept proposed by the SDT, we believe the language would be clearer if it read: “The LN does not transfer energy originating outside the LN for delivery through the LN to loads located outside the LN.” We believe the italicized language is necessary to distinguish between a transmission system, where power that originates outside a system is delivered through the system and passes through the system to a sink located somewhere outside the system, from a LN, in which power originating outside the LN passes through the LN and is delivered to retail load within the LN. To put it another way, the italicized language helps distinguish a transmission system from an LN, in which the LN “transfers energy originating outside the LN for delivery through the LN to loads located within the LN.” We also believe the language of subparagraph (a) of Exclusion 3 could be improved. Subparagraph (d) would make LNs part of the BES if they interconnect “non-retail generation greater than 75 MVA (gross nameplate rating).” For the reasons stated in our responses to Questions 3, 5 and 7, we urge the SDT to replace the reference to a hard 75 MVA threshold with the defined term

"Qualifying Aggregate Generation Resources" or some equivalent. We are also uncertain what is meant by the use of the term "non-retail generation" in subparagraph (a). From context, we believe the SDT considers "non-retail generation" to be the equivalent of generation that is located behind the retail meter, usually but not always owned by the customer and used to serve the customer's own load. We therefore suggest that the SDT replace the term "non-retail generation" with "generation located behind the retail customer's meter." Similarly, we are unsure what is meant by the phrase "the LN and its underlying Elements." We believe the phrase "and its underlying Elements" could simply be deleted from the definition without loss of meaning. In the alternative, the SDT might consider using the phrase "the LN, including all Elements located on the distribution side of any Automatic Fault Interrupting Devices (or other points of demarcation) separating the LN from the bulk interstate transmission system." We believe this phrase more accurately reflects the SDT's intent, which appears to be that generation exceeding 75 MVA in aggregate capacity interconnected anywhere within the LN disqualifies that LN from being excluded from the BES under Exclusion 3. CEC also believes that both subparagraphs (a) and (b) of Exclusion 3 could be safely eliminated as long as subparagraph (c) is retained. Subparagraph (c) makes a LN part of the BES if it is classified as a Flow Gate or Transfer Path. Flow Gates and Transfer Paths are, by definition, the key facilities that allow reliable transmission of bulk electric power on the interconnected grid. If a LN has not been identified as either a Flow Gate or a Transfer Path, it is unlikely the LN is necessary for the reliable transmission of electricity on the interconnected bulk system. Apart from these specific improvements that we believe could be achieved by modifying the language of Exclusion 3, we believe the SDT may need to re-examine certain assumptions that appear to underlie the current draft. Specifically, subparagraph (a) suggests that if BES generation is embedded within a LN, the LN itself must also be BES. But two NERC bodies have already addressed similar questions and concluded there is no technical basis for such concerns. NERC's Standards Drafting Team for Project 2010-07 and its predecessor, the "GO-TO Task Force" were formed to address how the dedicated interconnection facilities linking a BES generator to high-voltage transmission facilities should be treated under the NERC standards. The GO-TO Team concluded that by complying with a handful of reliability standards, primarily related to vegetation management, reliable operation of the bulk interconnected system could be protected without unduly burdening the owners of such interconnection systems. Therefore, there is no reason, according to the GO-TO Team, that dedicated high-voltage interconnection facilities must be treated as "Transmission" and classified as part of the BES in order to make reliability standards effective. See Final Report from the NERC Ad Hoc Group for Generator Requirements at the Transmission Interface (Nov. 16, 2009) (paper written by the GO-TO Task Force). Similarly, the Project 2010-07 Team observed that interconnection facilities "are most often not part of the integrated bulk power system, and as such should not be subject to the same level of standards applicable to Transmission Owners and Transmission Operators who own and operate transmission Facilities and Elements that are part of the integrated bulk power system." White Paper Proposal for Information Comment, NERC Project 2010-07: Generator Requirements at the Transmission Interface, at 3 (March 2011). Requiring Generation Owners and Operators to comply with the same standards as BES Transmission Owners and Operators "would do little, if anything, to improve the reliability of the Bulk Electric System," especially "when compared to the operation of the equipment that actually produces electricity – the generation equipment itself." Id. We believe that interconnection of BES generators within a LN is analogous and that, based on the findings of the Project 2010-07 and GO-TO Teams, automatically classifying a LN as "BES" simply because a large generator is embedded in the LN will result in substantial overregulation and unnecessary expense with little gain for bulk system reliability. If anything, generation interconnected through a LN is less likely to produce material impacts on the interconnected bulk transmission system than the equivalent generator interconnected through a single dedicated line because an LN is interconnected to the bulk system at several points, so that if one interconnection goes down, power can still flow from the BES generator to the bulk system on other interconnection points. Where a dedicated interconnection facility is involved, by contrast, if the interconnection line fails, the generator is unavailable to the interconnected bulk system. Similarly, we suggest that the SDT re-examine the assumptions underlying subparagraph (b), which seems to suggest that a local distribution system cannot be classified as a Local Network if power flows out of that system at any time, even if the amount is de minimis, the outward flow is only for a few hours, a year, or the outward flow occurs only in an extreme contingency. Accordingly, we suggest that the initial clause of subparagraph (b) be revised to read: "Except in unusual circumstances, power flows only into the LN." Finally, we note that the LN exclusion must not operate in any way as a substitution for the statutory prohibition on including "facilities used in the local

distribution of electric energy" in the BES. Therefore, even with the LN exclusion, the SDT must retain this statutory language in the core definition of the BES, as discussed in our answer to Question One. If a certain piece of equipment is a "facility used in the local distribution of electric energy," then it is not part of the BES in the first instance, and so consideration of the LN Exclusion, or of any other Exclusion, any Inclusion, or any Exception, would be both unnecessary and uncalled for.

Yes

CEC supports the revised language because retail reactive devices are used to address local customer or retail voltage issues, rather than voltage issues on the interconnected bulk grid, and such local devices should therefore be excluded from the BES definition.

No

CEC extends its thanks to the SDT and to the many industry entities that have actively participating in the Standards Development Process. CEC supports the current draft and believes, with certain refinements discussed in our comments, that the definition will serve the industry and reliability regulators well for many years to come. In addition, as noted earlier, CEC is encouraged that the 20/75 MVA generation thresholds referred to in the NERC Statement of Compliance Registry Criteria, which have been relied upon by the SDT largely as a matter of necessity, will be reviewed and a technical assessment will be performed to identify the appropriate generation unit and plant size threshold to ensure a reliable North America. Finally, we understand that the Rules of Procedure Team will continue to move forward with developing an Exceptions Process that will complement the BES Definition and ensure that, to the extent the BES Definition is over-inclusive, facilities that should not be classified as BES will be excluded from the BES. Because the Exceptions Process is integral to a workable BES Definition, we support the current process for moving forward with the Exceptions Process and the BES Definition on parallel paths. We note that CEC specifically supports the changes made by the SDT in the "Effective Date" provision of the BES Definition, which shortens the effective date of the new definition to the beginning of the first calendar quarter after regulatory approval (as opposed to the first calendar quarter twenty-four months after regulatory approval), with a 24-month transition period. CEC supports this conclusion because it will allow entities seeking deregistration under the terms of the new BES definition to obtain the benefits of the new definition without an unreasonable wait, while allowing any entities that may be newly-classified as BES owners or operators sufficient time to come into compliance with newly-applicable Reliability Standards. CEC also supports the 24-month transition period for the reasons laid out by the SDT.

Individual

Dave Hagen

Clearwater Power Company (CPC)

Yes

The Clearwater Power Company (CPC) believes the SDT continues to make substantial progress towards a clear and workable definition of the Bulk Electric System ("BES") that markedly improves both the existing definition and the SDT's previous proposal. CPC therefore supports the new definition, although our support is conditioned on: (1) a workable Exceptions process being developed in conjunction with the BES definition; and, (2) the SDT moving forward expeditiously on Phase II of the standards development process in accordance with the SAR recently put forward by the SDT, which would address a number of important technical issues that have been identified in the standards development process to date. CPC strongly supports the following elements of the revised BES definition: (1) Clarification of how lists of Inclusions and Exclusions applies: The revised core definition moves the phrase "Unless modified by the lists shown below" to the beginning of the definition. This change makes clear that the Inclusions and Exclusions apply to all Elements that would otherwise be included in or excluded from the core definition (i.e., "all Transmission Elements operated at 100kV or higher and Real Time and Reactive Power resources connected at 100kV or higher") and eliminates a latent ambiguity in the first draft of the definition, discussed further in our comments on the first draft. (2) The exclusion for "facilities used in the local distribution of electric energy." As the starting point for the BES definition, CPC supports the use of the phrase "all Transmission Elements" and the qualifying sentence: "This does not include facilities used in the local distribution of electric energy." This language helps ensure that FERC, NERC, and the Regional Entities ("REs") will act within the jurisdictional constraints Congress placed in Section 215 of the Federal Power Act ("FPA"). In Section 215(a)(1), Congress unequivocally excluded "facilities used in the local distribution of electric energy" from the keystone "bulk-power system" definition. 16 U.S.C.

§ 824o(a)(1). Including the same language in the definition helps ensure that entities involved in enforcement of reliability standards will act within their statutory limits. In addition, as a practical matter, inclusion of the language will help focus both the industry and responsible agencies on the high-voltage interstate transmission system, where the reliability problems Congress intended to regulate – “instability, uncontrolled separation, [and] cascading failures,” 16 U.S.C. § 824o(a)(4) – will originate. At the same time, level-of-service issues arising in local distribution systems will be left to the authority of state and local regulatory agencies and governing bodies, just as Congress intended. 16 U.S.C. § 824o(i)(2) (reserving to state and local authorities enforcement of standards for adequacy of service). CPC thanks the SDT for the excellent work to include this sentence. For similar reasons, CPC believes the use of the phrase “Transmission Elements” as the starting point for the base definition is desirable because both “Transmission” and “Elements” are already defined in the NERC Glossary of Terms Used in NERC Reliability Standards, and the term “Transmission” makes clear that the BES includes only Elements used in Transmission and therefore excludes Elements used in local distribution of electric power. (3) Appropriate Generator Thresholds. In the standards development process, it has become apparent that the thresholds for classifying generators as BES in the current NERC Statement of Compliance Registry Criteria (“SCRC”) (20 MVA for individual generators, 75 MVA for multiple generators aggregated at a single site), which predate the adoption of FPA Section 215, were never the product of a careful analysis to determine whether generators of that size are necessary for operation of the interconnected bulk transmission system. Ideally, such an analysis would be conducted as part of the current standards development process. CPC recognizes that, given the deadlines imposed by FERC in Order No. 743, it will not be possible for the SDT to conduct such an analysis within the time available. Accordingly, CPC agrees with the approach taken by the SDT, which is to propose a Phase II of the standards development process that would address the generator threshold issue and several other technical issues that have arisen during the current process. As long as Phase II proceeds expeditiously, CPC is prepared to support the BES definition as proposed by the SDT. While CPC supports the overall approach adopted by the SDT and much of the specific language incorporated into the second draft of the BES definition, we believe the second draft would benefit from further clarification or modification in a number of respects, most of which are detailed in our subsequent answers. Further, we believe a workable Exclusion Process is essential for a BES Definition that will meet the legal requirements of FPA Section 215, especially for systems operating in the Western Interconnection. As detailed in our previous comments, CPC believes a 200kV threshold would be more appropriate for WECC than a 100kV threshold. In addition, a 200kV threshold for the West is backed by solid technical analysis conducted by the WECC Bulk Electric System Definition Task Force, and repeated claims that there is no technical analysis to support this view are therefore incorrect. That said, we raise the issue here to emphasize the importance of the Exclusions for Local Networks and Radial Systems and the Exceptions process. These Exclusions and the Exceptions are essential for a definition that works in the Western Interconnection because the core definition will be over-inclusive in our region. As long as those Exclusions and the Exceptions Process are retained in a form substantially equivalent to those produced by the SDT at this juncture, CPC will support the SDT’s proposal.

Yes

We support the SDT’s changes to the first Inclusion because it is more clear and simple than the initial approach. That being said, we suggest that an additional sentence of clarification would help avoid future controversy about the meaning of Inclusion 1. As we understand it, the BES intends to include transformers only if both the primary and secondary terminals operate at 100kV or above, which is why the definition uses the word “and” (“the primary and secondary terminals”). We support this approach since it would exclude transformers where the secondary terminals serve distribution loads, and which therefore function as distribution rather than transmission facilities. We believe the SDT’s intent would be clarified by adding a sentence at the end of Inclusion 1 that reads: “Transformers with either primary or secondary terminals, or both, that operate at or below 100kV are not part of the BES.” This language will help ensure that there is no controversy over whether the SDT’s use of the word “and” in the phrase “the primary and secondary terminals” was intentional. We also support the SDT’s proposal to develop detailed guidance concerning the point of demarcation between BES and non-BES elements in the Phase II SAR. In this regard, we note that, while Inclusion 1 at least implicitly suggests that the dividing line between BES and non-BES Elements should be at the transformer where transmission-level voltages are stepped down to distribution-level voltages, we believe further clarification of this point of demarcation between the BES and non-BES Elements is necessary. Many different configurations of transformers and other equipment that may lie at the

junction between the BES and non-BES systems. If the point of demarcation is designated at the transformer without further elaboration, many entities that own equipment on the high side of a transformer will be swept into the BES, and thereby exposed to inappropriately stringent regulations and undue costs. For example, distribution-only utilities commonly own the switches, bus, and transformer protection devices on the high side of transformers where they take delivery from their transmission provider. Ownership of these protective devices and high-voltage bus on the high side of the transformer should not cause these entities to be classified as BES owners. As the Phase II process moves forward, we commend to the SDT the extensive work performed on the point of demarcation question by the WECC BESDTF. We also support the incorporation of language (“ . . . unless excluded under Exclusions E1 or E3”) making it clear that transformers that are operated as an integral part of a Radial System or Local Network should not be considered BES facilities, regardless of their operating voltage. Further clarification might be achieved by using the phrase “. . . unless the transformer is operated as part of a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2.”

Yes

CPC supports the changes made in Inclusion 2 and believes that the definition in its current form adds clarity. In particular, we support the SDT’s decision to collapse Inclusions 2 and 3 from the previous draft definition into a single Inclusion that addresses the treatment of generation for purposes of the BES definition. We also support the SDT’s proposal for a Phase II of the BES Definition process that would examine the technical justification for these thresholds and that would establish new thresholds based on a careful technical analysis. It is our understanding that the generator threshold issue will be vetted through the complete standards development process. We agree with this approach because if the generator threshold is treated as merely an element of NERC’s Rules of Procedure, it can be changed with considerably less process and industry input than the Standards Development Process. Compare NERC Rules of Procedure § 1400 (providing for changes to Rules of Procedure upon approval of the NERC board and FERC) with NERC Standards Process Manual (Sept. 3, 2010) (providing for, e.g., posting of SDT proposals for comment, successive balloting, and super-majority approval requirements). See also Order No. 743-A, 134 FERC ¶ 61,210 at P 4 (2011) (“Order No. 743 directed the ERO to revise the definition of ‘bulk electric system’ through the NERC Standards Development Process” (emph. added)). Addressing all aspects of Phase II through the Standards Development Process will improve the content of the definition by bringing to bear industry expertise on all aspects of the definition and will ensure that, once firm guidelines are established, they can be relied upon by both industry and regulators without threat that they will be changed with little notice and little process. CPC believes further clarification of the proposed language would be appropriate. The SDT proposes continued reliance upon the thresholds that are used in the NERC Statement of Compliance Registry Criteria for registration of Generation Owners and Generation Operators, which is currently 20 MVA for an individual generation unit and 75 MVA for multiple units on a single site. Conceptually, we are concerned about this approach because, as we understand it, the purpose of the Compliance Registry is to sweep in all generators that might be material to the reliable operation of the BES, and not to definitively determine whether a given generator is, in fact, material to the reliable operation of the BES. As the SCRC itself states, the SCRC is intended only to identify “candidates for registration.” SCRC at p.3, § 1 (emph. added). Accordingly, we believe that the generator threshold determined in Phase II should be incorporated directly into the BES Definition rather than being incorporated by reference from the SCRC. We also believe that the specific language proposed by the SDT could be further clarified. The SDT proposes that generation be included in the BES if the “Generation resource(s)” has a “nameplate rating per the ERO Statement of Compliance Registry.” We understand this language is intended to be a placeholder for the results of the technical analysis that would occur in Phase II but we believe simply stating that the threshold will be “per the ERO Statement of Compliance Registry” is ambiguous. Further, for the reasons noted above, we believe the threshold should be part of the BES Definition, and should not simply be a cross-reference to the SCRC (and, given the different purposes of the BES Definition and the SCRC, it is not clear that the same threshold should be used in both). We therefore propose that Inclusion 2 be rewritten to state: “Qualifying Individual Generation Resources or Qualifying Aggregate Resources connected at a voltage of 100kV or above.” Two definitions would then be added to the note at the end of the definition to read as follows: For purposes of this BES Definition, Qualifying Individual Generation Resources means an individual generating unit that meets the materiality threshold to be included in this definition or, in the absence of such a materiality threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of such a resource as a

Generation Owner under the ERO Statement of Compliance Registry Criteria. For purposes of this BES Definition, Qualifying Aggregate Generation Resources means any facility consisting of one or more generating units that are connected at a common bus that meets the materiality threshold to be included in this definition, or, in the absence of such a threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of multiple-unit generator as a Generation Owner under the ERO Statement of Compliance Registry Criteria. The "materiality threshold" is intended to refer to the generator threshold developed in Phase II. We suggest using definitions in this fashion for several reasons. First, we believe the language we suggest more clearly states the intention of the SDT, which we understand is to classify generation units as part of the BES if they are necessary for operation of the BES, but to exclude smaller generating units because they are not material to the operation of the interconnected transmission grid. Second, we believe use of the defined terms better reflects the intention of the SDT to reserve the specific question about generator thresholds to the technical analysis that will occur in Phase II without having to revise the BES Definition at the end of that process. That is, the definitions are designed to allow the SDT to include revised thresholds in the definition at the conclusion of the Phase II process based upon the technical analysis planned for Phase II, and the revised thresholds will be automatically incorporated into the BES Definition if the language we suggest is used. The thresholds used in the SCRC would only be a fall-back, to be used only until Phase II is completed. Third, the definitions can be incorporated into other parts of the BES Definition, which will add consistency and clarity. As noted in our answers to several of the questions below, the specific 75 MVA threshold is retained in several of the Exclusions and Inclusions, and we believe the industry would be better served if the revised thresholds arrived at after technical analysis in Phase II are automatically incorporated into all relevant provisions of the BES Definition. There is no reason for the SDT to continue to rely on the 75 MVA threshold once the analysis planned for Phase II on the threshold issue is completed. Fourth, the phrase "or that meets the materiality threshold to be included in this definition" is intended to preserve the SDT's flexibility to make a determination that generators below a specific threshold are not "necessary to" maintain the reliability of the interconnected transmission system, and to incorporate that finding as part of the definition itself, even if a different threshold is used in the SCRC to identify potential candidates for registration. Accordingly, our proposed language makes clear that a specific threshold in the definition controls over any threshold that might be included in the SCRC. For the reasons stated above, we believe it is highly desirable to include any material threshold in the BES Definition itself rather than relegating the threshold to the SCRC, which is merely a procedural rule rather than a full-fledged Reliability Standard. Finally, we agree with the SDT's decision to examine the question of where the line between BES and non-BES Elements should be drawn more closely in Phase II under the rubric of "contiguous vs. non-contiguous BES," and commend the work of the Project 2010-07 Standards Drafting Team and the GO-TO Team as a good starting point for the SDT's analysis on this issue. We understand Inclusion 2 would classify generators exceeding specific thresholds as part of the BES, but would not necessarily require facilities interconnecting such generators to be part of the BES. As discussed more fully in our answer to Question 9, based on extensive technical analysis that has already been performed by the NERC Project 2010-07 Standards Drafting Team and its predecessor, the NERC "GO-TO Team," regulating as part of the BES a dedicated interconnection facility connecting a BES generator to the interconnected bulk transmission grid will result in an unnecessary regulatory burden that produces considerable expense for the owner of the interconnection facility with little or no improvement in bulk system reliability. We also believe the clauses at the end of Inclusion 2 are somewhat confusing and that greater clarity would be achieved by changing ". . . including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100kV or above" so that the Inclusion covers transformers with terminals "connected at a voltage of 100kV or above, including the generator terminal(s) on the high side of the step-up transformer(s) if operated at a voltage of 100kV or above."

Yes

CPC supports the removal of the Cranking Path language in I3. As noted in our response to Question 9, there is no reason to classify as BES the facilities interconnecting a BES generator to the bulk interstate system. A Cranking Path is simply a specific type of such an interconnection facility.

Yes

CPC supports the revised language generally, but believes additional changes would make the language clearer. Specifically, we believe Inclusion 4 should not incorporate a hard 75 MVA generation threshold (i.e. "resources with aggregate capacity greater than 75 MVA (gross aggregate

nameplate rating)"). Instead, we urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," which we discuss in more detail in our response to Question 3. This language will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. More generally, we are not certain what is accomplished by Inclusion 4 that is not already accomplished by Inclusion 2, which also addresses whether generation should be defined as BES. The SDT's stated concern is with variable generation units such as wind and solar plants. It is not clear to us why this concern is not fully addressed in Inclusion 2, which addresses multiple generation units connected at a common bus, the configuration of most variable generation plants with multiple units. We are also concerned that the language, as proposed, could have unintended consequences and improperly classify local distribution systems as BES in certain circumstances. This is because multiple distributed generation units could render a local distribution system a "collector system" and the entire system the equivalent of an aggregated generation unit, causing the local distribution system to be improperly denied status as a Local Network. If many different distributed generation units are connected to a local distribution system, it is very unlikely that more than a few of those units would fail simultaneously, and it is therefore unlikely that multiple generation units would produce a measureable impact on the interconnected bulk transmission system, especially if the units individually do not otherwise exceed the materiality threshold to be established by the SDT in Phase II. Further, we are concerned that, if small distributed generation units become the industry norm, Inclusion 4 could unintentionally sweep in local distribution systems, especially where local policies favor the growth of small solar or other renewable generation systems for public policy reasons. Finally, we suggest that the SDT add the phrase ". . . unless the dispersed power producing resources operate within a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2." This language, which parallels the language included at the end of Inclusion I1, would make clear that dispersed small-scale generators scattered throughout a Radial System or Local Network serving retail load would not convert the Radial System or Local Network into a BES system, even if the aggregate capacity of those small generators exceeds the relevant threshold.

No

CPC has several concerns about the new language in Inclusion 5. First, because Reactive Power devices produce power, they are "power producing resources" and we therefore believe Inclusion 5 is duplicative of Inclusion 4, which addresses "power producing devices." Second, there is no capacity threshold specified in Inclusion 5 for Reactive Power devices that would be considered part of the BES. This is inconsistent with the approach taken in the balance of the definition, where thresholds are specified for generators and other types of power producing devices. Third, CPC believes the appropriate threshold for inclusion or exclusion of Reactive Power devices from the BES should be subject to the same technical analysis that will cover generators in the Phase II process. Finally, CPC believes this issue should be addressed in Phase 2 since there is not technical justification or analysis done to determine the thresholds. CPC strongly believes that there should be technical justification for thresholds for this issue and all other issues.

Yes

CPC continues to strongly support the radial system exclusion, which is necessary as a legal matter, because, among other reasons, FERC in Orders No. 743 and 743-A has required that the existing radial exemption in the NERC Statement of Compliance Registry Criteria be maintained. As a practical matter, radial systems are used for service to retail loads, usually in remote or rural areas, and not for the transmission of bulk power. Hence, operation of the radials has little or nothing to do with the reliable operation of the interconnected bulk transmission network. We also support the inclusion of the note discussing normally open switches because this language provides needed clarity for a common radial system configuration. We also agree with the substantive thrust of this language, which is that a radial system should not be considered part of the BES if it is interconnected at a single point, even if there is an alternative point of delivery that is normally open. While we support the Exclusion for Radial Systems, we believe several clarifications and refinements are necessary. (1) The term "transmission Elements" in the initial paragraph should be changed to "Elements." Radial systems are not transmission systems and including the word "transmission" in the Radial System exclusion is therefore unnecessary and confusing. (2) Subparagraph (b) of Exclusion 1 refers to "generation resources . . . with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)". We urge the SDT to replace this language with the defined term "Qualifying Aggregate

Generation Resources," discussed in more detail in our response to Question 3. This language will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. (3) Subparagraph (b) also seems to assume that if a Radial System contains a generator exceeding the 75 MVA threshold, the Radial System itself must be included in the BES because it links the generator to the interconnected bulk transmission system. As discussed more fully in our response to Question 9, below, NERC's Project 2010-17 Standards Drafting Team and GO-TO Task Force have both concluded that this assumption is unwarranted. (4) The "Note" as drafted by the SDT indicates that "a normally open switching device between radial systems" will not serve to disqualify the Radial from exclusion under Exclusion 1. As discussed above, CPC strongly supports the note conceptually. However, we believe this language should be included in a separate subparagraph (d), rather than a note, because treatment as a "note" suggests it is less important than other portions of the Exclusion. We also suggest the language be changed to read: (d) Normally-open switching devices between radial elements as depicted and identified on system one-line diagrams does not affect this exclusion. This will make clear that a radial with more than one normally-open switch connecting it to another radial is still a radial. From the perspective of the BES Definition, the key question is whether switches operating between Radials are normally open, not whether there is more than one normally-open switch.

Yes

CPC supports the revised language. The language provides clarity regarding the BES status of customer-owned cogeneration facilities. However, CPC urges the SDT to remove the reference to the 75 MVA threshold and replace it with the defined term "Qualifying Aggregate Generation Resources" or some equivalent language for the reasons stated in our responses to Questions 3, 5, and 7. In addition, we are concerned that Exclusion 2 will place local distribution utilities in a difficult position because, under Exclusion 1 or Exclusion 3 as drafted, they could lose their status as a Radial System or a Local Network through the actions of a customer constructing behind-the-meter generation. With respect to Radial Systems, the appearance of behind-the-meter generators could cause the Radial System to exceed the thresholds specified in subparagraphs (b) and (c) of Exclusion 1 through no fault of the Radial System owner. Similar, a Local Network could lose its status because behind-the-meter generation could be of sufficient size that power moves into the interconnected grid in certain hours or under certain contingencies, rather than moving purely onto the Local Network, as required in subparagraph (b) of Exclusion 3. The Exclusions for Radial Systems and Local Networks should be made consistent with the Exclusion for behind-the-meter generation. There is no technical reason to believe the power flowing from a behind-the-meter customer-owned generator will have less impact on the bulk system than an equivalent-sized generator owned by a utility operating a Radial System or LN.

Yes

CPC strongly supports the exclusion of Local Networks ("LNs") from the BES. The conversion of radial systems to local networks should be encouraged because networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. If the BES definition were to provide an exclusion for radials without providing a similar exclusion for LNs, however, it would discourage networking local distribution systems because of the significantly increased regulatory burdens faced by the local distribution utility if it elected to network its radial facilities. By placing radial systems and LNs on the same regulatory footing, the proposed definition will ensure that decisions about whether to network radial systems are made on the basis of costs and benefits to the retail customers served by those radials, and not on the basis of disparate regulatory treatment. Consumers would ultimately benefit. CPC also supports specific refinements made to the LN exclusion by the SDT in the current draft of the BES definition. In particular, CPC supports the clarification of the purposes of a LN. The current draft states that LNs connect at multiple points to "improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system." CPC supports this change in language because it reflects the fundamental purposes of a LN and emphasizes one of the key distinctions between LNs and bulk transmission facilities, namely, that LNs are designed primarily to serve local retail load while bulk transmission facilities are designed primarily to move bulk power from a bulk source (generally either the point of interconnection of a wholesale generator or a the point of interconnection with another bulk transmission system) to one or more wholesale purchasers. CPC believes further improvement of the language could be achieved with additional modifications and clarifications. With respect to the core

language of Exclusion 3, we believe the language making a “group of contiguous transmission Elements operated at or above 100kV” the starting point for identifying a LN would be improved by deleting the term “transmission” from this phrase. This is so because LNs are not used for transmission and the use of the term “transmission Elements” is therefore both confusing and unnecessary. There would be no room for argument about what the SDT intended by including the word “transmission” if the word is deleted and the Exclusion applies to any “group of Elements operated at 100kV or above” that meets the remaining requirement of the Exclusion. Further, any definitional value that is added by using the term “transmission Elements” is accomplished by using that term in the core definition, and there is no reason to carry the term through in the Exclusions. CPC also believes that subparagraphs (a) and (b) are redundant, because whatever protection is offered by the generation limit in subparagraph (a) is duplicated by the limit in subparagraph (b) requiring no flow out of the LN. We believe the SDT can eliminate subparagraph (a) of Exclusion 3 and simply rely on subparagraph (b) because if power only flows into the LN even if it interconnects more than 75 MVA of generation, the interconnected generation interconnected will have no significant interaction with the interconnected bulk transmission system. It will only interact with the LN. And, with the advent of distributed generation, it is easy to foresee a situation in which a large number of very small distributed generators are interconnected into a LN, so that the aggregate capacity of these generators exceeds 75 MVA. However, because the generators are small and dispersed and, under the criterion in subparagraph (b), would be wholly absorbed within the LN rather than transmitting power onto the interconnected grid, those generators would not have a material impact on the grid. We also suggest that subparagraph (b) of Exclusion 3 could be more clearly drafted. Subparagraph (b), as part of the requirement that power flow into a LN rather than out of it, includes this description: “The LN does not transfer energy originating outside the LN for delivery through the LN.” We understand this language is intended to distinguish a LN from a link in the transmission system – power on a transmission link passes through the transmission link to a load located elsewhere, while power in a LN enters the LN and is consumed by retail load within the LN. While we agree with the concept proposed by the SDT, we believe the language would be clearer if it read: “The LN does not transfer energy originating outside the LN for delivery through the LN to loads located outside the LN.” We believe the italicized language is necessary to distinguish between a transmission system, where power that originates outside a system is delivered through the system and passes through the system to a sink located somewhere outside the system, from a LN, in which power originating outside the LN passes through the LN and is delivered to retail load within the LN. To put it another way, the italicized language helps distinguish a transmission system from an LN, in which the LN “transfers energy originating outside the LN for delivery through the LN to loads located within the LN.” We also believe the language of subparagraph (a) of Exclusion 3 could be improved. Subparagraph (d) would make LNs part of the BES if they interconnect “non-retail generation greater than 75 MVA (gross nameplate rating).” For the reasons stated in our responses to Questions 3, 5 and 7, we urge the SDT to replace the reference to a hard 75 MVA threshold with the defined term “Qualifying Aggregate Generation Resources” or some equivalent. We are also uncertain what is meant by the use of the term “non-retail generation” in subparagraph (a). From context, we believe the SDT considers “non-retail generation” to be the equivalent of generation that is located behind the retail meter, usually but not always owned by the customer and used to serve the customer’s own load. We therefore suggest that the SDT replace the term “non-retail generation” with “generation located behind the retail customer’s meter.” Similarly, we are unsure what is meant by the phrase “the LN and its underlying Elements.” We believe the phrase “and its underlying Elements” could simply be deleted from the definition without loss of meaning. In the alternative, the SDT might consider using the phrase “the LN, including all Elements located on the distribution side of any Automatic Fault Interrupting Devices (or other points of demarcation) separating the LN from the bulk interstate transmission system.” We believe this phrase more accurately reflects the SDT’s intent, which appears to be that generation exceeding 75 MVA in aggregate capacity interconnected anywhere within the LN disqualifies that LN from being excluded from the BES under Exclusion 3. CPC also believes that both subparagraphs (a) and (b) of Exclusion 3 could be safely eliminated as long as subparagraph (c) is retained. Subparagraph (c) makes a LN part of the BES if it is classified as a Flow Gate or Transfer Path. Flow Gates and Transfer Paths are, by definition, the key facilities that allow reliable transmission of bulk electric power on the interconnected grid. If a LN has not been identified as either a Flow Gate or a Transfer Path, it is unlikely the LN is necessary for the reliable transmission of electricity on the interconnected bulk system. Apart from these specific improvements that we believe could be achieved by modifying the language of Exclusion 3, we believe the SDT may need to

re-examine certain assumptions that appear to underlie the current draft. Specifically, subparagraph (a) suggests that if BES generation is embedded within a LN, the LN itself must also be BES. But two NERC bodies have already addressed similar questions and concluded there is no technical basis for such concerns. NERC's Standards Drafting Team for Project 2010-07 and its predecessor, the "GO-TO Task Force" were formed to address how the dedicated interconnection facilities linking a BES generator to high-voltage transmission facilities should be treated under the NERC standards. The GO-TO Team concluded that by complying with a handful of reliability standards, primarily related to vegetation management, reliable operation of the bulk interconnected system could be protected without unduly burdening the owners of such interconnection systems. Therefore, there is no reason, according to the GO-TO Team, that dedicated high-voltage interconnection facilities must be treated as "Transmission" and classified as part of the BES in order to make reliability standards effective. See Final Report from the NERC Ad Hoc Group for Generator Requirements at the Transmission Interface (Nov. 16, 2009) (paper written by the GO-TO Task Force). Similarly, the Project 2010-07 Team observed that interconnection facilities "are most often not part of the integrated bulk power system, and as such should not be subject to the same level of standards applicable to Transmission Owners and Transmission Operators who own and operate transmission Facilities and Elements that are part of the integrated bulk power system." White Paper Proposal for Information Comment, NERC Project 2010-07: Generator Requirements at the Transmission Interface, at 3 (March 2011). Requiring Generation Owners and Operators to comply with the same standards as BES Transmission Owners and Operators "would do little, if anything, to improve the reliability of the Bulk Electric System," especially "when compared to the operation of the equipment that actually produces electricity – the generation equipment itself." Id. We believe that interconnection of BES generators within a LN is analogous and that, based on the findings of the Project 2010-07 and GO-TO Teams, automatically classifying a LN as "BES" simply because a large generator is embedded in the LN will result in substantial overregulation and unnecessary expense with little gain for bulk system reliability. If anything, generation interconnected through a LN is less likely to produce material impacts on the interconnected bulk transmission system than the equivalent generator interconnected through a single dedicated line because an LN is interconnected to the bulk system at several points, so that if one interconnection goes down, power can still flow from the BES generator to the bulk system on other interconnection points. Where a dedicated interconnection facility is involved, by contrast, if the interconnection line fails, the generator is unavailable to the interconnected bulk system. Similarly, we suggest that the SDT re-examine the assumptions underlying subparagraph (b), which seems to suggest that a local distribution system cannot be classified as a Local Network if power flows out of that system at any time, even if the amount is de minimis, the outward flow is only for a few hours, a year, or the outward flow occurs only in an extreme contingency. Accordingly, we suggest that the initial clause of subparagraph (b) be revised to read: "Except in unusual circumstances, power flows only into the LN." Finally, we note that the LN exclusion must not operate in any way as a substitution for the statutory prohibition on including "facilities used in the local distribution of electric energy" in the BES. Therefore, even with the LN exclusion, the SDT must retain this statutory language in the core definition of the BES, as discussed in our answer to Question One. If a certain piece of equipment is a "facility used in the local distribution of electric energy," then it is not part of the BES in the first instance, and so consideration of the LN Exclusion, or of any other Exclusion, any Inclusion, or any Exception, would be both unnecessary and uncalled for.

Yes

CPC supports the revised language because retail reactive devices are used to address local customer or retail voltage issues, rather than voltage issues on the interconnected bulk grid, and such local devices should therefore be excluded from the BES definition.

No

CPC extends its thanks to the SDT and to the many industry entities that have actively participating in the Standards Development Process. CPC supports the current draft and believes, with certain refinements discussed in our comments, that the definition will serve the industry and reliability regulators well for many years to come. In addition, as noted earlier, CPC is encouraged that the 20/75 MVA generation thresholds referred to in the NERC Statement of Compliance Registry Criteria, which have been relied upon by the SDT largely as a matter of necessity, will be reviewed and a technical assessment will be performed to identify the appropriate generation unit and plant size threshold to ensure a reliable North America. Finally, we understand that the Rules of Procedure Team will continue to move forward with developing an Exceptions Process that will complement the BES

Definition and ensure that, to the extent the BES Definition is over-inclusive, facilities that should not be classified as BES will be excluded from the BES. Because the Exceptions Process is integral to a workable BES Definition, we support the current process for moving forward with the Exceptions Process and the BES Definition on parallel paths. We note that CPC specifically supports the changes made by the SDT in the "Effective Date" provision of the BES Definition, which shortens the effective date of the new definition to the beginning of the first calendar quarter after regulatory approval (as opposed to the first calendar quarter twenty-four months after regulatory approval), with a 24-month transition period. CPC supports this conclusion because it will allow entities seeking deregistration under the terms of the new BES definition to obtain the benefits of the new definition without an unreasonable wait, while allowing any entities that may be newly-classified as BES owners or operators sufficient time to come into compliance with newly-applicable Reliability Standards. CPC also supports the 24-month transition period for the reasons laid out by the SDT.

Individual

Eric Lee Christensen

Snohomish County PUD

Yes

The Public Utility District No. 1 of Snohomish County ("SNPD") believes the SDT continues to make substantial progress towards a clear and workable definition of the Bulk Electric System ("BES") that markedly improves both the existing definition and the SDT's previous proposal. SNPD therefore strongly supports the new definition, although our support is conditioned on: (1) a workable Exceptions process being developed in conjunction with the BES definition; and, (2) the SDT moving forward expeditiously on Phase II of the standards development process in accordance with the SAR recently put forward by the SDT, which would address a number of important technical issues that have been identified in the standards development process to date. SNPD strongly supports the following elements of the revised BES definition: (1) Clarification of how lists of Inclusions and Exclusions applies: The revised core definition moves the phrase "Unless modified by the lists shown below" to the beginning of the definition. This change makes clear that the Inclusions and Exclusions apply to all Elements that would otherwise be included in or excluded from the core definition (i.e., "all Transmission Elements operated at 100 kV or higher and Real Time and Reactive Power resources connected at 100 kV or higher") and eliminates a latent ambiguity in the first draft of the definition, discussed further in our comments on the first draft. (2) The exclusion for Local Distribution Facilities. As the starting point for the BES definition, SNPD supports use of the phrase "all Transmission Elements" and the qualifying sentence: "This does not include facilities used in the local distribution of electric energy." This language helps ensure that FERC, NERC, and the Regional Entities ("REs") will act within the jurisdictional constraints Congress placed in Section 215 of the Federal Power Act ("FPA"). In Section 215(a)(1), Congress unequivocally excluded "facilities used in the local distribution of electric energy" from the keystone "bulk-power system" definition. 16 U.S.C. § 824o(a)(1). Including the same language in the definition helps ensure that entities involved in enforcement of reliability standards will act within their statutory limits. In addition, as a practical matter, inclusion of the language will help focus both the industry and responsible agencies on the high-voltage interstate transmission system, where the reliability problems Congress intended to regulate – "instability, uncontrolled separation, [and] cascading failures," 16 U.S.C. § 824o(a)(4) – will originate. At the same time, level-of-service issues arising in local distribution systems will be left to the authority of state and local regulatory agencies and governing bodies, just as Congress intended. 16 U.S.C. § 824o(i)(2) (reserving to state and local authorities enforcement of standards for adequacy of service). For similar reasons, Snohomish believes use of the phrase "Transmission Elements" as the starting point for the base definition is desirable because both "Transmission" and "Elements" are already defined in the NERC Glossary of Terms Used, and the term "Transmission" makes clear that the BES includes only Elements used in Transmission and therefore excludes Elements used in local distribution of electric power. (3) Appropriate Generator Thresholds. In the standards development process, it has become apparent that the thresholds for classifying generators as BES in the current NERC Statement of Compliance Registry Criteria ("SCRC") (20 MVA for individual generators, 75 MVA for multiple generators aggregated at a single site), which predate the adoption of FPA Section 215, were never the product of a careful analysis to determine whether generators of that size are necessary for operation of the interconnected bulk transmission system. Ideally, such an analysis would be conducted as part of the current standards development process. Snohomish recognizes that, given the deadlines imposed by FERC in Order No. 743, it will not be possible for the SDT to

conduct such an analysis within the time available. Accordingly, Snohomish agrees with the approach taken by the SDT, which is to propose a Phase II of the standards development process that would address the generator threshold issue and several other technical issues that have arisen during the current process. As long as Phase II proceeds expeditiously, Snohomish is prepared to support the BES definition as proposed by the SDT. While Snohomish strongly supports the overall approach adopted by the SDT and much of the specific language incorporated into the second draft of the BES definition, we believe the second draft would benefit from further clarification or modification in a number of respects, most of which are detailed in our subsequent answers. Our support for the definition is not contingent upon these changes being adopted. Further, we believe a workable Exclusion Process is essential for a BES Definition that will meet the legal requirements of FPA Section 215, especially for systems operating in the Western Interconnection. As detailed in our previous comments, Snohomish believes a 200-kV threshold would be more appropriate for WECC than a 100-kV threshold. In addition, a 200-kV threshold for the West is backed by solid technical analysis conducted by the WECC Bulk Electric System Definition Task Force, and repeated claims that there is no technical analysis to support this view is therefore incorrect. That being said, we raise the issue here to emphasize the importance of the Exclusions for Local Networks and Radial Systems and the Exceptions process. These Exclusions and the Exceptions are essential for a definition that works in the Western Interconnection because the core definition will be over-inclusive in our region. As long as those Exclusions and the Exceptions Process are retained in a form substantially equivalent to those produced by the SDT at this juncture, Snohomish will support the SDT's proposal and will not further pursue its claims regarding the 200-kV threshold. Finally, we suggest that the SDT address the circumstance when an Element is covered by both an Inclusion and an Exclusion. We note that some of the inclusions already contain language addressing this question. For example, Inclusion 1 indicates that transformers falling within the specified parameters are part of the BES ". . . unless excluded under Exclusions E1 or E3." Where it is not already included, similar language should be included in the other Inclusions and/or Exclusions to explain whether the SDT intends the Inclusions or the Exclusions to predominate in situations where facilities might be covered by both. We suggest clarifying language in our responses to Questions 2 and 5.

Yes

We support the SDT's changes to the first Inclusion because it is more clear and simple than the initial approach. That being said, we suggest that an additional sentence of clarification would help avoid future controversy about the meaning of Inclusion 1. As we understand it, the BES intends to include transformers only if both the primary and secondary terminals operate at 100 kV or above, which is why the definition uses the word "and" ("the primary and secondary terminals"). We support this approach since it would exclude transformers where the secondary terminals serve distribution loads, and which therefore function as distribution rather than transmission facilities. We believe the SDT's intent would be clarified by adding a sentence at the end of Inclusion 1 that reads: "Transformers with either primary or secondary terminals, or both, that operate at or below 100 kV are not part of the BES." This language will help ensure that there is no controversy over whether the SDT's use of the word "and" in the phrase "the primary and secondary terminals" was intentional. We also support the SDT's proposal to develop detailed guidance concerning the point of demarcation between BES and non-BES elements in the Phase II SAR. In this regard, we note that, while Inclusion 1 at least implicitly suggests that the dividing line between BES and non-BES Elements should be at the transformer where transmission-level voltages are stepped down to distribution-level voltages, we believe further clarification of this point of demarcation between the BES and non-BES Elements is necessary. Many different configurations of transformers and other equipment that may lie at the juncture between the BES and non-BES systems. If the point of demarcation is designated at the transformer without further elaboration, many entities that own equipment on the high side of a transformer will be swept into the BES, and thereby exposed to inappropriately stringent regulations and undue costs. For example, distribution-only utilities commonly own the switches, bus and transformer protection devices on the high side of transformers where they take delivery from their transmission provider. Ownership of these protective devices and high-voltage bus on the high side of the transformer should not cause these entities to be classified as BES owners. As the Phase II process moves forward, we commend to the SDT the extensive work performed on the point of demarcation question by the WECC BESDTF. We also support the incorporation of language (" . . . unless excluded under Exclusions E1 or E3") making it clear that transformers that are operated as an integral part of a Radial System or Local Network should not be considered BES facilities, regardless of their operating voltage. Further clarification might be achieved by using the phrase ". . . unless the

transformer is operated as part of a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2."

Yes

SNPD supports the changes made in Inclusion 2 and believe that the definition in its current form adds clarity. In particular, we support the SDT's decision to collapse Inclusions 2 and 3 from the previous draft definition into a single Inclusion that addresses the treatment of generation for purposes of the BES definition. We also support the SDT's proposal for a Phase II of the BES Definition process to examine the technical justification for these thresholds and to establish new thresholds based on a careful technical analysis. It is our understanding that the generator threshold issue will be vetted through the complete standards development process. We agree with this approach because if the generator threshold is treated as merely an element of NERC's Rules of Procedure, it can be changed with considerably less due process and industry input than the Standards Development Process. Compare NERC Rules of Procedure § 1400 (providing for changes to Rules of Procedure upon approval of the NERC board and FERC) with NERC Standards Process Manual (Sept. 3, 2010) (providing for, e.g., posting of SDT proposals for comment, successive balloting, and super-majority approval requirements). See also Order No. 743-A, 134 FERC ¶ 61,210 at P 4 (2011) ("Order No. 743 directed the ERO to revise the definition of 'bulk electric system' through the NERC Standards Development Process" (emph. added)). Addressing all aspects of Phase II through the Standards Development Process will improve the content of the definition by bringing to bear industry expertise on all aspects of the definition and will ensure that, once firm guidelines are established, they can be relied upon by both industry and regulators without threat that they will be changed with little notice and little due process. SNPD also believes further clarification of the proposed language would be appropriate. The SDT proposes continued reliance upon the thresholds that are used in the NERC Statement of Compliance Registry Criteria for registration of Generation Owners and Generation Operators, which is currently 20 MVA for an individual generation unit and 75 MVA for multiple units on a single site. Conceptually, we are concerned about this approach because, as we understand it, the purpose of the Compliance Registry is to sweep in all generators that might be material to the reliable operation of the BES, and not to definitively determine whether a given generator is, in fact, material to the reliable operation of the BES. As the SCRC itself states, the SCRC is intended only to identify "candidates for registration." SCRC at p.3, § 1 (emph. added). Accordingly, we believe that the generator threshold determined in Phase II should be incorporated directly into the BES Definition rather than being incorporated by reference from the SCRC. We also believe that the specific language proposed by the SDT could be further clarified. The SDT proposes to include generation in the BES if the "Generation resource(s)" has a "nameplate rating per the ERO Statement of Compliance Registry." We understand this language is intended to be a placeholder for the results of the technical analysis that would occur in Phase II but we believe simply stating that the threshold will be "per the ERO Statement of Compliance Registry" is ambiguous. Further, for the reasons noted above, we believe the threshold should be part of the BES Definition, and should not simply be a cross-reference to the SCRC (and, given the different purposes of the BES Definition and the SCRC, it is not clear that the same threshold should be used in both). We therefore propose that Inclusion 2 be rewritten to state: "Qualifying Individual Generation Resources or Qualifying Aggregate Resources connected at a voltage of 100 kV or above." Two definitions would then be added to the note at the end of the definition to read as follows: "For purposes of this BES Definition, Qualifying Individual Generation Resources means an individual generating unit that meets the materiality threshold to be included in this definition or, in the absence of such a materiality threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of such a resource as a Generation Owner under the ERO Statement of Compliance Registry Criteria." "For purposes of this BES Definition, Qualifying Aggregate Generation Resources means any facility consisting of one or more generating units that are connected at a common bus that meets the materiality threshold to be included in this definition, or, in the absence of such a threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of multiple-unit generator as a Generation Owner under the ERO Statement of Compliance Registry Criteria." The "materiality threshold" is intended to refer to the generator threshold developed in Phase II. We suggest using definitions in this fashion for several reasons. First, we believe the language we suggest more clearly states the intention of the SDT, which we understand is to classify generation units as part of the BES if they are necessary for operation of the BES, but to exclude smaller generating units because they are not material to the operation of the interconnected transmission grid. Second, we believe use of the defined terms better reflects the intention of the SDT to reserve the specific question about

generator thresholds to the technical analysis that will occur in Phase II without having to revise the BES Definition at the end of that process. That is, the definitions are designed to allow the SDT to include revised thresholds in the definition at the conclusion of the Phase II process based upon the technical analysis planned for Phase II, and the revised thresholds will be automatically incorporated into the BES Definition if the language we suggest is used. The thresholds used in the SCRC would only be a fall-back, to be used only until Phase II is completed. Third, the definitions can be incorporated into other parts of the BES Definition, which will add consistency and clarity. As noted in our answers to several of the questions below, the specific 75 MVA threshold is retained in several of the Exclusions and Inclusions, and we believe the industry would be better served if the revised thresholds arrived at after technical analysis in Phase II are automatically incorporated into all relevant provisions of the BES Definition. There is no reason for the SDT to continue to rely on the 75 MVA threshold once the analysis planned for Phase II on the threshold issue is completed. Fourth, the phrase "or that meets the materiality threshold to be included in this definition" is intended to preserve the SDT's flexibility to make a determination that generators below a specific threshold are not "necessary to" maintain the reliability of the interconnected transmission system, and to incorporate that finding as part of the definition itself, even if a different threshold is used in the SCRC to identify potential candidates for registration. Accordingly, our proposed language makes clear that a specific threshold in the definition controls over any threshold that might be included in the SCRC. For the reasons stated above, we believe it is highly desirable to include any material threshold in the BES Definition itself rather than relegating the threshold to the SCRC, which is merely a procedural rule rather than a full-fledged Reliability Standard. Hence, we agree with the SDT's decision to examine the question of where the line between BES and non-BES Elements should be drawn more closely in Phase II under the rubric of "contiguous vs. non-contiguous BES," and commend the work of the Project 2010-07 Standards Drafting Team and the GO-TO Team as a good starting point for the SDT's analysis on this issue. We understand Inclusion 2 would classify generators exceeding specific thresholds as part of the BES, but would not necessarily require facilities interconnecting such generators to be part of the BES. As discussed more fully in our answer to Question 9, based on extensive technical analysis that has already been performed by the NERC Project 2010-07 Standards Drafting Team and its predecessor, the NERC "GO-TO Team," regulating as part of the BES a dedicated interconnection facility connecting a BES generator to the interconnected bulk transmission grid will result in an unnecessary regulatory burden that produces considerable expense for the owner of the interconnection facility with little or no improvement in bulk system reliability. We also believe the clauses at the end of Inclusion 2 are somewhat confusing and that greater clarity would be achieved by changing ". . . including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100 kV or above" so that the Inclusion covers transformers with terminals "connected at a voltage of 100 kV or above, including the generator terminal(s) on the high side of the step-up transformer(s) if operated at a voltage of 100 kV or above." Finally, as discussed further in our answer to Questions 5 and 6, SNPD believes more clarity may be achieved by collapsing Inclusion 5, addressing Reactive Power resources, and Inclusion 4, which addresses dispersed renewable resources, into a single Inclusion that addresses "power producing resources" (the language used in current Inclusion 4).

Yes

SNPD supports the removal of the Cranking Path language in I3. As noted in our response to Question 9, there is no reason to classify as BES the facilities interconnecting a BES generator to the bulk interstate system. A Cranking Path is simply a specific type of such an interconnection facility.

Yes

SNPD supports the revised language generally, but believes additional changes would make the language clearer. Specifically, we believe Inclusion 4 should not incorporate a hard 75 MVA generation threshold (i.e., "resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)"). Instead, we urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," which is discussed in more detail in our response to Question 3. This language, or some equivalent, will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. More generally, we are not certain what is accomplished by Inclusion 4 that is not already accomplished by Inclusion 2, which also addresses whether generation should be defined as BES. The SDT's stated concern is with variable generation units such as wind and solar plants. It is not clear to us why this concern is not fully addressed in

Inclusion 2, which addresses multiple generation units connected at a common bus, the configuration of most variable generation plants with multiple units. We are also concerned that the language, as proposed, could have unintended consequences and improperly classify local distribution systems as BES in certain circumstances. This is because multiple distributed generation units could render a local distribution system a "collector system" and the entire system the equivalent of an aggregated generation unit, causing the local distribution system to be improperly denied status as a LN. If many different distributed generation units are connected to a local distribution system, it is very unlikely that more than a few of those units would fail simultaneously, and it is therefore unlikely that multiple generation units would produce a measureable impact on the interconnected bulk transmission system, especially if the units individually do not otherwise exceed the materiality threshold to be established by the SDT in Phase II. Further, we are concerned that, if small distributed generation units become the industry norm, Inclusion 4 could unintentionally sweep in local distribution systems, especially where local policies favor the growth of small solar or other renewable generation systems for public policy reasons. Finally, we suggest that the SDT add the phrase ". . . unless the dispersed power producing resources operate within a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2." This language, which parallels the language included at the end of Inclusion I1, would make clear that dispersed small-scale generators scattered throughout a Radial System or Local Network serving retail load would not convert the Radial System or Local Network into a BES system, even if the aggregate capacity of those small generators exceeds the relevant threshold.

No

SNPD has several concerns about the new language in Inclusion 5. First, because Reactive Power devices produce power, they are "power producing resources" and we therefore believe Inclusion 5 is duplicative of Inclusion 4, which addresses "power producing devices." Second, there is no capacity threshold specified in Inclusion 5 for Reactive Power devices that would be considered part of the BES. This is inconsistent with the approach taken in the balance of the definition, where thresholds are specified for generators and other types of power producing devices. Finally, SNPD believes the appropriate threshold for inclusion or exclusion of Reactive Power devices from the BES should be subject to the same technical analysis that will cover generators in the Phase II process.

Yes

SNPD continues to support the radial system exclusion, which is necessary as a legal matter, because, for example, FERC in Orders No. 743 and 743-A has required that the existing radial exemption in the NERC Statement of Compliance Registry Criteria be maintained. As a practical matter, radial systems are used for service to retail loads, usually in remote or rural areas, and not for the transmission of bulk power. Hence, operation of the radials has little or nothing to do with the reliable operation of the interconnected bulk transmission network. We also support the inclusion of the note discussing normally open switches because this language provides needed clarity for a common radial system configuration. We also agree with the substantive thrust of this language, which is that a radial system should not be considered part of the BES if it is interconnected at a single point, even if there is an alternative point of delivery that is normally open. While we support the Exclusion for Radial Systems, we believe several clarifications and refinements are necessary. (1) The term "transmission Elements" in the initial paragraph should be changed to "Elements." Radial systems are not transmission systems and including the word "transmission" in the Radial System exclusion is therefore unnecessary and confusing. (2) Subparagraph (b) of Exclusion 1 refers to "generation resources . . . with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)". We urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," discussed in more detail in our response to Question 3. This language, or some equivalent, will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. (3) Subparagraph (b) also seems to assume that if a Radial System contains a generator exceeding the 75 MVA threshold, the Radial System itself must be included in the BES because it links the generator to the interconnected bulk transmission system. As discussed more fully in our response to Question 9, below, NERC's Project 2010-17 Standards Drafting Team and GO-TO Task Force have both concluded that this assumption is unwarranted. (4) The "Note" as drafted by the SDT indicates that "a normally open switching device between radial systems" will not serve to disqualify the Radial from exclusion under Exclusion 1. As noted above, SNPD strongly supports the note conceptually. However, we believe this language should be included in a separate subparagraph (d),

rather than a note, because treatment as a “note” suggests it is less important than other portions of the Exclusion. We also suggest the language be changed to read: “d) Normally-open switching devices between radial elements as depicted and identified on system one-line diagrams does not affect this exclusion.” This will make clear that a radial with more than one normally-open switch connecting it to another radial is still a radial. From the perspective of the BES Definition, the key question is whether switches operating between Radials are normally open, not whether there is more than one normally-open switch.

Yes

SNPD supports the revised language. The language provides clarity regarding the BES status of customer-owned cogeneration facilities. However, SNPD urges the SDT to remove the reference to the 75 MVA threshold and replace it with the defined term “Qualifying Aggregate Generation Resources” or some equivalent language for the reasons stated in our responses to Questions 3, 5, and 7. In addition, we are concerned that Exclusion 2 will place local distribution utilities in a difficult position because, under Exclusion 1 or Exclusion 3 as drafted, they could lose their status as a Radial System or a Local Network through the actions of a customer constructing behind-the-meter generation. With respect to Radial Systems, the appearance of behind-the-meter generators could cause the Radial System to exceed the thresholds specified in subparagraphs (b) and (c) of Exclusion 1 through no fault of the Radial System owner. Similar, a Local Network could lose its status because behind-the-meter generation could be of sufficient size that power moves into the interconnected grid in certain hours or under certain contingencies, rather than moving purely onto the Local Network, as required in subparagraph (b) of Exclusion 3. The Exclusions for Radial Systems and Local Networks should be made consistent with the Exclusion for behind-the-meter generation. There is no technical reason to believe the power flowing from a behind-the-meter customer-owned generator will have less impact on the bulk system than an equivalent-sized generator owned by a utility operating a Radial System or LN.

Yes

SNPD strongly supports the categorical exclusion of Local Networks (“LNs”) from the BES. We believe the exclusion is necessary to ensure that the BES definition complies with the statutory requirement, discussed in our response to Question 1, to exclude all facilities used in the local distribution of electric power. LNs are, of course, probably the most common form of local distribution facility. Further, the conversion of radial systems to local distribution networks should be encouraged because networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. If the BES definition were to provide an exclusion for radials without providing a similar exclusion for LNs, however, it would discourage networking local distribution systems because of the significantly increased regulatory burdens faced by the local distribution utility if it elected to network its radial facilities. By placing radial systems and LNs on the same regulatory footing, the proposed definition will ensure that decisions about whether to network radial systems are made on the basis of costs and benefits to the retail customers served by those radials, and not on the basis of disparate regulatory treatment. Consumers will ultimately benefit from the path chosen by the SDT. SNPD also supports specific refinements made to the LN exclusion by the SDT in the current draft of the BES definition. In particular, SNPD supports the clarification of the purposes of a LN. The current draft states that LNs connect at multiple points to “improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system.” Snohomish supports this change in language because it reflects the fundamental purposes of a LN and emphasizes one of the key distinctions between LNs and bulk transmission facilities, namely, that LNs are designed primarily to serve local retail load while bulk transmission facilities are designed primarily to move bulk power from a bulk source (generally either the point of interconnection of a wholesale generator or a the point of interconnection with another bulk transmission system) to one or more wholesale purchasers. SNPD believes further improvement of the language could be achieved with additional modifications and clarifications. With respect to the core language of Exclusion 3, we believe the language making a “group of contiguous transmission Elements operated at or above 100 kV” the starting point for identifying a LN would be improved by deleting the term “transmission” from this phrase. This is so because LNs are not used for transmission and the use of the term “transmission Elements” is therefore both confusing and unnecessary. There would be no room for argument about what the SDT intended by including the word “transmission” if the word is deleted and the Exclusion applies to any “group of Elements operated at 100 kV or above” that meets the remaining requirement of the Exclusion. Further, any definitional value that is added by using the

term “transmission Elements” is accomplished by using that term in the core definition, and there is no reason to carry the term through in the Exclusions. SNPD also believes that subparagraphs (a) and (b) are redundant in the sense that whatever protection is offered by the generation limit in subparagraph (a) is duplicated by the limit in subparagraph (b) requiring no flow out of the LN. We believe the SDT can eliminate subparagraph (a) of Exclusion 3 and simply rely on subparagraph (b) because if power only flows into the LN even if it interconnects more than 75 MVA of generation, the interconnected generation interconnected will have no significant interaction with the interconnected bulk transmission system. It will only interact with the LN. And, with the advent of distributed generation, it is easy to foresee a situation in which a large number of very small distributed generators are interconnected into a LDN, so that the aggregate capacity of these generators exceeds 75 MVA. However, because the generators are small and dispersed and, under the criterion in subparagraph (b), would be wholly absorbed within the LN rather than transmitting power onto the interconnected grid, those generators would not have a material impact on the grid. We also suggest that subparagraph (b) of Exclusion 3 could be more clearly drafted. Subparagraph (b), as part of the requirement that power flow into a LN rather than out of it, includes this description: “The LN does not transfer energy originating outside the LN for delivery through the LN.” We understand this language is intended to distinguish a LN from a link in the transmission system – power on a transmission link passes through the transmission link to a load located elsewhere, while power in a LN enters the LN and is consumed by retail load within the LN. While we agree with the concept proposed by the SDT, we believe the language would be clearer if it read: “The LN does not transfer energy originating outside the LN for delivery through the LN to loads located outside the LN.” We believe the italicized language is necessary to distinguish between a transmission system, where power that originates outside a system is delivered through the system and passes through the system to a sink located somewhere outside the system, from a LN, in which power originating outside the LN passes through the LN and is delivered to retail load within the LN. To put it another way, the italicized language helps distinguish a transmission system from an LN, in which the LN “transfers energy originating outside the LN for delivery through the LN to loads located within the LN.” We also believe the language of subparagraph (a) of Exclusion 3 could be improved.

Subparagraph (d) would make LNs part of the BES if they interconnect “non-retail generation greater than 75 MVA (gross nameplate rating).” For the reasons stated in our responses to Questions 3, 5 and 7, we urge the SDT to replace the reference to a hard 75 MVA threshold with the defined term “Qualifying Aggregate Generation Resources” or some equivalent. We are also uncertain what is meant by the use of the term “non-retail generation” in subparagraph (a). From context, we believe the SDT considers “non-retail generation” to mean generation that is used by retail customers located within a LN rather than being exported and sold on wholesale markets outside the LN. We therefore suggest that the SDT replace the phrase “non-retail generation” with the phrase “generation sold in wholesale markets and transmitted outside the LN.” Similarly, we are unsure what is meant by the phrase “the LN and its underlying Elements.” We believe the phrase “and its underlying Elements” could simply be deleted from the definition without loss of meaning. In the alternative, the SDT might consider using the phrase “the LN, including all Elements located on the distribution side of any Automatic Fault Interrupting Devices (or other points of demarcation) separating the LN from the bulk interstate transmission system.” We believe this phrase more accurately reflects the SDT’s intent, which appears to be that generation exceeding 75 MVA in aggregate capacity interconnected anywhere within the LN disqualifies that LN from being excluded from the BES under Exclusion 3.

Finally, SNPD believes that both subparagraphs (a) and (b) of Exclusion 3 could be safely eliminated as long as subparagraph (c) is retained. Subparagraph (c) makes a LN part of the BES if it is classified as a Flow Gate or Transfer Path. Flow Gates and Transfer Paths are, by definition, the key facilities that allow reliable transmission of bulk electric power on the interconnected grid. If a LN has not been identified as either a Flow Gate or a Transfer Path, it is unlikely the LN is necessary for the reliable transmission of electricity on the interconnected bulk system. Apart from these specific improvements that we believe could be achieved by modifying the language of Exclusion 3, we believe the SDT may need to re-examine certain assumptions that appear to underlie the current draft. Specifically, subparagraph (a) suggests that if BES generation is embedded within a LN, the LN itself must also be BES. But two NERC bodies have already addressed similar questions and concluded there is no technical basis for such concerns. NERC’s Standards Drafting Team for Project 2010-07 and its predecessor, the “GO-TO Task Force” were formed to address how the dedicated interconnection facilities linking a BES generator to high-voltage transmission facilities should be treated under the NERC standards. The GO-TO Team concluded that by complying with a handful of reliability

standards, primarily related to vegetation management, reliable operation of the bulk interconnected system could be protected without unduly burdening the owners of such interconnection systems. Therefore, there is no reason, according to the GO-TO Team, that dedicated high-voltage interconnection facilities must be treated as "Transmission" and classified as part of the BES in order to make reliability standards effective. See Final Report from the NERC Ad Hoc Group for Generator Requirements at the Transmission Interface (Nov. 16, 2009) (paper written by the GO-TO Task Force). Similarly, the Project 2010-07 Team observed that interconnection facilities "are most often not part of the integrated bulk power system, and as such should not be subject to the same level of standards applicable to Transmission Owners and Transmission Operators who own and operate transmission Facilities and Elements that are part of the integrated bulk power system." White Paper Proposal for Information Comment, NERC Project 2010-07: Generator Requirements at the Transmission Interface, at 3 (March 2011). Requiring Generation Owners and Operators to comply with the same standards as BES Transmission Owners and Operators "would do little, if anything, to improve the reliability of the Bulk Electric System," especially "when compared to the operation of the equipment that actually produces electricity – the generation equipment itself." Id. We believe that interconnection of BES generators within a LN is analogous and that, based on the findings of the Project 2010-07 and GO-TO Teams, automatically classifying a LN as "BES" simply because a large generator is embedded in the LN will result in substantial overregulation and unnecessary expense with little gain for bulk system reliability. If anything, generation interconnected through a LN is less likely to produce material impacts on the interconnected bulk transmission system than the equivalent generator interconnected through a single dedicated line because an LN is interconnected to the bulk system at several points, so that if one interconnection goes down, power can still flow from the BES generator to the bulk system on other interconnection points. Where a dedicated interconnection facility is involved, by contrast, if the interconnection line fails, the generator is unavailable to the interconnected bulk system. Similarly, we suggest that the SDT re-examine the assumptions underlying subparagraph (b), which seems to suggest that a local distribution system cannot be classified as a Local Network if power flows out of that system at any time, even if the amount is de minimis, the outward flow is only for a few hours a year, or the outward flow occurs only in an extreme contingency. Accordingly, we suggest that the initial clause of subparagraph (b) be revised to read: "Except in unusual circumstances, power flows only into the LN."

Yes

Yes, SNPD supports the revised language because retail reactive devices are used to address local customer or retail voltage issues, rather than voltage issues on the interconnected bulk grid, and such local devices should therefore be excluded from the BES definition.

No

SNPD extends its thanks to the SDT and to the many industry entities that have actively participating in the Standards Development Process. SNPD strongly supports the current draft and believes, with certain refinements discussed in our comments, that the definition will serve the industry and reliability regulators well for many years to come. In addition, as noted earlier, SNPD is encouraged that the 20/75 MVA generation thresholds referred to in the NERC Statement of Compliance Registry Criteria, which have been relied upon by the SDT largely as a matter of necessity, will be reviewed and a technical assessment will be performed to identify the appropriate generation unit and plant size threshold to ensure a reliable North America. Finally, we understand that the Rules of Procedure Team will continue to move forward with developing an Exceptions Process that will complement the BES Definition and ensure that, to the extent the BES Definition is over-inclusive, facilities that should not be classified as BES will be excluded from the BES. Because the Exceptions Process is integral to a workable BES Definition, we support the current process for moving forward with the Exceptions Process and the BES Definition on parallel paths. We note that SNPD specifically supports the changes made by the SDT in the "Effective Date" provision of the BES Definition, which shortens the effective date of the new definition to the beginning of the first calendar quarter after regulatory approval (as opposed to the first calendar quarter twenty-four months after regulatory approval), with a 24-month transition period. SNPD supports this conclusion because it will allow entities seeking deregistration under the terms of the new BES definition to obtain the benefits of the new definition without an unreasonable wait, while allowing any entities that may be newly-classified as BES owners or operators sufficient time to come into compliance with newly-applicable Reliability Standards. SNPD also supports the 24-month transition period for the reasons laid out by the SDT.

Transmission Reliability Program
Yes
Yes
Yes
BPA agrees with the I2 changes and feels that they are excellent.
Yes
Yes
BPA suggests adding, "Including generating terminals of the high side" as clarifying language to the end of the sentence. (Specifically where the 100kV is to be measured as clarified in I2). BPA believes that Inclusion 4 is not intended to include each individual wind turbine/generator unit in a wind farm as a BES element, but rather to include the point at which the aggregation becomes large enough to meet the aggregate capacity threshold of 75 MVA.
Yes
No
BPA believes that a system left connected in a network configuration, via use of a normally open switch for temporary network connection, without the protections afforded through the standards that apply to BES should be limited to less than 24 hours. BPA believes that the term "non-retail generation" in E1(c) should be clearly defined. In addition, BPA believes that there needs to be a means to isolate the radial system from the BES during a fault on the radial system by means of a automatic fault interrupting device. Automatic fault interrupting device should be a defined term.
Yes
BPA believes that if E2 is intended to exclude behind-the-meter generation, the phrase "on the customer's side of the retail meter" should immediately follow "generating units" in the first line. Otherwise, the phrase could be seen as modifying "retail customer Load."
No
BPA has several concerns regarding Exclusion E3. First, BPA strongly believes that Exclusion E3 must retain the requirement that the local network (LN) be separable from the BES by an automatic fault interrupting device wherever the LN interconnects with the BES. BPA believes that this is necessary in order to protect both the BES and the LN during faults, especially if there is any possibility that backfeed could occur. BPA recommends retaining the original language: Separable by automatic fault interrupting devices: Wherever connected to the BES, the LN must be connected through automatic fault interrupting devices. In addition, as stated in our comments in May, 2011, "automatic fault interrupting device" should be a defined term. BPA strongly believes that Exclusion E3 should not be allowed for any facilities above 200kV instead of the 300kV limit in shown in the current proposal. Networks operated above 200kV have significant fault duties, carry much more power, and have a greater potential for cascading if something does not operate properly than networks operated below 200kV. Therefore, BPA believes that these networks should be part of the BES. BPA believes the term "non-retail generation" in E3(a) should also be defined.

Consumer's Power Inc.
Yes
The Consumers Power (CPI) believes the SDT continues to make substantial progress towards a clear

and workable definition of the Bulk Electric System (“BES”) that markedly improves both the existing definition and the SDT’s previous proposal. CPI therefore supports the new definition, although our support is conditioned on: (1) a workable Exceptions process being developed in conjunction with the BES definition; and, (2) the SDT moving forward expeditiously on Phase II of the standards development process in accordance with the SAR recently put forward by the SDT, which would address a number of important technical issues that have been identified in the standards development process to date. CPI strongly supports the following elements of the revised BES definition: (1) Clarification of how lists of Inclusions and Exclusions applies: The revised core definition moves the phrase “Unless modified by the lists shown below” to the beginning of the definition. This change makes clear that the Inclusions and Exclusions apply to all Elements that would otherwise be included in or excluded from the core definition (i.e., “all Transmission Elements operated at 100kV or higher and Real Time and Reactive Power resources connected at 100kV or higher”) and eliminates a latent ambiguity in the first draft of the definition, discussed further in our comments on the first draft. (2) The exclusion for “facilities used in the local distribution of electric energy.” As the starting point for the BES definition, CPI supports the use of the phrase “all Transmission Elements” and the qualifying sentence: “This does not include facilities used in the local distribution of electric energy.” This language helps ensure that FERC, NERC, and the Regional Entities (“REs”) will act within the jurisdictional constraints Congress placed in Section 215 of the Federal Power Act (“FPA”). In Section 215(a)(1), Congress unequivocally excluded “facilities used in the local distribution of electric energy” from the keystone “bulk-power system” definition. 16 U.S.C. § 824o(a)(1). Including the same language in the definition helps ensure that entities involved in enforcement of reliability standards will act within their statutory limits. In addition, as a practical matter, inclusion of the language will help focus both the industry and responsible agencies on the high-voltage interstate transmission system, where the reliability problems Congress intended to regulate – “instability, uncontrolled separation, [and] cascading failures,” 16 U.S.C. § 824o(a)(4) – will originate. At the same time, level-of-service issues arising in local distribution systems will be left to the authority of state and local regulatory agencies and governing bodies, just as Congress intended. 16 U.S.C. § 824o(i)(2) (reserving to state and local authorities enforcement of standards for adequacy of service). CPI thanks the SDT for the excellent work to include this sentence. For similar reasons, CPI believes the use of the phrase “Transmission Elements” as the starting point for the base definition is desirable because both “Transmission” and “Elements” are already defined in the NERC Glossary of Terms Used in NERC Reliability Standards, and the term “Transmission” makes clear that the BES includes only Elements used in Transmission and therefore excludes Elements used in local distribution of electric power. (3) Appropriate Generator Thresholds. In the standards development process, it has become apparent that the thresholds for classifying generators as BES in the current NERC Statement of Compliance Registry Criteria (“SCRC”) (20 MVA for individual generators, 75 MVA for multiple generators aggregated at a single site), which predate the adoption of FPA Section 215, were never the product of a careful analysis to determine whether generators of that size are necessary for operation of the interconnected bulk transmission system. Ideally, such an analysis would be conducted as part of the current standards development process. CPI recognizes that, given the deadlines imposed by FERC in Order No. 743, it will not be possible for the SDT to conduct such an analysis within the time available. Accordingly, CPI agrees with the approach taken by the SDT, which is to propose a Phase II of the standards development process that would address the generator threshold issue and several other technical issues that have arisen during the current process. As long as Phase II proceeds expeditiously, CPI is prepared to support the BES definition as proposed by the SDT. While CPI supports the overall approach adopted by the SDT and much of the specific language incorporated into the second draft of the BES definition, we believe the second draft would benefit from further clarification or modification in a number of respects, most of which are detailed in our subsequent answers. Further, we believe a workable Exclusion Process is essential for a BES Definition that will meet the legal requirements of FPA Section 215, especially for systems operating in the Western Interconnection. As detailed in our previous comments, CPI believes a 200kV threshold would be more appropriate for WECC than a 100kV threshold. In addition, a 200kV threshold for the West is backed by solid technical analysis conducted by the WECC Bulk Electric System Definition Task Force, and repeated claims that there is no technical analysis to support this view are therefore incorrect. That said, we raise the issue here to emphasize the importance of the Exclusions for Local Networks and Radial Systems and the Exceptions process. These Exclusions and the Exceptions are essential for a definition that works in the Western Interconnection because the core definition will be over-inclusive in our region. As long as those Exclusions and the Exceptions

Process are retained in a form substantially equivalent to those produced by the SDT at this juncture, CPI will support the SDT's proposal.

Yes

We support the SDT's changes to the first Inclusion because it is more clear and simple than the initial approach. That being said, we suggest that an additional sentence of clarification would help avoid future controversy about the meaning of Inclusion 1. As we understand it, the BES intends to include transformers only if both the primary and secondary terminals operate at 100kV or above, which is why the definition uses the word "and" ("the primary and secondary terminals"). We support this approach since it would exclude transformers where the secondary terminals serve distribution loads, and which therefore function as distribution rather than transmission facilities. We believe the SDT's intent would be clarified by adding a sentence at the end of Inclusion 1 that reads: "Transformers with either primary or secondary terminals, or both, that operate at or below 100kV are not part of the BES." This language will help ensure that there is no controversy over whether the SDT's use of the word "and" in the phrase "the primary and secondary terminals" was intentional. We also support the SDT's proposal to develop detailed guidance concerning the point of demarcation between BES and non-BES elements in the Phase II SAR. In this regard, we note that, while Inclusion 1 at least implicitly suggests that the dividing line between BES and non-BES Elements should be at the transformer where transmission-level voltages are stepped down to distribution-level voltages, we believe further clarification of this point of demarcation between the BES and non-BES Elements is necessary. Many different configurations of transformers and other equipment that may lie at the juncture between the BES and non-BES systems. If the point of demarcation is designated at the transformer without further elaboration, many entities that own equipment on the high side of a transformer will be swept into the BES, and thereby exposed to inappropriately stringent regulations and undue costs. For example, distribution-only utilities commonly own the switches, bus, and transformer protection devices on the high side of transformers where they take delivery from their transmission provider. Ownership of these protective devices and high-voltage bus on the high side of the transformer should not cause these entities to be classified as BES owners. As the Phase II process moves forward, we commend to the SDT the extensive work performed on the point of demarcation question by the WECC BESDTF. We also support the incorporation of language (" . . . unless excluded under Exclusions E1 or E3") making it clear that transformers that are operated as an integral part of a Radial System or Local Network should not be considered BES facilities, regardless of their operating voltage. Further clarification might be achieved by using the phrase ". . . unless the transformer is operated as part of a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2."

Yes

CPI supports the changes made in Inclusion 2 and believes that the definition in its current form adds clarity. In particular, we support the SDT's decision to collapse Inclusions 2 and 3 from the previous draft definition into a single Inclusion that addresses the treatment of generation for purposes of the BES definition. We also support the SDT's proposal for a Phase II of the BES Definition process that would examine the technical justification for these thresholds and that would establish new thresholds based on a careful technical analysis. It is our understanding that the generator threshold issue will be vetted through the complete standards development process. We agree with this approach because if the generator threshold is treated as merely an element of NERC's Rules of Procedure, it can be changed with considerably less process and industry input than the Standards Development Process. Compare NERC Rules of Procedure § 1400 (providing for changes to Rules of Procedure upon approval of the NERC board and FERC) with NERC Standards Process Manual (Sept. 3, 2010) (providing for, e.g., posting of SDT proposals for comment, successive balloting, and super-majority approval requirements). See also Order No. 743-A, 134 FERC ¶ 61,210 at P 4 (2011) ("Order No. 743 directed the ERO to revise the definition of 'bulk electric system' through the NERC Standards Development Process" (emph. added)). Addressing all aspects of Phase II through the Standards Development Process will improve the content of the definition by bringing to bear industry expertise on all aspects of the definition and will ensure that, once firm guidelines are established, they can be relied upon by both industry and regulators without threat that they will be changed with little notice and little process. CPI believes further clarification of the proposed language would be appropriate. The SDT proposes continued reliance upon the thresholds that are used in the NERC Statement of Compliance Registry Criteria for registration of Generation Owners and Generation Operators, which is currently 20 MVA for an individual generation unit and 75 MVA for multiple units on a single site.

Conceptually, we are concerned about this approach because, as we understand it, the purpose of the Compliance Registry is to sweep in all generators that might be material to the reliable operation of the BES, and not to definitively determine whether a given generator is, in fact, material to the reliable operation of the BES. As the SCRC itself states, the SCRC is intended only to identify "candidates for registration." SCRC at p.3, § 1 (emph. added). Accordingly, we believe that the generator threshold determined in Phase II should be incorporated directly into the BES Definition rather than being incorporated by reference from the SCRC. We also believe that the specific language proposed by the SDT could be further clarified. The SDT proposes that generation be included in the BES if the "Generation resource(s)" has a "nameplate rating per the ERO Statement of Compliance Registry." We understand this language is intended to be a placeholder for the results of the technical analysis that would occur in Phase II but we believe simply stating that the threshold will be "per the ERO Statement of Compliance Registry" is ambiguous. Further, for the reasons noted above, we believe the threshold should be part of the BES Definition, and should not simply be a cross-reference to the SCRC (and, given the different purposes of the BES Definition and the SCRC, it is not clear that the same threshold should be used in both). We therefore propose that Inclusion 2 be rewritten to state: "Qualifying Individual Generation Resources or Qualifying Aggregate Resources connected at a voltage of 100kV or above." Two definitions would then be added to the note at the end of the definition to read as follows: For purposes of this BES Definition, Qualifying Individual Generation Resources means an individual generating unit that meets the materiality threshold to be included in this definition or, in the absence of such a materiality threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of such a resource as a Generation Owner under the ERO Statement of Compliance Registry Criteria. For purposes of this BES Definition, Qualifying Aggregate Generation Resources means any facility consisting of one or more generating units that are connected at a common bus that meets the materiality threshold to be included in this definition, or, in the absence of such a threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of multiple-unit generator as a Generation Owner under the ERO Statement of Compliance Registry Criteria.. The "materiality threshold" is intended to refer to the generator threshold developed in Phase II. We suggest using definitions in this fashion for several reasons. First, we believe the language we suggest more clearly states the intention of the SDT, which we understand is to classify generation units as part of the BES if they are necessary for operation of the BES, but to exclude smaller generating units because they are not material to the operation of the interconnected transmission grid. Second, we believe use of the defined terms better reflects the intention of the SDT to reserve the specific question about generator thresholds to the technical analysis that will occur in Phase II without having to revise the BES Definition at the end of that process. That is, the definitions are designed to allow the SDT to include revised thresholds in the definition at the conclusion of the Phase II process based upon the technical analysis planned for Phase II, and the revised thresholds will be automatically incorporated into the BES Definition if the language we suggest is used. The thresholds used in the SCRC would only be a fall-back, to be used only until Phase II is completed. Third, the definitions can be incorporated into other parts of the BES Definition, which will add consistency and clarity. As noted in our answers to several of the questions below, the specific 75 MVA threshold is retained in several of the Exclusions and Inclusions, and we believe the industry would be better served if the revised thresholds arrived at after technical analysis in Phase II are automatically incorporated into all relevant provisions of the BES Definition. There is no reason for the SDT to continue to rely on the 75 MVA threshold once the analysis planned for Phase II on the threshold issue is completed. Fourth, the phrase "or that meets the materiality threshold to be included in this definition" is intended to preserve the SDT's flexibility to make a determination that generators below a specific threshold are not "necessary to" maintain the reliability of the interconnected transmission system, and to incorporate that finding as part of the definition itself, even if a different threshold is used in the SCRC to identify potential candidates for registration. Accordingly, our proposed language makes clear that a specific threshold in the definition controls over any threshold that might be included in the SCRC. For the reasons stated above, we believe it is highly desirable to include any material threshold in the BES Definition itself rather than relegating the threshold to the SCRC, which is merely a procedural rule rather than a full-fledged Reliability Standard. Finally, we agree with the SDT's decision to examine the question of where the line between BES and non-BES Elements should be drawn more closely in Phase II under the rubric of "contiguous vs. non-contiguous BES," and commend the work of the Project 2010-07 Standards Drafting Team and the GO-TO Team as a good starting point for the SDT's analysis on this issue. We understand Inclusion 2 would classify generators exceeding specific

thresholds as part of the BES, but would not necessarily require facilities interconnecting such generators to be part of the BES. As discussed more fully in our answer to Question 9, based on extensive technical analysis that has already been performed by the NERC Project 2010-07 Standards Drafting Team and its predecessor, the NERC "GO-TO Team," regulating as part of the BES a dedicated interconnection facility connecting a BES generator to the interconnected bulk transmission grid will result in an unnecessary regulatory burden that produces considerable expense for the owner of the interconnection facility with little or no improvement in bulk system reliability. We also believe the clauses at the end of Inclusion 2 are somewhat confusing and that greater clarity would be achieved by changing ". . . including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100kV or above" so that the Inclusion covers transformers with terminals "connected at a voltage of 100kV or above, including the generator terminal(s) on the high side of the step-up transformer(s) if operated at a voltage of 100kV or above."

Yes

CPI supports the removal of the Cranking Path language in I3. As noted in our response to Question 9, there is no reason to classify as BES the facilities interconnecting a BES generator to the bulk interstate system. A Cranking Path is simply a specific type of such an interconnection facility.

Yes

CPI supports the revised language generally, but believes additional changes would make the language clearer. Specifically, we believe Inclusion 4 should not incorporate a hard 75 MVA generation threshold (i.e., "resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)"). Instead, we urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," which we discuss in more detail in our response to Question 3. This language will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. More generally, we are not certain what is accomplished by Inclusion 4 that is not already accomplished by Inclusion 2, which also addresses whether generation should be defined as BES. The SDT's stated concern is with variable generation units such as wind and solar plants. It is not clear to us why this concern is not fully addressed in Inclusion 2, which addresses multiple generation units connected at a common bus, the configuration of most variable generation plants with multiple units. We are also concerned that the language, as proposed, could have unintended consequences and improperly classify local distribution systems as BES in certain circumstances. This is because multiple distributed generation units could render a local distribution system a "collector system" and the entire system the equivalent of an aggregated generation unit, causing the local distribution system to be improperly denied status as a Local Network. If many different distributed generation units are connected to a local distribution system, it is very unlikely that more than a few of those units would fail simultaneously, and it is therefore unlikely that multiple generation units would produce a measureable impact on the interconnected bulk transmission system, especially if the units individually do not otherwise exceed the materiality threshold to be established by the SDT in Phase II. Further, we are concerned that, if small distributed generation units become the industry norm, Inclusion 4 could unintentionally sweep in local distribution systems, especially where local policies favor the growth of small solar or other renewable generation systems for public policy reasons. Finally, we suggest that the SDT add the phrase ". . . unless the dispersed power producing resources operate within a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2." This language, which parallels the language included at the end of Inclusion I1, would make clear that dispersed small-scale generators scattered throughout a Radial System or Local Network serving retail load would not convert the Radial System or Local Network into a BES system, even if the aggregate capacity of those small generators exceeds the relevant threshold.

No

CPI has several concerns about the new language in Inclusion 5. First, because Reactive Power devices produce power, they are "power producing resources" and we therefore believe Inclusion 5 is duplicative of Inclusion 4, which addresses "power producing devices." Second, there is no capacity threshold specified in Inclusion 5 for Reactive Power devices that would be considered part of the BES. This is inconsistent with the approach taken in the balance of the definition, where thresholds are specified for generators and other types of power producing devices. Third, CPI believes the appropriate threshold for inclusion or exclusion of Reactive Power devices from the BES should be subject to the same technical analysis that will cover generators in the Phase II process. Finally, CPI

believes this issue should be addressed in Phase 2 since there is not technical justification or analysis done to determine the thresholds. CPI strongly believes that there should be technical justification for thresholds for this issue and all other issues.

Yes

CPI continues to strongly support the radial system exclusion, which is necessary as a legal matter, because, among other reasons, FERC in Orders No. 743 and 743-A has required that the existing radial exemption in the NERC Statement of Compliance Registry Criteria be maintained. As a practical matter, radial systems are used for service to retail loads, usually in remote or rural areas, and not for the transmission of bulk power. Hence, operation of the radials has little or nothing to do with the reliable operation of the interconnected bulk transmission network. We also support the inclusion of the note discussing normally open switches because this language provides needed clarity for a common radial system configuration. We also agree with the substantive thrust of this language, which is that a radial system should not be considered part of the BES if it is interconnected at a single point, even if there is an alternative point of delivery that is normally open. While we support the Exclusion for Radial Systems, we believe several clarifications and refinements are necessary. (1) The term "transmission Elements" in the initial paragraph should be changed to "Elements." Radial systems are not transmission systems and including the word "transmission" in the Radial System exclusion is therefore unnecessary and confusing. (2) Subparagraph (b) of Exclusion 1 refers to "generation resources . . . with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)". We urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," discussed in more detail in our response to Question 3. This language will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. (3) Subparagraph (b) also seems to assume that if a Radial System contains a generator exceeding the 75 MVA threshold, the Radial System itself must be included in the BES because it links the generator to the interconnected bulk transmission system. As discussed more fully in our response to Question 9, below, NERC's Project 2010-17 Standards Drafting Team and GO-TO Task Force have both concluded that this assumption is unwarranted. (4) The "Note" as drafted by the SDT indicates that "a normally open switching device between radial systems" will not serve to disqualify the Radial from exclusion under Exclusion 1. As discussed above, CPI strongly supports the note conceptually. However, we believe this language should be included in a separate subparagraph (d), rather than a note, because treatment as a "note" suggests it is less important than other portions of the Exclusion. We also suggest the language be changed to read: (d) Normally-open switching devices between radial elements as depicted and identified on system one-line diagrams does not affect this exclusion. This will make clear that a radial with more than one normally-open switch connecting it to another radial is still a radial. From the perspective of the BES Definition, the key question is whether switches operating between Radials are normally open, not whether there is more than one normally-open switch.

Yes

CPI supports the revised language. The language provides clarity regarding the BES status of customer-owned cogeneration facilities. However, CPI urges the SDT to remove the reference to the 75 MVA threshold and replace it with the defined term "Qualifying Aggregate Generation Resources" or some equivalent language for the reasons stated in our responses to Questions 3, 5, and 7. In addition, we are concerned that Exclusion 2 will place local distribution utilities in a difficult position because, under Exclusion 1 or Exclusion 3 as drafted, they could lose their status as a Radial System or a Local Network through the actions of a customer constructing behind-the-meter generation. With respect to Radial Systems, the appearance of behind-the-meter generators could cause the Radial System to exceed the thresholds specified in subparagraphs (b) and (c) of Exclusion 1 through no fault of the Radial System owner. Similar, a Local Network could lose its status because behind-the-meter generation could be of sufficient size that power moves into the interconnected grid in certain hours or under certain contingencies, rather than moving purely onto the Local Network, as required in subparagraph (b) of Exclusion 3. The Exclusions for Radial Systems and Local Networks should be made consistent with the Exclusion for behind-the-meter generation. There is no technical reason to believe the power flowing from a behind-the-meter customer-owned generator will have less impact on the bulk system than an equivalent-sized generator owned by a utility operating a Radial System or LN.

Yes

CPI strongly supports the exclusion of Local Networks (“LNs”) from the BES. The conversion of radial systems to local networks should be encouraged because networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. If the BES definition were to provide an exclusion for radials without providing a similar exclusion for LNs, however, it would discourage networking local distribution systems because of the significantly increased regulatory burdens faced by the local distribution utility if it elected to network its radial facilities. By placing radial systems and LNs on the same regulatory footing, the proposed definition will ensure that decisions about whether to network radial systems are made on the basis of costs and benefits to the retail customers served by those radials, and not on the basis of disparate regulatory treatment. Consumers would ultimately benefit. CPI also supports specific refinements made to the LN exclusion by the SDT in the current draft of the BES definition. In particular, CPI supports the clarification of the purposes of a LN. The current draft states that LNs connect at multiple points to “improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system.” CPI supports this change in language because it reflects the fundamental purposes of a LN and emphasizes one of the key distinctions between LNs and bulk transmission facilities, namely, that LNs are designed primarily to serve local retail load while bulk transmission facilities are designed primarily to move bulk power from a bulk source (generally either the point of interconnection of a wholesale generator or a the point of interconnection with another bulk transmission system) to one or more wholesale purchasers. CPI believes further improvement of the language could be achieved with additional modifications and clarifications. With respect to the core language of Exclusion 3, we believe the language making a “group of contiguous transmission Elements operated at or above 100kV” the starting point for identifying a LN would be improved by deleting the term “transmission” from this phrase. This is so because LNs are not used for transmission and the use of the term “transmission Elements” is therefore both confusing and unnecessary. There would be no room for argument about what the SDT intended by including the word “transmission” if the word is deleted and the Exclusion applies to any “group of Elements operated at 100kV or above” that meets the remaining requirement of the Exclusion. Further, any definitional value that is added by using the term “transmission Elements” is accomplished by using that term in the core definition, and there is no reason to carry the term through in the Exclusions. CPI also believes that subparagraphs (a) and (b) are redundant, because whatever protection is offered by the generation limit in subparagraph (a) is duplicated by the limit in subparagraph (b) requiring no flow out of the LN. We believe the SDT can eliminate subparagraph (a) of Exclusion 3 and simply rely on subparagraph (b) because if power only flows into the LN even if it interconnects more than 75 MVA of generation, the interconnected generation interconnected will have no significant interaction with the interconnected bulk transmission system. It will only interact with the LN. And, with the advent of distributed generation, it is easy to foresee a situation in which a large number of very small distributed generators are interconnected into a LN, so that the aggregate capacity of these generators exceeds 75 MVA. However, because the generators are small and dispersed and, under the criterion in subparagraph (b), would be wholly absorbed within the LN rather than transmitting power onto the interconnected grid, those generators would not have a material impact on the grid. We also suggest that subparagraph (b) of Exclusion 3 could be more clearly drafted. Subparagraph (b), as part of the requirement that power flow into a LN rather than out of it, includes this description: “The LN does not transfer energy originating outside the LN for delivery through the LN.” We understand this language is intended to distinguish a LN from a link in the transmission system – power on a transmission link passes through the transmission link to a load located elsewhere, while power in a LN enters the LN and is consumed by retail load within the LN. While we agree with the concept proposed by the SDT, we believe the language would be clearer if it read: “The LN does not transfer energy originating outside the LN for delivery through the LN to loads located outside the LN.” We believe the italicized language is necessary to distinguish between a transmission system, where power that originates outside a system is delivered through the system and passes through the system to a sink located somewhere outside the system, from a LN, in which power originating outside the LN passes through the LN and is delivered to retail load within the LN. To put it another way, the italicized language helps distinguish a transmission system from an LN, in which the LN “transfers energy originating outside the LN for delivery through the LN to loads located within the LN.” We also believe the language of subparagraph (a) of Exclusion 3 could be improved. Subparagraph (d) would make LNs part of the BES if they interconnect “non-retail generation greater than 75 MVA (gross nameplate rating).” For the reasons stated in our responses to Questions 3, 5 and 7, we urge the SDT to replace the reference to a hard 75 MVA threshold with the defined term

"Qualifying Aggregate Generation Resources" or some equivalent. We are also uncertain what is meant by the use of the term "non-retail generation" in subparagraph (a). From context, we believe the SDT considers "non-retail generation" to be the equivalent of generation that is located behind the retail meter, usually but not always owned by the customer and used to serve the customer's own load. We therefore suggest that the SDT replace the term "non-retail generation" with "generation located behind the retail customer's meter." Similarly, we are unsure what is meant by the phrase "the LN and its underlying Elements." We believe the phrase "and its underlying Elements" could simply be deleted from the definition without loss of meaning. In the alternative, the SDT might consider using the phrase "the LN, including all Elements located on the distribution side of any Automatic Fault Interrupting Devices (or other points of demarcation) separating the LN from the bulk interstate transmission system." We believe this phrase more accurately reflects the SDT's intent, which appears to be that generation exceeding 75 MVA in aggregate capacity interconnected anywhere within the LN disqualifies that LN from being excluded from the BES under Exclusion 3. CPI also believes that both subparagraphs (a) and (b) of Exclusion 3 could be safely eliminated as long as subparagraph (c) is retained. Subparagraph (c) makes a LN part of the BES if it is classified as a Flow Gate or Transfer Path. Flow Gates and Transfer Paths are, by definition, the key facilities that allow reliable transmission of bulk electric power on the interconnected grid. If a LN has not been identified as either a Flow Gate or a Transfer Path, it is unlikely the LN is necessary for the reliable transmission of electricity on the interconnected bulk system. Apart from these specific improvements that we believe could be achieved by modifying the language of Exclusion 3, we believe the SDT may need to re-examine certain assumptions that appear to underlie the current draft. Specifically, subparagraph (a) suggests that if BES generation is embedded within a LN, the LN itself must also be BES. But two NERC bodies have already addressed similar questions and concluded there is no technical basis for such concerns. NERC's Standards Drafting Team for Project 2010-07 and its predecessor, the "GO-TO Task Force" were formed to address how the dedicated interconnection facilities linking a BES generator to high-voltage transmission facilities should be treated under the NERC standards. The GO-TO Team concluded that by complying with a handful of reliability standards, primarily related to vegetation management, reliable operation of the bulk interconnected system could be protected without unduly burdening the owners of such interconnection systems. Therefore, there is no reason, according to the GO-TO Team, that dedicated high-voltage interconnection facilities must be treated as "Transmission" and classified as part of the BES in order to make reliability standards effective. See Final Report from the NERC Ad Hoc Group for Generator Requirements at the Transmission Interface (Nov. 16, 2009) (paper written by the GO-TO Task Force). Similarly, the Project 2010-07 Team observed that interconnection facilities "are most often not part of the integrated bulk power system, and as such should not be subject to the same level of standards applicable to Transmission Owners and Transmission Operators who own and operate transmission Facilities and Elements that are part of the integrated bulk power system." White Paper Proposal for Information Comment, NERC Project 2010-07: Generator Requirements at the Transmission Interface, at 3 (March 2011). Requiring Generation Owners and Operators to comply with the same standards as BES Transmission Owners and Operators "would do little, if anything, to improve the reliability of the Bulk Electric System," especially "when compared to the operation of the equipment that actually produces electricity – the generation equipment itself." Id. We believe that interconnection of BES generators within a LN is analogous and that, based on the findings of the Project 2010-07 and GO-TO Teams, automatically classifying a LN as "BES" simply because a large generator is embedded in the LN will result in substantial overregulation and unnecessary expense with little gain for bulk system reliability. If anything, generation interconnected through a LN is less likely to produce material impacts on the interconnected bulk transmission system than the equivalent generator interconnected through a single dedicated line because an LN is interconnected to the bulk system at several points, so that if one interconnection goes down, power can still flow from the BES generator to the bulk system on other interconnection points. Where a dedicated interconnection facility is involved, by contrast, if the interconnection line fails, the generator is unavailable to the interconnected bulk system. Similarly, we suggest that the SDT re-examine the assumptions underlying subparagraph (b), which seems to suggest that a local distribution system cannot be classified as a Local Network if power flows out of that system at any time, even if the amount is de minimis, the outward flow is only for a few hours, a year, or the outward flow occurs only in an extreme contingency. Accordingly, we suggest that the initial clause of subparagraph (b) be revised to read: "Except in unusual circumstances, power flows only into the LN." Finally, we note that the LN exclusion must not operate in any way as a substitution for the statutory prohibition on including "facilities used in the local

distribution of electric energy" in the BES. Therefore, even with the LN exclusion, the SDT must retain this statutory language in the core definition of the BES, as discussed in our answer to Question One. If a certain piece of equipment is a "facility used in the local distribution of electric energy," then it is not part of the BES in the first instance, and so consideration of the LN Exclusion, or of any other Exclusion, any Inclusion, or any Exception, would be both unnecessary and uncalled for.

Yes

CPI supports the revised language because retail reactive devices are used to address local customer or retail voltage issues, rather than voltage issues on the interconnected bulk grid, and such local devices should therefore be excluded from the BES definition.

No

CPI extends its thanks to the SDT and to the many industry entities that have actively participating in the Standards Development Process. CPI supports the current draft and believes, with certain refinements discussed in our comments, that the definition will serve the industry and reliability regulators well for many years to come. In addition, as noted earlier, CPI is encouraged that the 20/75 MVA generation thresholds referred to in the NERC Statement of Compliance Registry Criteria, which have been relied upon by the SDT largely as a matter of necessity, will be reviewed and a technical assessment will be performed to identify the appropriate generation unit and plant size threshold to ensure a reliable North America. Finally, we understand that the Rules of Procedure Team will continue to move forward with developing an Exceptions Process that will complement the BES Definition and ensure that, to the extent the BES Definition is over-inclusive, facilities that should not be classified as BES will be excluded from the BES. Because the Exceptions Process is integral to a workable BES Definition, we support the current process for moving forward with the Exceptions Process and the BES Definition on parallel paths. We note that CPI specifically supports the changes made by the SDT in the "Effective Date" provision of the BES Definition, which shortens the effective date of the new definition to the beginning of the first calendar quarter after regulatory approval (as opposed to the first calendar quarter twenty-four months after regulatory approval), with a 24-month transition period. CPI supports this conclusion because it will allow entities seeking deregistration under the terms of the new BES definition to obtain the benefits of the new definition without an unreasonable wait, while allowing any entities that may be newly-classified as BES owners or operators sufficient time to come into compliance with newly-applicable Reliability Standards. CPI also supports the 24-month transition period for the reasons laid out by the SDT.

Individual

Dave Sabala

Douglas Electric Cooperative (DEC)

Yes

The Douglas Electric Cooperative (DEC) believes the SDT continues to make substantial progress towards a clear and workable definition of the Bulk Electric System ("BES") that markedly improves both the existing definition and the SDT's previous proposal. DEC therefore supports the new definition, although our support is conditioned on: (1) a workable Exceptions process being developed in conjunction with the BES definition; and, (2) the SDT moving forward expeditiously on Phase II of the standards development process in accordance with the SAR recently put forward by the SDT, which would address a number of important technical issues that have been identified in the standards development process to date. DEC strongly supports the following elements of the revised BES definition: (1) Clarification of how lists of Inclusions and Exclusions applies: The revised core definition moves the phrase "Unless modified by the lists shown below" to the beginning of the definition. This change makes clear that the Inclusions and Exclusions apply to all Elements that would otherwise be included in or excluded from the core definition (i.e., "all Transmission Elements operated at 100kV or higher and Real Time and Reactive Power resources connected at 100kV or higher") and eliminates a latent ambiguity in the first draft of the definition, discussed further in our comments on the first draft. (2) The exclusion for "facilities used in the local distribution of electric energy." As the starting point for the BES definition, DEC supports the use of the phrase "all Transmission Elements" and the qualifying sentence: "This does not include facilities used in the local distribution of electric energy." This language helps ensure that FERC, NERC, and the Regional Entities ("REs") will act within the jurisdictional constraints Congress placed in Section 215 of the Federal Power Act ("FPA"). In Section 215(a)(1), Congress unequivocally excluded "facilities used in the local distribution of electric energy" from the keystone "bulk-power system" definition. 16 U.S.C.

§ 824o(a)(1). Including the same language in the definition helps ensure that entities involved in enforcement of reliability standards will act within their statutory limits. In addition, as a practical matter, inclusion of the language will help focus both the industry and responsible agencies on the high-voltage interstate transmission system, where the reliability problems Congress intended to regulate – “instability, uncontrolled separation, [and] cascading failures,” 16 U.S.C. § 824o(a)(4) – will originate. At the same time, level-of-service issues arising in local distribution systems will be left to the authority of state and local regulatory agencies and governing bodies, just as Congress intended. 16 U.S.C. § 824o(i)(2) (reserving to state and local authorities enforcement of standards for adequacy of service). DEC thanks the SDT for the excellent work to include this sentence. For similar reasons, DEC believes the use of the phrase “Transmission Elements” as the starting point for the base definition is desirable because both “Transmission” and “Elements” are already defined in the NERC Glossary of Terms Used in NERC Reliability Standards, and the term “Transmission” makes clear that the BES includes only Elements used in Transmission and therefore excludes Elements used in local distribution of electric power. (3) Appropriate Generator Thresholds. In the standards development process, it has become apparent that the thresholds for classifying generators as BES in the current NERC Statement of Compliance Registry Criteria (“SCRC”) (20 MVA for individual generators, 75 MVA for multiple generators aggregated at a single site), which predate the adoption of FPA Section 215, were never the product of a careful analysis to determine whether generators of that size are necessary for operation of the interconnected bulk transmission system. Ideally, such an analysis would be conducted as part of the current standards development process. DEC recognizes that, given the deadlines imposed by FERC in Order No. 743, it will not be possible for the SDT to conduct such an analysis within the time available. Accordingly, DEC agrees with the approach taken by the SDT, which is to propose a Phase II of the standards development process that would address the generator threshold issue and several other technical issues that have arisen during the current process. As long as Phase II proceeds expeditiously, DEC is prepared to support the BES definition as proposed by the SDT. While DEC supports the overall approach adopted by the SDT and much of the specific language incorporated into the second draft of the BES definition, we believe the second draft would benefit from further clarification or modification in a number of respects, most of which are detailed in our subsequent answers. Further, we believe a workable Exclusion Process is essential for a BES Definition that will meet the legal requirements of FPA Section 215, especially for systems operating in the Western Interconnection. As detailed in our previous comments, DEC believes a 200kV threshold would be more appropriate for WECC than a 100kV threshold. In addition, a 200kV threshold for the West is backed by solid technical analysis conducted by the WECC Bulk Electric System Definition Task Force, and repeated claims that there is no technical analysis to support this view are therefore incorrect. That said, we raise the issue here to emphasize the importance of the Exclusions for Local Networks and Radial Systems and the Exceptions process. These Exclusions and the Exceptions are essential for a definition that works in the Western Interconnection because the core definition will be over-inclusive in our region. As long as those Exclusions and the Exceptions Process are retained in a form substantially equivalent to those produced by the SDT at this juncture, DEC will support the SDT’s proposal.

Yes

We support the SDT’s changes to the first Inclusion because it is more clear and simple than the initial approach. That being said, we suggest that an additional sentence of clarification would help avoid future controversy about the meaning of Inclusion 1. As we understand it, the BES intends to include transformers only if both the primary and secondary terminals operate at 100kV or above, which is why the definition uses the word “and” (“the primary and secondary terminals”). We support this approach since it would exclude transformers where the secondary terminals serve distribution loads, and which therefore function as distribution rather than transmission facilities. We believe the SDT’s intent would be clarified by adding a sentence at the end of Inclusion 1 that reads: “Transformers with either primary or secondary terminals, or both, that operate at or below 100kV are not part of the BES.” This language will help ensure that there is no controversy over whether the SDT’s use of the word “and” in the phrase “the primary and secondary terminals” was intentional. We also support the SDT’s proposal to develop detailed guidance concerning the point of demarcation between BES and non-BES elements in the Phase II SAR. In this regard, we note that, while Inclusion 1 at least implicitly suggests that the dividing line between BES and non-BES Elements should be at the transformer where transmission-level voltages are stepped down to distribution-level voltages, we believe further clarification of this point of demarcation between the BES and non-BES Elements is necessary. Many different configurations of transformers and other equipment that may lie at the

junction between the BES and non-BES systems. If the point of demarcation is designated at the transformer without further elaboration, many entities that own equipment on the high side of a transformer will be swept into the BES, and thereby exposed to inappropriately stringent regulations and undue costs. For example, distribution-only utilities commonly own the switches, bus, and transformer protection devices on the high side of transformers where they take delivery from their transmission provider. Ownership of these protective devices and high-voltage bus on the high side of the transformer should not cause these entities to be classified as BES owners. As the Phase II process moves forward, we commend to the SDT the extensive work performed on the point of demarcation question by the WECC BESDTF. We also support the incorporation of language (“ . . . unless excluded under Exclusions E1 or E3”) making it clear that transformers that are operated as an integral part of a Radial System or Local Network should not be considered BES facilities, regardless of their operating voltage. Further clarification might be achieved by using the phrase “. . . unless the transformer is operated as part of a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2.”

Yes

DEC supports the changes made in Inclusion 2 and believes that the definition in its current form adds clarity. In particular, we support the SDT’s decision to collapse Inclusions 2 and 3 from the previous draft definition into a single Inclusion that addresses the treatment of generation for purposes of the BES definition. We also support the SDT’s proposal for a Phase II of the BES Definition process that would examine the technical justification for these thresholds and that would establish new thresholds based on a careful technical analysis. It is our understanding that the generator threshold issue will be vetted through the complete standards development process. We agree with this approach because if the generator threshold is treated as merely an element of NERC’s Rules of Procedure, it can be changed with considerably less process and industry input than the Standards Development Process. Compare NERC Rules of Procedure § 1400 (providing for changes to Rules of Procedure upon approval of the NERC board and FERC) with NERC Standards Process Manual (Sept. 3, 2010) (providing for, e.g., posting of SDT proposals for comment, successive balloting, and super-majority approval requirements). See also Order No. 743-A, 134 FERC ¶ 61,210 at P 4 (2011) (“Order No. 743 directed the ERO to revise the definition of ‘bulk electric system’ through the NERC Standards Development Process” (emph. added)). Addressing all aspects of Phase II through the Standards Development Process will improve the content of the definition by bringing to bear industry expertise on all aspects of the definition and will ensure that, once firm guidelines are established, they can be relied upon by both industry and regulators without threat that they will be changed with little notice and little process. DEC believes further clarification of the proposed language would be appropriate. The SDT proposes continued reliance upon the thresholds that are used in the NERC Statement of Compliance Registry Criteria for registration of Generation Owners and Generation Operators, which is currently 20 MVA for an individual generation unit and 75 MVA for multiple units on a single site. Conceptually, we are concerned about this approach because, as we understand it, the purpose of the Compliance Registry is to sweep in all generators that might be material to the reliable operation of the BES, and not to definitively determine whether a given generator is, in fact, material to the reliable operation of the BES. As the SCRC itself states, the SCRC is intended only to identify “candidates for registration.” SCRC at p.3, § 1 (emph. added). Accordingly, we believe that the generator threshold determined in Phase II should be incorporated directly into the BES Definition rather than being incorporated by reference from the SCRC. We also believe that the specific language proposed by the SDT could be further clarified. The SDT proposes that generation be included in the BES if the “Generation resource(s)” has a “nameplate rating per the ERO Statement of Compliance Registry.” We understand this language is intended to be a placeholder for the results of the technical analysis that would occur in Phase II but we believe simply stating that the threshold will be “per the ERO Statement of Compliance Registry” is ambiguous. Further, for the reasons noted above, we believe the threshold should be part of the BES Definition, and should not simply be a cross-reference to the SCRC (and, given the different purposes of the BES Definition and the SCRC, it is not clear that the same threshold should be used in both). We therefore propose that Inclusion 2 be rewritten to state: “Qualifying Individual Generation Resources or Qualifying Aggregate Resources connected at a voltage of 100kV or above.” Two definitions would then be added to the note at the end of the definition to read as follows: For purposes of this BES Definition, Qualifying Individual Generation Resources means an individual generating unit that meets the materiality threshold to be included in this definition or, in the absence of such a materiality threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of such a resource as a

Generation Owner under the ERO Statement of Compliance Registry Criteria. For purposes of this BES Definition, Qualifying Aggregate Generation Resources means any facility consisting of one or more generating units that are connected at a common bus that meets the materiality threshold to be included in this definition, or, in the absence of such a threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of multiple-unit generator as a Generation Owner under the ERO Statement of Compliance Registry Criteria. The "materiality threshold" is intended to refer to the generator threshold developed in Phase II. We suggest using definitions in this fashion for several reasons. First, we believe the language we suggest more clearly states the intention of the SDT, which we understand is to classify generation units as part of the BES if they are necessary for operation of the BES, but to exclude smaller generating units because they are not material to the operation of the interconnected transmission grid. Second, we believe use of the defined terms better reflects the intention of the SDT to reserve the specific question about generator thresholds to the technical analysis that will occur in Phase II without having to revise the BES Definition at the end of that process. That is, the definitions are designed to allow the SDT to include revised thresholds in the definition at the conclusion of the Phase II process based upon the technical analysis planned for Phase II, and the revised thresholds will be automatically incorporated into the BES Definition if the language we suggest is used. The thresholds used in the SCRC would only be a fall-back, to be used only until Phase II is completed. Third, the definitions can be incorporated into other parts of the BES Definition, which will add consistency and clarity. As noted in our answers to several of the questions below, the specific 75 MVA threshold is retained in several of the Exclusions and Inclusions, and we believe the industry would be better served if the revised thresholds arrived at after technical analysis in Phase II are automatically incorporated into all relevant provisions of the BES Definition. There is no reason for the SDT to continue to rely on the 75 MVA threshold once the analysis planned for Phase II on the threshold issue is completed. Fourth, the phrase "or that meets the materiality threshold to be included in this definition" is intended to preserve the SDT's flexibility to make a determination that generators below a specific threshold are not "necessary to" maintain the reliability of the interconnected transmission system, and to incorporate that finding as part of the definition itself, even if a different threshold is used in the SCRC to identify potential candidates for registration. Accordingly, our proposed language makes clear that a specific threshold in the definition controls over any threshold that might be included in the SCRC. For the reasons stated above, we believe it is highly desirable to include any material threshold in the BES Definition itself rather than relegating the threshold to the SCRC, which is merely a procedural rule rather than a full-fledged Reliability Standard. Finally, we agree with the SDT's decision to examine the question of where the line between BES and non-BES Elements should be drawn more closely in Phase II under the rubric of "contiguous vs. non-contiguous BES," and commend the work of the Project 2010-07 Standards Drafting Team and the GO-TO Team as a good starting point for the SDT's analysis on this issue. We understand Inclusion 2 would classify generators exceeding specific thresholds as part of the BES, but would not necessarily require facilities interconnecting such generators to be part of the BES. As discussed more fully in our answer to Question 9, based on extensive technical analysis that has already been performed by the NERC Project 2010-07 Standards Drafting Team and its predecessor, the NERC "GO-TO Team," regulating as part of the BES a dedicated interconnection facility connecting a BES generator to the interconnected bulk transmission grid will result in an unnecessary regulatory burden that produces considerable expense for the owner of the interconnection facility with little or no improvement in bulk system reliability. We also believe the clauses at the end of Inclusion 2 are somewhat confusing and that greater clarity would be achieved by changing ". . . including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100kV or above" so that the Inclusion covers transformers with terminals "connected at a voltage of 100kV or above, including the generator terminal(s) on the high side of the step-up transformer(s) if operated at a voltage of 100kV or above."

Yes

DEC supports the removal of the Cranking Path language in I3. As noted in our response to Question 9, there is no reason to classify as BES the facilities interconnecting a BES generator to the bulk interstate system. A Cranking Path is simply a specific type of such an interconnection facility.

Yes

DEC supports the revised language generally, but believes additional changes would make the language clearer. Specifically, we believe Inclusion 4 should not incorporate a hard 75 MVA generation threshold (i.e. "resources with aggregate capacity greater than 75 MVA (gross aggregate

nameplate rating)"). Instead, we urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," which we discuss in more detail in our response to Question 3. This language will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. More generally, we are not certain what is accomplished by Inclusion 4 that is not already accomplished by Inclusion 2, which also addresses whether generation should be defined as BES. The SDT's stated concern is with variable generation units such as wind and solar plants. It is not clear to us why this concern is not fully addressed in Inclusion 2, which addresses multiple generation units connected at a common bus, the configuration of most variable generation plants with multiple units. We are also concerned that the language, as proposed, could have unintended consequences and improperly classify local distribution systems as BES in certain circumstances. This is because multiple distributed generation units could render a local distribution system a "collector system" and the entire system the equivalent of an aggregated generation unit, causing the local distribution system to be improperly denied status as a Local Network. If many different distributed generation units are connected to a local distribution system, it is very unlikely that more than a few of those units would fail simultaneously, and it is therefore unlikely that multiple generation units would produce a measureable impact on the interconnected bulk transmission system, especially if the units individually do not otherwise exceed the materiality threshold to be established by the SDT in Phase II. Further, we are concerned that, if small distributed generation units become the industry norm, Inclusion 4 could unintentionally sweep in local distribution systems, especially where local policies favor the growth of small solar or other renewable generation systems for public policy reasons. Finally, we suggest that the SDT add the phrase ". . . unless the dispersed power producing resources operate within a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2." This language, which parallels the language included at the end of Inclusion I1, would make clear that dispersed small-scale generators scattered throughout a Radial System or Local Network serving retail load would not convert the Radial System or Local Network into a BES system, even if the aggregate capacity of those small generators exceeds the relevant threshold.

No

DEC has several concerns about the new language in Inclusion 5. First, because Reactive Power devices produce power, they are "power producing resources" and we therefore believe Inclusion 5 is duplicative of Inclusion 4, which addresses "power producing devices." Second, there is no capacity threshold specified in Inclusion 5 for Reactive Power devices that would be considered part of the BES. This is inconsistent with the approach taken in the balance of the definition, where thresholds are specified for generators and other types of power producing devices. Third, DEC believes the appropriate threshold for inclusion or exclusion of Reactive Power devices from the BES should be subject to the same technical analysis that will cover generators in the Phase II process. Finally, DEC believes this issue should be addressed in Phase 2 since there is not technical justification or analysis done to determine the thresholds. DEC strongly believes that there should be technical justification for thresholds for this issue and all other issues.

Yes

DEC continues to strongly support the radial system exclusion, which is necessary as a legal matter, because, among other reasons, FERC in Orders No. 743 and 743-A has required that the existing radial exemption in the NERC Statement of Compliance Registry Criteria be maintained. As a practical matter, radial systems are used for service to retail loads, usually in remote or rural areas, and not for the transmission of bulk power. Hence, operation of the radials has little or nothing to do with the reliable operation of the interconnected bulk transmission network. We also support the inclusion of the note discussing normally open switches because this language provides needed clarity for a common radial system configuration. We also agree with the substantive thrust of this language, which is that a radial system should not be considered part of the BES if it is interconnected at a single point, even if there is an alternative point of delivery that is normally open. While we support the Exclusion for Radial Systems, we believe several clarifications and refinements are necessary. (1) The term "transmission Elements" in the initial paragraph should be changed to "Elements." Radial systems are not transmission systems and including the word "transmission" in the Radial System exclusion is therefore unnecessary and confusing. (2) Subparagraph (b) of Exclusion 1 refers to "generation resources . . . with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)". We urge the SDT to replace this language with the defined term "Qualifying Aggregate

Generation Resources," discussed in more detail in our response to Question 3. This language will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. (3) Subparagraph (b) also seems to assume that if a Radial System contains a generator exceeding the 75 MVA threshold, the Radial System itself must be included in the BES because it links the generator to the interconnected bulk transmission system. As discussed more fully in our response to Question 9, below, NERC's Project 2010-17 Standards Drafting Team and GO-TO Task Force have both concluded that this assumption is unwarranted. (4) The "Note" as drafted by the SDT indicates that "a normally open switching device between radial systems" will not serve to disqualify the Radial from exclusion under Exclusion 1. As discussed above, DEC strongly supports the note conceptually. However, we believe this language should be included in a separate subparagraph (d), rather than a note, because treatment as a "note" suggests it is less important than other portions of the Exclusion. We also suggest the language be changed to read: (d) Normally-open switching devices between radial elements as depicted and identified on system one-line diagrams does not affect this exclusion. This will make clear that a radial with more than one normally-open switch connecting it to another radial is still a radial. From the perspective of the BES Definition, the key question is whether switches operating between Radials are normally open, not whether there is more than one normally-open switch.

Yes

DEC supports the revised language. The language provides clarity regarding the BES status of customer-owned cogeneration facilities. However, DEC urges the SDT to remove the reference to the 75 MVA threshold and replace it with the defined term "Qualifying Aggregate Generation Resources" or some equivalent language for the reasons stated in our responses to Questions 3, 5, and 7. In addition, we are concerned that Exclusion 2 will place local distribution utilities in a difficult position because, under Exclusion 1 or Exclusion 3 as drafted, they could lose their status as a Radial System or a Local Network through the actions of a customer constructing behind-the-meter generation. With respect to Radial Systems, the appearance of behind-the-meter generators could cause the Radial System to exceed the thresholds specified in subparagraphs (b) and (c) of Exclusion 1 through no fault of the Radial System owner. Similar, a Local Network could lose its status because behind-the-meter generation could be of sufficient size that power moves into the interconnected grid in certain hours or under certain contingencies, rather than moving purely onto the Local Network, as required in subparagraph (b) of Exclusion 3. The Exclusions for Radial Systems and Local Networks should be made consistent with the Exclusion for behind-the-meter generation. There is no technical reason to believe the power flowing from a behind-the-meter customer-owned generator will have less impact on the bulk system than an equivalent-sized generator owned by a utility operating a Radial System or LN.

Yes

DEC strongly supports the exclusion of Local Networks ("LNs") from the BES. The conversion of radial systems to local networks should be encouraged because networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. If the BES definition were to provide an exclusion for radials without providing a similar exclusion for LNs, however, it would discourage networking local distribution systems because of the significantly increased regulatory burdens faced by the local distribution utility if it elected to network its radial facilities. By placing radial systems and LNs on the same regulatory footing, the proposed definition will ensure that decisions about whether to network radial systems are made on the basis of costs and benefits to the retail customers served by those radials, and not on the basis of disparate regulatory treatment. Consumers would ultimately benefit. DEC also supports specific refinements made to the LN exclusion by the SDT in the current draft of the BES definition. In particular, DEC supports the clarification of the purposes of a LN. The current draft states that LNs connect at multiple points to "improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system." DEC supports this change in language because it reflects the fundamental purposes of a LN and emphasizes one of the key distinctions between LNs and bulk transmission facilities, namely, that LNs are designed primarily to serve local retail load while bulk transmission facilities are designed primarily to move bulk power from a bulk source (generally either the point of interconnection of a wholesale generator or a the point of interconnection with another bulk transmission system) to one or more wholesale purchasers. DEC believes further improvement of the language could be achieved with additional modifications and clarifications. With respect to the core

language of Exclusion 3, we believe the language making a “group of contiguous transmission Elements operated at or above 100kV” the starting point for identifying a LN would be improved by deleting the term “transmission” from this phrase. This is so because LNs are not used for transmission and the use of the term “transmission Elements” is therefore both confusing and unnecessary. There would be no room for argument about what the SDT intended by including the word “transmission” if the word is deleted and the Exclusion applies to any “group of Elements operated at 100kV or above” that meets the remaining requirement of the Exclusion. Further, any definitional value that is added by using the term “transmission Elements” is accomplished by using that term in the core definition, and there is no reason to carry the term through in the Exclusions. DEC also believes that subparagraphs (a) and (b) are redundant, because whatever protection is offered by the generation limit in subparagraph (a) is duplicated by the limit in subparagraph (b) requiring no flow out of the LN. We believe the SDT can eliminate subparagraph (a) of Exclusion 3 and simply rely on subparagraph (b) because if power only flows into the LN even if it interconnects more than 75 MVA of generation, the interconnected generation interconnected will have no significant interaction with the interconnected bulk transmission system. It will only interact with the LN. And, with the advent of distributed generation, it is easy to foresee a situation in which a large number of very small distributed generators are interconnected into a LN, so that the aggregate capacity of these generators exceeds 75 MVA. However, because the generators are small and dispersed and, under the criterion in subparagraph (b), would be wholly absorbed within the LN rather than transmitting power onto the interconnected grid, those generators would not have a material impact on the grid. We also suggest that subparagraph (b) of Exclusion 3 could be more clearly drafted. Subparagraph (b), as part of the requirement that power flow into a LN rather than out of it, includes this description: “The LN does not transfer energy originating outside the LN for delivery through the LN.” We understand this language is intended to distinguish a LN from a link in the transmission system – power on a transmission link passes through the transmission link to a load located elsewhere, while power in a LN enters the LN and is consumed by retail load within the LN. While we agree with the concept proposed by the SDT, we believe the language would be clearer if it read: “The LN does not transfer energy originating outside the LN for delivery through the LN to loads located outside the LN.” We believe the italicized language is necessary to distinguish between a transmission system, where power that originates outside a system is delivered through the system and passes through the system to a sink located somewhere outside the system, from a LN, in which power originating outside the LN passes through the LN and is delivered to retail load within the LN. To put it another way, the italicized language helps distinguish a transmission system from an LN, in which the LN “transfers energy originating outside the LN for delivery through the LN to loads located within the LN.” We also believe the language of subparagraph (a) of Exclusion 3 could be improved. Subparagraph (d) would make LNs part of the BES if they interconnect “non-retail generation greater than 75 MVA (gross nameplate rating).” For the reasons stated in our responses to Questions 3, 5 and 7, we urge the SDT to replace the reference to a hard 75 MVA threshold with the defined term “Qualifying Aggregate Generation Resources” or some equivalent. We are also uncertain what is meant by the use of the term “non-retail generation” in subparagraph (a). From context, we believe the SDT considers “non-retail generation” to be the equivalent of generation that is located behind the retail meter, usually but not always owned by the customer and used to serve the customer’s own load. We therefore suggest that the SDT replace the term “non-retail generation” with “generation located behind the retail customer’s meter.” Similarly, we are unsure what is meant by the phrase “the LN and its underlying Elements.” We believe the phrase “and its underlying Elements” could simply be deleted from the definition without loss of meaning. In the alternative, the SDT might consider using the phrase “the LN, including all Elements located on the distribution side of any Automatic Fault Interrupting Devices (or other points of demarcation) separating the LN from the bulk interstate transmission system.” We believe this phrase more accurately reflects the SDT’s intent, which appears to be that generation exceeding 75 MVA in aggregate capacity interconnected anywhere within the LN disqualifies that LN from being excluded from the BES under Exclusion 3. DEC also believes that both subparagraphs (a) and (b) of Exclusion 3 could be safely eliminated as long as subparagraph (c) is retained. Subparagraph (c) makes a LN part of the BES if it is classified as a Flow Gate or Transfer Path. Flow Gates and Transfer Paths are, by definition, the key facilities that allow reliable transmission of bulk electric power on the interconnected grid. If a LN has not been identified as either a Flow Gate or a Transfer Path, it is unlikely the LN is necessary for the reliable transmission of electricity on the interconnected bulk system. Apart from these specific improvements that we believe could be achieved by modifying the language of Exclusion 3, we believe the SDT may need to

re-examine certain assumptions that appear to underlie the current draft. Specifically, subparagraph (a) suggests that if BES generation is embedded within a LN, the LN itself must also be BES. But two NERC bodies have already addressed similar questions and concluded there is no technical basis for such concerns. NERC's Standards Drafting Team for Project 2010-07 and its predecessor, the "GO-TO Task Force" were formed to address how the dedicated interconnection facilities linking a BES generator to high-voltage transmission facilities should be treated under the NERC standards. The GO-TO Team concluded that by complying with a handful of reliability standards, primarily related to vegetation management, reliable operation of the bulk interconnected system could be protected without unduly burdening the owners of such interconnection systems. Therefore, there is no reason, according to the GO-TO Team, that dedicated high-voltage interconnection facilities must be treated as "Transmission" and classified as part of the BES in order to make reliability standards effective. See Final Report from the NERC Ad Hoc Group for Generator Requirements at the Transmission Interface (Nov. 16, 2009) (paper written by the GO-TO Task Force). Similarly, the Project 2010-07 Team observed that interconnection facilities "are most often not part of the integrated bulk power system, and as such should not be subject to the same level of standards applicable to Transmission Owners and Transmission Operators who own and operate transmission Facilities and Elements that are part of the integrated bulk power system." White Paper Proposal for Information Comment, NERC Project 2010-07: Generator Requirements at the Transmission Interface, at 3 (March 2011). Requiring Generation Owners and Operators to comply with the same standards as BES Transmission Owners and Operators "would do little, if anything, to improve the reliability of the Bulk Electric System," especially "when compared to the operation of the equipment that actually produces electricity – the generation equipment itself." Id. We believe that interconnection of BES generators within a LN is analogous and that, based on the findings of the Project 2010-07 and GO-TO Teams, automatically classifying a LN as "BES" simply because a large generator is embedded in the LN will result in substantial overregulation and unnecessary expense with little gain for bulk system reliability. If anything, generation interconnected through a LN is less likely to produce material impacts on the interconnected bulk transmission system than the equivalent generator interconnected through a single dedicated line because an LN is interconnected to the bulk system at several points, so that if one interconnection goes down, power can still flow from the BES generator to the bulk system on other interconnection points. Where a dedicated interconnection facility is involved, by contrast, if the interconnection line fails, the generator is unavailable to the interconnected bulk system. Similarly, we suggest that the SDT re-examine the assumptions underlying subparagraph (b), which seems to suggest that a local distribution system cannot be classified as a Local Network if power flows out of that system at any time, even if the amount is de minimis, the outward flow is only for a few hours, a year, or the outward flow occurs only in an extreme contingency. Accordingly, we suggest that the initial clause of subparagraph (b) be revised to read: "Except in unusual circumstances, power flows only into the LN." Finally, we note that the LN exclusion must not operate in any way as a substitution for the statutory prohibition on including "facilities used in the local distribution of electric energy" in the BES. Therefore, even with the LN exclusion, the SDT must retain this statutory language in the core definition of the BES, as discussed in our answer to Question One. If a certain piece of equipment is a "facility used in the local distribution of electric energy," then it is not part of the BES in the first instance, and so consideration of the LN Exclusion, or of any other Exclusion, any Inclusion, or any Exception, would be both unnecessary and uncalled for.

Yes

DEC supports the revised language because retail reactive devices are used to address local customer or retail voltage issues, rather than voltage issues on the interconnected bulk grid, and such local devices should therefore be excluded from the BES definition.

No

DEC extends its thanks to the SDT and to the many industry entities that have actively participating in the Standards Development Process. DEC supports the current draft and believes, with certain refinements discussed in our comments, that the definition will serve the industry and reliability regulators well for many years to come. In addition, as noted earlier, DEC is encouraged that the 20/75 MVA generation thresholds referred to in the NERC Statement of Compliance Registry Criteria, which have been relied upon by the SDT largely as a matter of necessity, will be reviewed and a technical assessment will be performed to identify the appropriate generation unit and plant size threshold to ensure a reliable North America. Finally, we understand that the Rules of Procedure Team will continue to move forward with developing an Exceptions Process that will complement the BES

Definition and ensure that, to the extent the BES Definition is over-inclusive, facilities that should not be classified as BES will be excluded from the BES. Because the Exceptions Process is integral to a workable BES Definition, we support the current process for moving forward with the Exceptions Process and the BES Definition on parallel paths. We note that DEC specifically supports the changes made by the SDT in the "Effective Date" provision of the BES Definition, which shortens the effective date of the new definition to the beginning of the first calendar quarter after regulatory approval (as opposed to the first calendar quarter twenty-four months after regulatory approval), with a 24-month transition period. DEC supports this conclusion because it will allow entities seeking deregistration under the terms of the new BES definition to obtain the benefits of the new definition without an unreasonable wait, while allowing any entities that may be newly-classified as BES owners or operators sufficient time to come into compliance with newly-applicable Reliability Standards. DEC also supports the 24-month transition period for the reasons laid out by the SDT.

Individual

Bryan Case

Fall River Rural Electric Cooperative (FALL)

Yes

The Fall River Rural Electric Cooperative (FALL) believes the SDT continues to make substantial progress towards a clear and workable definition of the Bulk Electric System ("BES") that markedly improves both the existing definition and the SDT's previous proposal. FALL therefore supports the new definition, although our support is conditioned on: (1) a workable Exceptions process being developed in conjunction with the BES definition; and, (2) the SDT moving forward expeditiously on Phase II of the standards development process in accordance with the SAR recently put forward by the SDT, which would address a number of important technical issues that have been identified in the standards development process to date. FALL strongly supports the following elements of the revised BES definition: (1) Clarification of how lists of Inclusions and Exclusions applies: The revised core definition moves the phrase "Unless modified by the lists shown below" to the beginning of the definition. This change makes clear that the Inclusions and Exclusions apply to all Elements that would otherwise be included in or excluded from the core definition (i.e., "all Transmission Elements operated at 100kV or higher and Real Time and Reactive Power resources connected at 100kV or higher") and eliminates a latent ambiguity in the first draft of the definition, discussed further in our comments on the first draft. (2) The exclusion for "facilities used in the local distribution of electric energy." As the starting point for the BES definition, FALL supports the use of the phrase "all Transmission Elements" and the qualifying sentence: "This does not include facilities used in the local distribution of electric energy." This language helps ensure that FERC, NERC, and the Regional Entities ("REs") will act within the jurisdictional constraints Congress placed in Section 215 of the Federal Power Act ("FPA"). In Section 215(a)(1), Congress unequivocally excluded "facilities used in the local distribution of electric energy" from the keystone "bulk-power system" definition. 16 U.S.C. § 824o(a)(1). Including the same language in the definition helps ensure that entities involved in enforcement of reliability standards will act within their statutory limits. In addition, as a practical matter, inclusion of the language will help focus both the industry and responsible agencies on the high-voltage interstate transmission system, where the reliability problems Congress intended to regulate – "instability, uncontrolled separation, [and] cascading failures," 16 U.S.C. § 824o(a)(4) – will originate. At the same time, level-of-service issues arising in local distribution systems will be left to the authority of state and local regulatory agencies and governing bodies, just as Congress intended. 16 U.S.C. § 824o(i)(2) (reserving to state and local authorities enforcement of standards for adequacy of service). FALL thanks the SDT for the excellent work to include this sentence. For similar reasons, FALL believes the use of the phrase "Transmission Elements" as the starting point for the base definition is desirable because both "Transmission" and "Elements" are already defined in the NERC Glossary of Terms Used in NERC Reliability Standards, and the term "Transmission" makes clear that the BES includes only Elements used in Transmission and therefore excludes Elements used in local distribution of electric power. (3) Appropriate Generator Thresholds. In the standards development process, it has become apparent that the thresholds for classifying generators as BES in the current NERC Statement of Compliance Registry Criteria ("SCRC") (20 MVA for individual generators, 75 MVA for multiple generators aggregated at a single site), which predate the adoption of FPA Section 215, were never the product of a careful analysis to determine whether generators of that size are necessary for operation of the interconnected bulk transmission system. Ideally, such an analysis would be conducted as part of the current standards development process. FALL recognizes

that, given the deadlines imposed by FERC in Order No. 743, it will not be possible for the SDT to conduct such an analysis within the time available. Accordingly, FALL agrees with the approach taken by the SDT, which is to propose a Phase II of the standards development process that would address the generator threshold issue and several other technical issues that have arisen during the current process. As long as Phase II proceeds expeditiously, FALL is prepared to support the BES definition as proposed by the SDT. While FALL supports the overall approach adopted by the SDT and much of the specific language incorporated into the second draft of the BES definition, we believe the second draft would benefit from further clarification or modification in a number of respects, most of which are detailed in our subsequent answers. Further, we believe a workable Exclusion Process is essential for a BES Definition that will meet the legal requirements of FPA Section 215, especially for systems operating in the Western Interconnection. As detailed in our previous comments, FALL believes a 200kV threshold would be more appropriate for WECC than a 100kV threshold. In addition, a 200kV threshold for the West is backed by solid technical analysis conducted by the WECC Bulk Electric System Definition Task Force, and repeated claims that there is no technical analysis to support this view are therefore incorrect. That said, we raise the issue here to emphasize the importance of the Exclusions for Local Networks and Radial Systems and the Exceptions process. These Exclusions and the Exceptions are essential for a definition that works in the Western Interconnection because the core definition will be over-inclusive in our region. As long as those Exclusions and the Exceptions Process are retained in a form substantially equivalent to those produced by the SDT at this juncture, FALL will support the SDT's proposal.

Yes

We support the SDT's changes to the first Inclusion because it is more clear and simple than the initial approach. That being said, we suggest that an additional sentence of clarification would help avoid future controversy about the meaning of Inclusion 1. As we understand it, the BES intends to include transformers only if both the primary and secondary terminals operate at 100kV or above, which is why the definition uses the word "and" ("the primary and secondary terminals"). We support this approach since it would exclude transformers where the secondary terminals serve distribution loads, and which therefore function as distribution rather than transmission facilities. We believe the SDT's intent would be clarified by adding a sentence at the end of Inclusion 1 that reads: "Transformers with either primary or secondary terminals, or both, that operate at or below 100kV are not part of the BES." This language will help ensure that there is no controversy over whether the SDT's use of the word "and" in the phrase "the primary and secondary terminals" was intentional. We also support the SDT's proposal to develop detailed guidance concerning the point of demarcation between BES and non-BES elements in the Phase II SAR. In this regard, we note that, while Inclusion 1 at least implicitly suggests that the dividing line between BES and non-BES Elements should be at the transformer where transmission-level voltages are stepped down to distribution-level voltages, we believe further clarification of this point of demarcation between the BES and non-BES Elements is necessary. Many different configurations of transformers and other equipment that may lie at the juncture between the BES and non-BES systems. If the point of demarcation is designated at the transformer without further elaboration, many entities that own equipment on the high side of a transformer will be swept into the BES, and thereby exposed to inappropriately stringent regulations and undue costs. For example, distribution-only utilities commonly own the switches, bus, and transformer protection devices on the high side of transformers where they take delivery from their transmission provider. Ownership of these protective devices and high-voltage bus on the high side of the transformer should not cause these entities to be classified as BES owners. As the Phase II process moves forward, we commend to the SDT the extensive work performed on the point of demarcation question by the WECC BESDTF. We also support the incorporation of language (" . . . unless excluded under Exclusions E1 or E3") making it clear that transformers that are operated as an integral part of a Radial System or Local Network should not be considered BES facilities, regardless of their operating voltage. Further clarification might be achieved by using the phrase ". . . unless the transformer is operated as part of a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2."

Yes

FALL supports the changes made in Inclusion 2 and believes that the definition in its current form adds clarity. In particular, we support the SDT's decision to collapse Inclusions 2 and 3 from the previous draft definition into a single Inclusion that addresses the treatment of generation for purposes of the BES definition. We also support the SDT's proposal for a Phase II of the BES

Definition process that would examine the technical justification for these thresholds and that would establish new thresholds based on a careful technical analysis. It is our understanding that the generator threshold issue will be vetted through the complete standards development process. We agree with this approach because if the generator threshold is treated as merely an element of NERC's Rules of Procedure, it can be changed with considerably less process and industry input than the Standards Development Process. Compare NERC Rules of Procedure § 1400 (providing for changes to Rules of Procedure upon approval of the NERC board and FERC) with NERC Standards Process Manual (Sept. 3, 2010) (providing for, e.g., posting of SDT proposals for comment, successive balloting, and super-majority approval requirements). See also Order No. 743-A, 134 FERC ¶ 61,210 at P 4 (2011) ("Order No. 743 directed the ERO to revise the definition of 'bulk electric system' through the NERC Standards Development Process" (emph. added)). Addressing all aspects of Phase II through the Standards Development Process will improve the content of the definition by bringing to bear industry expertise on all aspects of the definition and will ensure that, once firm guidelines are established, they can be relied upon by both industry and regulators without threat that they will be changed with little notice and little process. FALL believes further clarification of the proposed language would be appropriate. The SDT proposes continued reliance upon the thresholds that are used in the NERC Statement of Compliance Registry Criteria for registration of Generation Owners and Generation Operators, which is currently 20 MVA for an individual generation unit and 75 MVA for multiple units on a single site. Conceptually, we are concerned about this approach because, as we understand it, the purpose of the Compliance Registry is to sweep in all generators that might be material to the reliable operation of the BES, and not to definitively determine whether a given generator is, in fact, material to the reliable operation of the BES. As the SCRC itself states, the SCRC is intended only to identify "candidates for registration." SCRC at p.3, § 1 (emph. added). Accordingly, we believe that the generator threshold determined in Phase II should be incorporated directly into the BES Definition rather than being incorporated by reference from the SCRC. We also believe that the specific language proposed by the SDT could be further clarified. The SDT proposes that generation be included in the BES if the "Generation resource(s)" has a "nameplate rating per the ERO Statement of Compliance Registry." We understand this language is intended to be a placeholder for the results of the technical analysis that would occur in Phase II but we believe simply stating that the threshold will be "per the ERO Statement of Compliance Registry" is ambiguous. Further, for the reasons noted above, we believe the threshold should be part of the BES Definition, and should not simply be a cross-reference to the SCRC (and, given the different purposes of the BES Definition and the SCRC, it is not clear that the same threshold should be used in both). We therefore propose that Inclusion 2 be rewritten to state: "Qualifying Individual Generation Resources or Qualifying Aggregate Resources connected at a voltage of 100kV or above." Two definitions would then be added to the note at the end of the definition to read as follows: For purposes of this BES Definition, Qualifying Individual Generation Resources means an individual generating unit that meets the materiality threshold to be included in this definition or, in the absence of such a materiality threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of such a resource as a Generation Owner under the ERO Statement of Compliance Registry Criteria. For purposes of this BES Definition, Qualifying Aggregate Generation Resources means any facility consisting of one or more generating units that are connected at a common bus that meets the materiality threshold to be included in this definition, or, in the absence of such a threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of multiple-unit generator as a Generation Owner under the ERO Statement of Compliance Registry Criteria.. The "materiality threshold" is intended to refer to the generator threshold developed in Phase II. We suggest using definitions in this fashion for several reasons. First, we believe the language we suggest more clearly states the intention of the SDT, which we understand is to classify generation units as part of the BES if they are necessary for operation of the BES, but to exclude smaller generating units because they are not material to the operation of the interconnected transmission grid. Second, we believe use of the defined terms better reflects the intention of the SDT to reserve the specific question about generator thresholds to the technical analysis that will occur in Phase II without having to revise the BES Definition at the end of that process. That is, the definitions are designed to allow the SDT to include revised thresholds in the definition at the conclusion of the Phase II process based upon the technical analysis planned for Phase II, and the revised thresholds will be automatically incorporated into the BES Definition if the language we suggest is used. The thresholds used in the SCRC would only be a fall-back, to be used only until Phase II is completed. Third, the definitions can be incorporated into other parts of the BES Definition, which will add consistency and

clarity. As noted in our answers to several of the questions below, the specific 75 MVA threshold is retained in several of the Exclusions and Inclusions, and we believe the industry would be better served if the revised thresholds arrived at after technical analysis in Phase II are automatically incorporated into all relevant provisions of the BES Definition. There is no reason for the SDT to continue to rely on the 75 MVA threshold once the analysis planned for Phase II on the threshold issue is completed. Fourth, the phrase "or that meets the materiality threshold to be included in this definition" is intended to preserve the SDT's flexibility to make a determination that generators below a specific threshold are not "necessary to" maintain the reliability of the interconnected transmission system, and to incorporate that finding as part of the definition itself, even if a different threshold is used in the SCRC to identify potential candidates for registration. Accordingly, our proposed language makes clear that a specific threshold in the definition controls over any threshold that might be included in the SCRC. For the reasons stated above, we believe it is highly desirable to include any material threshold in the BES Definition itself rather than relegating the threshold to the SCRC, which is merely a procedural rule rather than a full-fledged Reliability Standard. Finally, we agree with the SDT's decision to examine the question of where the line between BES and non-BES Elements should be drawn more closely in Phase II under the rubric of "contiguous vs. non-contiguous BES," and commend the work of the Project 2010-07 Standards Drafting Team and the GO-TO Team as a good starting point for the SDT's analysis on this issue. We understand Inclusion 2 would classify generators exceeding specific thresholds as part of the BES, but would not necessarily require facilities interconnecting such generators to be part of the BES. As discussed more fully in our answer to Question 9, based on extensive technical analysis that has already been performed by the NERC Project 2010-07 Standards Drafting Team and its predecessor, the NERC "GO-TO Team," regulating as part of the BES a dedicated interconnection facility connecting a BES generator to the interconnected bulk transmission grid will result in an unnecessary regulatory burden that produces considerable expense for the owner of the interconnection facility with little or no improvement in bulk system reliability. We also believe the clauses at the end of Inclusion 2 are somewhat confusing and that greater clarity would be achieved by changing ". . . including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100kV or above" so that the Inclusion covers transformers with terminals "connected at a voltage of 100kV or above, including the generator terminal(s) on the high side of the step-up transformer(s) if operated at a voltage of 100kV or above."

Yes

FALL supports the removal of the Cranking Path language in I3. As noted in our response to Question 9, there is no reason to classify as BES the facilities interconnecting a BES generator to the bulk interstate system. A Cranking Path is simply a specific type of such an interconnection facility.

Yes

FALL supports the revised language generally, but believes additional changes would make the language clearer. Specifically, we believe Inclusion 4 should not incorporate a hard 75 MVA generation threshold (i.e., "resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)"). Instead, we urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," which we discuss in more detail in our response to Question 3. This language will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. More generally, we are not certain what is accomplished by Inclusion 4 that is not already accomplished by Inclusion 2, which also addresses whether generation should be defined as BES. The SDT's stated concern is with variable generation units such as wind and solar plants. It is not clear to us why this concern is not fully addressed in Inclusion 2, which addresses multiple generation units connected at a common bus, the configuration of most variable generation plants with multiple units. We are also concerned that the language, as proposed, could have unintended consequences and improperly classify local distribution systems as BES in certain circumstances. This is because multiple distributed generation units could render a local distribution system a "collector system" and the entire system the equivalent of an aggregated generation unit, causing the local distribution system to be improperly denied status as a Local Network. If many different distributed generation units are connected to a local distribution system, it is very unlikely that more than a few of those units would fail simultaneously, and it is therefore unlikely that multiple generation units would produce a measureable impact on the interconnected bulk transmission system, especially if the units individually do not otherwise exceed the materiality threshold to be

established by the SDT in Phase II. Further, we are concerned that, if small distributed generation units become the industry norm, Inclusion 4 could unintentionally sweep in local distribution systems, especially where local policies favor the growth of small solar or other renewable generation systems for public policy reasons. Finally, we suggest that the SDT add the phrase “. . . unless the dispersed power producing resources operate within a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2.” This language, which parallels the language included at the end of Inclusion I1, would make clear that dispersed small-scale generators scattered throughout a Radial System or Local Network serving retail load would not convert the Radial System or Local Network into a BES system, even if the aggregate capacity of those small generators exceeds the relevant threshold.

No

FALL has several concerns about the new language in Inclusion 5. First, because Reactive Power devices produce power, they are “power producing resources” and we therefore believe Inclusion 5 is duplicative of Inclusion 4, which addresses “power producing devices.” Second, there is no capacity threshold specified in Inclusion 5 for Reactive Power devices that would be considered part of the BES. This is inconsistent with the approach taken in the balance of the definition, where thresholds are specified for generators and other types of power producing devices. Third, FALL believes the appropriate threshold for inclusion or exclusion of Reactive Power devices from the BES should be subject to the same technical analysis that will cover generators in the Phase II process. Finally, FALL believes this issue should be addressed in Phase 2 since there is not technical justification or analysis done to determine the thresholds. FALL strongly believes that there should be technical justification for thresholds for this issue and all other issues.

Yes

FALL continues to strongly support the radial system exclusion, which is necessary as a legal matter, because, among other reasons, FERC in Orders No. 743 and 743-A has required that the existing radial exemption in the NERC Statement of Compliance Registry Criteria be maintained. As a practical matter, radial systems are used for service to retail loads, usually in remote or rural areas, and not for the transmission of bulk power. Hence, operation of the radials has little or nothing to do with the reliable operation of the interconnected bulk transmission network. We also support the inclusion of the note discussing normally open switches because this language provides needed clarity for a common radial system configuration. We also agree with the substantive thrust of this language, which is that a radial system should not be considered part of the BES if it is interconnected at a single point, even if there is an alternative point of delivery that is normally open. While we support the Exclusion for Radial Systems, we believe several clarifications and refinements are necessary. (1) The term “transmission Elements” in the initial paragraph should be changed to “Elements.” Radial systems are not transmission systems and including the word “transmission” in the Radial System exclusion is therefore unnecessary and confusing. (2) Subparagraph (b) of Exclusion 1 refers to “generation resources . . . with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)”. We urge the SDT to replace this language with the defined term “Qualifying Aggregate Generation Resources,” discussed in more detail in our response to Question 3. This language will preserve the SDT’s ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. (3) Subparagraph (b) also seems to assume that if a Radial System contains a generator exceeding the 75 MVA threshold, the Radial System itself must be included in the BES because it links the generator to the interconnected bulk transmission system. As discussed more fully in our response to Question 9, below, NERC’s Project 2010-17 Standards Drafting Team and GO-TO Task Force have both concluded that this assumption is unwarranted. (4) The “Note” as drafted by the SDT indicates that “a normally open switching device between radial systems” will not serve to disqualify the Radial from exclusion under Exclusion 1. As discussed above, FALL strongly supports the note conceptually. However, we believe this language should be included in a separate subparagraph (d), rather than a note, because treatment as a “note” suggests it is less important than other portions of the Exclusion. We also suggest the language be changed to read: (d) Normally-open switching devices between radial elements as depicted and identified on system one-line diagrams does not affect this exclusion. This will make clear that a radial with more than one normally-open switch connecting it to another radial is still a radial. From the perspective of the BES Definition, the key question is whether switches operating between Radials are normally open, not whether there is more than one normally-open switch.

Yes

FALL supports the revised language. The language provides clarity regarding the BES status of customer-owned cogeneration facilities. However, FALL urges the SDT to remove the reference to the 75 MVA threshold and replace it with the defined term "Qualifying Aggregate Generation Resources" or some equivalent language for the reasons stated in our responses to Questions 3, 5, and 7. In addition, we are concerned that Exclusion 2 will place local distribution utilities in a difficult position because, under Exclusion 1 or Exclusion 3 as drafted, they could lose their status as a Radial System or a Local Network through the actions of a customer constructing behind-the-meter generation. With respect to Radial Systems, the appearance of behind-the-meter generators could cause the Radial System to exceed the thresholds specified in subparagraphs (b) and (c) of Exclusion 1 through no fault of the Radial System owner. Similar, a Local Network could lose its status because behind-the-meter generation could be of sufficient size that power moves into the interconnected grid in certain hours or under certain contingencies, rather than moving purely onto the Local Network, as required in subparagraph (b) of Exclusion 3. The Exclusions for Radial Systems and Local Networks should be made consistent with the Exclusion for behind-the-meter generation. There is no technical reason to believe the power flowing from a behind-the-meter customer-owned generator will have less impact on the bulk system than an equivalent-sized generator owned by a utility operating a Radial System or LN.

Yes

FALL strongly supports the exclusion of Local Networks ("LNs") from the BES. The conversion of radial systems to local networks should be encouraged because networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. If the BES definition were to provide an exclusion for radials without providing a similar exclusion for LNs, however, it would discourage networking local distribution systems because of the significantly increased regulatory burdens faced by the local distribution utility if it elected to network its radial facilities. By placing radial systems and LNs on the same regulatory footing, the proposed definition will ensure that decisions about whether to network radial systems are made on the basis of costs and benefits to the retail customers served by those radials, and not on the basis of disparate regulatory treatment. Consumers would ultimately benefit. FALL also supports specific refinements made to the LN exclusion by the SDT in the current draft of the BES definition. In particular, FALL supports the clarification of the purposes of a LN. The current draft states that LNs connect at multiple points to "improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system." FALL supports this change in language because it reflects the fundamental purposes of a LN and emphasizes one of the key distinctions between LNs and bulk transmission facilities, namely, that LNs are designed primarily to serve local retail load while bulk transmission facilities are designed primarily to move bulk power from a bulk source (generally either the point of interconnection of a wholesale generator or a the point of interconnection with another bulk transmission system) to one or more wholesale purchasers. FALL believes further improvement of the language could be achieved with additional modifications and clarifications. With respect to the core language of Exclusion 3, we believe the language making a "group of contiguous transmission Elements operated at or above 100kV" the starting point for identifying a LN would be improved by deleting the term "transmission" from this phrase. This is so because LNs are not used for transmission and the use of the term "transmission Elements" is therefore both confusing and unnecessary. There would be no room for argument about what the SDT intended by including the word "transmission" if the word is deleted and the Exclusion applies to any "group of Elements operated at 100kV or above" that meets the remaining requirement of the Exclusion. Further, any definitional value that is added by using the term "transmission Elements" is accomplished by using that term in the core definition, and there is no reason to carry the term through in the Exclusions. FALL also believes that subparagraphs (a) and (b) are redundant, because whatever protection is offered by the generation limit in subparagraph (a) is duplicated by the limit in subparagraph (b) requiring no flow out of the LN. We believe the SDT can eliminate subparagraph (a) of Exclusion 3 and simply rely on subparagraph (b) because if power only flows into the LN even if it interconnects more than 75 MVA of generation, the interconnected generation interconnected will have no significant interaction with the interconnected bulk transmission system. It will only interact with the LN. And, with the advent of distributed generation, it is easy to foresee a situation in which a large number of very small distributed generators are interconnected into a LN, so that the aggregate capacity of these generators exceeds 75 MVA. However, because the generators are small and

dispersed and, under the criterion in subparagraph (b), would be wholly absorbed within the LN rather than transmitting power onto the interconnected grid, those generators would not have a material impact on the grid. We also suggest that subparagraph (b) of Exclusion 3 could be more clearly drafted. Subparagraph (b), as part of the requirement that power flow into a LN rather than out of it, includes this description: "The LN does not transfer energy originating outside the LN for delivery through the LN." We understand this language is intended to distinguish a LN from a link in the transmission system – power on a transmission link passes through the transmission link to a load located elsewhere, while power in a LN enters the LN and is consumed by retail load within the LN. While we agree with the concept proposed by the SDT, we believe the language would be clearer if it read: "The LN does not transfer energy originating outside the LN for delivery through the LN to loads located outside the LN." We believe the italicized language is necessary to distinguish between a transmission system, where power that originates outside a system is delivered through the system and passes through the system to a sink located somewhere outside the system, from a LN, in which power originating outside the LN passes through the LN and is delivered to retail load within the LN. To put it another way, the italicized language helps distinguish a transmission system from an LN, in which the LN "transfers energy originating outside the LN for delivery through the LN to loads located within the LN." We also believe the language of subparagraph (a) of Exclusion 3 could be improved. Subparagraph (d) would make LNs part of the BES if they interconnect "non-retail generation greater than 75 MVA (gross nameplate rating)." For the reasons stated in our responses to Questions 3, 5 and 7, we urge the SDT to replace the reference to a hard 75 MVA threshold with the defined term "Qualifying Aggregate Generation Resources" or some equivalent. We are also uncertain what is meant by the use of the term "non-retail generation" in subparagraph (a). From context, we believe the SDT considers "non-retail generation" to be the equivalent of generation that is located behind the retail meter, usually but not always owned by the customer and used to serve the customer's own load. We therefore suggest that the SDT replace the term "non-retail generation" with "generation located behind the retail customer's meter." Similarly, we are unsure what is meant by the phrase "the LN and its underlying Elements." We believe the phrase "and its underlying Elements" could simply be deleted from the definition without loss of meaning. In the alternative, the SDT might consider using the phrase "the LN, including all Elements located on the distribution side of any Automatic Fault Interrupting Devices (or other points of demarcation) separating the LN from the bulk interstate transmission system." We believe this phrase more accurately reflects the SDT's intent, which appears to be that generation exceeding 75 MVA in aggregate capacity interconnected anywhere within the LN disqualifies that LN from being excluded from the BES under Exclusion 3. FALL also believes that both subparagraphs (a) and (b) of Exclusion 3 could be safely eliminated as long as subparagraph (c) is retained. Subparagraph (c) makes a LN part of the BES if it is classified as a Flow Gate or Transfer Path. Flow Gates and Transfer Paths are, by definition, the key facilities that allow reliable transmission of bulk electric power on the interconnected grid. If a LN has not been identified as either a Flow Gate or a Transfer Path, it is unlikely the LN is necessary for the reliable transmission of electricity on the interconnected bulk system. Apart from these specific improvements that we believe could be achieved by modifying the language of Exclusion 3, we believe the SDT may need to re-examine certain assumptions that appear to underlie the current draft. Specifically, subparagraph (a) suggests that if BES generation is embedded within a LN, the LN itself must also be BES. But two NERC bodies have already addressed similar questions and concluded there is no technical basis for such concerns. NERC's Standards Drafting Team for Project 2010-07 and its predecessor, the "GO-TO Task Force" were formed to address how the dedicated interconnection facilities linking a BES generator to high-voltage transmission facilities should be treated under the NERC standards. The GO-TO Team concluded that by complying with a handful of reliability standards, primarily related to vegetation management, reliable operation of the bulk interconnected system could be protected without unduly burdening the owners of such interconnection systems. Therefore, there is no reason, according to the GO-TO Team, that dedicated high-voltage interconnection facilities must be treated as "Transmission" and classified as part of the BES in order to make reliability standards effective. See Final Report from the NERC Ad Hoc Group for Generator Requirements at the Transmission Interface (Nov. 16, 2009) (paper written by the GO-TO Task Force). Similarly, the Project 2010-07 Team observed that interconnection facilities "are most often not part of the integrated bulk power system, and as such should not be subject to the same level of standards applicable to Transmission Owners and Transmission Operators who own and operate transmission facilities and elements that are part of the integrated bulk power system." White Paper Proposal for Information Comment, NERC Project 2010-07: Generator Requirements at the

Transmission Interface, at 3 (March 2011). Requiring Generation Owners and Operators to comply with the same standards as BES Transmission Owners and Operators “would do little, if anything, to improve the reliability of the Bulk Electric System,” especially “when compared to the operation of the equipment that actually produces electricity – the generation equipment itself.” Id. We believe that interconnection of BES generators within a LN is analogous and that, based on the findings of the Project 2010-07 and GO-TO Teams, automatically classifying a LN as “BES” simply because a large generator is embedded in the LN will result in substantial overregulation and unnecessary expense with little gain for bulk system reliability. If anything, generation interconnected through a LN is less likely to produce material impacts on the interconnected bulk transmission system than the equivalent generator interconnected through a single dedicated line because an LN is interconnected to the bulk system at several points, so that if one interconnection goes down, power can still flow from the BES generator to the bulk system on other interconnection points. Where a dedicated interconnection facility is involved, by contrast, if the interconnection line fails, the generator is unavailable to the interconnected bulk system. Similarly, we suggest that the SDT re-examine the assumptions underlying subparagraph (b), which seems to suggest that a local distribution system cannot be classified as a Local Network if power flows out of that system at any time, even if the amount is de minimis, the outward flow is only for a few hours, a year, or the outward flow occurs only in an extreme contingency. Accordingly, we suggest that the initial clause of subparagraph (b) be revised to read: “Except in unusual circumstances, power flows only into the LN.” Finally, we note that the LN exclusion must not operate in any way as a substitution for the statutory prohibition on including “facilities used in the local distribution of electric energy” in the BES. Therefore, even with the LN exclusion, the SDT must retain this statutory language in the core definition of the BES, as discussed in our answer to Question One. If a certain piece of equipment is a “facility used in the local distribution of electric energy,” then it is not part of the BES in the first instance, and so consideration of the LN Exclusion, or of any other Exclusion, any Inclusion, or any Exception, would be both unnecessary and uncalled for.

Yes

FALL supports the revised language because retail reactive devices are used to address local customer or retail voltage issues, rather than voltage issues on the interconnected bulk grid, and such local devices should therefore be excluded from the BES definition.

No

FALL extends its thanks to the SDT and to the many industry entities that have actively participating in the Standards Development Process. FALL supports the current draft and believes, with certain refinements discussed in our comments, that the definition will serve the industry and reliability regulators well for many years to come. In addition, as noted earlier, FALL is encouraged that the 20/75 MVA generation thresholds referred to in the NERC Statement of Compliance Registry Criteria, which have been relied upon by the SDT largely as a matter of necessity, will be reviewed and a technical assessment will be performed to identify the appropriate generation unit and plant size threshold to ensure a reliable North America. Finally, we understand that the Rules of Procedure Team will continue to move forward with developing an Exceptions Process that will complement the BES Definition and ensure that, to the extent the BES Definition is over-inclusive, facilities that should not be classified as BES will be excluded from the BES. Because the Exceptions Process is integral to a workable BES Definition, we support the current process for moving forward with the Exceptions Process and the BES Definition on parallel paths. We note that FALL specifically supports the changes made by the SDT in the “Effective Date” provision of the BES Definition, which shortens the effective date of the new definition to the beginning of the first calendar quarter after regulatory approval (as opposed to the first calendar quarter twenty-four months after regulatory approval), with a 24-month transition period. FALL supports this conclusion because it will allow entities seeking deregistration under the terms of the new BES definition to obtain the benefits of the new definition without an unreasonable wait, while allowing any entities that may be newly-classified as BES owners or operators sufficient time to come into compliance with newly-applicable Reliability Standards. FALL also supports the 24-month transition period for the reasons laid out by the SDT.

Lane Electric Cooperative (LEC)

Yes

The Lane Electric Cooperative (LEC) believes the SDT continues to make substantial progress towards a clear and workable definition of the Bulk Electric System ("BES") that markedly improves both the existing definition and the SDT's previous proposal. LEC therefore supports the new definition, although our support is conditioned on: (1) a workable Exceptions process being developed in conjunction with the BES definition; and, (2) the SDT moving forward expeditiously on Phase II of the standards development process in accordance with the SAR recently put forward by the SDT, which would address a number of important technical issues that have been identified in the standards development process to date. LEC strongly supports the following elements of the revised BES definition: (1) Clarification of how lists of Inclusions and Exclusions applies: The revised core definition moves the phrase "Unless modified by the lists shown below" to the beginning of the definition. This change makes clear that the Inclusions and Exclusions apply to all Elements that would otherwise be included in or excluded from the core definition (i.e., "all Transmission Elements operated at 100kV or higher and Real Time and Reactive Power resources connected at 100kV or higher") and eliminates a latent ambiguity in the first draft of the definition, discussed further in our comments on the first draft. (2) The exclusion for "facilities used in the local distribution of electric energy." As the starting point for the BES definition, LEC supports the use of the phrase "all Transmission Elements" and the qualifying sentence: "This does not include facilities used in the local distribution of electric energy." This language helps ensure that FERC, NERC, and the Regional Entities ("REs") will act within the jurisdictional constraints Congress placed in Section 215 of the Federal Power Act ("FPA"). In Section 215(a)(1), Congress unequivocally excluded "facilities used in the local distribution of electric energy" from the keystone "bulk-power system" definition. 16 U.S.C. § 824o(a)(1). Including the same language in the definition helps ensure that entities involved in enforcement of reliability standards will act within their statutory limits. In addition, as a practical matter, inclusion of the language will help focus both the industry and responsible agencies on the high-voltage interstate transmission system, where the reliability problems Congress intended to regulate – "instability, uncontrolled separation, [and] cascading failures," 16 U.S.C. § 824o(a)(4) – will originate. At the same time, level-of-service issues arising in local distribution systems will be left to the authority of state and local regulatory agencies and governing bodies, just as Congress intended. 16 U.S.C. § 824o(i)(2) (reserving to state and local authorities enforcement of standards for adequacy of service). LEC thanks the SDT for the excellent work to include this sentence. For similar reasons, LEC believes the use of the phrase "Transmission Elements" as the starting point for the base definition is desirable because both "Transmission" and "Elements" are already defined in the NERC Glossary of Terms Used in NERC Reliability Standards, and the term "Transmission" makes clear that the BES includes only Elements used in Transmission and therefore excludes Elements used in local distribution of electric power. (3) Appropriate Generator Thresholds. In the standards development process, it has become apparent that the thresholds for classifying generators as BES in the current NERC Statement of Compliance Registry Criteria ("SCRC") (20 MVA for individual generators, 75 MVA for multiple generators aggregated at a single site), which predate the adoption of FPA Section 215, were never the product of a careful analysis to determine whether generators of that size are necessary for operation of the interconnected bulk transmission system. Ideally, such an analysis would be conducted as part of the current standards development process. LEC recognizes that, given the deadlines imposed by FERC in Order No. 743, it will not be possible for the SDT to conduct such an analysis within the time available. Accordingly, LEC agrees with the approach taken by the SDT, which is to propose a Phase II of the standards development process that would address the generator threshold issue and several other technical issues that have arisen during the current process. As long as Phase II proceeds expeditiously, LEC is prepared to support the BES definition as proposed by the SDT. While LEC supports the overall approach adopted by the SDT and much of the specific language incorporated into the second draft of the BES definition, we believe the second draft would benefit from further clarification or modification in a number of respects, most of which are detailed in our subsequent answers. Further, we believe a workable Exclusion Process is essential for a BES Definition that will meet the legal requirements of FPA Section 215, especially for systems operating in the Western Interconnection. As detailed in our previous comments, LEC believes a 200kV threshold would be more appropriate for WECC than a 100kV threshold. In addition, a 200kV threshold for the West is backed by solid technical analysis conducted by the WECC Bulk Electric System Definition Task Force, and repeated claims that there is no technical analysis to support this view are therefore incorrect. That said, we raise the issue here to emphasize the importance of the Exclusions for Local Networks and Radial Systems and the Exceptions process. These Exclusions and the Exceptions are essential for a definition that works in the Western Interconnection because the

core definition will be over-inclusive in our region. As long as those Exclusions and the Exceptions Process are retained in a form substantially equivalent to those produced by the SDT at this juncture, LEC will support the SDT's proposal.

Yes

We support the SDT's changes to the first Inclusion because it is more clear and simple than the initial approach. That being said, we suggest that an additional sentence of clarification would help avoid future controversy about the meaning of Inclusion 1. As we understand it, the BES intends to include transformers only if both the primary and secondary terminals operate at 100kV or above, which is why the definition uses the word "and" ("the primary and secondary terminals"). We support this approach since it would exclude transformers where the secondary terminals serve distribution loads, and which therefore function as distribution rather than transmission facilities. We believe the SDT's intent would be clarified by adding a sentence at the end of Inclusion 1 that reads: "Transformers with either primary or secondary terminals, or both, that operate at or below 100kV are not part of the BES." This language will help ensure that there is no controversy over whether the SDT's use of the word "and" in the phrase "the primary and secondary terminals" was intentional. We also support the SDT's proposal to develop detailed guidance concerning the point of demarcation between BES and non-BES elements in the Phase II SAR. In this regard, we note that, while Inclusion 1 at least implicitly suggests that the dividing line between BES and non-BES Elements should be at the transformer where transmission-level voltages are stepped down to distribution-level voltages, we believe further clarification of this point of demarcation between the BES and non-BES Elements is necessary. Many different configurations of transformers and other equipment that may lie at the juncture between the BES and non-BES systems. If the point of demarcation is designated at the transformer without further elaboration, many entities that own equipment on the high side of a transformer will be swept into the BES, and thereby exposed to inappropriately stringent regulations and undue costs. For example, distribution-only utilities commonly own the switches, bus, and transformer protection devices on the high side of transformers where they take delivery from their transmission provider. Ownership of these protective devices and high-voltage bus on the high side of the transformer should not cause these entities to be classified as BES owners. As the Phase II process moves forward, we commend to the SDT the extensive work performed on the point of demarcation question by the WECC BESDTF. We also support the incorporation of language (" . . . unless excluded under Exclusions E1 or E3") making it clear that transformers that are operated as an integral part of a Radial System or Local Network should not be considered BES facilities, regardless of their operating voltage. Further clarification might be achieved by using the phrase ". . . unless the transformer is operated as part of a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2."

Yes

LEC supports the changes made in Inclusion 2 and believes that the definition in its current form adds clarity. In particular, we support the SDT's decision to collapse Inclusions 2 and 3 from the previous draft definition into a single Inclusion that addresses the treatment of generation for purposes of the BES definition. We also support the SDT's proposal for a Phase II of the BES Definition process that would examine the technical justification for these thresholds and that would establish new thresholds based on a careful technical analysis. It is our understanding that the generator threshold issue will be vetted through the complete standards development process. We agree with this approach because if the generator threshold is treated as merely an element of NERC's Rules of Procedure, it can be changed with considerably less process and industry input than the Standards Development Process. Compare NERC Rules of Procedure § 1400 (providing for changes to Rules of Procedure upon approval of the NERC board and FERC) with NERC Standards Process Manual (Sept. 3, 2010) (providing for, e.g., posting of SDT proposals for comment, successive balloting, and super-majority approval requirements). See also Order No. 743-A, 134 FERC ¶ 61,210 at P 4 (2011) ("Order No. 743 directed the ERO to revise the definition of 'bulk electric system' through the NERC Standards Development Process" (emph. added)). Addressing all aspects of Phase II through the Standards Development Process will improve the content of the definition by bringing to bear industry expertise on all aspects of the definition and will ensure that, once firm guidelines are established, they can be relied upon by both industry and regulators without threat that they will be changed with little notice and little process. LEC believes further clarification of the proposed language would be appropriate. The SDT proposes continued reliance upon the thresholds that are used in the NERC Statement of Compliance Registry Criteria for registration of Generation Owners and Generation Operators, which is

currently 20 MVA for an individual generation unit and 75 MVA for multiple units on a single site. Conceptually, we are concerned about this approach because, as we understand it, the purpose of the Compliance Registry is to sweep in all generators that might be material to the reliable operation of the BES, and not to definitively determine whether a given generator is, in fact, material to the reliable operation of the BES. As the SCRC itself states, the SCRC is intended only to identify "candidates for registration." SCRC at p.3, § 1 (emph. added). Accordingly, we believe that the generator threshold determined in Phase II should be incorporated directly into the BES Definition rather than being incorporated by reference from the SCRC. We also believe that the specific language proposed by the SDT could be further clarified. The SDT proposes that generation be included in the BES if the "Generation resource(s)" has a "nameplate rating per the ERO Statement of Compliance Registry." We understand this language is intended to be a placeholder for the results of the technical analysis that would occur in Phase II but we believe simply stating that the threshold will be "per the ERO Statement of Compliance Registry" is ambiguous. Further, for the reasons noted above, we believe the threshold should be part of the BES Definition, and should not simply be a cross-reference to the SCRC (and, given the different purposes of the BES Definition and the SCRC, it is not clear that the same threshold should be used in both). We therefore propose that Inclusion 2 be rewritten to state: "Qualifying Individual Generation Resources or Qualifying Aggregate Resources connected at a voltage of 100kV or above." Two definitions would then be added to the note at the end of the definition to read as follows: For purposes of this BES Definition, Qualifying Individual Generation Resources means an individual generating unit that meets the materiality threshold to be included in this definition or, in the absence of such a materiality threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of such a resource as a Generation Owner under the ERO Statement of Compliance Registry Criteria. For purposes of this BES Definition, Qualifying Aggregate Generation Resources means any facility consisting of one or more generating units that are connected at a common bus that meets the materiality threshold to be included in this definition, or, in the absence of such a threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of multiple-unit generator as a Generation Owner under the ERO Statement of Compliance Registry Criteria. The "materiality threshold" is intended to refer to the generator threshold developed in Phase II. We suggest using definitions in this fashion for several reasons. First, we believe the language we suggest more clearly states the intention of the SDT, which we understand is to classify generation units as part of the BES if they are necessary for operation of the BES, but to exclude smaller generating units because they are not material to the operation of the interconnected transmission grid. Second, we believe use of the defined terms better reflects the intention of the SDT to reserve the specific question about generator thresholds to the technical analysis that will occur in Phase II without having to revise the BES Definition at the end of that process. That is, the definitions are designed to allow the SDT to include revised thresholds in the definition at the conclusion of the Phase II process based upon the technical analysis planned for Phase II, and the revised thresholds will be automatically incorporated into the BES Definition if the language we suggest is used. The thresholds used in the SCRC would only be a fall-back, to be used only until Phase II is completed. Third, the definitions can be incorporated into other parts of the BES Definition, which will add consistency and clarity. As noted in our answers to several of the questions below, the specific 75 MVA threshold is retained in several of the Exclusions and Inclusions, and we believe the industry would be better served if the revised thresholds arrived at after technical analysis in Phase II are automatically incorporated into all relevant provisions of the BES Definition. There is no reason for the SDT to continue to rely on the 75 MVA threshold once the analysis planned for Phase II on the threshold issue is completed. Fourth, the phrase "or that meets the materiality threshold to be included in this definition" is intended to preserve the SDT's flexibility to make a determination that generators below a specific threshold are not "necessary to" maintain the reliability of the interconnected transmission system, and to incorporate that finding as part of the definition itself, even if a different threshold is used in the SCRC to identify potential candidates for registration. Accordingly, our proposed language makes clear that a specific threshold in the definition controls over any threshold that might be included in the SCRC. For the reasons stated above, we believe it is highly desirable to include any material threshold in the BES Definition itself rather than relegating the threshold to the SCRC, which is merely a procedural rule rather than a full-fledged Reliability Standard. Finally, we agree with the SDT's decision to examine the question of where the line between BES and non-BES Elements should be drawn more closely in Phase II under the rubric of "contiguous vs. non-contiguous BES," and commend the work of the Project 2010-07 Standards Drafting Team and the GO-TO Team as a good starting point for the

SDT's analysis on this issue. We understand Inclusion 2 would classify generators exceeding specific thresholds as part of the BES, but would not necessarily require facilities interconnecting such generators to be part of the BES. As discussed more fully in our answer to Question 9, based on extensive technical analysis that has already been performed by the NERC Project 2010-07 Standards Drafting Team and its predecessor, the NERC "GO-TO Team," regulating as part of the BES a dedicated interconnection facility connecting a BES generator to the interconnected bulk transmission grid will result in an unnecessary regulatory burden that produces considerable expense for the owner of the interconnection facility with little or no improvement in bulk system reliability. We also believe the clauses at the end of Inclusion 2 are somewhat confusing and that greater clarity would be achieved by changing ". . . including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100kV or above" so that the Inclusion covers transformers with terminals "connected at a voltage of 100kV or above, including the generator terminal(s) on the high side of the step-up transformer(s) if operated at a voltage of 100kV or above."

Yes

LEC supports the removal of the Cranking Path language in I3. As noted in our response to Question 9, there is no reason to classify as BES the facilities interconnecting a BES generator to the bulk interstate system. A Cranking Path is simply a specific type of such an interconnection facility.

Yes

LEC supports the revised language generally, but believes additional changes would make the language clearer. Specifically, we believe Inclusion 4 should not incorporate a hard 75 MVA generation threshold (i.e., "resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)"). Instead, we urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," which we discuss in more detail in our response to Question 3. This language will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. More generally, we are not certain what is accomplished by Inclusion 4 that is not already accomplished by Inclusion 2, which also addresses whether generation should be defined as BES. The SDT's stated concern is with variable generation units such as wind and solar plants. It is not clear to us why this concern is not fully addressed in Inclusion 2, which addresses multiple generation units connected at a common bus, the configuration of most variable generation plants with multiple units. We are also concerned that the language, as proposed, could have unintended consequences and improperly classify local distribution systems as BES in certain circumstances. This is because multiple distributed generation units could render a local distribution system a "collector system" and the entire system the equivalent of an aggregated generation unit, causing the local distribution system to be improperly denied status as a Local Network. If many different distributed generation units are connected to a local distribution system, it is very unlikely that more than a few of those units would fail simultaneously, and it is therefore unlikely that multiple generation units would produce a measureable impact on the interconnected bulk transmission system, especially if the units individually do not otherwise exceed the materiality threshold to be established by the SDT in Phase II. Further, we are concerned that, if small distributed generation units become the industry norm, Inclusion 4 could unintentionally sweep in local distribution systems, especially where local policies favor the growth of small solar or other renewable generation systems for public policy reasons. Finally, we suggest that the SDT add the phrase ". . . unless the dispersed power producing resources operate within a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2." This language, which parallels the language included at the end of Inclusion I1, would make clear that dispersed small-scale generators scattered throughout a Radial System or Local Network serving retail load would not convert the Radial System or Local Network into a BES system, even if the aggregate capacity of those small generators exceeds the relevant threshold.

No

LEC has several concerns about the new language in Inclusion 5. First, because Reactive Power devices produce power, they are "power producing resources" and we therefore believe Inclusion 5 is duplicative of Inclusion 4, which addresses "power producing devices." Second, there is no capacity threshold specified in Inclusion 5 for Reactive Power devices that would be considered part of the BES. This is inconsistent with the approach taken in the balance of the definition, where thresholds are specified for generators and other types of power producing devices. Third, LEC believes the appropriate threshold for inclusion or exclusion of Reactive Power devices from the BES should be

subject to the same technical analysis that will cover generators in the Phase II process. Finally, LEC believes this issue should be addressed in Phase 2 since there is not technical justification or analysis done to determine the thresholds. LEC strongly believes that there should be technical justification for thresholds for this issue and all other issues.

Yes

LEC continues to strongly support the radial system exclusion, which is necessary as a legal matter, because, among other reasons, FERC in Orders No. 743 and 743-A has required that the existing radial exemption in the NERC Statement of Compliance Registry Criteria be maintained. As a practical matter, radial systems are used for service to retail loads, usually in remote or rural areas, and not for the transmission of bulk power. Hence, operation of the radials has little or nothing to do with the reliable operation of the interconnected bulk transmission network. We also support the inclusion of the note discussing normally open switches because this language provides needed clarity for a common radial system configuration. We also agree with the substantive thrust of this language, which is that a radial system should not be considered part of the BES if it is interconnected at a single point, even if there is an alternative point of delivery that is normally open. While we support the Exclusion for Radial Systems, we believe several clarifications and refinements are necessary. (1) The term "transmission Elements" in the initial paragraph should be changed to "Elements." Radial systems are not transmission systems and including the word "transmission" in the Radial System exclusion is therefore unnecessary and confusing. (2) Subparagraph (b) of Exclusion 1 refers to "generation resources . . . with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)". We urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," discussed in more detail in our response to Question 3. This language will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. (3) Subparagraph (b) also seems to assume that if a Radial System contains a generator exceeding the 75 MVA threshold, the Radial System itself must be included in the BES because it links the generator to the interconnected bulk transmission system. As discussed more fully in our response to Question 9, below, NERC's Project 2010-17 Standards Drafting Team and GO-TO Task Force have both concluded that this assumption is unwarranted. (4) The "Note" as drafted by the SDT indicates that "a normally open switching device between radial systems" will not serve to disqualify the Radial from exclusion under Exclusion 1. As discussed above, LEC strongly supports the note conceptually. However, we believe this language should be included in a separate subparagraph (d), rather than a note, because treatment as a "note" suggests it is less important than other portions of the Exclusion. We also suggest the language be changed to read: (d) Normally-open switching devices between radial elements as depicted and identified on system one-line diagrams does not affect this exclusion. This will make clear that a radial with more than one normally-open switch connecting it to another radial is still a radial. From the perspective of the BES Definition, the key question is whether switches operating between Radials are normally open, not whether there is more than one normally-open switch.

Yes

LEC supports the revised language. The language provides clarity regarding the BES status of customer-owned cogeneration facilities. However, LEC urges the SDT to remove the reference to the 75 MVA threshold and replace it with the defined term "Qualifying Aggregate Generation Resources" or some equivalent language for the reasons stated in our responses to Questions 3, 5, and 7. In addition, we are concerned that Exclusion 2 will place local distribution utilities in a difficult position because, under Exclusion 1 or Exclusion 3 as drafted, they could lose their status as a Radial System or a Local Network through the actions of a customer constructing behind-the-meter generation. With respect to Radial Systems, the appearance of behind-the-meter generators could cause the Radial System to exceed the thresholds specified in subparagraphs (b) and (c) of Exclusion 1 through no fault of the Radial System owner. Similar, a Local Network could lose its status because behind-the-meter generation could be of sufficient size that power moves into the interconnected grid in certain hours or under certain contingencies, rather than moving purely onto the Local Network, as required in subparagraph (b) of Exclusion 3. The Exclusions for Radial Systems and Local Networks should be made consistent with the Exclusion for behind-the-meter generation. There is no technical reason to believe the power flowing from a behind-the-meter customer-owned generator will have less impact on the bulk system than an equivalent-sized generator owned by a utility operating a Radial System or LN.

Yes

LEC strongly supports the exclusion of Local Networks (“LNs”) from the BES. The conversion of radial systems to local networks should be encouraged because networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. If the BES definition were to provide an exclusion for radials without providing a similar exclusion for LNs, however, it would discourage networking local distribution systems because of the significantly increased regulatory burdens faced by the local distribution utility if it elected to network its radial facilities. By placing radial systems and LNs on the same regulatory footing, the proposed definition will ensure that decisions about whether to network radial systems are made on the basis of costs and benefits to the retail customers served by those radials, and not on the basis of disparate regulatory treatment. Consumers would ultimately benefit. LEC also supports specific refinements made to the LN exclusion by the SDT in the current draft of the BES definition. In particular, LEC supports the clarification of the purposes of a LN. The current draft states that LNs connect at multiple points to “improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system.” LEC supports this change in language because it reflects the fundamental purposes of a LN and emphasizes one of the key distinctions between LNs and bulk transmission facilities, namely, that LNs are designed primarily to serve local retail load while bulk transmission facilities are designed primarily to move bulk power from a bulk source (generally either the point of interconnection of a wholesale generator or a the point of interconnection with another bulk transmission system) to one or more wholesale purchasers. LEC believes further improvement of the language could be achieved with additional modifications and clarifications. With respect to the core language of Exclusion 3, we believe the language making a “group of contiguous transmission Elements operated at or above 100kV” the starting point for identifying a LN would be improved by deleting the term “transmission” from this phrase. This is so because LNs are not used for transmission and the use of the term “transmission Elements” is therefore both confusing and unnecessary. There would be no room for argument about what the SDT intended by including the word “transmission” if the word is deleted and the Exclusion applies to any “group of Elements operated at 100kV or above” that meets the remaining requirement of the Exclusion. Further, any definitional value that is added by using the term “transmission Elements” is accomplished by using that term in the core definition, and there is no reason to carry the term through in the Exclusions. LEC also believes that subparagraphs (a) and (b) are redundant, because whatever protection is offered by the generation limit in subparagraph (a) is duplicated by the limit in subparagraph (b) requiring no flow out of the LN. We believe the SDT can eliminate subparagraph (a) of Exclusion 3 and simply rely on subparagraph (b) because if power only flows into the LN even if it interconnects more than 75 MVA of generation, the interconnected generation interconnected will have no significant interaction with the interconnected bulk transmission system. It will only interact with the LN. And, with the advent of distributed generation, it is easy to foresee a situation in which a large number of very small distributed generators are interconnected into a LN, so that the aggregate capacity of these generators exceeds 75 MVA. However, because the generators are small and dispersed and, under the criterion in subparagraph (b), would be wholly absorbed within the LN rather than transmitting power onto the interconnected grid, those generators would not have a material impact on the grid. We also suggest that subparagraph (b) of Exclusion 3 could be more clearly drafted. Subparagraph (b), as part of the requirement that power flow into a LN rather than out of it, includes this description: “The LN does not transfer energy originating outside the LN for delivery through the LN.” We understand this language is intended to distinguish a LN from a link in the transmission system – power on a transmission link passes through the transmission link to a load located elsewhere, while power in a LN enters the LN and is consumed by retail load within the LN. While we agree with the concept proposed by the SDT, we believe the language would be clearer if it read: “The LN does not transfer energy originating outside the LN for delivery through the LN to loads located outside the LN.” We believe the italicized language is necessary to distinguish between a transmission system, where power that originates outside a system is delivered through the system and passes through the system to a sink located somewhere outside the system, from a LN, in which power originating outside the LN passes through the LN and is delivered to retail load within the LN. To put it another way, the italicized language helps distinguish a transmission system from an LN, in which the LN “transfers energy originating outside the LN for delivery through the LN to loads located within the LN.” We also believe the language of subparagraph (a) of Exclusion 3 could be improved. Subparagraph (d) would make LNs part of the BES if they interconnect “non-retail generation greater than 75 MVA (gross nameplate rating).” For the reasons stated in our responses to Questions 3, 5 and

7, we urge the SDT to replace the reference to a hard 75 MVA threshold with the defined term "Qualifying Aggregate Generation Resources" or some equivalent. We are also uncertain what is meant by the use of the term "non-retail generation" in subparagraph (a). From context, we believe the SDT considers "non-retail generation" to be the equivalent of generation that is located behind the retail meter, usually but not always owned by the customer and used to serve the customer's own load. We therefore suggest that the SDT replace the term "non-retail generation" with "generation located behind the retail customer's meter." Similarly, we are unsure what is meant by the phrase "the LN and its underlying Elements." We believe the phrase "and its underlying Elements" could simply be deleted from the definition without loss of meaning. In the alternative, the SDT might consider using the phrase "the LN, including all Elements located on the distribution side of any Automatic Fault Interrupting Devices (or other points of demarcation) separating the LN from the bulk interstate transmission system." We believe this phrase more accurately reflects the SDT's intent, which appears to be that generation exceeding 75 MVA in aggregate capacity interconnected anywhere within the LN disqualifies that LN from being excluded from the BES under Exclusion 3. LEC also believes that both subparagraphs (a) and (b) of Exclusion 3 could be safely eliminated as long as subparagraph (c) is retained. Subparagraph (c) makes a LN part of the BES if it is classified as a Flow Gate or Transfer Path. Flow Gates and Transfer Paths are, by definition, the key facilities that allow reliable transmission of bulk electric power on the interconnected grid. If a LN has not been identified as either a Flow Gate or a Transfer Path, it is unlikely the LN is necessary for the reliable transmission of electricity on the interconnected bulk system. Apart from these specific improvements that we believe could be achieved by modifying the language of Exclusion 3, we believe the SDT may need to re-examine certain assumptions that appear to underlie the current draft. Specifically, subparagraph (a) suggests that if BES generation is embedded within a LN, the LN itself must also be BES. But two NERC bodies have already addressed similar questions and concluded there is no technical basis for such concerns. NERC's Standards Drafting Team for Project 2010-07 and its predecessor, the "GO-TO Task Force" were formed to address how the dedicated interconnection facilities linking a BES generator to high-voltage transmission facilities should be treated under the NERC standards. The GO-TO Team concluded that by complying with a handful of reliability standards, primarily related to vegetation management, reliable operation of the bulk interconnected system could be protected without unduly burdening the owners of such interconnection systems. Therefore, there is no reason, according to the GO-TO Team, that dedicated high-voltage interconnection facilities must be treated as "Transmission" and classified as part of the BES in order to make reliability standards effective. See Final Report from the NERC Ad Hoc Group for Generator Requirements at the Transmission Interface (Nov. 16, 2009) (paper written by the GO-TO Task Force). Similarly, the Project 2010-07 Team observed that interconnection facilities "are most often not part of the integrated bulk power system, and as such should not be subject to the same level of standards applicable to Transmission Owners and Transmission Operators who own and operate transmission Facilities and Elements that are part of the integrated bulk power system." White Paper Proposal for Information Comment, NERC Project 2010-07: Generator Requirements at the Transmission Interface, at 3 (March 2011). Requiring Generation Owners and Operators to comply with the same standards as BES Transmission Owners and Operators "would do little, if anything, to improve the reliability of the Bulk Electric System," especially "when compared to the operation of the equipment that actually produces electricity – the generation equipment itself." Id. We believe that interconnection of BES generators within a LN is analogous and that, based on the findings of the Project 2010-07 and GO-TO Teams, automatically classifying a LN as "BES" simply because a large generator is embedded in the LN will result in substantial overregulation and unnecessary expense with little gain for bulk system reliability. If anything, generation interconnected through a LN is less likely to produce material impacts on the interconnected bulk transmission system than the equivalent generator interconnected through a single dedicated line because an LN is interconnected to the bulk system at several points, so that if one interconnection goes down, power can still flow from the BES generator to the bulk system on other interconnection points. Where a dedicated interconnection facility is involved, by contrast, if the interconnection line fails, the generator is unavailable to the interconnected bulk system. Similarly, we suggest that the SDT re-examine the assumptions underlying subparagraph (b), which seems to suggest that a local distribution system cannot be classified as a Local Network if power flows out of that system at any time, even if the amount is de minimis, the outward flow is only for a few hours, a year, or the outward flow occurs only in an extreme contingency. Accordingly, we suggest that the initial clause of subparagraph (b) be revised to read: "Except in unusual circumstances, power flows only into the LN." Finally, we note that the LN exclusion must not operate

in any way as a substitution for the statutory prohibition on including “facilities used in the local distribution of electric energy” in the BES. Therefore, even with the LN exclusion, the SDT must retain this statutory language in the core definition of the BES, as discussed in our answer to Question One. If a certain piece of equipment is a “facility used in the local distribution of electric energy,” then it is not part of the BES in the first instance, and so consideration of the LN Exclusion, or of any other Exclusion, any Inclusion, or any Exception, would be both unnecessary and uncalled for.

Yes

LEC supports the revised language because retail reactive devices are used to address local customer or retail voltage issues, rather than voltage issues on the interconnected bulk grid, and such local devices should therefore be excluded from the BES definition.

No

LEC extends its thanks to the SDT and to the many industry entities that have actively participating in the Standards Development Process. LEC supports the current draft and believes, with certain refinements discussed in our comments, that the definition will serve the industry and reliability regulators well for many years to come. In addition, as noted earlier, LEC is encouraged that the 20/75 MVA generation thresholds referred to in the NERC Statement of Compliance Registry Criteria, which have been relied upon by the SDT largely as a matter of necessity, will be reviewed and a technical assessment will be performed to identify the appropriate generation unit and plant size threshold to ensure a reliable North America. Finally, we understand that the Rules of Procedure Team will continue to move forward with developing an Exceptions Process that will complement the BES Definition and ensure that, to the extent the BES Definition is over-inclusive, facilities that should not be classified as BES will be excluded from the BES. Because the Exceptions Process is integral to a workable BES Definition, we support the current process for moving forward with the Exceptions Process and the BES Definition on parallel paths. We note that LEC specifically supports the changes made by the SDT in the “Effective Date” provision of the BES Definition, which shortens the effective date of the new definition to the beginning of the first calendar quarter after regulatory approval (as opposed to the first calendar quarter twenty-four months after regulatory approval), with a 24-month transition period. LEC supports this conclusion because it will allow entities seeking deregistration under the terms of the new BES definition to obtain the benefits of the new definition without an unreasonable wait, while allowing any entities that may be newly-classified as BES owners or operators sufficient time to come into compliance with newly-applicable Reliability Standards. LEC also supports the 24-month transition period for the reasons laid out by the SDT.

Individual

Michael Henry

Lincoln Electric Cooperative (LEC)

Yes

The Lincoln Electric Cooperative (LEC) believes the SDT continues to make substantial progress towards a clear and workable definition of the Bulk Electric System (“BES”) that markedly improves both the existing definition and the SDT’s previous proposal. LEC therefore supports the new definition, although our support is conditioned on: (1) a workable Exceptions process being developed in conjunction with the BES definition; and, (2) the SDT moving forward expeditiously on Phase II of the standards development process in accordance with the SAR recently put forward by the SDT, which would address a number of important technical issues that have been identified in the standards development process to date. LEC strongly supports the following elements of the revised BES definition: (1) Clarification of how lists of Inclusions and Exclusions applies: The revised core definition moves the phrase “Unless modified by the lists shown below” to the beginning of the definition. This change makes clear that the Inclusions and Exclusions apply to all Elements that would otherwise be included in or excluded from the core definition (i.e., “all Transmission Elements operated at 100kV or higher and Real Time and Reactive Power resources connected at 100kV or higher”) and eliminates a latent ambiguity in the first draft of the definition, discussed further in our comments on the first draft. (2) The exclusion for “facilities used in the local distribution of electric energy.” As the starting point for the BES definition, LEC supports the use of the phrase “all Transmission Elements” and the qualifying sentence: “This does not include facilities used in the local distribution of electric energy.” This language helps ensure that FERC, NERC, and the Regional Entities (“REs”) will act within the jurisdictional constraints Congress placed in Section 215 of the Federal Power Act (“FPA”). In Section 215(a)(1), Congress unequivocally excluded “facilities used in

the local distribution of electric energy" from the keystone "bulk-power system" definition. 16 U.S.C. § 824o(a)(1). Including the same language in the definition helps ensure that entities involved in enforcement of reliability standards will act within their statutory limits. In addition, as a practical matter, inclusion of the language will help focus both the industry and responsible agencies on the high-voltage interstate transmission system, where the reliability problems Congress intended to regulate – "instability, uncontrolled separation, [and] cascading failures," 16 U.S.C. § 824o(a)(4) – will originate. At the same time, level-of-service issues arising in local distribution systems will be left to the authority of state and local regulatory agencies and governing bodies, just as Congress intended. 16 U.S.C. § 824o(i)(2) (reserving to state and local authorities enforcement of standards for adequacy of service). LEC thanks the SDT for the excellent work to include this sentence. For similar reasons, LEC believes the use of the phrase "Transmission Elements" as the starting point for the base definition is desirable because both "Transmission" and "Elements" are already defined in the NERC Glossary of Terms Used in NERC Reliability Standards, and the term "Transmission" makes clear that the BES includes only Elements used in Transmission and therefore excludes Elements used in local distribution of electric power. (3) Appropriate Generator Thresholds. In the standards development process, it has become apparent that the thresholds for classifying generators as BES in the current NERC Statement of Compliance Registry Criteria ("SCRC") (20 MVA for individual generators, 75 MVA for multiple generators aggregated at a single site), which predate the adoption of FPA Section 215, were never the product of a careful analysis to determine whether generators of that size are necessary for operation of the interconnected bulk transmission system. Ideally, such an analysis would be conducted as part of the current standards development process. LEC recognizes that, given the deadlines imposed by FERC in Order No. 743, it will not be possible for the SDT to conduct such an analysis within the time available. Accordingly, LEC agrees with the approach taken by the SDT, which is to propose a Phase II of the standards development process that would address the generator threshold issue and several other technical issues that have arisen during the current process. As long as Phase II proceeds expeditiously, LEC is prepared to support the BES definition as proposed by the SDT. While LEC supports the overall approach adopted by the SDT and much of the specific language incorporated into the second draft of the BES definition, we believe the second draft would benefit from further clarification or modification in a number of respects, most of which are detailed in our subsequent answers. Further, we believe a workable Exclusion Process is essential for a BES Definition that will meet the legal requirements of FPA Section 215, especially for systems operating in the Western Interconnection. As detailed in our previous comments, LEC believes a 200kV threshold would be more appropriate for WECC than a 100kV threshold. In addition, a 200kV threshold for the West is backed by solid technical analysis conducted by the WECC Bulk Electric System Definition Task Force, and repeated claims that there is no technical analysis to support this view are therefore incorrect. That said, we raise the issue here to emphasize the importance of the Exclusions for Local Networks and Radial Systems and the Exceptions process. These Exclusions and the Exceptions are essential for a definition that works in the Western Interconnection because the core definition will be over-inclusive in our region. As long as those Exclusions and the Exceptions Process are retained in a form substantially equivalent to those produced by the SDT at this juncture, LEC will support the SDT's proposal.

Yes

We support the SDT's changes to the first Inclusion because it is more clear and simple than the initial approach. That being said, we suggest that an additional sentence of clarification would help avoid future controversy about the meaning of Inclusion 1. As we understand it, the BES intends to include transformers only if both the primary and secondary terminals operate at 100kV or above, which is why the definition uses the word "and" ("the primary and secondary terminals"). We support this approach since it would exclude transformers where the secondary terminals serve distribution loads, and which therefore function as distribution rather than transmission facilities. We believe the SDT's intent would be clarified by adding a sentence at the end of Inclusion 1 that reads: "Transformers with either primary or secondary terminals, or both, that operate at or below 100kV are not part of the BES." This language will help ensure that there is no controversy over whether the SDT's use of the word "and" in the phrase "the primary and secondary terminals" was intentional. We also support the SDT's proposal to develop detailed guidance concerning the point of demarcation between BES and non-BES elements in the Phase II SAR. In this regard, we note that, while Inclusion 1 at least implicitly suggests that the dividing line between BES and non-BES Elements should be at the transformer where transmission-level voltages are stepped down to distribution-level voltages, we believe further clarification of this point of demarcation between the BES and non-BES Elements is

necessary. Many different configurations of transformers and other equipment that may lie at the juncture between the BES and non-BES systems. If the point of demarcation is designated at the transformer without further elaboration, many entities that own equipment on the high side of a transformer will be swept into the BES, and thereby exposed to inappropriately stringent regulations and undue costs. For example, distribution-only utilities commonly own the switches, bus, and transformer protection devices on the high side of transformers where they take delivery from their transmission provider. Ownership of these protective devices and high-voltage bus on the high side of the transformer should not cause these entities to be classified as BES owners. As the Phase II process moves forward, we commend to the SDT the extensive work performed on the point of demarcation question by the WECC BESDTF. We also support the incorporation of language (“ . . . unless excluded under Exclusions E1 or E3”) making it clear that transformers that are operated as an integral part of a Radial System or Local Network should not be considered BES facilities, regardless of their operating voltage. Further clarification might be achieved by using the phrase “. . . unless the transformer is operated as part of a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2.”

Yes

LEC supports the changes made in Inclusion 2 and believes that the definition in its current form adds clarity. In particular, we support the SDT’s decision to collapse Inclusions 2 and 3 from the previous draft definition into a single Inclusion that addresses the treatment of generation for purposes of the BES definition. We also support the SDT’s proposal for a Phase II of the BES Definition process that would examine the technical justification for these thresholds and that would establish new thresholds based on a careful technical analysis. It is our understanding that the generator threshold issue will be vetted through the complete standards development process. We agree with this approach because if the generator threshold is treated as merely an element of NERC’s Rules of Procedure, it can be changed with considerably less process and industry input than the Standards Development Process. Compare NERC Rules of Procedure § 1400 (providing for changes to Rules of Procedure upon approval of the NERC board and FERC) with NERC Standards Process Manual (Sept. 3, 2010) (providing for, e.g., posting of SDT proposals for comment, successive balloting, and super-majority approval requirements). See also Order No. 743-A, 134 FERC ¶ 61,210 at P 4 (2011) (“Order No. 743 directed the ERO to revise the definition of ‘bulk electric system’ through the NERC Standards Development Process” (emph. added)). Addressing all aspects of Phase II through the Standards Development Process will improve the content of the definition by bringing to bear industry expertise on all aspects of the definition and will ensure that, once firm guidelines are established, they can be relied upon by both industry and regulators without threat that they will be changed with little notice and little process. LEC believes further clarification of the proposed language would be appropriate. The SDT proposes continued reliance upon the thresholds that are used in the NERC Statement of Compliance Registry Criteria for registration of Generation Owners and Generation Operators, which is currently 20 MVA for an individual generation unit and 75 MVA for multiple units on a single site. Conceptually, we are concerned about this approach because, as we understand it, the purpose of the Compliance Registry is to sweep in all generators that might be material to the reliable operation of the BES, and not to definitively determine whether a given generator is, in fact, material to the reliable operation of the BES. As the SCRC itself states, the SCRC is intended only to identify “candidates for registration.” SCRC at p.3, § 1 (emph. added). Accordingly, we believe that the generator threshold determined in Phase II should be incorporated directly into the BES Definition rather than being incorporated by reference from the SCRC. We also believe that the specific language proposed by the SDT could be further clarified. The SDT proposes that generation be included in the BES if the “Generation resource(s)” has a “nameplate rating per the ERO Statement of Compliance Registry.” We understand this language is intended to be a placeholder for the results of the technical analysis that would occur in Phase II but we believe simply stating that the threshold will be “per the ERO Statement of Compliance Registry” is ambiguous. Further, for the reasons noted above, we believe the threshold should be part of the BES Definition, and should not simply be a cross-reference to the SCRC (and, given the different purposes of the BES Definition and the SCRC, it is not clear that the same threshold should be used in both). We therefore propose that Inclusion 2 be rewritten to state: “Qualifying Individual Generation Resources or Qualifying Aggregate Resources connected at a voltage of 100kV or above.” Two definitions would then be added to the note at the end of the definition to read as follows: For purposes of this BES Definition, Qualifying Individual Generation Resources means an individual generating unit that meets the materiality threshold to be included in this definition or, in the absence of such a materiality threshold, that meets the gross

nameplate capacity voltage threshold requiring registration of the owner of such a resource as a Generation Owner under the ERO Statement of Compliance Registry Criteria. For purposes of this BES Definition, Qualifying Aggregate Generation Resources means any facility consisting of one or more generating units that are connected at a common bus that meets the materiality threshold to be included in this definition, or, in the absence of such a threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of multiple-unit generator as a Generation Owner under the ERO Statement of Compliance Registry Criteria. The "materiality threshold" is intended to refer to the generator threshold developed in Phase II. We suggest using definitions in this fashion for several reasons. First, we believe the language we suggest more clearly states the intention of the SDT, which we understand is to classify generation units as part of the BES if they are necessary for operation of the BES, but to exclude smaller generating units because they are not material to the operation of the interconnected transmission grid. Second, we believe use of the defined terms better reflects the intention of the SDT to reserve the specific question about generator thresholds to the technical analysis that will occur in Phase II without having to revise the BES Definition at the end of that process. That is, the definitions are designed to allow the SDT to include revised thresholds in the definition at the conclusion of the Phase II process based upon the technical analysis planned for Phase II, and the revised thresholds will be automatically incorporated into the BES Definition if the language we suggest is used. The thresholds used in the SCRC would only be a fall-back, to be used only until Phase II is completed. Third, the definitions can be incorporated into other parts of the BES Definition, which will add consistency and clarity. As noted in our answers to several of the questions below, the specific 75 MVA threshold is retained in several of the Exclusions and Inclusions, and we believe the industry would be better served if the revised thresholds arrived at after technical analysis in Phase II are automatically incorporated into all relevant provisions of the BES Definition. There is no reason for the SDT to continue to rely on the 75 MVA threshold once the analysis planned for Phase II on the threshold issue is completed. Fourth, the phrase "or that meets the materiality threshold to be included in this definition" is intended to preserve the SDT's flexibility to make a determination that generators below a specific threshold are not "necessary to" maintain the reliability of the interconnected transmission system, and to incorporate that finding as part of the definition itself, even if a different threshold is used in the SCRC to identify potential candidates for registration. Accordingly, our proposed language makes clear that a specific threshold in the definition controls over any threshold that might be included in the SCRC. For the reasons stated above, we believe it is highly desirable to include any material threshold in the BES Definition itself rather than relegating the threshold to the SCRC, which is merely a procedural rule rather than a full-fledged Reliability Standard. Finally, we agree with the SDT's decision to examine the question of where the line between BES and non-BES Elements should be drawn more closely in Phase II under the rubric of "contiguous vs. non-contiguous BES," and commend the work of the Project 2010-07 Standards Drafting Team and the GO-TO Team as a good starting point for the SDT's analysis on this issue. We understand Inclusion 2 would classify generators exceeding specific thresholds as part of the BES, but would not necessarily require facilities interconnecting such generators to be part of the BES. As discussed more fully in our answer to Question 9, based on extensive technical analysis that has already been performed by the NERC Project 2010-07 Standards Drafting Team and its predecessor, the NERC "GO-TO Team," regulating as part of the BES a dedicated interconnection facility connecting a BES generator to the interconnected bulk transmission grid will result in an unnecessary regulatory burden that produces considerable expense for the owner of the interconnection facility with little or no improvement in bulk system reliability. We also believe the clauses at the end of Inclusion 2 are somewhat confusing and that greater clarity would be achieved by changing ". . . including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100kV or above" so that the Inclusion covers transformers with terminals "connected at a voltage of 100kV or above, including the generator terminal(s) on the high side of the step-up transformer(s) if operated at a voltage of 100kV or above."

Yes

LEC supports the removal of the Cranking Path language in I3. As noted in our response to Question 9, there is no reason to classify as BES the facilities interconnecting a BES generator to the bulk interstate system. A Cranking Path is simply a specific type of such an interconnection facility.

Yes

LEC supports the revised language generally, but believes additional changes would make the language clearer. Specifically, we believe Inclusion 4 should not incorporate a hard 75 MVA

generation threshold (i.e., "resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)"). Instead, we urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," which we discuss in more detail in our response to Question 3. This language will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. More generally, we are not certain what is accomplished by Inclusion 4 that is not already accomplished by Inclusion 2, which also addresses whether generation should be defined as BES. The SDT's stated concern is with variable generation units such as wind and solar plants. It is not clear to us why this concern is not fully addressed in Inclusion 2, which addresses multiple generation units connected at a common bus, the configuration of most variable generation plants with multiple units. We are also concerned that the language, as proposed, could have unintended consequences and improperly classify local distribution systems as BES in certain circumstances. This is because multiple distributed generation units could render a local distribution system a "collector system" and the entire system the equivalent of an aggregated generation unit, causing the local distribution system to be improperly denied status as a Local Network. If many different distributed generation units are connected to a local distribution system, it is very unlikely that more than a few of those units would fail simultaneously, and it is therefore unlikely that multiple generation units would produce a measureable impact on the interconnected bulk transmission system, especially if the units individually do not otherwise exceed the materiality threshold to be established by the SDT in Phase II. Further, we are concerned that, if small distributed generation units become the industry norm, Inclusion 4 could unintentionally sweep in local distribution systems, especially where local policies favor the growth of small solar or other renewable generation systems for public policy reasons. Finally, we suggest that the SDT add the phrase ". . . unless the dispersed power producing resources operate within a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2." This language, which parallels the language included at the end of Inclusion I1, would make clear that dispersed small-scale generators scattered throughout a Radial System or Local Network serving retail load would not convert the Radial System or Local Network into a BES system, even if the aggregate capacity of those small generators exceeds the relevant threshold.

No

LEC has several concerns about the new language in Inclusion 5. First, because Reactive Power devices produce power, they are "power producing resources" and we therefore believe Inclusion 5 is duplicative of Inclusion 4, which addresses "power producing devices." Second, there is no capacity threshold specified in Inclusion 5 for Reactive Power devices that would be considered part of the BES. This is inconsistent with the approach taken in the balance of the definition, where thresholds are specified for generators and other types of power producing devices. Third, LEC believes the appropriate threshold for inclusion or exclusion of Reactive Power devices from the BES should be subject to the same technical analysis that will cover generators in the Phase II process. Finally, LEC believes this issue should be addressed in Phase 2 since there is not technical justification or analysis done to determine the thresholds. LEC strongly believes that there should be technical justification for thresholds for this issue and all other issues.

Yes

LEC continues to strongly support the radial system exclusion, which is necessary as a legal matter, because, among other reasons, FERC in Orders No. 743 and 743-A has required that the existing radial exemption in the NERC Statement of Compliance Registry Criteria be maintained. As a practical matter, radial systems are used for service to retail loads, usually in remote or rural areas, and not for the transmission of bulk power. Hence, operation of the radials has little or nothing to do with the reliable operation of the interconnected bulk transmission network. We also support the inclusion of the note discussing normally open switches because this language provides needed clarity for a common radial system configuration. We also agree with the substantive thrust of this language, which is that a radial system should not be considered part of the BES if it is interconnected at a single point, even if there is an alternative point of delivery that is normally open. While we support the Exclusion for Radial Systems, we believe several clarifications and refinements are necessary. (1) The term "transmission Elements" in the initial paragraph should be changed to "Elements." Radial systems are not transmission systems and including the word "transmission" in the Radial System exclusion is therefore unnecessary and confusing. (2) Subparagraph (b) of Exclusion 1 refers to "generation resources . . . with aggregate capacity greater than 75 MVA (gross aggregate nameplate

rating)"). We urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," discussed in more detail in our response to Question 3. This language will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. (3) Subparagraph (b) also seems to assume that if a Radial System contains a generator exceeding the 75 MVA threshold, the Radial System itself must be included in the BES because it links the generator to the interconnected bulk transmission system. As discussed more fully in our response to Question 9, below, NERC's Project 2010-17 Standards Drafting Team and GO-TO Task Force have both concluded that this assumption is unwarranted. (4) The "Note" as drafted by the SDT indicates that "a normally open switching device between radial systems" will not serve to disqualify the Radial from exclusion under Exclusion 1. As discussed above, LEC strongly supports the note conceptually. However, we believe this language should be included in a separate subparagraph (d), rather than a note, because treatment as a "note" suggests it is less important than other portions of the Exclusion. We also suggest the language be changed to read: (d) Normally-open switching devices between radial elements as depicted and identified on system one-line diagrams does not affect this exclusion. This will make clear that a radial with more than one normally-open switch connecting it to another radial is still a radial. From the perspective of the BES Definition, the key question is whether switches operating between Radials are normally open, not whether there is more than one normally-open switch.

Yes

LEC supports the revised language. The language provides clarity regarding the BES status of customer-owned cogeneration facilities. However, LEC urges the SDT to remove the reference to the 75 MVA threshold and replace it with the defined term "Qualifying Aggregate Generation Resources" or some equivalent language for the reasons stated in our responses to Questions 3, 5, and 7. In addition, we are concerned that Exclusion 2 will place local distribution utilities in a difficult position because, under Exclusion 1 or Exclusion 3 as drafted, they could lose their status as a Radial System or a Local Network through the actions of a customer constructing behind-the-meter generation. With respect to Radial Systems, the appearance of behind-the-meter generators could cause the Radial System to exceed the thresholds specified in subparagraphs (b) and (c) of Exclusion 1 through no fault of the Radial System owner. Similar, a Local Network could lose its status because behind-the-meter generation could be of sufficient size that power moves into the interconnected grid in certain hours or under certain contingencies, rather than moving purely onto the Local Network, as required in subparagraph (b) of Exclusion 3. The Exclusions for Radial Systems and Local Networks should be made consistent with the Exclusion for behind-the-meter generation. There is no technical reason to believe the power flowing from a behind-the-meter customer-owned generator will have less impact on the bulk system than an equivalent-sized generator owned by a utility operating a Radial System or LN.

Yes

LEC strongly supports the exclusion of Local Networks ("LNs") from the BES. The conversion of radial systems to local networks should be encouraged because networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. If the BES definition were to provide an exclusion for radials without providing a similar exclusion for LNs, however, it would discourage networking local distribution systems because of the significantly increased regulatory burdens faced by the local distribution utility if it elected to network its radial facilities. By placing radial systems and LNs on the same regulatory footing, the proposed definition will ensure that decisions about whether to network radial systems are made on the basis of costs and benefits to the retail customers served by those radials, and not on the basis of disparate regulatory treatment. Consumers would ultimately benefit. LEC also supports specific refinements made to the LN exclusion by the SDT in the current draft of the BES definition. In particular, LEC supports the clarification of the purposes of a LN. The current draft states that LNs connect at multiple points to "improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system." LEC supports this change in language because it reflects the fundamental purposes of a LN and emphasizes one of the key distinctions between LNs and bulk transmission facilities, namely, that LNs are designed primarily to serve local retail load while bulk transmission facilities are designed primarily to move bulk power from a bulk source (generally either the point of interconnection of a wholesale generator or a the point of interconnection with another bulk transmission system) to one or more wholesale purchasers. LEC believes further improvement of the

language could be achieved with additional modifications and clarifications. With respect to the core language of Exclusion 3, we believe the language making a “group of contiguous transmission Elements operated at or above 100kV” the starting point for identifying a LN would be improved by deleting the term “transmission” from this phrase. This is so because LNs are not used for transmission and the use of the term “transmission Elements” is therefore both confusing and unnecessary. There would be no room for argument about what the SDT intended by including the word “transmission” if the word is deleted and the Exclusion applies to any “group of Elements operated at 100kV or above” that meets the remaining requirement of the Exclusion. Further, any definitional value that is added by using the term “transmission Elements” is accomplished by using that term in the core definition, and there is no reason to carry the term through in the Exclusions. LEC also believes that subparagraphs (a) and (b) are redundant, because whatever protection is offered by the generation limit in subparagraph (a) is duplicated by the limit in subparagraph (b) requiring no flow out of the LN. We believe the SDT can eliminate subparagraph (a) of Exclusion 3 and simply rely on subparagraph (b) because if power only flows into the LN even if it interconnects more than 75 MVA of generation, the interconnected generation interconnected will have no significant interaction with the interconnected bulk transmission system. It will only interact with the LN. And, with the advent of distributed generation, it is easy to foresee a situation in which a large number of very small distributed generators are interconnected into a LN, so that the aggregate capacity of these generators exceeds 75 MVA. However, because the generators are small and dispersed and, under the criterion in subparagraph (b), would be wholly absorbed within the LN rather than transmitting power onto the interconnected grid, those generators would not have a material impact on the grid. We also suggest that subparagraph (b) of Exclusion 3 could be more clearly drafted. Subparagraph (b), as part of the requirement that power flow into a LN rather than out of it, includes this description: “The LN does not transfer energy originating outside the LN for delivery through the LN.” We understand this language is intended to distinguish a LN from a link in the transmission system – power on a transmission link passes through the transmission link to a load located elsewhere, while power in a LN enters the LN and is consumed by retail load within the LN. While we agree with the concept proposed by the SDT, we believe the language would be clearer if it read: “The LN does not transfer energy originating outside the LN for delivery through the LN to loads located outside the LN.” We believe the italicized language is necessary to distinguish between a transmission system, where power that originates outside a system is delivered through the system and passes through the system to a sink located somewhere outside the system, from a LN, in which power originating outside the LN passes through the LN and is delivered to retail load within the LN. To put it another way, the italicized language helps distinguish a transmission system from an LN, in which the LN “transfers energy originating outside the LN for delivery through the LN to loads located within the LN.” We also believe the language of subparagraph (a) of Exclusion 3 could be improved. Subparagraph (d) would make LNs part of the BES if they interconnect “non-retail generation greater than 75 MVA (gross nameplate rating).” For the reasons stated in our responses to Questions 3, 5 and 7, we urge the SDT to replace the reference to a hard 75 MVA threshold with the defined term “Qualifying Aggregate Generation Resources” or some equivalent. We are also uncertain what is meant by the use of the term “non-retail generation” in subparagraph (a). From context, we believe the SDT considers “non-retail generation” to be the equivalent of generation that is located behind the retail meter, usually but not always owned by the customer and used to serve the customer’s own load. We therefore suggest that the SDT replace the term “non-retail generation” with “generation located behind the retail customer’s meter.” Similarly, we are unsure what is meant by the phrase “the LN and its underlying Elements.” We believe the phrase “and its underlying Elements” could simply be deleted from the definition without loss of meaning. In the alternative, the SDT might consider using the phrase “the LN, including all Elements located on the distribution side of any Automatic Fault Interrupting Devices (or other points of demarcation) separating the LN from the bulk interstate transmission system.” We believe this phrase more accurately reflects the SDT’s intent, which appears to be that generation exceeding 75 MVA in aggregate capacity interconnected anywhere within the LN disqualifies that LN from being excluded from the BES under Exclusion 3. LEC also believes that both subparagraphs (a) and (b) of Exclusion 3 could be safely eliminated as long as subparagraph (c) is retained. Subparagraph (c) makes a LN part of the BES if it is classified as a Flow Gate or Transfer Path. Flow Gates and Transfer Paths are, by definition, the key facilities that allow reliable transmission of bulk electric power on the interconnected grid. If a LN has not been identified as either a Flow Gate or a Transfer Path, it is unlikely the LN is necessary for the reliable transmission of electricity on the interconnected bulk system. Apart from these specific improvements that we

believe could be achieved by modifying the language of Exclusion 3, we believe the SDT may need to re-examine certain assumptions that appear to underlie the current draft. Specifically, subparagraph (a) suggests that if BES generation is embedded within a LN, the LN itself must also be BES. But two NERC bodies have already addressed similar questions and concluded there is no technical basis for such concerns. NERC's Standards Drafting Team for Project 2010-07 and its predecessor, the "GO-TO Task Force" were formed to address how the dedicated interconnection facilities linking a BES generator to high-voltage transmission facilities should be treated under the NERC standards. The GO-TO Team concluded that by complying with a handful of reliability standards, primarily related to vegetation management, reliable operation of the bulk interconnected system could be protected without unduly burdening the owners of such interconnection systems. Therefore, there is no reason, according to the GO-TO Team, that dedicated high-voltage interconnection facilities must be treated as "Transmission" and classified as part of the BES in order to make reliability standards effective. See Final Report from the NERC Ad Hoc Group for Generator Requirements at the Transmission Interface (Nov. 16, 2009) (paper written by the GO-TO Task Force). Similarly, the Project 2010-07 Team observed that interconnection facilities "are most often not part of the integrated bulk power system, and as such should not be subject to the same level of standards applicable to Transmission Owners and Transmission Operators who own and operate transmission Facilities and Elements that are part of the integrated bulk power system." White Paper Proposal for Information Comment, NERC Project 2010-07: Generator Requirements at the Transmission Interface, at 3 (March 2011). Requiring Generation Owners and Operators to comply with the same standards as BES Transmission Owners and Operators "would do little, if anything, to improve the reliability of the Bulk Electric System," especially "when compared to the operation of the equipment that actually produces electricity – the generation equipment itself." Id. We believe that interconnection of BES generators within a LN is analogous and that, based on the findings of the Project 2010-07 and GO-TO Teams, automatically classifying a LN as "BES" simply because a large generator is embedded in the LN will result in substantial overregulation and unnecessary expense with little gain for bulk system reliability. If anything, generation interconnected through a LN is less likely to produce material impacts on the interconnected bulk transmission system than the equivalent generator interconnected through a single dedicated line because an LN is interconnected to the bulk system at several points, so that if one interconnection goes down, power can still flow from the BES generator to the bulk system on other interconnection points. Where a dedicated interconnection facility is involved, by contrast, if the interconnection line fails, the generator is unavailable to the interconnected bulk system. Similarly, we suggest that the SDT re-examine the assumptions underlying subparagraph (b), which seems to suggest that a local distribution system cannot be classified as a Local Network if power flows out of that system at any time, even if the amount is de minimis, the outward flow is only for a few hours, a year, or the outward flow occurs only in an extreme contingency. Accordingly, we suggest that the initial clause of subparagraph (b) be revised to read: "Except in unusual circumstances, power flows only into the LN." Finally, we note that the LN exclusion must not operate in any way as a substitution for the statutory prohibition on including "facilities used in the local distribution of electric energy" in the BES. Therefore, even with the LN exclusion, the SDT must retain this statutory language in the core definition of the BES, as discussed in our answer to Question One. If a certain piece of equipment is a "facility used in the local distribution of electric energy," then it is not part of the BES in the first instance, and so consideration of the LN Exclusion, or of any other Exclusion, any Inclusion, or any Exception, would be both unnecessary and uncalled for.

Yes

LEC supports the revised language because retail reactive devices are used to address local customer or retail voltage issues, rather than voltage issues on the interconnected bulk grid, and such local devices should therefore be excluded from the BES definition.

No

LEC extends its thanks to the SDT and to the many industry entities that have actively participating in the Standards Development Process. LEC supports the current draft and believes, with certain refinements discussed in our comments, that the definition will serve the industry and reliability regulators well for many years to come. In addition, as noted earlier, LEC is encouraged that the 20/75 MVA generation thresholds referred to in the NERC Statement of Compliance Registry Criteria, which have been relied upon by the SDT largely as a matter of necessity, will be reviewed and a technical assessment will be performed to identify the appropriate generation unit and plant size threshold to ensure a reliable North America. Finally, we understand that the Rules of Procedure Team

will continue to move forward with developing an Exceptions Process that will complement the BES Definition and ensure that, to the extent the BES Definition is over-inclusive, facilities that should not be classified as BES will be excluded from the BES. Because the Exceptions Process is integral to a workable BES Definition, we support the current process for moving forward with the Exceptions Process and the BES Definition on parallel paths. We note that LEC specifically supports the changes made by the SDT in the "Effective Date" provision of the BES Definition, which shortens the effective date of the new definition to the beginning of the first calendar quarter after regulatory approval (as opposed to the first calendar quarter twenty-four months after regulatory approval), with a 24-month transition period. LEC supports this conclusion because it will allow entities seeking deregistration under the terms of the new BES definition to obtain the benefits of the new definition without an unreasonable wait, while allowing any entities that may be newly-classified as BES owners or operators sufficient time to come into compliance with newly-applicable Reliability Standards. LEC also supports the 24-month transition period for the reasons laid out by the SDT.

Individual

Northern Lights Inc. (NLI)

Yes

The Northern Lights (NLI) believes the SDT continues to make substantial progress towards a clear and workable definition of the Bulk Electric System ("BES") that markedly improves both the existing definition and the SDT's previous proposal. NLI therefore supports the new definition, although our support is conditioned on: (1) a workable Exceptions process being developed in conjunction with the BES definition; and, (2) the SDT moving forward expeditiously on Phase II of the standards development process in accordance with the SAR recently put forward by the SDT, which would address a number of important technical issues that have been identified in the standards development process to date. NLI strongly supports the following elements of the revised BES definition: (1) Clarification of how lists of Inclusions and Exclusions applies: The revised core definition moves the phrase "Unless modified by the lists shown below" to the beginning of the definition. This change makes clear that the Inclusions and Exclusions apply to all Elements that would otherwise be included in or excluded from the core definition (i.e., "all Transmission Elements operated at 100kV or higher and Real Time and Reactive Power resources connected at 100kV or higher") and eliminates a latent ambiguity in the first draft of the definition, discussed further in our comments on the first draft. (2) The exclusion for "facilities used in the local distribution of electric energy." As the starting point for the BES definition, NLI supports the use of the phrase "all Transmission Elements" and the qualifying sentence: "This does not include facilities used in the local distribution of electric energy." This language helps ensure that FERC, NERC, and the Regional Entities ("REs") will act within the jurisdictional constraints Congress placed in Section 215 of the Federal Power Act ("FPA"). In Section 215(a)(1), Congress unequivocally excluded "facilities used in the local distribution of electric energy" from the keystone "bulk-power system" definition. 16 U.S.C. § 824o(a)(1). Including the same language in the definition helps ensure that entities involved in enforcement of reliability standards will act within their statutory limits. In addition, as a practical matter, inclusion of the language will help focus both the industry and responsible agencies on the high-voltage interstate transmission system, where the reliability problems Congress intended to regulate – "instability, uncontrolled separation, [and] cascading failures," 16 U.S.C. § 824o(a)(4) – will originate. At the same time, level-of-service issues arising in local distribution systems will be left to the authority of state and local regulatory agencies and governing bodies, just as Congress intended. 16 U.S.C. § 824o(i)(2) (reserving to state and local authorities enforcement of standards for adequacy of service). NLI thanks the SDT for the excellent work to include this sentence. For similar reasons, NLI believes the use of the phrase "Transmission Elements" as the starting point for the base definition is desirable because both "Transmission" and "Elements" are already defined in the NERC Glossary of Terms Used in NERC Reliability Standards, and the term "Transmission" makes clear that the BES includes only Elements used in Transmission and therefore excludes Elements used in local distribution of electric power. (3) Appropriate Generator Thresholds. In the standards development process, it has become apparent that the thresholds for classifying generators as BES in the current NERC Statement of Compliance Registry Criteria ("SCRC") (20 MVA for individual generators, 75 MVA for multiple generators aggregated at a single site), which predate the adoption of FPA Section 215, were never the product of a careful analysis to determine whether generators of that size are necessary for operation of the interconnected bulk transmission system. Ideally, such an

analysis would be conducted as part of the current standards development process. NLI recognizes that, given the deadlines imposed by FERC in Order No. 743, it will not be possible for the SDT to conduct such an analysis within the time available. Accordingly, NLI agrees with the approach taken by the SDT, which is to propose a Phase II of the standards development process that would address the generator threshold issue and several other technical issues that have arisen during the current process. As long as Phase II proceeds expeditiously, NLI is prepared to support the BES definition as proposed by the SDT. While NLI supports the overall approach adopted by the SDT and much of the specific language incorporated into the second draft of the BES definition, we believe the second draft would benefit from further clarification or modification in a number of respects, most of which are detailed in our subsequent answers. Further, we believe a workable Exclusion Process is essential for a BES Definition that will meet the legal requirements of FPA Section 215, especially for systems operating in the Western Interconnection. As detailed in our previous comments, NLI believes a 200kV threshold would be more appropriate for WECC than a 100kV threshold. In addition, a 200kV threshold for the West is backed by solid technical analysis conducted by the WECC Bulk Electric System Definition Task Force, and repeated claims that there is no technical analysis to support this view are therefore incorrect. That said, we raise the issue here to emphasize the importance of the Exclusions for Local Networks and Radial Systems and the Exceptions process. These Exclusions and the Exceptions are essential for a definition that works in the Western Interconnection because the core definition will be over-inclusive in our region. As long as those Exclusions and the Exceptions Process are retained in a form substantially equivalent to those produced by the SDT at this juncture, NLI will support the SDT's proposal.

Yes

We support the SDT's changes to the first Inclusion because it is more clear and simple than the initial approach. That being said, we suggest that an additional sentence of clarification would help avoid future controversy about the meaning of Inclusion 1. As we understand it, the BES intends to include transformers only if both the primary and secondary terminals operate at 100kV or above, which is why the definition uses the word "and" ("the primary and secondary terminals"). We support this approach since it would exclude transformers where the secondary terminals serve distribution loads, and which therefore function as distribution rather than transmission facilities. We believe the SDT's intent would be clarified by adding a sentence at the end of Inclusion 1 that reads: "Transformers with either primary or secondary terminals, or both, that operate at or below 100kV are not part of the BES." This language will help ensure that there is no controversy over whether the SDT's use of the word "and" in the phrase "the primary and secondary terminals" was intentional. We also support the SDT's proposal to develop detailed guidance concerning the point of demarcation between BES and non-BES elements in the Phase II SAR. In this regard, we note that, while Inclusion 1 at least implicitly suggests that the dividing line between BES and non-BES Elements should be at the transformer where transmission-level voltages are stepped down to distribution-level voltages, we believe further clarification of this point of demarcation between the BES and non-BES Elements is necessary. Many different configurations of transformers and other equipment that may lie at the juncture between the BES and non-BES systems. If the point of demarcation is designated at the transformer without further elaboration, many entities that own equipment on the high side of a transformer will be swept into the BES, and thereby exposed to inappropriately stringent regulations and undue costs. For example, distribution-only utilities commonly own the switches, bus, and transformer protection devices on the high side of transformers where they take delivery from their transmission provider. Ownership of these protective devices and high-voltage bus on the high side of the transformer should not cause these entities to be classified as BES owners. As the Phase II process moves forward, we commend to the SDT the extensive work performed on the point of demarcation question by the WECC BESDTF. We also support the incorporation of language (" . . . unless excluded under Exclusions E1 or E3") making it clear that transformers that are operated as an integral part of a Radial System or Local Network should not be considered BES facilities, regardless of their operating voltage. Further clarification might be achieved by using the phrase ". . . unless the transformer is operated as part of a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2."

Yes

NLI supports the changes made in Inclusion 2 and believes that the definition in its current form adds clarity. In particular, we support the SDT's decision to collapse Inclusions 2 and 3 from the previous draft definition into a single Inclusion that addresses the treatment of generation for purposes of the

BES definition. We also support the SDT's proposal for a Phase II of the BES Definition process that would examine the technical justification for these thresholds and that would establish new thresholds based on a careful technical analysis. It is our understanding that the generator threshold issue will be vetted through the complete standards development process. We agree with this approach because if the generator threshold is treated as merely an element of NERC's Rules of Procedure, it can be changed with considerably less process and industry input than the Standards Development Process. Compare NERC Rules of Procedure § 1400 (providing for changes to Rules of Procedure upon approval of the NERC board and FERC) with NERC Standards Process Manual (Sept. 3, 2010) (providing for, e.g., posting of SDT proposals for comment, successive balloting, and super-majority approval requirements). See also Order No. 743-A, 134 FERC ¶ 61,210 at P 4 (2011) ("Order No. 743 directed the ERO to revise the definition of 'bulk electric system' through the NERC Standards Development Process" (emph. added)). Addressing all aspects of Phase II through the Standards Development Process will improve the content of the definition by bringing to bear industry expertise on all aspects of the definition and will ensure that, once firm guidelines are established, they can be relied upon by both industry and regulators without threat that they will be changed with little notice and little process. NLI believes further clarification of the proposed language would be appropriate. The SDT proposes continued reliance upon the thresholds that are used in the NERC Statement of Compliance Registry Criteria for registration of Generation Owners and Generation Operators, which is currently 20 MVA for an individual generation unit and 75 MVA for multiple units on a single site. Conceptually, we are concerned about this approach because, as we understand it, the purpose of the Compliance Registry is to sweep in all generators that might be material to the reliable operation of the BES, and not to definitively determine whether a given generator is, in fact, material to the reliable operation of the BES. As the SCRC itself states, the SCRC is intended only to identify "candidates for registration." SCRC at p.3, § 1 (emph. added). Accordingly, we believe that the generator threshold determined in Phase II should be incorporated directly into the BES Definition rather than being incorporated by reference from the SCRC. We also believe that the specific language proposed by the SDT could be further clarified. The SDT proposes that generation be included in the BES if the "Generation resource(s)" has a "nameplate rating per the ERO Statement of Compliance Registry." We understand this language is intended to be a placeholder for the results of the technical analysis that would occur in Phase II but we believe simply stating that the threshold will be "per the ERO Statement of Compliance Registry" is ambiguous. Further, for the reasons noted above, we believe the threshold should be part of the BES Definition, and should not simply be a cross-reference to the SCRC (and, given the different purposes of the BES Definition and the SCRC, it is not clear that the same threshold should be used in both). We therefore propose that Inclusion 2 be rewritten to state: "Qualifying Individual Generation Resources or Qualifying Aggregate Resources connected at a voltage of 100kV or above." Two definitions would then be added to the note at the end of the definition to read as follows: For purposes of this BES Definition, Qualifying Individual Generation Resources means an individual generating unit that meets the materiality threshold to be included in this definition or, in the absence of such a materiality threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of such a resource as a Generation Owner under the ERO Statement of Compliance Registry Criteria. For purposes of this BES Definition, Qualifying Aggregate Generation Resources means any facility consisting of one or more generating units that are connected at a common bus that meets the materiality threshold to be included in this definition, or, in the absence of such a threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of multiple-unit generator as a Generation Owner under the ERO Statement of Compliance Registry Criteria. The "materiality threshold" is intended to refer to the generator threshold developed in Phase II. We suggest using definitions in this fashion for several reasons. First, we believe the language we suggest more clearly states the intention of the SDT, which we understand is to classify generation units as part of the BES if they are necessary for operation of the BES, but to exclude smaller generating units because they are not material to the operation of the interconnected transmission grid. Second, we believe use of the defined terms better reflects the intention of the SDT to reserve the specific question about generator thresholds to the technical analysis that will occur in Phase II without having to revise the BES Definition at the end of that process. That is, the definitions are designed to allow the SDT to include revised thresholds in the definition at the conclusion of the Phase II process based upon the technical analysis planned for Phase II, and the revised thresholds will be automatically incorporated into the BES Definition if the language we suggest is used. The thresholds used in the SCRC would only be a fall-back, to be used only until Phase II is completed. Third, the definitions can be

incorporated into other parts of the BES Definition, which will add consistency and clarity. As noted in our answers to several of the questions below, the specific 75 MVA threshold is retained in several of the Exclusions and Inclusions, and we believe the industry would be better served if the revised thresholds arrived at after technical analysis in Phase II are automatically incorporated into all relevant provisions of the BES Definition. There is no reason for the SDT to continue to rely on the 75 MVA threshold once the analysis planned for Phase II on the threshold issue is completed. Fourth, the phrase "or that meets the materiality threshold to be included in this definition" is intended to preserve the SDT's flexibility to make a determination that generators below a specific threshold are not "necessary to" maintain the reliability of the interconnected transmission system, and to incorporate that finding as part of the definition itself, even if a different threshold is used in the SCRC to identify potential candidates for registration. Accordingly, our proposed language makes clear that a specific threshold in the definition controls over any threshold that might be included in the SCRC. For the reasons stated above, we believe it is highly desirable to include any material threshold in the BES Definition itself rather than relegating the threshold to the SCRC, which is merely a procedural rule rather than a full-fledged Reliability Standard. Finally, we agree with the SDT's decision to examine the question of where the line between BES and non-BES Elements should be drawn more closely in Phase II under the rubric of "contiguous vs. non-contiguous BES," and commend the work of the Project 2010-07 Standards Drafting Team and the GO-TO Team as a good starting point for the SDT's analysis on this issue. We understand Inclusion 2 would classify generators exceeding specific thresholds as part of the BES, but would not necessarily require facilities interconnecting such generators to be part of the BES. As discussed more fully in our answer to Question 9, based on extensive technical analysis that has already been performed by the NERC Project 2010-07 Standards Drafting Team and its predecessor, the NERC "GO-TO Team," regulating as part of the BES a dedicated interconnection facility connecting a BES generator to the interconnected bulk transmission grid will result in an unnecessary regulatory burden that produces considerable expense for the owner of the interconnection facility with little or no improvement in bulk system reliability. We also believe the clauses at the end of Inclusion 2 are somewhat confusing and that greater clarity would be achieved by changing ". . . including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100kV or above" so that the Inclusion covers transformers with terminals "connected at a voltage of 100kV or above, including the generator terminal(s) on the high side of the step-up transformer(s) if operated at a voltage of 100kV or above."

Yes

NLI supports the removal of the Cranking Path language in I3. As noted in our response to Question 9, there is no reason to classify as BES the facilities interconnecting a BES generator to the bulk interstate system. A Cranking Path is simply a specific type of such an interconnection facility.

Yes

NLI supports the revised language generally, but believes additional changes would make the language clearer. Specifically, we believe Inclusion 4 should not incorporate a hard 75 MVA generation threshold (i.e., "resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)"). Instead, we urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," which we discuss in more detail in our response to Question 3. This language will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. More generally, we are not certain what is accomplished by Inclusion 4 that is not already accomplished by Inclusion 2, which also addresses whether generation should be defined as BES. The SDT's stated concern is with variable generation units such as wind and solar plants. It is not clear to us why this concern is not fully addressed in Inclusion 2, which addresses multiple generation units connected at a common bus, the configuration of most variable generation plants with multiple units. We are also concerned that the language, as proposed, could have unintended consequences and improperly classify local distribution systems as BES in certain circumstances. This is because multiple distributed generation units could render a local distribution system a "collector system" and the entire system the equivalent of an aggregated generation unit, causing the local distribution system to be improperly denied status as a Local Network. If many different distributed generation units are connected to a local distribution system, it is very unlikely that more than a few of those units would fail simultaneously, and it is therefore unlikely that multiple generation units would produce a measureable impact on the interconnected bulk transmission system, especially if the units individually do not otherwise exceed the materiality threshold to be

established by the SDT in Phase II. Further, we are concerned that, if small distributed generation units become the industry norm, Inclusion 4 could unintentionally sweep in local distribution systems, especially where local policies favor the growth of small solar or other renewable generation systems for public policy reasons. Finally, we suggest that the SDT add the phrase “. . . unless the dispersed power producing resources operate within a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2.” This language, which parallels the language included at the end of Inclusion I1, would make clear that dispersed small-scale generators scattered throughout a Radial System or Local Network serving retail load would not convert the Radial System or Local Network into a BES system, even if the aggregate capacity of those small generators exceeds the relevant threshold.

No

NLI has several concerns about the new language in Inclusion 5. First, because Reactive Power devices produce power, they are “power producing resources” and we therefore believe Inclusion 5 is duplicative of Inclusion 4, which addresses “power producing devices.” Second, there is no capacity threshold specified in Inclusion 5 for Reactive Power devices that would be considered part of the BES. This is inconsistent with the approach taken in the balance of the definition, where thresholds are specified for generators and other types of power producing devices. Third, NLI believes the appropriate threshold for inclusion or exclusion of Reactive Power devices from the BES should be subject to the same technical analysis that will cover generators in the Phase II process. Finally, NLI believes this issue should be addressed in Phase 2 since there is not technical justification or analysis done to determine the thresholds. NLI strongly believes that there should be technical justification for thresholds for this issue and all other issues.

Yes

NLI continues to strongly support the radial system exclusion, which is necessary as a legal matter, because, among other reasons, FERC in Orders No. 743 and 743-A has required that the existing radial exemption in the NERC Statement of Compliance Registry Criteria be maintained. As a practical matter, radial systems are used for service to retail loads, usually in remote or rural areas, and not for the transmission of bulk power. Hence, operation of the radials has little or nothing to do with the reliable operation of the interconnected bulk transmission network. We also support the inclusion of the note discussing normally open switches because this language provides needed clarity for a common radial system configuration. We also agree with the substantive thrust of this language, which is that a radial system should not be considered part of the BES if it is interconnected at a single point, even if there is an alternative point of delivery that is normally open. While we support the Exclusion for Radial Systems, we believe several clarifications and refinements are necessary. (1) The term “transmission Elements” in the initial paragraph should be changed to “Elements.” Radial systems are not transmission systems and including the word “transmission” in the Radial System exclusion is therefore unnecessary and confusing. (2) Subparagraph (b) of Exclusion 1 refers to “generation resources . . . with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)”. We urge the SDT to replace this language with the defined term “Qualifying Aggregate Generation Resources,” discussed in more detail in our response to Question 3. This language will preserve the SDT’s ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. (3) Subparagraph (b) also seems to assume that if a Radial System contains a generator exceeding the 75 MVA threshold, the Radial System itself must be included in the BES because it links the generator to the interconnected bulk transmission system. As discussed more fully in our response to Question 9, below, NERC’s Project 2010-17 Standards Drafting Team and GO-TO Task Force have both concluded that this assumption is unwarranted. (4) The “Note” as drafted by the SDT indicates that “a normally open switching device between radial systems” will not serve to disqualify the Radial from exclusion under Exclusion 1. As discussed above, NLI strongly supports the note conceptually. However, we believe this language should be included in a separate subparagraph (d), rather than a note, because treatment as a “note” suggests it is less important than other portions of the Exclusion. We also suggest the language be changed to read: (d) Normally-open switching devices between radial elements as depicted and identified on system one-line diagrams does not affect this exclusion. This will make clear that a radial with more than one normally-open switch connecting it to another radial is still a radial. From the perspective of the BES Definition, the key question is whether switches operating between Radials are normally open, not whether there is more than one normally-open switch.

Yes

NLI supports the revised language. The language provides clarity regarding the BES status of customer-owned cogeneration facilities. However, NLI urges the SDT to remove the reference to the 75 MVA threshold and replace it with the defined term "Qualifying Aggregate Generation Resources" or some equivalent language for the reasons stated in our responses to Questions 3, 5, and 7. In addition, we are concerned that Exclusion 2 will place local distribution utilities in a difficult position because, under Exclusion 1 or Exclusion 3 as drafted, they could lose their status as a Radial System or a Local Network through the actions of a customer constructing behind-the-meter generation. With respect to Radial Systems, the appearance of behind-the-meter generators could cause the Radial System to exceed the thresholds specified in subparagraphs (b) and (c) of Exclusion 1 through no fault of the Radial System owner. Similar, a Local Network could lose its status because behind-the-meter generation could be of sufficient size that power moves into the interconnected grid in certain hours or under certain contingencies, rather than moving purely onto the Local Network, as required in subparagraph (b) of Exclusion 3. The Exclusions for Radial Systems and Local Networks should be made consistent with the Exclusion for behind-the-meter generation. There is no technical reason to believe the power flowing from a behind-the-meter customer-owned generator will have less impact on the bulk system than an equivalent-sized generator owned by a utility operating a Radial System or LN.

Yes

NLI strongly supports the exclusion of Local Networks ("LNs") from the BES. The conversion of radial systems to local networks should be encouraged because networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. If the BES definition were to provide an exclusion for radials without providing a similar exclusion for LNs, however, it would discourage networking local distribution systems because of the significantly increased regulatory burdens faced by the local distribution utility if it elected to network its radial facilities. By placing radial systems and LNs on the same regulatory footing, the proposed definition will ensure that decisions about whether to network radial systems are made on the basis of costs and benefits to the retail customers served by those radials, and not on the basis of disparate regulatory treatment. Consumers would ultimately benefit. NLI also supports specific refinements made to the LN exclusion by the SDT in the current draft of the BES definition. In particular, NLI supports the clarification of the purposes of a LN. The current draft states that LNs connect at multiple points to "improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system." NLI supports this change in language because it reflects the fundamental purposes of a LN and emphasizes one of the key distinctions between LNs and bulk transmission facilities, namely, that LNs are designed primarily to serve local retail load while bulk transmission facilities are designed primarily to move bulk power from a bulk source (generally either the point of interconnection of a wholesale generator or a the point of interconnection with another bulk transmission system) to one or more wholesale purchasers. NLI believes further improvement of the language could be achieved with additional modifications and clarifications. With respect to the core language of Exclusion 3, we believe the language making a "group of contiguous transmission Elements operated at or above 100kV" the starting point for identifying a LN would be improved by deleting the term "transmission" from this phrase. This is so because LNs are not used for transmission and the use of the term "transmission Elements" is therefore both confusing and unnecessary. There would be no room for argument about what the SDT intended by including the word "transmission" if the word is deleted and the Exclusion applies to any "group of Elements operated at 100kV or above" that meets the remaining requirement of the Exclusion. Further, any definitional value that is added by using the term "transmission Elements" is accomplished by using that term in the core definition, and there is no reason to carry the term through in the Exclusions. NLI also believes that subparagraphs (a) and (b) are redundant, because whatever protection is offered by the generation limit in subparagraph (a) is duplicated by the limit in subparagraph (b) requiring no flow out of the LN. We believe the SDT can eliminate subparagraph (a) of Exclusion 3 and simply rely on subparagraph (b) because if power only flows into the LN even if it interconnects more than 75 MVA of generation, the interconnected generation interconnected will have no significant interaction with the interconnected bulk transmission system. It will only interact with the LN. And, with the advent of distributed generation, it is easy to foresee a situation in which a large number of very small distributed generators are interconnected into a LN, so that the aggregate capacity of these generators exceeds 75 MVA. However, because the generators are small and

dispersed and, under the criterion in subparagraph (b), would be wholly absorbed within the LN rather than transmitting power onto the interconnected grid, those generators would not have a material impact on the grid. We also suggest that subparagraph (b) of Exclusion 3 could be more clearly drafted. Subparagraph (b), as part of the requirement that power flow into a LN rather than out of it, includes this description: "The LN does not transfer energy originating outside the LN for delivery through the LN." We understand this language is intended to distinguish a LN from a link in the transmission system – power on a transmission link passes through the transmission link to a load located elsewhere, while power in a LN enters the LN and is consumed by retail load within the LN. While we agree with the concept proposed by the SDT, we believe the language would be clearer if it read: "The LN does not transfer energy originating outside the LN for delivery through the LN to loads located outside the LN." We believe the italicized language is necessary to distinguish between a transmission system, where power that originates outside a system is delivered through the system and passes through the system to a sink located somewhere outside the system, from a LN, in which power originating outside the LN passes through the LN and is delivered to retail load within the LN. To put it another way, the italicized language helps distinguish a transmission system from an LN, in which the LN "transfers energy originating outside the LN for delivery through the LN to loads located within the LN." We also believe the language of subparagraph (a) of Exclusion 3 could be improved. Subparagraph (d) would make LNs part of the BES if they interconnect "non-retail generation greater than 75 MVA (gross nameplate rating)." For the reasons stated in our responses to Questions 3, 5 and 7, we urge the SDT to replace the reference to a hard 75 MVA threshold with the defined term "Qualifying Aggregate Generation Resources" or some equivalent. We are also uncertain what is meant by the use of the term "non-retail generation" in subparagraph (a). From context, we believe the SDT considers "non-retail generation" to be the equivalent of generation that is located behind the retail meter, usually but not always owned by the customer and used to serve the customer's own load. We therefore suggest that the SDT replace the term "non-retail generation" with "generation located behind the retail customer's meter." Similarly, we are unsure what is meant by the phrase "the LN and its underlying Elements." We believe the phrase "and its underlying Elements" could simply be deleted from the definition without loss of meaning. In the alternative, the SDT might consider using the phrase "the LN, including all Elements located on the distribution side of any Automatic Fault Interrupting Devices (or other points of demarcation) separating the LN from the bulk interstate transmission system." We believe this phrase more accurately reflects the SDT's intent, which appears to be that generation exceeding 75 MVA in aggregate capacity interconnected anywhere within the LN disqualifies that LN from being excluded from the BES under Exclusion 3. NLI also believes that both subparagraphs (a) and (b) of Exclusion 3 could be safely eliminated as long as subparagraph (c) is retained. Subparagraph (c) makes a LN part of the BES if it is classified as a Flow Gate or Transfer Path. Flow Gates and Transfer Paths are, by definition, the key facilities that allow reliable transmission of bulk electric power on the interconnected grid. If a LN has not been identified as either a Flow Gate or a Transfer Path, it is unlikely the LN is necessary for the reliable transmission of electricity on the interconnected bulk system. Apart from these specific improvements that we believe could be achieved by modifying the language of Exclusion 3, we believe the SDT may need to re-examine certain assumptions that appear to underlie the current draft. Specifically, subparagraph (a) suggests that if BES generation is embedded within a LN, the LN itself must also be BES. But two NERC bodies have already addressed similar questions and concluded there is no technical basis for such concerns. NERC's Standards Drafting Team for Project 2010-07 and its predecessor, the "GO-TO Task Force" were formed to address how the dedicated interconnection facilities linking a BES generator to high-voltage transmission facilities should be treated under the NERC standards. The GO-TO Team concluded that by complying with a handful of reliability standards, primarily related to vegetation management, reliable operation of the bulk interconnected system could be protected without unduly burdening the owners of such interconnection systems. Therefore, there is no reason, according to the GO-TO Team, that dedicated high-voltage interconnection facilities must be treated as "Transmission" and classified as part of the BES in order to make reliability standards effective. See Final Report from the NERC Ad Hoc Group for Generator Requirements at the Transmission Interface (Nov. 16, 2009) (paper written by the GO-TO Task Force). Similarly, the Project 2010-07 Team observed that interconnection facilities "are most often not part of the integrated bulk power system, and as such should not be subject to the same level of standards applicable to Transmission Owners and Transmission Operators who own and operate transmission Facilities and Elements that are part of the integrated bulk power system." White Paper Proposal for Information Comment, NERC Project 2010-07: Generator Requirements at the Transmission Interface, at 3 (March 2011).

Requiring Generation Owners and Operators to comply with the same standards as BES Transmission Owners and Operators “would do little, if anything, to improve the reliability of the Bulk Electric System,” especially “when compared to the operation of the equipment that actually produces electricity – the generation equipment itself.” Id. We believe that interconnection of BES generators within a LN is analogous and that, based on the findings of the Project 2010-07 and GO-TO Teams, automatically classifying a LN as “BES” simply because a large generator is embedded in the LN will result in substantial overregulation and unnecessary expense with little gain for bulk system reliability. If anything, generation interconnected through a LN is less likely to produce material impacts on the interconnected bulk transmission system than the equivalent generator interconnected through a single dedicated line because an LN is interconnected to the bulk system at several points, so that if one interconnection goes down, power can still flow from the BES generator to the bulk system on other interconnection points. Where a dedicated interconnection facility is involved, by contrast, if the interconnection line fails, the generator is unavailable to the interconnected bulk system. Similarly, we suggest that the SDT re-examine the assumptions underlying subparagraph (b), which seems to suggest that a local distribution system cannot be classified as a Local Network if power flows out of that system at any time, even if the amount is de minimis, the outward flow is only for a few hours, a year, or the outward flow occurs only in an extreme contingency. Accordingly, we suggest that the initial clause of subparagraph (b) be revised to read: “Except in unusual circumstances, power flows only into the LN.” Finally, we note that the LN exclusion must not operate in any way as a substitution for the statutory prohibition on including “facilities used in the local distribution of electric energy” in the BES. Therefore, even with the LN exclusion, the SDT must retain this statutory language in the core definition of the BES, as discussed in our answer to Question One. If a certain piece of equipment is a “facility used in the local distribution of electric energy,” then it is not part of the BES in the first instance, and so consideration of the LN Exclusion, or of any other Exclusion, any Inclusion, or any Exception, would be both unnecessary and uncalled for.

Yes

NLI supports the revised language because retail reactive devices are used to address local customer or retail voltage issues, rather than voltage issues on the interconnected bulk grid, and such local devices should therefore be excluded from the BES definition.

No

NLI extends its thanks to the SDT and to the many industry entities that have actively participating in the Standards Development Process. NLI supports the current draft and believes, with certain refinements discussed in our comments, that the definition will serve the industry and reliability regulators well for many years to come. In addition, as noted earlier, NLI is encouraged that the 20/75 MVA generation thresholds referred to in the NERC Statement of Compliance Registry Criteria, which have been relied upon by the SDT largely as a matter of necessity, will be reviewed and a technical assessment will be performed to identify the appropriate generation unit and plant size threshold to ensure a reliable North America. Finally, we understand that the Rules of Procedure Team will continue to move forward with developing an Exceptions Process that will complement the BES Definition and ensure that, to the extent the BES Definition is over-inclusive, facilities that should not be classified as BES will be excluded from the BES. Because the Exceptions Process is integral to a workable BES Definition, we support the current process for moving forward with the Exceptions Process and the BES Definition on parallel paths. We note that NLI specifically supports the changes made by the SDT in the “Effective Date” provision of the BES Definition, which shortens the effective date of the new definition to the beginning of the first calendar quarter after regulatory approval (as opposed to the first calendar quarter twenty-four months after regulatory approval), with a 24-month transition period. NLI supports this conclusion because it will allow entities seeking deregistration under the terms of the new BES definition to obtain the benefits of the new definition without an unreasonable wait, while allowing any entities that may be newly-classified as BES owners or operators sufficient time to come into compliance with newly-applicable Reliability Standards. NLI also supports the 24-month transition period for the reasons laid out by the SDT.

NBPT

Yes

- When an exclusion and inclusion principles overlap which takes precedence? For example 15 may be excluded if in a LN (E3)
- The Local Network Exclusion criterion does not appear to consider voltage support and the effects of shifting of load or impacts due to a loss of load. The 75 MW generation threshold has no technical basis. The LN exclusion should allow for studies demonstrating no through flow benefit regardless if there is.
- 75 MW Generation has no technical justification.
- Black Start resources should not be included in all GO/GOP standards except for those standards specific to black start units.

Okanogan County Electric Cooperative (OCEC)

Yes

The Okanogan County Electric Cooperative (OCEC) believes the SDT continues to make substantial progress towards a clear and workable definition of the Bulk Electric System (“BES”) that markedly improves both the existing definition and the SDT’s previous proposal. OCEC therefore supports the new definition, although our support is conditioned on: (1) a workable Exceptions process being developed in conjunction with the BES definition; and, (2) the SDT moving forward expeditiously on Phase II of the standards development process in accordance with the SAR recently put forward by the SDT, which would address a number of important technical issues that have been identified in the standards development process to date. OCEC strongly supports the following elements of the revised BES definition: (1) Clarification of how lists of Inclusions and Exclusions applies: The revised core definition moves the phrase “Unless modified by the lists shown below” to the beginning of the definition. This change makes clear that the Inclusions and Exclusions apply to all Elements that would otherwise be included in or excluded from the core definition (i.e., “all Transmission Elements operated at 100kV or higher and Real Time and Reactive Power resources connected at 100kV or higher”) and eliminates a latent ambiguity in the first draft of the definition, discussed further in our comments on the first draft. (2) The exclusion for “facilities used in the local distribution of electric energy.” As the starting point for the BES definition, OCEC supports the use of the phrase “all Transmission Elements” and the qualifying sentence: “This does not include facilities used in the local distribution of electric energy.” This language helps ensure that FERC, NERC, and the Regional Entities (“REs”) will act within the jurisdictional constraints Congress placed in Section 215 of the Federal Power Act (“FPA”). In Section 215(a)(1), Congress unequivocally excluded “facilities used in the local distribution of electric energy” from the keystone “bulk-power system” definition. 16 U.S.C. § 824o(a)(1). Including the same language in the definition helps ensure that entities involved in enforcement of reliability standards will act within their statutory limits. In addition, as a practical matter, inclusion of the language will help focus both the industry and responsible agencies on the high-voltage interstate transmission system, where the reliability problems Congress intended to regulate – “instability, uncontrolled separation, [and] cascading failures,” 16 U.S.C. § 824o(a)(4) – will originate. At the same time, level-of-service issues arising in local distribution systems will be left to the authority of state and local regulatory agencies and governing bodies, just as Congress intended. 16 U.S.C. § 824o(i)(2) (reserving to state and local authorities enforcement of standards for adequacy of service). OCEC thanks the SDT for the excellent work to include this sentence. For similar reasons, OCEC believes the use of the phrase “Transmission Elements” as the starting point for the base definition is desirable because both “Transmission” and “Elements” are already defined in the NERC Glossary of Terms Used in NERC Reliability Standards, and the term “Transmission” makes clear that the BES includes only Elements used in Transmission and therefore excludes Elements used in local distribution of electric power. (3) Appropriate Generator Thresholds. In the standards

development process, it has become apparent that the thresholds for classifying generators as BES in the current NERC Statement of Compliance Registry Criteria ("SCRC") (20 MVA for individual generators, 75 MVA for multiple generators aggregated at a single site), which predate the adoption of FPA Section 215, were never the product of a careful analysis to determine whether generators of that size are necessary for operation of the interconnected bulk transmission system. Ideally, such an analysis would be conducted as part of the current standards development process. OCEC recognizes that, given the deadlines imposed by FERC in Order No. 743, it will not be possible for the SDT to conduct such an analysis within the time available. Accordingly, OCEC agrees with the approach taken by the SDT, which is to propose a Phase II of the standards development process that would address the generator threshold issue and several other technical issues that have arisen during the current process. As long as Phase II proceeds expeditiously, OCEC is prepared to support the BES definition as proposed by the SDT. While OCEC supports the overall approach adopted by the SDT and much of the specific language incorporated into the second draft of the BES definition, we believe the second draft would benefit from further clarification or modification in a number of respects, most of which are detailed in our subsequent answers. Further, we believe a workable Exclusion Process is essential for a BES Definition that will meet the legal requirements of FPA Section 215, especially for systems operating in the Western Interconnection. As detailed in our previous comments, OCEC believes a 200kV threshold would be more appropriate for WECC than a 100kV threshold. In addition, a 200kV threshold for the West is backed by solid technical analysis conducted by the WECC Bulk Electric System Definition Task Force, and repeated claims that there is no technical analysis to support this view are therefore incorrect. That said, we raise the issue here to emphasize the importance of the Exclusions for Local Networks and Radial Systems and the Exceptions process. These Exclusions and the Exceptions are essential for a definition that works in the Western Interconnection because the core definition will be over-inclusive in our region. As long as those Exclusions and the Exceptions Process are retained in a form substantially equivalent to those produced by the SDT at this juncture, OCEC will support the SDT's proposal.

Yes

We support the SDT's changes to the first Inclusion because it is more clear and simple than the initial approach. That being said, we suggest that an additional sentence of clarification would help avoid future controversy about the meaning of Inclusion 1. As we understand it, the BES intends to include transformers only if both the primary and secondary terminals operate at 100kV or above, which is why the definition uses the word "and" ("the primary and secondary terminals"). We support this approach since it would exclude transformers where the secondary terminals serve distribution loads, and which therefore function as distribution rather than transmission facilities. We believe the SDT's intent would be clarified by adding a sentence at the end of Inclusion 1 that reads: "Transformers with either primary or secondary terminals, or both, that operate at or below 100kV are not part of the BES." This language will help ensure that there is no controversy over whether the SDT's use of the word "and" in the phrase "the primary and secondary terminals" was intentional. We also support the SDT's proposal to develop detailed guidance concerning the point of demarcation between BES and non-BES elements in the Phase II SAR. In this regard, we note that, while Inclusion 1 at least implicitly suggests that the dividing line between BES and non-BES Elements should be at the transformer where transmission-level voltages are stepped down to distribution-level voltages, we believe further clarification of this point of demarcation between the BES and non-BES Elements is necessary. Many different configurations of transformers and other equipment that may lie at the juncture between the BES and non-BES systems. If the point of demarcation is designated at the transformer without further elaboration, many entities that own equipment on the high side of a transformer will be swept into the BES, and thereby exposed to inappropriately stringent regulations and undue costs. For example, distribution-only utilities commonly own the switches, bus, and transformer protection devices on the high side of transformers where they take delivery from their transmission provider. Ownership of these protective devices and high-voltage bus on the high side of the transformer should not cause these entities to be classified as BES owners. As the Phase II process moves forward, we commend to the SDT the extensive work performed on the point of demarcation question by the WECC BESDTF. We also support the incorporation of language (" . . . unless excluded under Exclusions E1 or E3") making it clear that transformers that are operated as an integral part of a Radial System or Local Network should not be considered BES facilities, regardless of their operating voltage. Further clarification might be achieved by using the phrase ". . . unless the transformer is operated as part of a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2."

Yes

OCEC supports the changes made in Inclusion 2 and believes that the definition in its current form adds clarity. In particular, we support the SDT's decision to collapse Inclusions 2 and 3 from the previous draft definition into a single Inclusion that addresses the treatment of generation for purposes of the BES definition. We also support the SDT's proposal for a Phase II of the BES Definition process that would examine the technical justification for these thresholds and that would establish new thresholds based on a careful technical analysis. It is our understanding that the generator threshold issue will be vetted through the complete standards development process. We agree with this approach because if the generator threshold is treated as merely an element of NERC's Rules of Procedure, it can be changed with considerably less process and industry input than the Standards Development Process. Compare NERC Rules of Procedure § 1400 (providing for changes to Rules of Procedure upon approval of the NERC board and FERC) with NERC Standards Process Manual (Sept. 3, 2010) (providing for, e.g., posting of SDT proposals for comment, successive balloting, and super-majority approval requirements). See also Order No. 743-A, 134 FERC ¶ 61,210 at P 4 (2011) ("Order No. 743 directed the ERO to revise the definition of 'bulk electric system' through the NERC Standards Development Process" (emph. added)). Addressing all aspects of Phase II through the Standards Development Process will improve the content of the definition by bringing to bear industry expertise on all aspects of the definition and will ensure that, once firm guidelines are established, they can be relied upon by both industry and regulators without threat that they will be changed with little notice and little process. OCEC believes further clarification of the proposed language would be appropriate. The SDT proposes continued reliance upon the thresholds that are used in the NERC Statement of Compliance Registry Criteria for registration of Generation Owners and Generation Operators, which is currently 20 MVA for an individual generation unit and 75 MVA for multiple units on a single site. Conceptually, we are concerned about this approach because, as we understand it, the purpose of the Compliance Registry is to sweep in all generators that might be material to the reliable operation of the BES, and not to definitively determine whether a given generator is, in fact, material to the reliable operation of the BES. As the SCRC itself states, the SCRC is intended only to identify "candidates for registration." SCRC at p.3, § 1 (emph. added). Accordingly, we believe that the generator threshold determined in Phase II should be incorporated directly into the BES Definition rather than being incorporated by reference from the SCRC. We also believe that the specific language proposed by the SDT could be further clarified. The SDT proposes that generation be included in the BES if the "Generation resource(s)" has a "nameplate rating per the ERO Statement of Compliance Registry." We understand this language is intended to be a placeholder for the results of the technical analysis that would occur in Phase II but we believe simply stating that the threshold will be "per the ERO Statement of Compliance Registry" is ambiguous. Further, for the reasons noted above, we believe the threshold should be part of the BES Definition, and should not simply be a cross-reference to the SCRC (and, given the different purposes of the BES Definition and the SCRC, it is not clear that the same threshold should be used in both). We therefore propose that Inclusion 2 be rewritten to state: "Qualifying Individual Generation Resources or Qualifying Aggregate Resources connected at a voltage of 100kV or above." Two definitions would then be added to the note at the end of the definition to read as follows: For purposes of this BES Definition, Qualifying Individual Generation Resources means an individual generating unit that meets the materiality threshold to be included in this definition or, in the absence of such a materiality threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of such a resource as a Generation Owner under the ERO Statement of Compliance Registry Criteria. For purposes of this BES Definition, Qualifying Aggregate Generation Resources means any facility consisting of one or more generating units that are connected at a common bus that meets the materiality threshold to be included in this definition, or, in the absence of such a threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of multiple-unit generator as a Generation Owner under the ERO Statement of Compliance Registry Criteria.. The "materiality threshold" is intended to refer to the generator threshold developed in Phase II. We suggest using definitions in this fashion for several reasons. First, we believe the language we suggest more clearly states the intention of the SDT, which we understand is to classify generation units as part of the BES if they are necessary for operation of the BES, but to exclude smaller generating units because they are not material to the operation of the interconnected transmission grid. Second, we believe use of the defined terms better reflects the intention of the SDT to reserve the specific question about generator thresholds to the technical analysis that will occur in Phase II without having to revise the BES Definition at the end of that process. That is, the definitions are designed to

allow the SDT to include revised thresholds in the definition at the conclusion of the Phase II process based upon the technical analysis planned for Phase II, and the revised thresholds will be automatically incorporated into the BES Definition if the language we suggest is used. The thresholds used in the SCRC would only be a fall-back, to be used only until Phase II is completed. Third, the definitions can be incorporated into other parts of the BES Definition, which will add consistency and clarity. As noted in our answers to several of the questions below, the specific 75 MVA threshold is retained in several of the Exclusions and Inclusions, and we believe the industry would be better served if the revised thresholds arrived at after technical analysis in Phase II are automatically incorporated into all relevant provisions of the BES Definition. There is no reason for the SDT to continue to rely on the 75 MVA threshold once the analysis planned for Phase II on the threshold issue is completed. Fourth, the phrase "or that meets the materiality threshold to be included in this definition" is intended to preserve the SDT's flexibility to make a determination that generators below a specific threshold are not "necessary to" maintain the reliability of the interconnected transmission system, and to incorporate that finding as part of the definition itself, even if a different threshold is used in the SCRC to identify potential candidates for registration. Accordingly, our proposed language makes clear that a specific threshold in the definition controls over any threshold that might be included in the SCRC. For the reasons stated above, we believe it is highly desirable to include any material threshold in the BES Definition itself rather than relegating the threshold to the SCRC, which is merely a procedural rule rather than a full-fledged Reliability Standard. Finally, we agree with the SDT's decision to examine the question of where the line between BES and non-BES Elements should be drawn more closely in Phase II under the rubric of "contiguous vs. non-contiguous BES," and commend the work of the Project 2010-07 Standards Drafting Team and the GO-TO Team as a good starting point for the SDT's analysis on this issue. We understand Inclusion 2 would classify generators exceeding specific thresholds as part of the BES, but would not necessarily require facilities interconnecting such generators to be part of the BES. As discussed more fully in our answer to Question 9, based on extensive technical analysis that has already been performed by the NERC Project 2010-07 Standards Drafting Team and its predecessor, the NERC "GO-TO Team," regulating as part of the BES a dedicated interconnection facility connecting a BES generator to the interconnected bulk transmission grid will result in an unnecessary regulatory burden that produces considerable expense for the owner of the interconnection facility with little or no improvement in bulk system reliability. We also believe the clauses at the end of Inclusion 2 are somewhat confusing and that greater clarity would be achieved by changing ". . . including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100kV or above" so that the Inclusion covers transformers with terminals "connected at a voltage of 100kV or above, including the generator terminal(s) on the high side of the step-up transformer(s) if operated at a voltage of 100kV or above."

Yes

OCEC supports the removal of the Cranking Path language in I3. As noted in our response to Question 9, there is no reason to classify as BES the facilities interconnecting a BES generator to the bulk interstate system. A Cranking Path is simply a specific type of such an interconnection facility.

Yes

OCEC supports the revised language generally, but believes additional changes would make the language clearer. Specifically, we believe Inclusion 4 should not incorporate a hard 75 MVA generation threshold (i.e., "resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)"). Instead, we urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," which we discuss in more detail in our response to Question 3. This language will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. More generally, we are not certain what is accomplished by Inclusion 4 that is not already accomplished by Inclusion 2, which also addresses whether generation should be defined as BES. The SDT's stated concern is with variable generation units such as wind and solar plants. It is not clear to us why this concern is not fully addressed in Inclusion 2, which addresses multiple generation units connected at a common bus, the configuration of most variable generation plants with multiple units. We are also concerned that the language, as proposed, could have unintended consequences and improperly classify local distribution systems as BES in certain circumstances. This is because multiple distributed generation units could render a local distribution system a "collector system" and the entire system the equivalent of an aggregated generation unit.

causing the local distribution system to be improperly denied status as a Local Network. If many different distributed generation units are connected to a local distribution system, it is very unlikely that more than a few of those units would fail simultaneously, and it is therefore unlikely that multiple generation units would produce a measureable impact on the interconnected bulk transmission system, especially if the units individually do not otherwise exceed the materiality threshold to be established by the SDT in Phase II. Further, we are concerned that, if small distributed generation units become the industry norm, Inclusion 4 could unintentionally sweep in local distribution systems, especially where local policies favor the growth of small solar or other renewable generation systems for public policy reasons. Finally, we suggest that the SDT add the phrase “. . . unless the dispersed power producing resources operate within a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2.” This language, which parallels the language included at the end of Inclusion I1, would make clear that dispersed small-scale generators scattered throughout a Radial System or Local Network serving retail load would not convert the Radial System or Local Network into a BES system, even if the aggregate capacity of those small generators exceeds the relevant threshold.

No

OCEC has several concerns about the new language in Inclusion 5. First, because Reactive Power devices produce power, they are “power producing resources” and we therefore believe Inclusion 5 is duplicative of Inclusion 4, which addresses “power producing devices.” Second, there is no capacity threshold specified in Inclusion 5 for Reactive Power devices that would be considered part of the BES. This is inconsistent with the approach taken in the balance of the definition, where thresholds are specified for generators and other types of power producing devices. Third, OCEC believes the appropriate threshold for inclusion or exclusion of Reactive Power devices from the BES should be subject to the same technical analysis that will cover generators in the Phase II process. Finally, OCEC believes this issue should be addressed in Phase 2 since there is not technical justification or analysis done to determine the thresholds. OCEC strongly believes that there should be technical justification for thresholds for this issue and all other issues.

Yes

OCEC continues to strongly support the radial system exclusion, which is necessary as a legal matter, because, among other reasons, FERC in Orders No. 743 and 743-A has required that the existing radial exemption in the NERC Statement of Compliance Registry Criteria be maintained. As a practical matter, radial systems are used for service to retail loads, usually in remote or rural areas, and not for the transmission of bulk power. Hence, operation of the radials has little or nothing to do with the reliable operation of the interconnected bulk transmission network. We also support the inclusion of the note discussing normally open switches because this language provides needed clarity for a common radial system configuration. We also agree with the substantive thrust of this language, which is that a radial system should not be considered part of the BES if it is interconnected at a single point, even if there is an alternative point of delivery that is normally open. While we support the Exclusion for Radial Systems, we believe several clarifications and refinements are necessary. (1) The term “transmission Elements” in the initial paragraph should be changed to “Elements.” Radial systems are not transmission systems and including the word “transmission” in the Radial System exclusion is therefore unnecessary and confusing. (2) Subparagraph (b) of Exclusion 1 refers to “generation resources . . . with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)”. We urge the SDT to replace this language with the defined term “Qualifying Aggregate Generation Resources,” discussed in more detail in our response to Question 3. This language will preserve the SDT’s ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. (3) Subparagraph (b) also seems to assume that if a Radial System contains a generator exceeding the 75 MVA threshold, the Radial System itself must be included in the BES because it links the generator to the interconnected bulk transmission system. As discussed more fully in our response to Question 9, below, NERC’s Project 2010-17 Standards Drafting Team and GO-TO Task Force have both concluded that this assumption is unwarranted. (4) The “Note” as drafted by the SDT indicates that “a normally open switching device between radial systems” will not serve to disqualify the Radial from exclusion under Exclusion 1. As discussed above, OCEC strongly supports the note conceptually. However, we believe this language should be included in a separate subparagraph (d), rather than a note, because treatment as a “note” suggests it is less important than other portions of the Exclusion. We also suggest the language be changed to read: (d) Normally-open switching devices between

radial elements as depicted and identified on system one-line diagrams does not affect this exclusion. This will make clear that a radial with more than one normally-open switch connecting it to another radial is still a radial. From the perspective of the BES Definition, the key question is whether switches operating between Radials are normally open, not whether there is more than one normally-open switch.

Yes

OCEC supports the revised language. The language provides clarity regarding the BES status of customer-owned cogeneration facilities. However, OCEC urges the SDT to remove the reference to the 75 MVA threshold and replace it with the defined term "Qualifying Aggregate Generation Resources" or some equivalent language for the reasons stated in our responses to Questions 3, 5, and 7. In addition, we are concerned that Exclusion 2 will place local distribution utilities in a difficult position because, under Exclusion 1 or Exclusion 3 as drafted, they could lose their status as a Radial System or a Local Network through the actions of a customer constructing behind-the-meter generation. With respect to Radial Systems, the appearance of behind-the-meter generators could cause the Radial System to exceed the thresholds specified in subparagraphs (b) and (c) of Exclusion 1 through no fault of the Radial System owner. Similar, a Local Network could lose its status because behind-the-meter generation could be of sufficient size that power moves into the interconnected grid in certain hours or under certain contingencies, rather than moving purely onto the Local Network, as required in subparagraph (b) of Exclusion 3. The Exclusions for Radial Systems and Local Networks should be made consistent with the Exclusion for behind-the-meter generation. There is no technical reason to believe the power flowing from a behind-the-meter customer-owned generator will have less impact on the bulk system than an equivalent-sized generator owned by a utility operating a Radial System or LN.

Yes

OCEC strongly supports the exclusion of Local Networks ("LNs") from the BES. The conversion of radial systems to local networks should be encouraged because networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. If the BES definition were to provide an exclusion for radials without providing a similar exclusion for LNs, however, it would discourage networking local distribution systems because of the significantly increased regulatory burdens faced by the local distribution utility if it elected to network its radial facilities. By placing radial systems and LNs on the same regulatory footing, the proposed definition will ensure that decisions about whether to network radial systems are made on the basis of costs and benefits to the retail customers served by those radials, and not on the basis of disparate regulatory treatment. Consumers would ultimately benefit. OCEC also supports specific refinements made to the LN exclusion by the SDT in the current draft of the BES definition. In particular, OCEC supports the clarification of the purposes of a LN. The current draft states that LNs connect at multiple points to "improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system." OCEC supports this change in language because it reflects the fundamental purposes of a LN and emphasizes one of the key distinctions between LNs and bulk transmission facilities, namely, that LNs are designed primarily to serve local retail load while bulk transmission facilities are designed primarily to move bulk power from a bulk source (generally either the point of interconnection of a wholesale generator or a the point of interconnection with another bulk transmission system) to one or more wholesale purchasers. OCEC believes further improvement of the language could be achieved with additional modifications and clarifications. With respect to the core language of Exclusion 3, we believe the language making a "group of contiguous transmission Elements operated at or above 100kV" the starting point for identifying a LN would be improved by deleting the term "transmission" from this phrase. This is so because LNs are not used for transmission and the use of the term "transmission Elements" is therefore both confusing and unnecessary. There would be no room for argument about what the SDT intended by including the word "transmission" if the word is deleted and the Exclusion applies to any "group of Elements operated at 100kV or above" that meets the remaining requirement of the Exclusion. Further, any definitional value that is added by using the term "transmission Elements" is accomplished by using that term in the core definition, and there is no reason to carry the term through in the Exclusions. OCEC also believes that subparagraphs (a) and (b) are redundant, because whatever protection is offered by the generation limit in subparagraph (a) is duplicated by the limit in subparagraph (b) requiring no flow out of the LN. We believe the SDT can eliminate subparagraph (a) of Exclusion 3 and simply rely on subparagraph (b) because if power only flows into the LN even if it interconnects

more than 75 MVA of generation, the interconnected generation interconnected will have no significant interaction with the interconnected bulk transmission system. It will only interact with the LN. And, with the advent of distributed generation, it is easy to foresee a situation in which a large number of very small distributed generators are interconnected into a LN, so that the aggregate capacity of these generators exceeds 75 MVA. However, because the generators are small and dispersed and, under the criterion in subparagraph (b), would be wholly absorbed within the LN rather than transmitting power onto the interconnected grid, those generators would not have a material impact on the grid. We also suggest that subparagraph (b) of Exclusion 3 could be more clearly drafted. Subparagraph (b), as part of the requirement that power flow into a LN rather than out of it, includes this description: "The LN does not transfer energy originating outside the LN for delivery through the LN." We understand this language is intended to distinguish a LN from a link in the transmission system – power on a transmission link passes through the transmission link to a load located elsewhere, while power in a LN enters the LN and is consumed by retail load within the LN. While we agree with the concept proposed by the SDT, we believe the language would be clearer if it read: "The LN does not transfer energy originating outside the LN for delivery through the LN to loads located outside the LN." We believe the italicized language is necessary to distinguish between a transmission system, where power that originates outside a system is delivered through the system and passes through the system to a sink located somewhere outside the system, from a LN, in which power originating outside the LN passes through the LN and is delivered to retail load within the LN. To put it another way, the italicized language helps distinguish a transmission system from an LN, in which the LN "transfers energy originating outside the LN for delivery through the LN to loads located within the LN." We also believe the language of subparagraph (a) of Exclusion 3 could be improved. Subparagraph (d) would make LNs part of the BES if they interconnect "non-retail generation greater than 75 MVA (gross nameplate rating)." For the reasons stated in our responses to Questions 3, 5 and 7, we urge the SDT to replace the reference to a hard 75 MVA threshold with the defined term "Qualifying Aggregate Generation Resources" or some equivalent. We are also uncertain what is meant by the use of the term "non-retail generation" in subparagraph (a). From context, we believe the SDT considers "non-retail generation" to be the equivalent of generation that is located behind the retail meter, usually but not always owned by the customer and used to serve the customer's own load. We therefore suggest that the SDT replace the term "non-retail generation" with "generation located behind the retail customer's meter." Similarly, we are unsure what is meant by the phrase "the LN and its underlying Elements." We believe the phrase "and its underlying Elements" could simply be deleted from the definition without loss of meaning. In the alternative, the SDT might consider using the phrase "the LN, including all Elements located on the distribution side of any Automatic Fault Interrupting Devices (or other points of demarcation) separating the LN from the bulk interstate transmission system." We believe this phrase more accurately reflects the SDT's intent, which appears to be that generation exceeding 75 MVA in aggregate capacity interconnected anywhere within the LN disqualifies that LN from being excluded from the BES under Exclusion 3. OCEC also believes that both subparagraphs (a) and (b) of Exclusion 3 could be safely eliminated as long as subparagraph (c) is retained. Subparagraph (c) makes a LN part of the BES if it is classified as a Flow Gate or Transfer Path. Flow Gates and Transfer Paths are, by definition, the key facilities that allow reliable transmission of bulk electric power on the interconnected grid. If a LN has not been identified as either a Flow Gate or a Transfer Path, it is unlikely the LN is necessary for the reliable transmission of electricity on the interconnected bulk system. Apart from these specific improvements that we believe could be achieved by modifying the language of Exclusion 3, we believe the SDT may need to re-examine certain assumptions that appear to underlie the current draft. Specifically, subparagraph (a) suggests that if BES generation is embedded within a LN, the LN itself must also be BES. But two NERC bodies have already addressed similar questions and concluded there is no technical basis for such concerns. NERC's Standards Drafting Team for Project 2010-07 and its predecessor, the "GO-TO Task Force" were formed to address how the dedicated interconnection facilities linking a BES generator to high-voltage transmission facilities should be treated under the NERC standards. The GO-TO Team concluded that by complying with a handful of reliability standards, primarily related to vegetation management, reliable operation of the bulk interconnected system could be protected without unduly burdening the owners of such interconnection systems. Therefore, there is no reason, according to the GO-TO Team, that dedicated high-voltage interconnection facilities must be treated as "Transmission" and classified as part of the BES in order to make reliability standards effective. See Final Report from the NERC Ad Hoc Group for Generator Requirements at the Transmission Interface (Nov. 16, 2009) (paper written by the GO-TO Task

Force). Similarly, the Project 2010-07 Team observed that interconnection facilities “are most often not part of the integrated bulk power system, and as such should not be subject to the same level of standards applicable to Transmission Owners and Transmission Operators who own and operate transmission Facilities and Elements that are part of the integrated bulk power system.” White Paper Proposal for Information Comment, NERC Project 2010-07: Generator Requirements at the Transmission Interface, at 3 (March 2011). Requiring Generation Owners and Operators to comply with the same standards as BES Transmission Owners and Operators “would do little, if anything, to improve the reliability of the Bulk Electric System,” especially “when compared to the operation of the equipment that actually produces electricity – the generation equipment itself.” Id. We believe that interconnection of BES generators within a LN is analogous and that, based on the findings of the Project 2010-07 and GO-TO Teams, automatically classifying a LN as “BES” simply because a large generator is embedded in the LN will result in substantial overregulation and unnecessary expense with little gain for bulk system reliability. If anything, generation interconnected through a LN is less likely to produce material impacts on the interconnected bulk transmission system than the equivalent generator interconnected through a single dedicated line because an LN is interconnected to the bulk system at several points, so that if one interconnection goes down, power can still flow from the BES generator to the bulk system on other interconnection points. Where a dedicated interconnection facility is involved, by contrast, if the interconnection line fails, the generator is unavailable to the interconnected bulk system. Similarly, we suggest that the SDT re-examine the assumptions underlying subparagraph (b), which seems to suggest that a local distribution system cannot be classified as a Local Network if power flows out of that system at any time, even if the amount is de minimis, the outward flow is only for a few hours, a year, or the outward flow occurs only in an extreme contingency. Accordingly, we suggest that the initial clause of subparagraph (b) be revised to read: “Except in unusual circumstances, power flows only into the LN.” Finally, we note that the LN exclusion must not operate in any way as a substitution for the statutory prohibition on including “facilities used in the local distribution of electric energy” in the BES. Therefore, even with the LN exclusion, the SDT must retain this statutory language in the core definition of the BES, as discussed in our answer to Question One. If a certain piece of equipment is a “facility used in the local distribution of electric energy,” then it is not part of the BES in the first instance, and so consideration of the LN Exclusion, or of any other Exclusion, any Inclusion, or any Exception, would be both unnecessary and uncalled for.

Yes

OCEC supports the revised language because retail reactive devices are used to address local customer or retail voltage issues, rather than voltage issues on the interconnected bulk grid, and such local devices should therefore be excluded from the BES definition.

No

OCEC extends its thanks to the SDT and to the many industry entities that have actively participating in the Standards Development Process. OCEC supports the current draft and believes, with certain refinements discussed in our comments, that the definition will serve the industry and reliability regulators well for many years to come. In addition, as noted earlier, OCEC is encouraged that the 20/75 MVA generation thresholds referred to in the NERC Statement of Compliance Registry Criteria, which have been relied upon by the SDT largely as a matter of necessity, will be reviewed and a technical assessment will be performed to identify the appropriate generation unit and plant size threshold to ensure a reliable North America. Finally, we understand that the Rules of Procedure Team will continue to move forward with developing an Exceptions Process that will complement the BES Definition and ensure that, to the extent the BES Definition is over-inclusive, facilities that should not be classified as BES will be excluded from the BES. Because the Exceptions Process is integral to a workable BES Definition, we support the current process for moving forward with the Exceptions Process and the BES Definition on parallel paths. We note that OCEC specifically supports the changes made by the SDT in the “Effective Date” provision of the BES Definition, which shortens the effective date of the new definition to the beginning of the first calendar quarter after regulatory approval (as opposed to the first calendar quarter twenty-four months after regulatory approval), with a 24-month transition period. OCEC supports this conclusion because it will allow entities seeking deregistration under the terms of the new BES definition to obtain the benefits of the new definition without an unreasonable wait, while allowing any entities that may be newly-classified as BES owners or operators sufficient time to come into compliance with newly-applicable Reliability Standards. OCEC also supports the 24-month transition period for the reasons laid out by the SDT.

Texas Reliability Entity
No
We feel that the Cranking Path should be included in the BES definition. Inclusion of the Cranking Path is vital to a functional, sustainable and reliable system restoration (and restoration plan) regardless of where the Cranking Path is located. CIP-002-4 Attachment 1 recognizes the critical nature of the Cranking Path.
No
There should be language that includes UFLS, UVLS, or load fully removable for Reserves even in a local network to avoid a lapse in reliability in operation of the BES. Even if it is to be included in any Phase 2 work, it should be mentioned here to avoid gaps.
Yes
(1) It is unclear exactly what is intended by "non-retail generation" in Exclusion E1(c). We suggest that the term be explained or defined in the BES definition or in a collateral document. This term does not have a commonly understood unambiguous meaning in our Region. (2) Phase 2 has to be completed or explicitly defined/scoped to fully capture all of the components necessary for reliable operation of the BES.
Individual
Diane Barney
New York State Dept of Public Service
No
The core definition is still deficient due to a lack of technical support for basing the BES definition on 100 kV and for lack of any cost/benefit analysis.
No
• I1 lacks specificity that can lead to confusion and required clarifications. Suggested wording change: All transformers (including auto-transformers, voltage regulators, and phase angle regulators and all windings) with primary and secondary terminals operated at or above 100 kV, and generator step-up (GSU) transformers with one terminal operated at or above 100 kV, unless excluded by E1 or E3.
No
In I2, there is a reference to the Statement of Compliance Registry Criteria. However, the Statement references the BES definition. This circular logic results in a fatally flawed definition. The statement reference should be replaced with the actual intended words.
No
I4 reference to a "common point" lacks clarity that can lead to confusion and required clarifications. Suggested wording change: "... connected at a common point through a dedicated step-up transformer with a high-side voltage of 100 kV or above."
No
I5 – which has been newly added and significantly expands the BES definition – should be dropped due to lack of technical justification.

Yes
<ul style="list-style-type: none"> <li>• Per NERC's obligations under the Energy Power Act of 2005 to provide FERC technical advice, no technical justification has been provided for basing the BES definition on the 100 kV and MVA thresholds.</li> <li>• No cost analysis on either the reliability benefits of the overall definition or on the implementation plan has been performed to determine whether the likely high cost of the definition to ratepayers is justified.</li> <li>• The definition of the BES should be the driver for the application of all other NERC reliability standards and criteria. The definition uses the Statement of Compliance Registry Criteria as a driver of the definition when the reverse should be taking place; contents of the Statement should be driven by the BES definition.</li> </ul>

Pacific Northwest Generating Cooperative (PNGC)
Yes
<p>The Pacific Northwest Generating Cooperative (PNGC) believes the SDT continues to make substantial progress towards a clear and workable definition of the Bulk Electric System ("BES") that markedly improves both the existing definition and the SDT's previous proposal. PNGC therefore supports the new definition, although our support is conditioned on: (1) a workable Exceptions process being developed in conjunction with the BES definition; and, (2) the SDT moving forward expeditiously on Phase II of the standards development process in accordance with the SAR recently put forward by the SDT, which would address a number of important technical issues that have been identified in the standards development process to date. PNGC strongly supports the following elements of the revised BES definition: (1) Clarification of how lists of Inclusions and Exclusions applies: The revised core definition moves the phrase "Unless modified by the lists shown below" to the beginning of the definition. This change makes clear that the Inclusions and Exclusions apply to all Elements that would otherwise be included in or excluded from the core definition (i.e., "all Transmission Elements operated at 100kV or higher and Real Time and Reactive Power resources connected at 100kV or higher") and eliminates a latent ambiguity in the first draft of the definition, discussed further in our comments on the first draft. (2) The exclusion for "facilities used in the local distribution of electric energy." As the starting point for the BES definition, PNGC supports the use of the phrase "all Transmission Elements" and the qualifying sentence: "This does not include facilities used in the local distribution of electric energy." This language helps ensure that FERC, NERC, and the Regional Entities ("REs") will act within the jurisdictional constraints Congress placed in Section 215 of the Federal Power Act ("FPA"). In Section 215(a)(1), Congress unequivocally excluded "facilities used in the local distribution of electric energy" from the keystone "bulk-power system" definition. 16 U.S.C. § 824o(a)(1). Including the same language in the definition helps ensure that entities involved in enforcement of reliability standards will act within their statutory limits. In addition, as a practical matter, inclusion of the language will help focus both the industry and responsible agencies on the high-voltage interstate transmission system, where the reliability problems Congress intended to regulate – "instability, uncontrolled separation, [and] cascading failures," 16 U.S.C. § 824o(a)(4) – will originate. At the same time, level-of-service issues arising in local distribution systems will be left to the authority of state and local regulatory agencies and governing bodies, just as Congress intended. 16 U.S.C. § 824o(i)(2) (reserving to state and local authorities enforcement of standards for adequacy of service). PNGC thanks the SDT for the excellent work to include this sentence. For similar reasons, PNGC believes the use of the phrase "Transmission Elements" as the starting point for the base definition is desirable because both "Transmission" and "Elements" are already defined in the NERC Glossary of Terms Used in NERC Reliability Standards, and the term "Transmission" makes clear that the BES includes only Elements used in Transmission and therefore excludes Elements used in local distribution of electric power. (3) Appropriate Generator Thresholds. In the standards development process, it has become apparent that the thresholds for classifying generators as BES in the current NERC Statement of Compliance Registry Criteria ("SCRC") (20 MVA for individual generators, 75 MVA for multiple generators aggregated at a single site), which predate the adoption of FPA Section 215, were never the product of a careful analysis to determine whether generators of that size are necessary for operation of the interconnected bulk transmission system. Ideally, such an analysis would be conducted as part of the current standards development process. PNGC recognizes</p>

that, given the deadlines imposed by FERC in Order No. 743, it will not be possible for the SDT to conduct such an analysis within the time available. Accordingly, PNGC agrees with the approach taken by the SDT, which is to propose a Phase II of the standards development process that would address the generator threshold issue and several other technical issues that have arisen during the current process. As long as Phase II proceeds expeditiously, PNGC is prepared to support the BES definition as proposed by the SDT. While PNGC supports the overall approach adopted by the SDT and much of the specific language incorporated into the second draft of the BES definition, we believe the second draft would benefit from further clarification or modification in a number of respects, most of which are detailed in our subsequent answers. Further, we believe a workable Exclusion Process is essential for a BES Definition that will meet the legal requirements of FPA Section 215, especially for systems operating in the Western Interconnection. As detailed in our previous comments, PNGC believes a 200kV threshold would be more appropriate for WECC than a 100kV threshold. In addition, a 200kV threshold for the West is backed by solid technical analysis conducted by the WECC Bulk Electric System Definition Task Force, and repeated claims that there is no technical analysis to support this view are therefore incorrect. That said, we raise the issue here to emphasize the importance of the Exclusions for Local Networks and Radial Systems and the Exceptions process. These Exclusions and the Exceptions are essential for a definition that works in the Western Interconnection because the core definition will be over-inclusive in our region. As long as those Exclusions and the Exceptions Process are retained in a form substantially equivalent to those produced by the SDT at this juncture, PNGC will support the SDT's proposal.

Yes

We support the SDT's changes to the first Inclusion because it is more clear and simple than the initial approach. That being said, we suggest that an additional sentence of clarification would help avoid future controversy about the meaning of Inclusion 1. As we understand it, the BES intends to include transformers only if both the primary and secondary terminals operate at 100kV or above, which is why the definition uses the word "and" ("the primary and secondary terminals"). We support this approach since it would exclude transformers where the secondary terminals serve distribution loads, and which therefore function as distribution rather than transmission facilities. We believe the SDT's intent would be clarified by adding a sentence at the end of Inclusion 1 that reads: "Transformers with either primary or secondary terminals, or both, that operate at or below 100kV are not part of the BES." This language will help ensure that there is no controversy over whether the SDT's use of the word "and" in the phrase "the primary and secondary terminals" was intentional. We also support the SDT's proposal to develop detailed guidance concerning the point of demarcation between BES and non-BES elements in the Phase II SAR. In this regard, we note that, while Inclusion 1 at least implicitly suggests that the dividing line between BES and non-BES Elements should be at the transformer where transmission-level voltages are stepped down to distribution-level voltages, we believe further clarification of this point of demarcation between the BES and non-BES Elements is necessary. Many different configurations of transformers and other equipment that may lie at the juncture between the BES and non-BES systems. If the point of demarcation is designated at the transformer without further elaboration, many entities that own equipment on the high side of a transformer will be swept into the BES, and thereby exposed to inappropriately stringent regulations and undue costs. For example, distribution-only utilities commonly own the switches, bus, and transformer protection devices on the high side of transformers where they take delivery from their transmission provider. Ownership of these protective devices and high-voltage bus on the high side of the transformer should not cause these entities to be classified as BES owners. As the Phase II process moves forward, we commend to the SDT the extensive work performed on the point of demarcation question by the WECC BESDTF. We also support the incorporation of language (" . . . unless excluded under Exclusions E1 or E3") making it clear that transformers that are operated as an integral part of a Radial System or Local Network should not be considered BES facilities, regardless of their operating voltage. Further clarification might be achieved by using the phrase ". . . unless the transformer is operated as part of a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2."

Yes

PNGC supports the changes made in Inclusion 2 and believes that the definition in its current form adds clarity. In particular, we support the SDT's decision to collapse Inclusions 2 and 3 from the previous draft definition into a single Inclusion that addresses the treatment of generation for purposes of the BES definition. We also support the SDT's proposal for a Phase II of the BES

Definition process that would examine the technical justification for these thresholds and that would establish new thresholds based on a careful technical analysis. It is our understanding that the generator threshold issue will be vetted through the complete standards development process. We agree with this approach because if the generator threshold is treated as merely an element of NERC's Rules of Procedure, it can be changed with considerably less process and industry input than the Standards Development Process. Compare NERC Rules of Procedure § 1400 (providing for changes to Rules of Procedure upon approval of the NERC board and FERC) with NERC Standards Process Manual (Sept. 3, 2010) (providing for, e.g., posting of SDT proposals for comment, successive balloting, and super-majority approval requirements). See also Order No. 743-A, 134 FERC ¶ 61,210 at P 4 (2011) ("Order No. 743 directed the ERO to revise the definition of 'bulk electric system' through the NERC Standards Development Process" (emph. added)). Addressing all aspects of Phase II through the Standards Development Process will improve the content of the definition by bringing to bear industry expertise on all aspects of the definition and will ensure that, once firm guidelines are established, they can be relied upon by both industry and regulators without threat that they will be changed with little notice and little process. PNGC believes further clarification of the proposed language would be appropriate. The SDT proposes continued reliance upon the thresholds that are used in the NERC Statement of Compliance Registry Criteria for registration of Generation Owners and Generation Operators, which is currently 20 MVA for an individual generation unit and 75 MVA for multiple units on a single site. Conceptually, we are concerned about this approach because, as we understand it, the purpose of the Compliance Registry is to sweep in all generators that might be material to the reliable operation of the BES, and not to definitively determine whether a given generator is, in fact, material to the reliable operation of the BES. As the SCRC itself states, the SCRC is intended only to identify "candidates for registration." SCRC at p.3, § 1 (emph. added). Accordingly, we believe that the generator threshold determined in Phase II should be incorporated directly into the BES Definition rather than being incorporated by reference from the SCRC. We also believe that the specific language proposed by the SDT could be further clarified. The SDT proposes that generation be included in the BES if the "Generation resource(s)" has a "nameplate rating per the ERO Statement of Compliance Registry." We understand this language is intended to be a placeholder for the results of the technical analysis that would occur in Phase II but we believe simply stating that the threshold will be "per the ERO Statement of Compliance Registry" is ambiguous. Further, for the reasons noted above, we believe the threshold should be part of the BES Definition, and should not simply be a cross-reference to the SCRC (and, given the different purposes of the BES Definition and the SCRC, it is not clear that the same threshold should be used in both). We therefore propose that Inclusion 2 be rewritten to state: "Qualifying Individual Generation Resources or Qualifying Aggregate Resources connected at a voltage of 100kV or above." Two definitions would then be added to the note at the end of the definition to read as follows: For purposes of this BES Definition, Qualifying Individual Generation Resources means an individual generating unit that meets the materiality threshold to be included in this definition or, in the absence of such a materiality threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of such a resource as a Generation Owner under the ERO Statement of Compliance Registry Criteria. For purposes of this BES Definition, Qualifying Aggregate Generation Resources means any facility consisting of one or more generating units that are connected at a common bus that meets the materiality threshold to be included in this definition, or, in the absence of such a threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of multiple-unit generator as a Generation Owner under the ERO Statement of Compliance Registry Criteria.. The "materiality threshold" is intended to refer to the generator threshold developed in Phase II. We suggest using definitions in this fashion for several reasons. First, we believe the language we suggest more clearly states the intention of the SDT, which we understand is to classify generation units as part of the BES if they are necessary for operation of the BES, but to exclude smaller generating units because they are not material to the operation of the interconnected transmission grid. Second, we believe use of the defined terms better reflects the intention of the SDT to reserve the specific question about generator thresholds to the technical analysis that will occur in Phase II without having to revise the BES Definition at the end of that process. That is, the definitions are designed to allow the SDT to include revised thresholds in the definition at the conclusion of the Phase II process based upon the technical analysis planned for Phase II, and the revised thresholds will be automatically incorporated into the BES Definition if the language we suggest is used. The thresholds used in the SCRC would only be a fall-back, to be used only until Phase II is completed. Third, the definitions can be incorporated into other parts of the BES Definition, which will add consistency and

clarity. As noted in our answers to several of the questions below, the specific 75 MVA threshold is retained in several of the Exclusions and Inclusions, and we believe the industry would be better served if the revised thresholds arrived at after technical analysis in Phase II are automatically incorporated into all relevant provisions of the BES Definition. There is no reason for the SDT to continue to rely on the 75 MVA threshold once the analysis planned for Phase II on the threshold issue is completed. Fourth, the phrase "or that meets the materiality threshold to be included in this definition" is intended to preserve the SDT's flexibility to make a determination that generators below a specific threshold are not "necessary to" maintain the reliability of the interconnected transmission system, and to incorporate that finding as part of the definition itself, even if a different threshold is used in the SCRC to identify potential candidates for registration. Accordingly, our proposed language makes clear that a specific threshold in the definition controls over any threshold that might be included in the SCRC. For the reasons stated above, we believe it is highly desirable to include any material threshold in the BES Definition itself rather than relegating the threshold to the SCRC, which is merely a procedural rule rather than a full-fledged Reliability Standard. Finally, we agree with the SDT's decision to examine the question of where the line between BES and non-BES Elements should be drawn more closely in Phase II under the rubric of "contiguous vs. non-contiguous BES," and commend the work of the Project 2010-07 Standards Drafting Team and the GO-TO Team as a good starting point for the SDT's analysis on this issue. We understand Inclusion 2 would classify generators exceeding specific thresholds as part of the BES, but would not necessarily require facilities interconnecting such generators to be part of the BES. As discussed more fully in our answer to Question 9, based on extensive technical analysis that has already been performed by the NERC Project 2010-07 Standards Drafting Team and its predecessor, the NERC "GO-TO Team," regulating as part of the BES a dedicated interconnection facility connecting a BES generator to the interconnected bulk transmission grid will result in an unnecessary regulatory burden that produces considerable expense for the owner of the interconnection facility with little or no improvement in bulk system reliability. We also believe the clauses at the end of Inclusion 2 are somewhat confusing and that greater clarity would be achieved by changing ". . . including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100kV or above" so that the Inclusion covers transformers with terminals "connected at a voltage of 100kV or above, including the generator terminal(s) on the high side of the step-up transformer(s) if operated at a voltage of 100kV or above."

Yes

PNGC supports the removal of the Cranking Path language in I3. As noted in our response to Question 9, there is no reason to classify as BES the facilities interconnecting a BES generator to the bulk interstate system. A Cranking Path is simply a specific type of such an interconnection facility.

Yes

PNGC supports the revised language generally, but believes additional changes would make the language clearer. Specifically, we believe Inclusion 4 should not incorporate a hard 75 MVA generation threshold (i.e., "resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)"). Instead, we urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," which we discuss in more detail in our response to Question 3. This language will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. More generally, we are not certain what is accomplished by Inclusion 4 that is not already accomplished by Inclusion 2, which also addresses whether generation should be defined as BES. The SDT's stated concern is with variable generation units such as wind and solar plants. It is not clear to us why this concern is not fully addressed in Inclusion 2, which addresses multiple generation units connected at a common bus, the configuration of most variable generation plants with multiple units. We are also concerned that the language, as proposed, could have unintended consequences and improperly classify local distribution systems as BES in certain circumstances. This is because multiple distributed generation units could render a local distribution system a "collector system" and the entire system the equivalent of an aggregated generation unit, causing the local distribution system to be improperly denied status as a Local Network. If many different distributed generation units are connected to a local distribution system, it is very unlikely that more than a few of those units would fail simultaneously, and it is therefore unlikely that multiple generation units would produce a measureable impact on the interconnected bulk transmission system, especially if the units individually do not otherwise exceed the materiality threshold to be

established by the SDT in Phase II. Further, we are concerned that, if small distributed generation units become the industry norm, Inclusion 4 could unintentionally sweep in local distribution systems, especially where local policies favor the growth of small solar or other renewable generation systems for public policy reasons. Finally, we suggest that the SDT add the phrase “. . . unless the dispersed power producing resources operate within a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2.” This language, which parallels the language included at the end of Inclusion I1, would make clear that dispersed small-scale generators scattered throughout a Radial System or Local Network serving retail load would not convert the Radial System or Local Network into a BES system, even if the aggregate capacity of those small generators exceeds the relevant threshold.

No

PNGC has several concerns about the new language in Inclusion 5. First, because Reactive Power devices produce power, they are “power producing resources” and we therefore believe Inclusion 5 is duplicative of Inclusion 4, which addresses “power producing devices.” Second, there is no capacity threshold specified in Inclusion 5 for Reactive Power devices that would be considered part of the BES. This is inconsistent with the approach taken in the balance of the definition, where thresholds are specified for generators and other types of power producing devices. Third, PNGC believes the appropriate threshold for inclusion or exclusion of Reactive Power devices from the BES should be subject to the same technical analysis that will cover generators in the Phase II process. Finally, PNGC believes this issue should be addressed in Phase 2 since there is not technical justification or analysis done to determine the thresholds. PNGC strongly believes that there should be technical justification for thresholds for this issue and all other issues.

Yes

PNGC continues to strongly support the radial system exclusion, which is necessary as a legal matter, because, among other reasons, FERC in Orders No. 743 and 743-A has required that the existing radial exemption in the NERC Statement of Compliance Registry Criteria be maintained. As a practical matter, radial systems are used for service to retail loads, usually in remote or rural areas, and not for the transmission of bulk power. Hence, operation of the radials has little or nothing to do with the reliable operation of the interconnected bulk transmission network. We also support the inclusion of the note discussing normally open switches because this language provides needed clarity for a common radial system configuration. We also agree with the substantive thrust of this language, which is that a radial system should not be considered part of the BES if it is interconnected at a single point, even if there is an alternative point of delivery that is normally open. While we support the Exclusion for Radial Systems, we believe several clarifications and refinements are necessary. (1) The term “transmission Elements” in the initial paragraph should be changed to “Elements.” Radial systems are not transmission systems and including the word “transmission” in the Radial System exclusion is therefore unnecessary and confusing. (2) Subparagraph (b) of Exclusion 1 refers to “generation resources . . . with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)”. We urge the SDT to replace this language with the defined term “Qualifying Aggregate Generation Resources,” discussed in more detail in our response to Question 3. This language will preserve the SDT’s ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. (3) Subparagraph (b) also seems to assume that if a Radial System contains a generator exceeding the 75 MVA threshold, the Radial System itself must be included in the BES because it links the generator to the interconnected bulk transmission system. As discussed more fully in our response to Question 9, below, NERC’s Project 2010-17 Standards Drafting Team and GO-TO Task Force have both concluded that this assumption is unwarranted. (4) The “Note” as drafted by the SDT indicates that “a normally open switching device between radial systems” will not serve to disqualify the Radial from exclusion under Exclusion 1. As discussed above, PNGC strongly supports the note conceptually. However, we believe this language should be included in a separate subparagraph (d), rather than a note, because treatment as a “note” suggests it is less important than other portions of the Exclusion. We also suggest the language be changed to read: (d) Normally-open switching devices between radial elements as depicted and identified on system one-line diagrams does not affect this exclusion. This will make clear that a radial with more than one normally-open switch connecting it to another radial is still a radial. From the perspective of the BES Definition, the key question is whether switches operating between Radials are normally open, not whether there is more than one normally-open switch.

Yes

PNGC supports the revised language. The language provides clarity regarding the BES status of customer-owned cogeneration facilities. However, PNGC urges the SDT to remove the reference to the 75 MVA threshold and replace it with the defined term "Qualifying Aggregate Generation Resources" or some equivalent language for the reasons stated in our responses to Questions 3, 5, and 7. In addition, we are concerned that Exclusion 2 will place local distribution utilities in a difficult position because, under Exclusion 1 or Exclusion 3 as drafted, they could lose their status as a Radial System or a Local Network through the actions of a customer constructing behind-the-meter generation. With respect to Radial Systems, the appearance of behind-the-meter generators could cause the Radial System to exceed the thresholds specified in subparagraphs (b) and (c) of Exclusion 1 through no fault of the Radial System owner. Similar, a Local Network could lose its status because behind-the-meter generation could be of sufficient size that power moves into the interconnected grid in certain hours or under certain contingencies, rather than moving purely onto the Local Network, as required in subparagraph (b) of Exclusion 3. The Exclusions for Radial Systems and Local Networks should be made consistent with the Exclusion for behind-the-meter generation. There is no technical reason to believe the power flowing from a behind-the-meter customer-owned generator will have less impact on the bulk system than an equivalent-sized generator owned by a utility operating a Radial System or LN.

Yes

PNGC strongly supports the exclusion of Local Networks ("LNs") from the BES. The conversion of radial systems to local networks should be encouraged because networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. If the BES definition were to provide an exclusion for radials without providing a similar exclusion for LNs, however, it would discourage networking local distribution systems because of the significantly increased regulatory burdens faced by the local distribution utility if it elected to network its radial facilities. By placing radial systems and LNs on the same regulatory footing, the proposed definition will ensure that decisions about whether to network radial systems are made on the basis of costs and benefits to the retail customers served by those radials, and not on the basis of disparate regulatory treatment. Consumers would ultimately benefit. PNGC also supports specific refinements made to the LN exclusion by the SDT in the current draft of the BES definition. In particular, PNGC supports the clarification of the purposes of a LN. The current draft states that LNs connect at multiple points to "improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system." PNGC supports this change in language because it reflects the fundamental purposes of a LN and emphasizes one of the key distinctions between LNs and bulk transmission facilities, namely, that LNs are designed primarily to serve local retail load while bulk transmission facilities are designed primarily to move bulk power from a bulk source (generally either the point of interconnection of a wholesale generator or a the point of interconnection with another bulk transmission system) to one or more wholesale purchasers. PNGC believes further improvement of the language could be achieved with additional modifications and clarifications. With respect to the core language of Exclusion 3, we believe the language making a "group of contiguous transmission Elements operated at or above 100kV" the starting point for identifying a LN would be improved by deleting the term "transmission" from this phrase. This is so because LNs are not used for transmission and the use of the term "transmission Elements" is therefore both confusing and unnecessary. There would be no room for argument about what the SDT intended by including the word "transmission" if the word is deleted and the Exclusion applies to any "group of Elements operated at 100kV or above" that meets the remaining requirement of the Exclusion. Further, any definitional value that is added by using the term "transmission Elements" is accomplished by using that term in the core definition, and there is no reason to carry the term through in the Exclusions. PNGC also believes that subparagraphs (a) and (b) are redundant, because whatever protection is offered by the generation limit in subparagraph (a) is duplicated by the limit in subparagraph (b) requiring no flow out of the LN. We believe the SDT can eliminate subparagraph (a) of Exclusion 3 and simply rely on subparagraph (b) because if power only flows into the LN even if it interconnects more than 75 MVA of generation, the interconnected generation interconnected will have no significant interaction with the interconnected bulk transmission system. It will only interact with the LN. And, with the advent of distributed generation, it is easy to foresee a situation in which a large number of very small distributed generators are interconnected into a LN, so that the aggregate capacity of these generators exceeds 75 MVA. However, because the generators are small and

dispersed and, under the criterion in subparagraph (b), would be wholly absorbed within the LN rather than transmitting power onto the interconnected grid, those generators would not have a material impact on the grid. We also suggest that subparagraph (b) of Exclusion 3 could be more clearly drafted. Subparagraph (b), as part of the requirement that power flow into a LN rather than out of it, includes this description: "The LN does not transfer energy originating outside the LN for delivery through the LN." We understand this language is intended to distinguish a LN from a link in the transmission system – power on a transmission link passes through the transmission link to a load located elsewhere, while power in a LN enters the LN and is consumed by retail load within the LN. While we agree with the concept proposed by the SDT, we believe the language would be clearer if it read: "The LN does not transfer energy originating outside the LN for delivery through the LN to loads located outside the LN." We believe the italicized language is necessary to distinguish between a transmission system, where power that originates outside a system is delivered through the system and passes through the system to a sink located somewhere outside the system, from a LN, in which power originating outside the LN passes through the LN and is delivered to retail load within the LN. To put it another way, the italicized language helps distinguish a transmission system from an LN, in which the LN "transfers energy originating outside the LN for delivery through the LN to loads located within the LN." We also believe the language of subparagraph (a) of Exclusion 3 could be improved. Subparagraph (d) would make LNs part of the BES if they interconnect "non-retail generation greater than 75 MVA (gross nameplate rating)." For the reasons stated in our responses to Questions 3, 5 and 7, we urge the SDT to replace the reference to a hard 75 MVA threshold with the defined term "Qualifying Aggregate Generation Resources" or some equivalent. We are also uncertain what is meant by the use of the term "non-retail generation" in subparagraph (a). From context, we believe the SDT considers "non-retail generation" to be the equivalent of generation that is located behind the retail meter, usually but not always owned by the customer and used to serve the customer's own load. We therefore suggest that the SDT replace the term "non-retail generation" with "generation located behind the retail customer's meter." Similarly, we are unsure what is meant by the phrase "the LN and its underlying Elements." We believe the phrase "and its underlying Elements" could simply be deleted from the definition without loss of meaning. In the alternative, the SDT might consider using the phrase "the LN, including all Elements located on the distribution side of any Automatic Fault Interrupting Devices (or other points of demarcation) separating the LN from the bulk interstate transmission system." We believe this phrase more accurately reflects the SDT's intent, which appears to be that generation exceeding 75 MVA in aggregate capacity interconnected anywhere within the LN disqualifies that LN from being excluded from the BES under Exclusion 3. PNGC also believes that both subparagraphs (a) and (b) of Exclusion 3 could be safely eliminated as long as subparagraph (c) is retained. Subparagraph (c) makes a LN part of the BES if it is classified as a Flow Gate or Transfer Path. Flow Gates and Transfer Paths are, by definition, the key facilities that allow reliable transmission of bulk electric power on the interconnected grid. If a LN has not been identified as either a Flow Gate or a Transfer Path, it is unlikely the LN is necessary for the reliable transmission of electricity on the interconnected bulk system. Apart from these specific improvements that we believe could be achieved by modifying the language of Exclusion 3, we believe the SDT may need to re-examine certain assumptions that appear to underlie the current draft. Specifically, subparagraph (a) suggests that if BES generation is embedded within a LN, the LN itself must also be BES. But two NERC bodies have already addressed similar questions and concluded there is no technical basis for such concerns. NERC's Standards Drafting Team for Project 2010-07 and its predecessor, the "GO-TO Task Force" were formed to address how the dedicated interconnection facilities linking a BES generator to high-voltage transmission facilities should be treated under the NERC standards. The GO-TO Team concluded that by complying with a handful of reliability standards, primarily related to vegetation management, reliable operation of the bulk interconnected system could be protected without unduly burdening the owners of such interconnection systems. Therefore, there is no reason, according to the GO-TO Team, that dedicated high-voltage interconnection facilities must be treated as "Transmission" and classified as part of the BES in order to make reliability standards effective. See Final Report from the NERC Ad Hoc Group for Generator Requirements at the Transmission Interface (Nov. 16, 2009) (paper written by the GO-TO Task Force). Similarly, the Project 2010-07 Team observed that interconnection facilities "are most often not part of the integrated bulk power system, and as such should not be subject to the same level of standards applicable to Transmission Owners and Transmission Operators who own and operate transmission facilities and elements that are part of the integrated bulk power system." White Paper Proposal for Information Comment, NERC Project 2010-07: Generator Requirements at the

Transmission Interface, at 3 (March 2011). Requiring Generation Owners and Operators to comply with the same standards as BES Transmission Owners and Operators “would do little, if anything, to improve the reliability of the Bulk Electric System,” especially “when compared to the operation of the equipment that actually produces electricity – the generation equipment itself.” Id. We believe that interconnection of BES generators within a LN is analogous and that, based on the findings of the Project 2010-07 and GO-TO Teams, automatically classifying a LN as “BES” simply because a large generator is embedded in the LN will result in substantial overregulation and unnecessary expense with little gain for bulk system reliability. If anything, generation interconnected through a LN is less likely to produce material impacts on the interconnected bulk transmission system than the equivalent generator interconnected through a single dedicated line because an LN is interconnected to the bulk system at several points, so that if one interconnection goes down, power can still flow from the BES generator to the bulk system on other interconnection points. Where a dedicated interconnection facility is involved, by contrast, if the interconnection line fails, the generator is unavailable to the interconnected bulk system. Similarly, we suggest that the SDT re-examine the assumptions underlying subparagraph (b), which seems to suggest that a local distribution system cannot be classified as a Local Network if power flows out of that system at any time, even if the amount is de minimis, the outward flow is only for a few hours, a year, or the outward flow occurs only in an extreme contingency. Accordingly, we suggest that the initial clause of subparagraph (b) be revised to read: “Except in unusual circumstances, power flows only into the LN.” Finally, we note that the LN exclusion must not operate in any way as a substitution for the statutory prohibition on including “facilities used in the local distribution of electric energy” in the BES. Therefore, even with the LN exclusion, the SDT must retain this statutory language in the core definition of the BES, as discussed in our answer to Question One. If a certain piece of equipment is a “facility used in the local distribution of electric energy,” then it is not part of the BES in the first instance, and so consideration of the LN Exclusion, or of any other Exclusion, any Inclusion, or any Exception, would be both unnecessary and uncalled for.

Yes

PNGC supports the revised language because retail reactive devices are used to address local customer or retail voltage issues, rather than voltage issues on the interconnected bulk grid, and such local devices should therefore be excluded from the BES definition.

No

PNGC extends its thanks to the SDT and to the many industry entities that have actively participating in the Standards Development Process. PNGC supports the current draft and believes, with certain refinements discussed in our comments, that the definition will serve the industry and reliability regulators well for many years to come. In addition, as noted earlier, PNGC is encouraged that the 20/75 MVA generation thresholds referred to in the NERC Statement of Compliance Registry Criteria, which have been relied upon by the SDT largely as a matter of necessity, will be reviewed and a technical assessment will be performed to identify the appropriate generation unit and plant size threshold to ensure a reliable North America. Finally, we understand that the Rules of Procedure Team will continue to move forward with developing an Exceptions Process that will complement the BES Definition and ensure that, to the extent the BES Definition is over-inclusive, facilities that should not be classified as BES will be excluded from the BES. Because the Exceptions Process is integral to a workable BES Definition, we support the current process for moving forward with the Exceptions Process and the BES Definition on parallel paths. We note that PNGC specifically supports the changes made by the SDT in the “Effective Date” provision of the BES Definition, which shortens the effective date of the new definition to the beginning of the first calendar quarter after regulatory approval (as opposed to the first calendar quarter twenty-four months after regulatory approval), with a 24-month transition period. PNGC supports this conclusion because it will allow entities seeking deregistration under the terms of the new BES definition to obtain the benefits of the new definition without an unreasonable wait, while allowing any entities that may be newly-classified as BES owners or operators sufficient time to come into compliance with newly-applicable Reliability Standards. PNGC also supports the 24-month transition period for the reasons laid out by the SDT.

Raft River Rural Electric Cooperative (RAFT)

Yes

The Raft River Rural Electric Cooperative (RAFT) believes the SDT continues to make substantial progress towards a clear and workable definition of the Bulk Electric System ("BES") that markedly improves both the existing definition and the SDT's previous proposal. RAFT therefore supports the new definition, although our support is conditioned on: (1) a workable Exceptions process being developed in conjunction with the BES definition; and, (2) the SDT moving forward expeditiously on Phase II of the standards development process in accordance with the SAR recently put forward by the SDT, which would address a number of important technical issues that have been identified in the standards development process to date. RAFT strongly supports the following elements of the revised BES definition: (1) Clarification of how lists of Inclusions and Exclusions applies: The revised core definition moves the phrase "Unless modified by the lists shown below" to the beginning of the definition. This change makes clear that the Inclusions and Exclusions apply to all Elements that would otherwise be included in or excluded from the core definition (i.e., "all Transmission Elements operated at 100kV or higher and Real Time and Reactive Power resources connected at 100kV or higher") and eliminates a latent ambiguity in the first draft of the definition, discussed further in our comments on the first draft. (2) The exclusion for "facilities used in the local distribution of electric energy." As the starting point for the BES definition, RAFT supports the use of the phrase "all Transmission Elements" and the qualifying sentence: "This does not include facilities used in the local distribution of electric energy." This language helps ensure that FERC, NERC, and the Regional Entities ("REs") will act within the jurisdictional constraints Congress placed in Section 215 of the Federal Power Act ("FPA"). In Section 215(a)(1), Congress unequivocally excluded "facilities used in the local distribution of electric energy" from the keystone "bulk-power system" definition. 16 U.S.C. § 824o(a)(1). Including the same language in the definition helps ensure that entities involved in enforcement of reliability standards will act within their statutory limits. In addition, as a practical matter, inclusion of the language will help focus both the industry and responsible agencies on the high-voltage interstate transmission system, where the reliability problems Congress intended to regulate – "instability, uncontrolled separation, [and] cascading failures," 16 U.S.C. § 824o(a)(4) – will originate. At the same time, level-of-service issues arising in local distribution systems will be left to the authority of state and local regulatory agencies and governing bodies, just as Congress intended. 16 U.S.C. § 824o(i)(2) (reserving to state and local authorities enforcement of standards for adequacy of service). RAFT thanks the SDT for the excellent work to include this sentence. For similar reasons, RAFT believes the use of the phrase "Transmission Elements" as the starting point for the base definition is desirable because both "Transmission" and "Elements" are already defined in the NERC Glossary of Terms Used in NERC Reliability Standards, and the term "Transmission" makes clear that the BES includes only Elements used in Transmission and therefore excludes Elements used in local distribution of electric power. (3) Appropriate Generator Thresholds. In the standards development process, it has become apparent that the thresholds for classifying generators as BES in the current NERC Statement of Compliance Registry Criteria ("SCRC") (20 MVA for individual generators, 75 MVA for multiple generators aggregated at a single site), which predate the adoption of FPA Section 215, were never the product of a careful analysis to determine whether generators of that size are necessary for operation of the interconnected bulk transmission system. Ideally, such an analysis would be conducted as part of the current standards development process. RAFT recognizes that, given the deadlines imposed by FERC in Order No. 743, it will not be possible for the SDT to conduct such an analysis within the time available. Accordingly, RAFT agrees with the approach taken by the SDT, which is to propose a Phase II of the standards development process that would address the generator threshold issue and several other technical issues that have arisen during the current process. As long as Phase II proceeds expeditiously, RAFT is prepared to support the BES definition as proposed by the SDT. While RAFT supports the overall approach adopted by the SDT and much of the specific language incorporated into the second draft of the BES definition, we believe the second draft would benefit from further clarification or modification in a number of respects, most of which are detailed in our subsequent answers. Further, we believe a workable Exclusion Process is essential for a BES Definition that will meet the legal requirements of FPA Section 215, especially for systems operating in the Western Interconnection. As detailed in our previous comments, RAFT believes a 200kV threshold would be more appropriate for WECC than a 100kV threshold. In addition, a 200kV threshold for the West is backed by solid technical analysis conducted by the WECC Bulk Electric System Definition Task Force, and repeated claims that there is no technical analysis to support this view are therefore incorrect. That said, we raise the issue here to emphasize the importance of the Exclusions for Local Networks and Radial Systems and the Exceptions process. These Exclusions and the Exceptions are essential for a definition that works in the Western Interconnection because the

core definition will be over-inclusive in our region. As long as those Exclusions and the Exceptions Process are retained in a form substantially equivalent to those produced by the SDT at this juncture, RAFT will support the SDT's proposal.

Yes

We support the SDT's changes to the first Inclusion because it is more clear and simple than the initial approach. That being said, we suggest that an additional sentence of clarification would help avoid future controversy about the meaning of Inclusion 1. As we understand it, the BES intends to include transformers only if both the primary and secondary terminals operate at 100kV or above, which is why the definition uses the word "and" ("the primary and secondary terminals"). We support this approach since it would exclude transformers where the secondary terminals serve distribution loads, and which therefore function as distribution rather than transmission facilities. We believe the SDT's intent would be clarified by adding a sentence at the end of Inclusion 1 that reads: "Transformers with either primary or secondary terminals, or both, that operate at or below 100kV are not part of the BES." This language will help ensure that there is no controversy over whether the SDT's use of the word "and" in the phrase "the primary and secondary terminals" was intentional. We also support the SDT's proposal to develop detailed guidance concerning the point of demarcation between BES and non-BES elements in the Phase II SAR. In this regard, we note that, while Inclusion 1 at least implicitly suggests that the dividing line between BES and non-BES Elements should be at the transformer where transmission-level voltages are stepped down to distribution-level voltages, we believe further clarification of this point of demarcation between the BES and non-BES Elements is necessary. Many different configurations of transformers and other equipment that may lie at the juncture between the BES and non-BES systems. If the point of demarcation is designated at the transformer without further elaboration, many entities that own equipment on the high side of a transformer will be swept into the BES, and thereby exposed to inappropriately stringent regulations and undue costs. For example, distribution-only utilities commonly own the switches, bus, and transformer protection devices on the high side of transformers where they take delivery from their transmission provider. Ownership of these protective devices and high-voltage bus on the high side of the transformer should not cause these entities to be classified as BES owners. As the Phase II process moves forward, we commend to the SDT the extensive work performed on the point of demarcation question by the WECC BESDTF. We also support the incorporation of language (" . . . unless excluded under Exclusions E1 or E3") making it clear that transformers that are operated as an integral part of a Radial System or Local Network should not be considered BES facilities, regardless of their operating voltage. Further clarification might be achieved by using the phrase ". . . unless the transformer is operated as part of a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2."

Yes

RAFT supports the changes made in Inclusion 2 and believes that the definition in its current form adds clarity. In particular, we support the SDT's decision to collapse Inclusions 2 and 3 from the previous draft definition into a single Inclusion that addresses the treatment of generation for purposes of the BES definition. We also support the SDT's proposal for a Phase II of the BES Definition process that would examine the technical justification for these thresholds and that would establish new thresholds based on a careful technical analysis. It is our understanding that the generator threshold issue will be vetted through the complete standards development process. We agree with this approach because if the generator threshold is treated as merely an element of NERC's Rules of Procedure, it can be changed with considerably less process and industry input than the Standards Development Process. Compare NERC Rules of Procedure § 1400 (providing for changes to Rules of Procedure upon approval of the NERC board and FERC) with NERC Standards Process Manual (Sept. 3, 2010) (providing for, e.g., posting of SDT proposals for comment, successive balloting, and super-majority approval requirements). See also Order No. 743-A, 134 FERC ¶ 61,210 at P 4 (2011) ("Order No. 743 directed the ERO to revise the definition of 'bulk electric system' through the NERC Standards Development Process" (emph. added)). Addressing all aspects of Phase II through the Standards Development Process will improve the content of the definition by bringing to bear industry expertise on all aspects of the definition and will ensure that, once firm guidelines are established, they can be relied upon by both industry and regulators without threat that they will be changed with little notice and little process. RAFT believes further clarification of the proposed language would be appropriate. The SDT proposes continued reliance upon the thresholds that are used in the NERC Statement of Compliance Registry Criteria for registration of Generation

Owners and Generation Operators, which is currently 20 MVA for an individual generation unit and 75 MVA for multiple units on a single site. Conceptually, we are concerned about this approach because, as we understand it, the purpose of the Compliance Registry is to sweep in all generators that might be material to the reliable operation of the BES, and not to definitively determine whether a given generator is, in fact, material to the reliable operation of the BES. As the SCRC itself states, the SCRC is intended only to identify "candidates for registration." SCRC at p.3, § 1 (emph. added).

Accordingly, we believe that the generator threshold determined in Phase II should be incorporated directly into the BES Definition rather than being incorporated by reference from the SCRC. We also believe that the specific language proposed by the SDT could be further clarified. The SDT proposes that generation be included in the BES if the "Generation resource(s)" has a "nameplate rating per the ERO Statement of Compliance Registry." We understand this language is intended to be a placeholder for the results of the technical analysis that would occur in Phase II but we believe simply stating that the threshold will be "per the ERO Statement of Compliance Registry" is ambiguous. Further, for the reasons noted above, we believe the threshold should be part of the BES Definition, and should not simply be a cross-reference to the SCRC (and, given the different purposes of the BES Definition and the SCRC, it is not clear that the same threshold should be used in both). We therefore propose that Inclusion 2 be rewritten to state: "Qualifying Individual Generation Resources or Qualifying Aggregate Resources connected at a voltage of 100kV or above." Two definitions would then be added to the note at the end of the definition to read as follows: For purposes of this BES Definition, Qualifying Individual Generation Resources means an individual generating unit that meets the materiality threshold to be included in this definition or, in the absence of such a materiality threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of such a resource as a Generation Owner under the ERO Statement of Compliance Registry Criteria. For purposes of this BES Definition, Qualifying Aggregate Generation Resources means any facility consisting of one or more generating units that are connected at a common bus that meets the materiality threshold to be included in this definition, or, in the absence of such a threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of multiple-unit generator as a Generation Owner under the ERO Statement of Compliance Registry Criteria.. The "materiality threshold" is intended to refer to the generator threshold developed in Phase II. We suggest using definitions in this fashion for several reasons. First, we believe the language we suggest more clearly states the intention of the SDT, which we understand is to classify generation units as part of the BES if they are necessary for operation of the BES, but to exclude smaller generating units because they are not material to the operation of the interconnected transmission grid. Second, we believe use of the defined terms better reflects the intention of the SDT to reserve the specific question about generator thresholds to the technical analysis that will occur in Phase II without having to revise the BES Definition at the end of that process. That is, the definitions are designed to allow the SDT to include revised thresholds in the definition at the conclusion of the Phase II process based upon the technical analysis planned for Phase II, and the revised thresholds will be automatically incorporated into the BES Definition if the language we suggest is used. The thresholds used in the SCRC would only be a fall-back, to be used only until Phase II is completed. Third, the definitions can be incorporated into other parts of the BES Definition, which will add consistency and clarity. As noted in our answers to several of the questions below, the specific 75 MVA threshold is retained in several of the Exclusions and Inclusions, and we believe the industry would be better served if the revised thresholds arrived at after technical analysis in Phase II are automatically incorporated into all relevant provisions of the BES Definition. There is no reason for the SDT to continue to rely on the 75 MVA threshold once the analysis planned for Phase II on the threshold issue is completed. Fourth, the phrase "or that meets the materiality threshold to be included in this definition" is intended to preserve the SDT's flexibility to make a determination that generators below a specific threshold are not "necessary to" maintain the reliability of the interconnected transmission system, and to incorporate that finding as part of the definition itself, even if a different threshold is used in the SCRC to identify potential candidates for registration. Accordingly, our proposed language makes clear that a specific threshold in the definition controls over any threshold that might be included in the SCRC. For the reasons stated above, we believe it is highly desirable to include any material threshold in the BES Definition itself rather than relegating the threshold to the SCRC, which is merely a procedural rule rather than a full-fledged Reliability Standard. Finally, we agree with the SDT's decision to examine the question of where the line between BES and non-BES Elements should be drawn more closely in Phase II under the rubric of "contiguous vs. non-contiguous BES," and commend the work of the Project 2010-07 Standards Drafting Team and the GO-TO Team as a good

starting point for the SDT's analysis on this issue. We understand Inclusion 2 would classify generators exceeding specific thresholds as part of the BES, but would not necessarily require facilities interconnecting such generators to be part of the BES. As discussed more fully in our answer to Question 9, based on extensive technical analysis that has already been performed by the NERC Project 2010-07 Standards Drafting Team and its predecessor, the NERC "GO-TO Team," regulating as part of the BES a dedicated interconnection facility connecting a BES generator to the interconnected bulk transmission grid will result in an unnecessary regulatory burden that produces considerable expense for the owner of the interconnection facility with little or no improvement in bulk system reliability. We also believe the clauses at the end of Inclusion 2 are somewhat confusing and that greater clarity would be achieved by changing ". . . including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100kV or above" so that the Inclusion covers transformers with terminals "connected at a voltage of 100kV or above, including the generator terminal(s) on the high side of the step-up transformer(s) if operated at a voltage of 100kV or above."

Yes

RAFT supports the removal of the Cranking Path language in I3. As noted in our response to Question 9, there is no reason to classify as BES the facilities interconnecting a BES generator to the bulk interstate system. A Cranking Path is simply a specific type of such an interconnection facility.

Yes

RAFT supports the revised language generally, but believes additional changes would make the language clearer. Specifically, we believe Inclusion 4 should not incorporate a hard 75 MVA generation threshold (i.e., "resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)"). Instead, we urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," which we discuss in more detail in our response to Question 3. This language will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. More generally, we are not certain what is accomplished by Inclusion 4 that is not already accomplished by Inclusion 2, which also addresses whether generation should be defined as BES. The SDT's stated concern is with variable generation units such as wind and solar plants. It is not clear to us why this concern is not fully addressed in Inclusion 2, which addresses multiple generation units connected at a common bus, the configuration of most variable generation plants with multiple units. We are also concerned that the language, as proposed, could have unintended consequences and improperly classify local distribution systems as BES in certain circumstances. This is because multiple distributed generation units could render a local distribution system a "collector system" and the entire system the equivalent of an aggregated generation unit, causing the local distribution system to be improperly denied status as a Local Network. If many different distributed generation units are connected to a local distribution system, it is very unlikely that more than a few of those units would fail simultaneously, and it is therefore unlikely that multiple generation units would produce a measureable impact on the interconnected bulk transmission system, especially if the units individually do not otherwise exceed the materiality threshold to be established by the SDT in Phase II. Further, we are concerned that, if small distributed generation units become the industry norm, Inclusion 4 could unintentionally sweep in local distribution systems, especially where local policies favor the growth of small solar or other renewable generation systems for public policy reasons. Finally, we suggest that the SDT add the phrase ". . . unless the dispersed power producing resources operate within a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2." This language, which parallels the language included at the end of Inclusion I1, would make clear that dispersed small-scale generators scattered throughout a Radial System or Local Network serving retail load would not convert the Radial System or Local Network into a BES system, even if the aggregate capacity of those small generators exceeds the relevant threshold.

No

RAFT has several concerns about the new language in Inclusion 5. First, because Reactive Power devices produce power, they are "power producing resources" and we therefore believe Inclusion 5 is duplicative of Inclusion 4, which addresses "power producing devices." Second, there is no capacity threshold specified in Inclusion 5 for Reactive Power devices that would be considered part of the BES. This is inconsistent with the approach taken in the balance of the definition, where thresholds are specified for generators and other types of power producing devices. Third, RAFT believes the

appropriate threshold for inclusion or exclusion of Reactive Power devices from the BES should be subject to the same technical analysis that will cover generators in the Phase II process. Finally, RAFT believes this issue should be addressed in Phase 2 since there is not technical justification or analysis done to determine the thresholds. RAFT strongly believes that there should be technical justification for thresholds for this issue and all other issues.

Yes

RAFT continues to strongly support the radial system exclusion, which is necessary as a legal matter, because, among other reasons, FERC in Orders No. 743 and 743-A has required that the existing radial exemption in the NERC Statement of Compliance Registry Criteria be maintained. As a practical matter, radial systems are used for service to retail loads, usually in remote or rural areas, and not for the transmission of bulk power. Hence, operation of the radials has little or nothing to do with the reliable operation of the interconnected bulk transmission network. We also support the inclusion of the note discussing normally open switches because this language provides needed clarity for a common radial system configuration. We also agree with the substantive thrust of this language, which is that a radial system should not be considered part of the BES if it is interconnected at a single point, even if there is an alternative point of delivery that is normally open. While we support the Exclusion for Radial Systems, we believe several clarifications and refinements are necessary. (1) The term "transmission Elements" in the initial paragraph should be changed to "Elements." Radial systems are not transmission systems and including the word "transmission" in the Radial System exclusion is therefore unnecessary and confusing. (2) Subparagraph (b) of Exclusion 1 refers to "generation resources . . . with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)". We urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," discussed in more detail in our response to Question 3. This language will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. (3) Subparagraph (b) also seems to assume that if a Radial System contains a generator exceeding the 75 MVA threshold, the Radial System itself must be included in the BES because it links the generator to the interconnected bulk transmission system. As discussed more fully in our response to Question 9, below, NERC's Project 2010-17 Standards Drafting Team and GO-TO Task Force have both concluded that this assumption is unwarranted. (4) The "Note" as drafted by the SDT indicates that "a normally open switching device between radial systems" will not serve to disqualify the Radial from exclusion under Exclusion 1. As discussed above, RAFT strongly supports the note conceptually. However, we believe this language should be included in a separate subparagraph (d), rather than a note, because treatment as a "note" suggests it is less important than other portions of the Exclusion. We also suggest the language be changed to read: (d) Normally-open switching devices between radial elements as depicted and identified on system one-line diagrams does not affect this exclusion. This will make clear that a radial with more than one normally-open switch connecting it to another radial is still a radial. From the perspective of the BES Definition, the key question is whether switches operating between Radials are normally open, not whether there is more than one normally-open switch.

Yes

RAFT supports the revised language. The language provides clarity regarding the BES status of customer-owned cogeneration facilities. However, RAFT urges the SDT to remove the reference to the 75 MVA threshold and replace it with the defined term "Qualifying Aggregate Generation Resources" or some equivalent language for the reasons stated in our responses to Questions 3, 5, and 7. In addition, we are concerned that Exclusion 2 will place local distribution utilities in a difficult position because, under Exclusion 1 or Exclusion 3 as drafted, they could lose their status as a Radial System or a Local Network through the actions of a customer constructing behind-the-meter generation. With respect to Radial Systems, the appearance of behind-the-meter generators could cause the Radial System to exceed the thresholds specified in subparagraphs (b) and (c) of Exclusion 1 through no fault of the Radial System owner. Similar, a Local Network could lose its status because behind-the-meter generation could be of sufficient size that power moves into the interconnected grid in certain hours or under certain contingencies, rather than moving purely onto the Local Network, as required in subparagraph (b) of Exclusion 3. The Exclusions for Radial Systems and Local Networks should be made consistent with the Exclusion for behind-the-meter generation. There is no technical reason to believe the power flowing from a behind-the-meter customer-owned generator will have less impact on the bulk system than an equivalent-sized generator owned by a utility operating a Radial System

or LN.

Yes

RAFT strongly supports the exclusion of Local Networks (“LNs”) from the BES. The conversion of radial systems to local networks should be encouraged because networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. If the BES definition were to provide an exclusion for radials without providing a similar exclusion for LNs, however, it would discourage networking local distribution systems because of the significantly increased regulatory burdens faced by the local distribution utility if it elected to network its radial facilities. By placing radial systems and LNs on the same regulatory footing, the proposed definition will ensure that decisions about whether to network radial systems are made on the basis of costs and benefits to the retail customers served by those radials, and not on the basis of disparate regulatory treatment. Consumers would ultimately benefit. RAFT also supports specific refinements made to the LN exclusion by the SDT in the current draft of the BES definition. In particular, RAFT supports the clarification of the purposes of a LN. The current draft states that LNs connect at multiple points to “improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system.” RAFT supports this change in language because it reflects the fundamental purposes of a LN and emphasizes one of the key distinctions between LNs and bulk transmission facilities, namely, that LNs are designed primarily to serve local retail load while bulk transmission facilities are designed primarily to move bulk power from a bulk source (generally either the point of interconnection of a wholesale generator or a the point of interconnection with another bulk transmission system) to one or more wholesale purchasers. RAFT believes further improvement of the language could be achieved with additional modifications and clarifications. With respect to the core language of Exclusion 3, we believe the language making a “group of contiguous transmission Elements operated at or above 100kV” the starting point for identifying a LN would be improved by deleting the term “transmission” from this phrase. This is so because LNs are not used for transmission and the use of the term “transmission Elements” is therefore both confusing and unnecessary. There would be no room for argument about what the SDT intended by including the word “transmission” if the word is deleted and the Exclusion applies to any “group of Elements operated at 100kV or above” that meets the remaining requirement of the Exclusion. Further, any definitional value that is added by using the term “transmission Elements” is accomplished by using that term in the core definition, and there is no reason to carry the term through in the Exclusions. RAFT also believes that subparagraphs (a) and (b) are redundant, because whatever protection is offered by the generation limit in subparagraph (a) is duplicated by the limit in subparagraph (b) requiring no flow out of the LN. We believe the SDT can eliminate subparagraph (a) of Exclusion 3 and simply rely on subparagraph (b) because if power only flows into the LN even if it interconnects more than 75 MVA of generation, the interconnected generation interconnected will have no significant interaction with the interconnected bulk transmission system. It will only interact with the LN. And, with the advent of distributed generation, it is easy to foresee a situation in which a large number of very small distributed generators are interconnected into a LN, so that the aggregate capacity of these generators exceeds 75 MVA. However, because the generators are small and dispersed and, under the criterion in subparagraph (b), would be wholly absorbed within the LN rather than transmitting power onto the interconnected grid, those generators would not have a material impact on the grid. We also suggest that subparagraph (b) of Exclusion 3 could be more clearly drafted. Subparagraph (b), as part of the requirement that power flow into a LN rather than out of it, includes this description: “The LN does not transfer energy originating outside the LN for delivery through the LN.” We understand this language is intended to distinguish a LN from a link in the transmission system – power on a transmission link passes through the transmission link to a load located elsewhere, while power in a LN enters the LN and is consumed by retail load within the LN. While we agree with the concept proposed by the SDT, we believe the language would be clearer if it read: “The LN does not transfer energy originating outside the LN for delivery through the LN to loads located outside the LN.” We believe the italicized language is necessary to distinguish between a transmission system, where power that originates outside a system is delivered through the system and passes through the system to a sink located somewhere outside the system, from a LN, in which power originating outside the LN passes through the LN and is delivered to retail load within the LN. To put it another way, the italicized language helps distinguish a transmission system from an LN, in which the LN “transfers energy originating outside the LN for delivery through the LN to loads located within the LN.” We also believe the language of subparagraph (a) of Exclusion 3 could be improved. Subparagraph (d) would make LNs part of the BES if they interconnect “non-retail generation greater

than 75 MVA (gross nameplate rating)." For the reasons stated in our responses to Questions 3, 5 and 7, we urge the SDT to replace the reference to a hard 75 MVA threshold with the defined term "Qualifying Aggregate Generation Resources" or some equivalent. We are also uncertain what is meant by the use of the term "non-retail generation" in subparagraph (a). From context, we believe the SDT considers "non-retail generation" to be the equivalent of generation that is located behind the retail meter, usually but not always owned by the customer and used to serve the customer's own load. We therefore suggest that the SDT replace the term "non-retail generation" with "generation located behind the retail customer's meter." Similarly, we are unsure what is meant by the phrase "the LN and its underlying Elements." We believe the phrase "and its underlying Elements" could simply be deleted from the definition without loss of meaning. In the alternative, the SDT might consider using the phrase "the LN, including all Elements located on the distribution side of any Automatic Fault Interrupting Devices (or other points of demarcation) separating the LN from the bulk interstate transmission system." We believe this phrase more accurately reflects the SDT's intent, which appears to be that generation exceeding 75 MVA in aggregate capacity interconnected anywhere within the LN disqualifies that LN from being excluded from the BES under Exclusion 3. RAFT also believes that both subparagraphs (a) and (b) of Exclusion 3 could be safely eliminated as long as subparagraph (c) is retained. Subparagraph (c) makes a LN part of the BES if it is classified as a Flow Gate or Transfer Path. Flow Gates and Transfer Paths are, by definition, the key facilities that allow reliable transmission of bulk electric power on the interconnected grid. If a LN has not been identified as either a Flow Gate or a Transfer Path, it is unlikely the LN is necessary for the reliable transmission of electricity on the interconnected bulk system. Apart from these specific improvements that we believe could be achieved by modifying the language of Exclusion 3, we believe the SDT may need to re-examine certain assumptions that appear to underlie the current draft. Specifically, subparagraph (a) suggests that if BES generation is embedded within a LN, the LN itself must also be BES. But two NERC bodies have already addressed similar questions and concluded there is no technical basis for such concerns. NERC's Standards Drafting Team for Project 2010-07 and its predecessor, the "GO-TO Task Force" were formed to address how the dedicated interconnection facilities linking a BES generator to high-voltage transmission facilities should be treated under the NERC standards. The GO-TO Team concluded that by complying with a handful of reliability standards, primarily related to vegetation management, reliable operation of the bulk interconnected system could be protected without unduly burdening the owners of such interconnection systems. Therefore, there is no reason, according to the GO-TO Team, that dedicated high-voltage interconnection facilities must be treated as "Transmission" and classified as part of the BES in order to make reliability standards effective. See Final Report from the NERC Ad Hoc Group for Generator Requirements at the Transmission Interface (Nov. 16, 2009) (paper written by the GO-TO Task Force). Similarly, the Project 2010-07 Team observed that interconnection facilities "are most often not part of the integrated bulk power system, and as such should not be subject to the same level of standards applicable to Transmission Owners and Transmission Operators who own and operate transmission Facilities and Elements that are part of the integrated bulk power system." White Paper Proposal for Information Comment, NERC Project 2010-07: Generator Requirements at the Transmission Interface, at 3 (March 2011). Requiring Generation Owners and Operators to comply with the same standards as BES Transmission Owners and Operators "would do little, if anything, to improve the reliability of the Bulk Electric System," especially "when compared to the operation of the equipment that actually produces electricity – the generation equipment itself." Id. We believe that interconnection of BES generators within a LN is analogous and that, based on the findings of the Project 2010-07 and GO-TO Teams, automatically classifying a LN as "BES" simply because a large generator is embedded in the LN will result in substantial overregulation and unnecessary expense with little gain for bulk system reliability. If anything, generation interconnected through a LN is less likely to produce material impacts on the interconnected bulk transmission system than the equivalent generator interconnected through a single dedicated line because an LN is interconnected to the bulk system at several points, so that if one interconnection goes down, power can still flow from the BES generator to the bulk system on other interconnection points. Where a dedicated interconnection facility is involved, by contrast, if the interconnection line fails, the generator is unavailable to the interconnected bulk system. Similarly, we suggest that the SDT re-examine the assumptions underlying subparagraph (b), which seems to suggest that a local distribution system cannot be classified as a Local Network if power flows out of that system at any time, even if the amount is de minimis, the outward flow is only for a few hours, a year, or the outward flow occurs only in an extreme contingency. Accordingly, we suggest that the initial clause of subparagraph (b) be

revised to read: "Except in unusual circumstances, power flows only into the LN." Finally, we note that the LN exclusion must not operate in any way as a substitution for the statutory prohibition on including "facilities used in the local distribution of electric energy" in the BES. Therefore, even with the LN exclusion, the SDT must retain this statutory language in the core definition of the BES, as discussed in our answer to Question One. If a certain piece of equipment is a "facility used in the local distribution of electric energy," then it is not part of the BES in the first instance, and so consideration of the LN Exclusion, or of any other Exclusion, any Inclusion, or any Exception, would be both unnecessary and uncalled for.

Yes

RAFT supports the revised language because retail reactive devices are used to address local customer or retail voltage issues, rather than voltage issues on the interconnected bulk grid, and such local devices should therefore be excluded from the BES definition.

No

RAFT extends its thanks to the SDT and to the many industry entities that have actively participating in the Standards Development Process. RAFT supports the current draft and believes, with certain refinements discussed in our comments, that the definition will serve the industry and reliability regulators well for many years to come. In addition, as noted earlier, RAFT is encouraged that the 20/75 MVA generation thresholds referred to in the NERC Statement of Compliance Registry Criteria, which have been relied upon by the SDT largely as a matter of necessity, will be reviewed and a technical assessment will be performed to identify the appropriate generation unit and plant size threshold to ensure a reliable North America. Finally, we understand that the Rules of Procedure Team will continue to move forward with developing an Exceptions Process that will complement the BES Definition and ensure that, to the extent the BES Definition is over-inclusive, facilities that should not be classified as BES will be excluded from the BES. Because the Exceptions Process is integral to a workable BES Definition, we support the current process for moving forward with the Exceptions Process and the BES Definition on parallel paths. We note that RAFT specifically supports the changes made by the SDT in the "Effective Date" provision of the BES Definition, which shortens the effective date of the new definition to the beginning of the first calendar quarter after regulatory approval (as opposed to the first calendar quarter twenty-four months after regulatory approval), with a 24-month transition period. RAFT supports this conclusion because it will allow entities seeking deregistration under the terms of the new BES definition to obtain the benefits of the new definition without an unreasonable wait, while allowing any entities that may be newly-classified as BES owners or operators sufficient time to come into compliance with newly-applicable Reliability Standards. RAFT also supports the 24-month transition period for the reasons laid out by the SDT.

Individual

Marc Farmer

West Oregon Electric Cooperative

Yes

The West Oregon Electric Cooperative (WOEC) believes the SDT continues to make substantial progress towards a clear and workable definition of the Bulk Electric System ("BES") that markedly improves both the existing definition and the SDT's previous proposal. WOEC therefore supports the new definition, although our support is conditioned on: (1) a workable Exceptions process being developed in conjunction with the BES definition; and, (2) the SDT moving forward expeditiously on Phase II of the standards development process in accordance with the SAR recently put forward by the SDT, which would address a number of important technical issues that have been identified in the standards development process to date. WOEC strongly supports the following elements of the revised BES definition: (1) Clarification of how lists of Inclusions and Exclusions applies: The revised core definition moves the phrase "Unless modified by the lists shown below" to the beginning of the definition. This change makes clear that the Inclusions and Exclusions apply to all Elements that would otherwise be included in or excluded from the core definition (i.e., "all Transmission Elements operated at 100kV or higher and Real Time and Reactive Power resources connected at 100kV or higher") and eliminates a latent ambiguity in the first draft of the definition, discussed further in our comments on the first draft. (2) The exclusion for "facilities used in the local distribution of electric energy." As the starting point for the BES definition, WOEC supports the use of the phrase "all Transmission Elements" and the qualifying sentence: "This does not include facilities used in the local distribution of electric energy." This language helps ensure that FERC, NERC, and the Regional

Entities (“RES”) will act within the jurisdictional constraints Congress placed in Section 215 of the Federal Power Act (“FPA”). In Section 215(a)(1), Congress unequivocally excluded “facilities used in the local distribution of electric energy” from the keystone “bulk-power system” definition. 16 U.S.C. § 824o(a)(1). Including the same language in the definition helps ensure that entities involved in enforcement of reliability standards will act within their statutory limits. In addition, as a practical matter, inclusion of the language will help focus both the industry and responsible agencies on the high-voltage interstate transmission system, where the reliability problems Congress intended to regulate – “instability, uncontrolled separation, [and] cascading failures,” 16 U.S.C. § 824o(a)(4) – will originate. At the same time, level-of-service issues arising in local distribution systems will be left to the authority of state and local regulatory agencies and governing bodies, just as Congress intended. 16 U.S.C. § 824o(i)(2) (reserving to state and local authorities enforcement of standards for adequacy of service). WOEEC thanks the SDT for the excellent work to include this sentence. For similar reasons, WOEEC believes the use of the phrase “Transmission Elements” as the starting point for the base definition is desirable because both “Transmission” and “Elements” are already defined in the NERC Glossary of Terms Used in NERC Reliability Standards, and the term “Transmission” makes clear that the BES includes only Elements used in Transmission and therefore excludes Elements used in local distribution of electric power. (3) Appropriate Generator Thresholds. In the standards development process, it has become apparent that the thresholds for classifying generators as BES in the current NERC Statement of Compliance Registry Criteria (“SCRC”) (20 MVA for individual generators, 75 MVA for multiple generators aggregated at a single site), which predate the adoption of FPA Section 215, were never the product of a careful analysis to determine whether generators of that size are necessary for operation of the interconnected bulk transmission system. Ideally, such an analysis would be conducted as part of the current standards development process. WOEEC recognizes that, given the deadlines imposed by FERC in Order No. 743, it will not be possible for the SDT to conduct such an analysis within the time available. Accordingly, WOEEC agrees with the approach taken by the SDT, which is to propose a Phase II of the standards development process that would address the generator threshold issue and several other technical issues that have arisen during the current process. As long as Phase II proceeds expeditiously, WOEEC is prepared to support the BES definition as proposed by the SDT. While WOEEC supports the overall approach adopted by the SDT and much of the specific language incorporated into the second draft of the BES definition, we believe the second draft would benefit from further clarification or modification in a number of respects, most of which are detailed in our subsequent answers. Further, we believe a workable Exclusion Process is essential for a BES Definition that will meet the legal requirements of FPA Section 215, especially for systems operating in the Western Interconnection. As detailed in our previous comments, WOEEC believes a 200kV threshold would be more appropriate for WECC than a 100kV threshold. In addition, a 200kV threshold for the West is backed by solid technical analysis conducted by the WECC Bulk Electric System Definition Task Force, and repeated claims that there is no technical analysis to support this view are therefore incorrect. That said, we raise the issue here to emphasize the importance of the Exclusions for Local Networks and Radial Systems and the Exceptions process. These Exclusions and the Exceptions are essential for a definition that works in the Western Interconnection because the core definition will be over-inclusive in our region. As long as those Exclusions and the Exceptions Process are retained in a form substantially equivalent to those produced by the SDT at this juncture, WOEEC will support the SDT’s proposal.

Yes

We support the SDT’s changes to the first Inclusion because it is more clear and simple than the initial approach. That being said, we suggest that an additional sentence of clarification would help avoid future controversy about the meaning of Inclusion 1. As we understand it, the BES intends to include transformers only if both the primary and secondary terminals operate at 100kV or above, which is why the definition uses the word “and” (“the primary and secondary terminals”). We support this approach since it would exclude transformers where the secondary terminals serve distribution loads, and which therefore function as distribution rather than transmission facilities. We believe the SDT’s intent would be clarified by adding a sentence at the end of Inclusion 1 that reads: “Transformers with either primary or secondary terminals, or both, that operate at or below 100kV are not part of the BES.” This language will help ensure that there is no controversy over whether the SDT’s use of the word “and” in the phrase “the primary and secondary terminals” was intentional. We also support the SDT’s proposal to develop detailed guidance concerning the point of demarcation between BES and non-BES elements in the Phase II SAR. In this regard, we note that, while Inclusion 1 at least implicitly suggests that the dividing line between BES and non-BES Elements should be at

the transformer where transmission-level voltages are stepped down to distribution-level voltages, we believe further clarification of this point of demarcation between the BES and non-BES Elements is necessary. Many different configurations of transformers and other equipment that may lie at the juncture between the BES and non-BES systems. If the point of demarcation is designated at the transformer without further elaboration, many entities that own equipment on the high side of a transformer will be swept into the BES, and thereby exposed to inappropriately stringent regulations and undue costs. For example, distribution-only utilities commonly own the switches, bus, and transformer protection devices on the high side of transformers where they take delivery from their transmission provider. Ownership of these protective devices and high-voltage bus on the high side of the transformer should not cause these entities to be classified as BES owners. As the Phase II process moves forward, we commend to the SDT the extensive work performed on the point of demarcation question by the WECC BESDTF. We also support the incorporation of language (“ . . . unless excluded under Exclusions E1 or E3”) making it clear that transformers that are operated as an integral part of a Radial System or Local Network should not be considered BES facilities, regardless of their operating voltage. Further clarification might be achieved by using the phrase “. . . unless the transformer is operated as part of a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2.”

Yes

WOEC supports the changes made in Inclusion 2 and believes that the definition in its current form adds clarity. In particular, we support the SDT’s decision to collapse Inclusions 2 and 3 from the previous draft definition into a single Inclusion that addresses the treatment of generation for purposes of the BES definition. We also support the SDT’s proposal for a Phase II of the BES Definition process that would examine the technical justification for these thresholds and that would establish new thresholds based on a careful technical analysis. It is our understanding that the generator threshold issue will be vetted through the complete standards development process. We agree with this approach because if the generator threshold is treated as merely an element of NERC’s Rules of Procedure, it can be changed with considerably less process and industry input than the Standards Development Process. Compare NERC Rules of Procedure § 1400 (providing for changes to Rules of Procedure upon approval of the NERC board and FERC) with NERC Standards Process Manual (Sept. 3, 2010) (providing for, e.g., posting of SDT proposals for comment, successive balloting, and super-majority approval requirements). See also Order No. 743-A, 134 FERC ¶ 61,210 at P 4 (2011) (“Order No. 743 directed the ERO to revise the definition of ‘bulk electric system’ through the NERC Standards Development Process” (emph. added)). Addressing all aspects of Phase II through the Standards Development Process will improve the content of the definition by bringing to bear industry expertise on all aspects of the definition and will ensure that, once firm guidelines are established, they can be relied upon by both industry and regulators without threat that they will be changed with little notice and little process. WOEC believes further clarification of the proposed language would be appropriate. The SDT proposes continued reliance upon the thresholds that are used in the NERC Statement of Compliance Registry Criteria for registration of Generation Owners and Generation Operators, which is currently 20 MVA for an individual generation unit and 75 MVA for multiple units on a single site. Conceptually, we are concerned about this approach because, as we understand it, the purpose of the Compliance Registry is to sweep in all generators that might be material to the reliable operation of the BES, and not to definitively determine whether a given generator is, in fact, material to the reliable operation of the BES. As the SCRC itself states, the SCRC is intended only to identify “candidates for registration.” SCRC at p.3, § 1 (emph. added). Accordingly, we believe that the generator threshold determined in Phase II should be incorporated directly into the BES Definition rather than being incorporated by reference from the SCRC. We also believe that the specific language proposed by the SDT could be further clarified. The SDT proposes that generation be included in the BES if the “Generation resource(s)” has a “nameplate rating per the ERO Statement of Compliance Registry.” We understand this language is intended to be a placeholder for the results of the technical analysis that would occur in Phase II but we believe simply stating that the threshold will be “per the ERO Statement of Compliance Registry” is ambiguous. Further, for the reasons noted above, we believe the threshold should be part of the BES Definition, and should not simply be a cross-reference to the SCRC (and, given the different purposes of the BES Definition and the SCRC, it is not clear that the same threshold should be used in both). We therefore propose that Inclusion 2 be rewritten to state: “Qualifying Individual Generation Resources or Qualifying Aggregate Resources connected at a voltage of 100kV or above.” Two definitions would then be added to the note at the end of the definition to read as follows: For purposes of this BES Definition, Qualifying

Individual Generation Resources means an individual generating unit that meets the materiality threshold to be included in this definition or, in the absence of such a materiality threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of such a resource as a Generation Owner under the ERO Statement of Compliance Registry Criteria. For purposes of this BES Definition, Qualifying Aggregate Generation Resources means any facility consisting of one or more generating units that are connected at a common bus that meets the materiality threshold to be included in this definition, or, in the absence of such a threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of multiple-unit generator as a Generation Owner under the ERO Statement of Compliance Registry Criteria. The "materiality threshold" is intended to refer to the generator threshold developed in Phase II. We suggest using definitions in this fashion for several reasons. First, we believe the language we suggest more clearly states the intention of the SDT, which we understand is to classify generation units as part of the BES if they are necessary for operation of the BES, but to exclude smaller generating units because they are not material to the operation of the interconnected transmission grid. Second, we believe use of the defined terms better reflects the intention of the SDT to reserve the specific question about generator thresholds to the technical analysis that will occur in Phase II without having to revise the BES Definition at the end of that process. That is, the definitions are designed to allow the SDT to include revised thresholds in the definition at the conclusion of the Phase II process based upon the technical analysis planned for Phase II, and the revised thresholds will be automatically incorporated into the BES Definition if the language we suggest is used. The thresholds used in the SCRC would only be a fall-back, to be used only until Phase II is completed. Third, the definitions can be incorporated into other parts of the BES Definition, which will add consistency and clarity. As noted in our answers to several of the questions below, the specific 75 MVA threshold is retained in several of the Exclusions and Inclusions, and we believe the industry would be better served if the revised thresholds arrived at after technical analysis in Phase II are automatically incorporated into all relevant provisions of the BES Definition. There is no reason for the SDT to continue to rely on the 75 MVA threshold once the analysis planned for Phase II on the threshold issue is completed. Fourth, the phrase "or that meets the materiality threshold to be included in this definition" is intended to preserve the SDT's flexibility to make a determination that generators below a specific threshold are not "necessary to" maintain the reliability of the interconnected transmission system, and to incorporate that finding as part of the definition itself, even if a different threshold is used in the SCRC to identify potential candidates for registration. Accordingly, our proposed language makes clear that a specific threshold in the definition controls over any threshold that might be included in the SCRC. For the reasons stated above, we believe it is highly desirable to include any material threshold in the BES Definition itself rather than relegating the threshold to the SCRC, which is merely a procedural rule rather than a full-fledged Reliability Standard. Finally, we agree with the SDT's decision to examine the question of where the line between BES and non-BES Elements should be drawn more closely in Phase II under the rubric of "contiguous vs. non-contiguous BES," and commend the work of the Project 2010-07 Standards Drafting Team and the GO-TO Team as a good starting point for the SDT's analysis on this issue. We understand Inclusion 2 would classify generators exceeding specific thresholds as part of the BES, but would not necessarily require facilities interconnecting such generators to be part of the BES. As discussed more fully in our answer to Question 9, based on extensive technical analysis that has already been performed by the NERC Project 2010-07 Standards Drafting Team and its predecessor, the NERC "GO-TO Team," regulating as part of the BES a dedicated interconnection facility connecting a BES generator to the interconnected bulk transmission grid will result in an unnecessary regulatory burden that produces considerable expense for the owner of the interconnection facility with little or no improvement in bulk system reliability. We also believe the clauses at the end of Inclusion 2 are somewhat confusing and that greater clarity would be achieved by changing ". . . including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100kV or above" so that the Inclusion covers transformers with terminals "connected at a voltage of 100kV or above, including the generator terminal(s) on the high side of the step-up transformer(s) if operated at a voltage of 100kV or above."

Yes

WOEC supports the removal of the Cranking Path language in I3. As noted in our response to Question 9, there is no reason to classify as BES the facilities interconnecting a BES generator to the bulk interstate system. A Cranking Path is simply a specific type of such an interconnection facility.

Yes

WOEC supports the revised language generally, but believes additional changes would make the language clearer. Specifically, we believe Inclusion 4 should not incorporate a hard 75 MVA generation threshold (i.e., “resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)”). Instead, we urge the SDT to replace this language with the defined term “Qualifying Aggregate Generation Resources,” which we discuss in more detail in our response to Question 3. This language will preserve the SDT’s ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. More generally, we are not certain what is accomplished by Inclusion 4 that is not already accomplished by Inclusion 2, which also addresses whether generation should be defined as BES. The SDT’s stated concern is with variable generation units such as wind and solar plants. It is not clear to us why this concern is not fully addressed in Inclusion 2, which addresses multiple generation units connected at a common bus, the configuration of most variable generation plants with multiple units. We are also concerned that the language, as proposed, could have unintended consequences and improperly classify local distribution systems as BES in certain circumstances. This is because multiple distributed generation units could render a local distribution system a “collector system” and the entire system the equivalent of an aggregated generation unit, causing the local distribution system to be improperly denied status as a Local Network. If many different distributed generation units are connected to a local distribution system, it is very unlikely that more than a few of those units would fail simultaneously, and it is therefore unlikely that multiple generation units would produce a measureable impact on the interconnected bulk transmission system, especially if the units individually do not otherwise exceed the materiality threshold to be established by the SDT in Phase II. Further, we are concerned that, if small distributed generation units become the industry norm, Inclusion 4 could unintentionally sweep in local distribution systems, especially where local policies favor the growth of small solar or other renewable generation systems for public policy reasons. Finally, we suggest that the SDT add the phrase “. . . unless the dispersed power producing resources operate within a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2.” This language, which parallels the language included at the end of Inclusion I1, would make clear that dispersed small-scale generators scattered throughout a Radial System or Local Network serving retail load would not convert the Radial System or Local Network into a BES system, even if the aggregate capacity of those small generators exceeds the relevant threshold.

No

WOEC has several concerns about the new language in Inclusion 5. First, because Reactive Power devices produce power, they are “power producing resources” and we therefore believe Inclusion 5 is duplicative of Inclusion 4, which addresses “power producing devices.” Second, there is no capacity threshold specified in Inclusion 5 for Reactive Power devices that would be considered part of the BES. This is inconsistent with the approach taken in the balance of the definition, where thresholds are specified for generators and other types of power producing devices. Third, WOEC believes the appropriate threshold for inclusion or exclusion of Reactive Power devices from the BES should be subject to the same technical analysis that will cover generators in the Phase II process. Finally, WOEC believes this issue should be addressed in Phase 2 since there is not technical justification or analysis done to determine the thresholds. WOEC strongly believes that there should be technical justification for thresholds for this issue and all other issues.

Yes

WOEC continues to strongly support the radial system exclusion, which is necessary as a legal matter, because, among other reasons, FERC in Orders No. 743 and 743-A has required that the existing radial exemption in the NERC Statement of Compliance Registry Criteria be maintained. As a practical matter, radial systems are used for service to retail loads, usually in remote or rural areas, and not for the transmission of bulk power. Hence, operation of the radials has little or nothing to do with the reliable operation of the interconnected bulk transmission network. We also support the inclusion of the note discussing normally open switches because this language provides needed clarity for a common radial system configuration. We also agree with the substantive thrust of this language, which is that a radial system should not be considered part of the BES if it is interconnected at a single point, even if there is an alternative point of delivery that is normally open. While we support the Exclusion for Radial Systems, we believe several clarifications and refinements are necessary. (1) The term “transmission Elements” in the initial paragraph should be changed to “Elements.” Radial

systems are not transmission systems and including the word “transmission” in the Radial System exclusion is therefore unnecessary and confusing. (2) Subparagraph (b) of Exclusion 1 refers to “generation resources . . . with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)”. We urge the SDT to replace this language with the defined term “Qualifying Aggregate Generation Resources,” discussed in more detail in our response to Question 3. This language will preserve the SDT’s ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. (3) Subparagraph (b) also seems to assume that if a Radial System contains a generator exceeding the 75 MVA threshold, the Radial System itself must be included in the BES because it links the generator to the interconnected bulk transmission system. As discussed more fully in our response to Question 9, below, NERC’s Project 2010-17 Standards Drafting Team and GO-TO Task Force have both concluded that this assumption is unwarranted. (4) The “Note” as drafted by the SDT indicates that “a normally open switching device between radial systems” will not serve to disqualify the Radial from exclusion under Exclusion 1. As discussed above, WOEC strongly supports the note conceptually. However, we believe this language should be included in a separate subparagraph (d), rather than a note, because treatment as a “note” suggests it is less important than other portions of the Exclusion. We also suggest the language be changed to read: (d) Normally-open switching devices between radial elements as depicted and identified on system one-line diagrams does not affect this exclusion. This will make clear that a radial with more than one normally-open switch connecting it to another radial is still a radial. From the perspective of the BES Definition, the key question is whether switches operating between Radials are normally open, not whether there is more than one normally-open switch.

Yes

WOEC supports the revised language. The language provides clarity regarding the BES status of customer-owned cogeneration facilities. However, WOEC urges the SDT to remove the reference to the 75 MVA threshold and replace it with the defined term “Qualifying Aggregate Generation Resources” or some equivalent language for the reasons stated in our responses to Questions 3, 5, and 7. In addition, we are concerned that Exclusion 2 will place local distribution utilities in a difficult position because, under Exclusion 1 or Exclusion 3 as drafted, they could lose their status as a Radial System or a Local Network through the actions of a customer constructing behind-the-meter generation. With respect to Radial Systems, the appearance of behind-the-meter generators could cause the Radial System to exceed the thresholds specified in subparagraphs (b) and (c) of Exclusion 1 through no fault of the Radial System owner. Similar, a Local Network could lose its status because behind-the-meter generation could be of sufficient size that power moves into the interconnected grid in certain hours or under certain contingencies, rather than moving purely onto the Local Network, as required in subparagraph (b) of Exclusion 3. The Exclusions for Radial Systems and Local Networks should be made consistent with the Exclusion for behind-the-meter generation. There is no technical reason to believe the power flowing from a behind-the-meter customer-owned generator will have less impact on the bulk system than an equivalent-sized generator owned by a utility operating a Radial System or LN.

Yes

WOEC strongly supports the exclusion of Local Networks (“LNs”) from the BES. The conversion of radial systems to local networks should be encouraged because networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. If the BES definition were to provide an exclusion for radials without providing a similar exclusion for LNs, however, it would discourage networking local distribution systems because of the significantly increased regulatory burdens faced by the local distribution utility if it elected to network its radial facilities. By placing radial systems and LNs on the same regulatory footing, the proposed definition will ensure that decisions about whether to network radial systems are made on the basis of costs and benefits to the retail customers served by those radials, and not on the basis of disparate regulatory treatment. Consumers would ultimately benefit. WOEC also supports specific refinements made to the LN exclusion by the SDT in the current draft of the BES definition. In particular, WOEC supports the clarification of the purposes of a LN. The current draft states that LNs connect at multiple points to “improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system.” WOEC supports this change in language because it reflects the fundamental purposes of a LN and emphasizes one of the key distinctions between LNs and bulk transmission facilities, namely, that LNs are designed primarily to serve local retail load

while bulk transmission facilities are designed primarily to move bulk power from a bulk source (generally either the point of interconnection of a wholesale generator or a the point of interconnection with another bulk transmission system) to one or more wholesale purchasers. WOEEC believes further improvement of the language could be achieved with additional modifications and clarifications. With respect to the core language of Exclusion 3, we believe the language making a "group of contiguous transmission Elements operated at or above 100kV" the starting point for identifying a LN would be improved by deleting the term "transmission" from this phrase. This is so because LNs are not used for transmission and the use of the term "transmission Elements" is therefore both confusing and unnecessary. There would be no room for argument about what the SDT intended by including the word "transmission" if the word is deleted and the Exclusion applies to any "group of Elements operated at 100kV or above" that meets the remaining requirement of the Exclusion. Further, any definitional value that is added by using the term "transmission Elements" is accomplished by using that term in the core definition, and there is no reason to carry the term through in the Exclusions. WOEEC also believes that subparagraphs (a) and (b) are redundant, because whatever protection is offered by the generation limit in subparagraph (a) is duplicated by the limit in subparagraph (b) requiring no flow out of the LN. We believe the SDT can eliminate subparagraph (a) of Exclusion 3 and simply rely on subparagraph (b) because if power only flows into the LN even if it interconnects more than 75 MVA of generation, the interconnected generation interconnected will have no significant interaction with the interconnected bulk transmission system. It will only interact with the LN. And, with the advent of distributed generation, it is easy to foresee a situation in which a large number of very small distributed generators are interconnected into a LN, so that the aggregate capacity of these generators exceeds 75 MVA. However, because the generators are small and dispersed and, under the criterion in subparagraph (b), would be wholly absorbed within the LN rather than transmitting power onto the interconnected grid, those generators would not have a material impact on the grid. We also suggest that subparagraph (b) of Exclusion 3 could be more clearly drafted. Subparagraph (b), as part of the requirement that power flow into a LN rather than out of it, includes this description: "The LN does not transfer energy originating outside the LN for delivery through the LN." We understand this language is intended to distinguish a LN from a link in the transmission system – power on a transmission link passes through the transmission link to a load located elsewhere, while power in a LN enters the LN and is consumed by retail load within the LN. While we agree with the concept proposed by the SDT, we believe the language would be clearer if it read: "The LN does not transfer energy originating outside the LN for delivery through the LN to loads located outside the LN." We believe the italicized language is necessary to distinguish between a transmission system, where power that originates outside a system is delivered through the system and passes through the system to a sink located somewhere outside the system, from a LN, in which power originating outside the LN passes through the LN and is delivered to retail load within the LN. To put it another way, the italicized language helps distinguish a transmission system from an LN, in which the LN "transfers energy originating outside the LN for delivery through the LN to loads located within the LN." We also believe the language of subparagraph (a) of Exclusion 3 could be improved. Subparagraph (d) would make LNs part of the BES if they interconnect "non-retail generation greater than 75 MVA (gross nameplate rating)." For the reasons stated in our responses to Questions 3, 5 and 7, we urge the SDT to replace the reference to a hard 75 MVA threshold with the defined term "Qualifying Aggregate Generation Resources" or some equivalent. We are also uncertain what is meant by the use of the term "non-retail generation" in subparagraph (a). From context, we believe the SDT considers "non-retail generation" to be the equivalent of generation that is located behind the retail meter, usually but not always owned by the customer and used to serve the customer's own load. We therefore suggest that the SDT replace the term "non-retail generation" with "generation located behind the retail customer's meter." Similarly, we are unsure what is meant by the phrase "the LN and its underlying Elements." We believe the phrase "and its underlying Elements" could simply be deleted from the definition without loss of meaning. In the alternative, the SDT might consider using the phrase "the LN, including all Elements located on the distribution side of any Automatic Fault Interrupting Devices (or other points of demarcation) separating the LN from the bulk interstate transmission system." We believe this phrase more accurately reflects the SDT's intent, which appears to be that generation exceeding 75 MVA in aggregate capacity interconnected anywhere within the LN disqualifies that LN from being excluded from the BES under Exclusion 3. WOEEC also believes that both subparagraphs (a) and (b) of Exclusion 3 could be safely eliminated as long as subparagraph (c) is retained. Subparagraph (c) makes a LN part of the BES if it is classified as a Flow Gate or Transfer Path. Flow Gates and Transfer Paths are, by definition, the key facilities that

allow reliable transmission of bulk electric power on the interconnected grid. If a LN has not been identified as either a Flow Gate or a Transfer Path, it is unlikely the LN is necessary for the reliable transmission of electricity on the interconnected bulk system. Apart from these specific improvements that we believe could be achieved by modifying the language of Exclusion 3, we believe the SDT may need to re-examine certain assumptions that appear to underlie the current draft. Specifically, subparagraph (a) suggests that if BES generation is embedded within a LN, the LN itself must also be BES. But two NERC bodies have already addressed similar questions and concluded there is no technical basis for such concerns. NERC's Standards Drafting Team for Project 2010-07 and its predecessor, the "GO-TO Task Force" were formed to address how the dedicated interconnection facilities linking a BES generator to high-voltage transmission facilities should be treated under the NERC standards. The GO-TO Team concluded that by complying with a handful of reliability standards, primarily related to vegetation management, reliable operation of the bulk interconnected system could be protected without unduly burdening the owners of such interconnection systems. Therefore, there is no reason, according to the GO-TO Team, that dedicated high-voltage interconnection facilities must be treated as "Transmission" and classified as part of the BES in order to make reliability standards effective. See Final Report from the NERC Ad Hoc Group for Generator Requirements at the Transmission Interface (Nov. 16, 2009) (paper written by the GO-TO Task Force). Similarly, the Project 2010-07 Team observed that interconnection facilities "are most often not part of the integrated bulk power system, and as such should not be subject to the same level of standards applicable to Transmission Owners and Transmission Operators who own and operate transmission Facilities and Elements that are part of the integrated bulk power system." White Paper Proposal for Information Comment, NERC Project 2010-07: Generator Requirements at the Transmission Interface, at 3 (March 2011). Requiring Generation Owners and Operators to comply with the same standards as BES Transmission Owners and Operators "would do little, if anything, to improve the reliability of the Bulk Electric System," especially "when compared to the operation of the equipment that actually produces electricity – the generation equipment itself." Id. We believe that interconnection of BES generators within a LN is analogous and that, based on the findings of the Project 2010-07 and GO-TO Teams, automatically classifying a LN as "BES" simply because a large generator is embedded in the LN will result in substantial overregulation and unnecessary expense with little gain for bulk system reliability. If anything, generation interconnected through a LN is less likely to produce material impacts on the interconnected bulk transmission system than the equivalent generator interconnected through a single dedicated line because an LN is interconnected to the bulk system at several points, so that if one interconnection goes down, power can still flow from the BES generator to the bulk system on other interconnection points. Where a dedicated interconnection facility is involved, by contrast, if the interconnection line fails, the generator is unavailable to the interconnected bulk system. Similarly, we suggest that the SDT re-examine the assumptions underlying subparagraph (b), which seems to suggest that a local distribution system cannot be classified as a Local Network if power flows out of that system at any time, even if the amount is de minimis, the outward flow is only for a few hours, a year, or the outward flow occurs only in an extreme contingency. Accordingly, we suggest that the initial clause of subparagraph (b) be revised to read: "Except in unusual circumstances, power flows only into the LN." Finally, we note that the LN exclusion must not operate in any way as a substitution for the statutory prohibition on including "facilities used in the local distribution of electric energy" in the BES. Therefore, even with the LN exclusion, the SDT must retain this statutory language in the core definition of the BES, as discussed in our answer to Question One. If a certain piece of equipment is a "facility used in the local distribution of electric energy," then it is not part of the BES in the first instance, and so consideration of the LN Exclusion, or of any other Exclusion, any Inclusion, or any Exception, would be both unnecessary and uncalled for.

Yes

WOEC supports the revised language because retail reactive devices are used to address local customer or retail voltage issues, rather than voltage issues on the interconnected bulk grid, and such local devices should therefore be excluded from the BES definition.

No

WOEC extends its thanks to the SDT and to the many industry entities that have actively participating in the Standards Development Process. WOEC supports the current draft and believes, with certain refinements discussed in our comments, that the definition will serve the industry and reliability regulators well for many years to come. In addition, as noted earlier, WOEC is encouraged that the

20/75 MVA generation thresholds referred to in the NERC Statement of Compliance Registry Criteria, which have been relied upon by the SDT largely as a matter of necessity, will be reviewed and a technical assessment will be performed to identify the appropriate generation unit and plant size threshold to ensure a reliable North America. Finally, we understand that the Rules of Procedure Team will continue to move forward with developing an Exceptions Process that will complement the BES Definition and ensure that, to the extent the BES Definition is over-inclusive, facilities that should not be classified as BES will be excluded from the BES. Because the Exceptions Process is integral to a workable BES Definition, we support the current process for moving forward with the Exceptions Process and the BES Definition on parallel paths. We note that WOEC specifically supports the changes made by the SDT in the "Effective Date" provision of the BES Definition, which shortens the effective date of the new definition to the beginning of the first calendar quarter after regulatory approval (as opposed to the first calendar quarter twenty-four months after regulatory approval), with a 24-month transition period. WOEC supports this conclusion because it will allow entities seeking deregistration under the terms of the new BES definition to obtain the benefits of the new definition without an unreasonable wait, while allowing any entities that may be newly-classified as BES owners or operators sufficient time to come into compliance with newly-applicable Reliability Standards. WOEC also supports the 24-month transition period for the reasons laid out by the SDT.

1. If a 50 MVA generator that is included per I2 is connected to an excluded radial system, would the generator be excluded or included per E1b)? If yes, then the language "unless excluded under Exclusion E1 and E3" in I1 needs to be added to I2, I4, and I5. 2. Non-retail generation in E1c) was described behind-the-meter generation in the Webinar. The term "non-retail generation" should be defined because one could infer that generation defined by E2 is "retail generation." Also, is the 75 MVA limit intended apply to the generator (as stated) or its net capacity as defined in E2? If it means the generator MVA, does that mean that generation excluded in E2 cannot exceed 75 MVA when connected to an excluded radial system? 3. In general, the definition needs to better define the impact that "exclusion" has on a different "inclusion" or "exclusion."

Yes
However, one of the FERC directives in Order 743 charged NERC with delineating the difference between transmission and distribution. The Inclusions and Exclusions are a step in that direction, but this subject will need more consideration in Phase II.
Yes
No
Since an aggregate of 75 MVA is allowed at a single site, there is no basis for maintaining the 20 MVA for a single generator. The proposed MOD-026 assigns thresholds by region that are much higher than 20 MVA for modeling purposes. Since modeling generally would require more granularity than what is necessary for the reliable operation of the interconnected transmission system (BES), the SDT might want to review the threshold basis for NERC Project 2007-09 (Generator Verification).
Yes
Yes
To distinguish this Inclusion from Inclusion I2, the SDT might want to clarify that the collection system (usually at voltage below 100 KV anyway) is not part of the BES—just the resources and any transformers included by I1, if this is indeed the intent of this Inclusion.
Yes
Yes
This is a much needed change from the first posting, as this will maintain the status quo referred to in the introduction text.
Yes
Yes
This Exclusion and Exclusion E1 aid in the delineation of distribution versus transmission.
Yes
This is a needed exception to Inclusion I5 as these reactive power resources are used by retail customers for power factor correction at their own facilities in order avoid imposed power factor penalties.
Yes
It might be worthwhile to explain the relationship (timeline) between the BES Definition implementation plan and the compliance implementation plan proposed in the BES RoP team's new Appendix 5C for the NERC Rules of Procedure.

No
The proposed revision to the definition maintaining this bright line of 100 kV would expand significantly what is considered to be BES in HQT's case (the amount of added facilities could be ten times more). Since the main structure of Quebec system is included in the BES where the best norms and standards apply, the inclusion in the BES of sub-systems at lower voltage and including generation will not bring significant impact on the reliable operation of the interconnected system, because of the nature of the Quebec Interconnection. Furthermore for HQT's system, the proposed BES definition combined with the exception procedure are presently incompatible or at least inconsistent with the regulatory framework applicable in Quebec. The proposed changes have not address this concern, neither the SDT's responses to our previous comments last May (Q.1 and 12). We reiterate that the definition and the exception procedure shall be determined by Quebec's regulator, the Régie de l'Énergie du Québec, (Quebec Energy Board) which has the responsibility to ensure that electric power transmission in Quebec is carried out according to the reliability standards

it adopts. Per se, it would be necessary that E1 and E3 grant exclusions with much higher level of generation. It would also be necessary to allow for several levels of application for the Reliability Standards, in accordance with the Régie de l'énergie du Québec approach: the Bulk Power System (BPS) as determined using an impact-based methodology, the Main Transmission System (MTS), and other parts of Regional System. Standards related to the protection system (PRC-004-1 and PRC-005-1) and those related to the design of the transmission system (TPL 001-0 to TPL-004-0) shall be applicable to the first level, but all other reliability standards shall be applied to the second level, the MTS. The MTS definition is somewhat different than the Bulk Electric System definition, and it includes elements that impact the reliability of the grid, supply-demand balance and interchanges. We argue that it would be necessary for NERC to address the regulatory issues outside of the present context of the SDT and ROP team.

Yes

We believe that automatic inclusion of such generation and the path to connect them to the BES would bring a great amount of facilities in the BES. Generation should be considered on a different level such as "BES Support Elements" and provisions should be made so that some specific reliability standards would apply to them.

Yes

Same comment than Q. 3. Also, since the path to connect the dispersed generation is often done at distribution voltage, that lower voltage path should not be included in BES.

No

No

Even with the modification proposed, it is too much restrictive to refuse exclusion of radial system when they have generator or multiple generating units of aggregate capacity greater than 75 MVA, especially when a system is able to function reliably with the loss of generation much higher than this amount. To count on the exception procedure to exclude radial system with greater generation is risky since no specific criteria have been given to guide such exclusion. In most cases for radial or local system including generation, the path that connects the generation should not be included in the BES. Generators should be allowed to be considered "BES support elements" and reliability standards should apply to them in specific.

Same comment than Q7.

Yes

Yes

In the Implementation plan, it is given only 24 months for compliance after applicable regulatory approval. Considering the possibility that a proposed transition plan may involve commissioning of long term projects, a provision for such situation should be made with longer delay.

Yes

Yes

Yes

While we agree with Inclusion I2, we suggest removing the parentheses enclosing the text "with gross individual..." since their inclusion may lead to an erroneous reading of provision to include generators that do not meet ERO Statement of Compliance Registry Criteria.

No

We thank the SDT for excluding the cranking paths from the BES definition, a point we had raised in our comments to the previous posting. However, we had also disagreed with the inclusion of Blackstart Resources and reiterate our view that their inclusion is superfluous given there is already a designation specific for system restoration covered by an existing standard, to recognize their reliability impacts and to ensure their expected performance. NERC Standards EOP-005-2 stipulates the requirements for testing blackstart resource and cranking paths. This testing requirement suffices to ensure that the facilities critical to system restoration are functional when needed, which meets the intent of identifying their criticality to reliability. We therefore suggest removing Inclusion I3 entirely.

Yes

The revised Inclusion I4 does indeed clarify that there is no requirement for a contiguous BES path from the dispersed generation resources to the point of interconnection to the BES.

Yes

The provisions of Inclusion I5 fully address the concerns we expressed in our previous comments.

No

We support the provisions of E1 in principle but require clarification of some issues and suggest alternative wording in some cases. It is unclear if the connection voltage of generation referred to in E1.b affects whether a radial system could be excluded under E1 although from the context it appears that it would. For clarity we suggest appending "connected at 100 kV or higher." Please provide in the BES definition document an explanation of "non-retail" and "retail" generation used in E1.c. Additionally, despite the fact the revisions to Inclusion I3 (Blackstart Resources) removed any reference to Cranking Paths, Exclusion 1 (b) and (c) both indicate that the exclusion of a radial system would not be allowed if generation identified in I3 were connected to it. This implies that the Cranking Path for this Blackstart Resource would have to be BES. This appears to be an inconsistency. We suggest removing the phrase "not identified in Inclusion I3" in both instances. We disagree with notion that the capacity of generation connected to a radial system ought to determine whether that radial system should be classified as BES. Firstly, it is a given that the generation connected to the subject radial that meets the registry criteria would already be captured within the core BES definition and Inclusion I2. The function served by a radial that is of importance in the current context is that of delivering surplus power to the rest of the bulk power system and so, the impact on the BES of loss of the radial system or its connected generation needs to be considered. In our view, the "BES-status" of the radial itself is immaterial and so too is the aggregate capacity of generation resources connected to it. Detailed arguments regarding impact on the BES can be made in support of an application for an exclusion under the Exception Process, but it would be beneficial to avoid unnecessarily including a radial merely because it has more than 75 MVA of qualifying generation connected to it, without equal consideration of the connected load. To put a "bright line" on the consideration of impact referred to above, we suggest: In E1 (b): Replace "an aggregate capacity less than or equal to 75 MVA (gross nameplate rating)" with "a net capacity provided to the BES of less than or equal to 75 MVA." In E1 (c): Replace "an aggregate capacity of non-retail generation less than or equal to 75 MVA (gross nameplate rating)" with "a net capacity of non-retail generation provided to the BES of 75 MVA." This wording would be consistent with E2 (i). Finally the word "affect" stated in the note accompanying E1 lends itself to mis-interpretation. We therefore suggest the following revision to achieve greater clarity: "This exclusion applies to radial systems connected by a normally open switch."

Yes

No

Consistent with our comments in response to Q7, we propose removing E3 (a) since, as explicitly described in E3 (b), one of the characteristic of the LN is that power flows only into the LN. The level of generation contained within the LN is therefore immaterial, particularly where the most onerous contingency or system operating condition occurring within the LN, results in acceptable BES performance as defined by the applicable criteria of the NERC transmission planning standards. The generation connected within the LN that meets the registry criteria would already be captured within the definition of the BES as provided for in Inclusion I2.

Yes

Yes

We wish to also express our support for phased approach proposed in the draft supplemental SAR. Development of the revised BES definition is an important and complex undertaking. The product of this work is fundamental to establishing the applicability of NERC Reliability Standards. The issues identified for attention in Phase 2 of this project warrant careful investigation and as such allowing additional time to properly research and stakeholder them is justified. The draft Implementation Plan for the BES definition states "Compliance obligations for Elements included by the definition shall begin 24 months after the applicable effective date of the definition." We are concerned that the stated implementation period may be insufficient time to (1) prepare and file exception requests and have these assessed; and (2) in cases where these exception requests are not approved, to develop and complete transition plans for newly identified BES Elements and Facilities, particularly where those plans require major investments for the procurement, installation and commissioning of additional equipment. We therefore propose the following alternative wording for the Implementation Plan: "Compliance obligations for elements included by the definition shall be evaluated and an implementation schedule established within 24 months." Throughout the document various phrases are used to describe generating units/resource, viz. "generation resources", "generating resources", "generating unit" and "power producing resources". Please review these to identify and address any possible inconsistencies.

Rochester Gas & Electric and New York State Electric & Gas

No

The second sentence, "This does not include facilities used in the local distribution of electric energy," is vague and not sufficiently clear for northeast industry expert colleagues to be certain of what is "not included." This sentence seems to apply only to distribution facilities that have already been classified based on the FERC "Seven Factor Test" in Order 888. If so, this sentence be re-written as follows for clarity: "This does not include facilities classified as distribution facilities." For US entities, this classification is clearly delineated in our annual FERC Form 1 filing.

No

We generally agree, but suggest modification to the language of Inclusion I1 to clarify its application for transformers with more than two windings: "Transformers with two or more terminals operated at 100 kV or higher, unless excluded under Exclusion E1 and E3." Based on this wording, transformer tertiary windings would also be BES – is that the intent?

No

Inclusion I2 should remove the reference to the Statement of Compliance Registry Criteria. The definition should stand on its own. I2 should be revised to read: "Generators with a gross nameplate rating of 20 MVA or greater, or a generating plant/facility connected at a common bus, with a gross aggregate nameplate rating of 75 MVA or greater and is directly connected at a voltage of 100 kV or above. BES includes the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100 kV or above." This is consistent with the proposed I2 and the current Compliance Registry Criteria.

No

Inclusion I3 should be changed to include the phrase, "material to," currently in the Statement of Compliance Registry Criteria (Section 3C3). Based on the definition wording, the Generator Step-Up transformer (GSU) would not be BES if the generator would not otherwise already be included as BES under another definition provision.

No

The term "common point" needs clarification and/or definition. (e.g., is it intended to apply to the risk of single mode failure, where all the resources could be lost for a single event?) Some northeast industry expert colleagues interpret I2 to mean the collector system itself needs to be 100 kV or above in order to be BES. I2 seems to not include the collector system itself in BES. I4 be restated as follows: "Dispersed power producing resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating) utilizing a collector system connected at a common point. BES includes the interconnecting substation with the step-up transformer(s) connected at a voltage of 100 kV or above." [alternatively, replace the bold italics with, "generator terminals through the high-side of"] Also note that some wind collector systems require supplemental dynamic reactive resources or

special control system to meet reliability standards. As written, these reactive resources or controls may not be considered to be BES.

Yes

There is no such thing as “supplying or absorbing Reactive Power” but the intended meaning is sufficiently clear since it is industry ‘shorthand’. Suggest alternative wording: “Static or dynamic Reactive Power resources that are connected at 100 kV or higher, or...”

No

E1 needs to be revised to make it less confusing. “Radial systems” leaves the impression that E1 is not simply a “radial line exclusion”, because of the plural and the word “systems.” Northeast industry expert colleagues are not clear at all what this sentence specifies: “A group of contiguous transmission Elements that emanates from a single point of connection of 100 kV or higher.” • Does E1 apply only to a single radial transmission line (and its associated “group of Elements”)? • Alternatively, does E1 apply to multiple radial lines “emanating from” the same substation regardless of the bus configuration – would a ring bus or a two-bus system that is connected with a tie breaker be considered as “a single point of connection”? This definition is not clear. Clarity is imperative. E1(c) should define or replace the term “non-retail”. Industry needs clarity on exactly what generation this applies to, in order to properly apply this definition. The Note referring to the “Normally Open switch” needs further clarification. As written, it seems to conflict with FERC order 743, paragraph 55: “While commenters would like to expand the scope of the term “radial” to exclude certain transmission facilities such as tap lines and secondary feeds via a normally open line, we are not persuaded that such categorical exemption is warranted.” E1 should be restated as follows: “Radial systems: A single transmission line or transformer not otherwise identified in the Inclusions above, with a single point of connection of 100 kV or higher and: a) Only serves Load. Or, b) Only includes generation resources, not identified in the Inclusions above. Or, c) Both serves Load and only includes generation resources, not identified in the Inclusions above.

No

E2 should be consistent with the Statement of Compliance Registry Criteria. References to Balancing Authority, Generator Owner, and Generator Operator should not be included in the BES definition. “Net capacity” is unclear – must flow never exceed 75 MVA on an instantaneous or integrated hourly energy basis per either design or operating experience? There is a potential for hundreds of MW to be interconnected at a customer facility, with the “net capacity” (= flow into the transmission system? Instantaneous? Annual average? On an integrated hourly basis at any hour?) being less than 75 MVA – are hundreds of MW of generation “not material” to BES reliability? The conditions under which direction of flow (i.e., “net capacity”) is assessed are critical, but E2(i) is silent on this. In E2(ii), the “and”, “or”, and “or” are not clear – what are the necessary terms of the referenced “binding obligation” and what is an “applicable regulatory authority”? Are “standby” and “back-up” and “maintenance” power services independently defined and provided by a GOP, GO, or BA? Northeast industry expert colleagues do not understand the relevance of E2(ii) to BES reliability. E2 should be restated as follows: “A generating unit or multiple generating units that serve all or part of retail customer Load with electric energy on the customer’s side of the meter if the flow to or from the BES never exceeds 75 MVA”

No

“Local Network” is capitalized (network not capitalized at the beginning of E3) throughout E3, yet it is not defined in the NERC Glossary. This exclusion is vague. This exclusion applies to a network with “multiple points of connection” with the purpose “to improve the level of service to retail customer load” – this phrase is intent-based and not reliability-based – most/all transmission “improves service” compared to it not being there. In essence, this exclusion can be obtained if a portion of the network: 1. Doesn’t have significant generation (again, “non-retail” phrase is unclear) 2. Power only flows “into” this portion of the network, and not (ever? Even under any TPL design contingencies?) “out.” Is this considering only pre-contingency steady state conditions? During contingency conditions and for the period following a contingency the LN could supply power to other parts of the network depending on the nature of the contingency. The conditions under which direction of flow is assessed are critical, but E3(b) is silent on this. 3. This portion of the network is not part of a monitored transmission interface This “Local Network Exclusion” is supported by a technical analysis which relied on transfer distribution factors (see

[http://www.nerc.com/docs/standards/sar/bes\\_definition\\_technical\\_justification\\_local\\_network\\_20110](http://www.nerc.com/docs/standards/sar/bes_definition_technical_justification_local_network_20110)

819.pdf on the NERC BES Definition standard page [http://www.nerc.com/filez/standards/Project2010-17\\_BES.html](http://www.nerc.com/filez/standards/Project2010-17_BES.html) ). This transfer distribution factor (TDF) method was rejected by FERC in Order 743. Paragraph 85 of the Order states: "Given the questionable and inconsistent exclusions of facilities from the bulk electric system by the material impact assessment and the variable results of the Transmission Distribution Factor test proposed in NPCC's compliance filing in Docket No. RC09-3, there are no grounds on which to reasonably assume that the results of the material impact assessment are accurate, consistent, and comprehensive.<sup>93</sup> Additionally, we have noted how the results of multiple material impact tests can vary depending on how the test is implemented." Unless E3 is made more specific and clear, it should be stricken.

No

Consider using other wording to replace "retail".

Yes

If the definition and inclusions and exclusions are not sufficiently specific and clear, stakeholders will flood NERC and RROs with interpretation requests and/or apply the definition and its inclusions or exclusions incorrectly. Explanatory figures with one-line diagrams should be developed and shared to illustrate the system configurations included and excluded in this BES Definition. This would be very helpful for definition clarity. This should be done as part of an "Application Guide" for the BES Definition – this has precedence in CIP-002 version 5. Attached is a sample set of one-line diagrams with interpretations based upon the inclusions and exclusions developed by Northeast Power Coordinating Council members for discussion purposes as an example, but note that there is not a uniform agreement on these diagrams based on the BES Definition as written, due to lack of clarity.

Group

David Kiguel

Hydro One Newtoeks Inc.

No

Although we agree with the concept and commend the SDT for developing explicit inclusions and exclusions as part of the definition, we believe there are several outstanding issues and concerns listed as our response to Q11 that need to be addressed by the SDT and by NERC as the ERO.

Yes

No

No

We do not agree with the thresholds of 20 MVA for a single unit and 75 MVA aggregate at a plant, carried forward from the compliance registry. We understand the suggested phased approach and expect that the issue will be dealt with at that future time. With the exception of units that are must runs for reliability reasons, we suggest that the SDT should consider units smaller than 75 MVA or x MVA is designated as BES support element and not BES element. These units should only be required to comply with a handful of relevant NERC Standards. For example, • Voltage and frequency ride through capability • Voltage control (AVR, etc.) • Underfrequency trip setting • Protection relay setting coordination • Data submission for modeling; verification of capability and model These smaller and geographically dispersed generating resources should neither be designated as BES element nor be required to have its connection path be designated as BES. We suggest removing the parentheses enclosing the text "with gross individual..." since their inclusion may lead to an erroneous reading of provision to include generators that do not meet ERO Statement of Compliance Registry Criteria.

No

We agree with the SDT in excluding the cranking paths from the BES definition, a point we had raised in our comments to the previous posting. We also disagree with the inclusion of blackstart resources and reiterate our view that their inclusion is superfluous given there is already a designation specific for system restoration covered by an existing standard, to recognize their reliability impacts and to ensure their expected performance. NERC Standard EOP-005-2 stipulates the requirements for testing blackstart resources and cranking paths. This testing requirement suffices to ensure that the facilities critical to system restoration are functional when needed, which meets the intent of identifying their criticality to reliability. We therefore suggest completely removing Inclusion I3. We suggest the SDT to drop I3 on the basis that: • The availability and performance expectations of blackstart resources are ensured by existing related standards: and • Unless they meet the BES definition under inclusion

I2, there is no perceived reliability value in everyday operation of the BES.

No

Although we agree with the I4 concept, we suggest that the SDT should consider that this category primarily includes wind and solar farms and their collector system. We believe these facilities should not be included as BES elements but rather as supporting elements (see comments under I2) for the following reasons: a) Any additional benefit of classifying these resources as BES is insignificant for the reliability of supply (capacity and energy), considering the intermittent and widely variable nature of these resources. The planning and operational standards and practices make sure that their unavailability or unexpected (sudden) loss, which are significantly more likely due to the natural elements than those due to mechanical or electrical causes, will not jeopardize the reliability of the supply; and b) The reliability of the aspects of the collector system of these resources (their impact on reliability of the bulk transmission system) is not different from that of distribution systems (load serving feeders) which are excluded from the BES. We agree with the revised portion of Inclusion I4 which does indeed clarify that there is no requirement for a contiguous BES path from the dispersed generation resources to the point of interconnection to the BES.

Yes

No

Although we agree with the exclusion of radial systems, we believe that the reliability of the interconnected transmission network should not be determined by the amount of installed generation on the radial system. We believe that the generation limit is restrictive and has little or no technical basis. It is not the size of a unit on the radial system that should determine the reliability impact on the BES but more importantly its location, configuration and system characteristics such as reliability must run unit. We believe that there is no reason to divide E1 in three subsets of a, b and c. The end result is that a radial system is excluded if it does not have more than 75 MW of aggregate non-retail generation. However, consistent with E2 we suggest replacing "an aggregate capacity of non-retail generation less than or equal to 75 MVA (gross nameplate rating)" with "a maximum net capacity of non-retail generation provided to the BES of 75 MVA." We suggest deleting the references to I3 in E1 and E3 because we believe that this reference is in contradiction to I3 and probably an oversight and should be corrected. I3 does not require path to be BES but it implies here that a radial system cannot be excluded if there is a Blackstart unit on it.

Yes

No

We agree with the exclusion concept of LN. However, the reliability of the interconnected transmission network should not be determined by the amount of installed generation in the local network. We believe that the generation limit is restrictive and has little or no technical basis. It is not the size of a unit in the LN that will determine the reliability impact on the BES but more importantly its location, configuration and system characteristics such as reliability must run unit. We suggest that the SDT should address this in phase 2 to increase the installed generation limit in a LN. We suggest deleting the references to I3 in E1 and E3 because we believe that this reference is in contradiction to I3 and probably an oversight and should be corrected. I3 does not require a path to be BES but it implies here that a radial system cannot be excluded if there is a Blackstart unit on it.

Yes

Yes

- The definition of the Bulk Electric System (BES) is a foundational construct for the North American Electric Reliability Corporation (NERC). FERC Orders 743 and 743-A do not mandate a 100 kV approach. Instead, it states that a 100 kV bright line threshold is one approach to defining the BES. It further states that only "some" 115/138 kV facilities are necessary for the reliable operation of the bulk system. We believe that if one subset issue (such as 20 MVA vs. 75 MVA) of the entire definition, requires more time and resources to arrive at the correct answer, the much larger and more fundamental issue of how to define BES should not have been dismissed without the appropriate analysis before another definition is proposed to be adopted by the ERO.
- The proposed definition, in combination with other new and/or modified Reliability Standards such as newly modified and

approved TPL Standards will require significant system upgrades with high dollar investments. We are deeply concerned that a) no such assessment has been undertaken by the SDT and/or the ERO and b) the proposed definition of the BES is not based on a technical analysis that will enhance the reliability of the interconnected transmission network. o The NERC as the ERO should at least undertake a cost and incremental reliability benefit analysis for its proposed definition of BES. Furthermore, cost impacts and reliability benefit assessments of the BES definition coupled with other new and modified reliability standards (such as the TPL Standards) must also be undertaken and weighed against the potential benefits, if any, of this or any proposal. Not providing such an assessment but using the 100 kV level as a starting point for the BES definition, gives no assurances of benefits for any stakeholder including respective governmental and regulatory authorities and rate payers in Canada or the USA. o The proposed definition would significantly increase the population of BES elements. Many of the standards requirements for these new elements will introduce administrative burden and operating expenses. This would impose significant costs, costs that ratepayers will have to bear, with little or no gain in reliability benefits for the interconnected transmission system. We suggest that the resulting BES definition must identify incremental reliability benefits by the ERO for the interconnected transmission network based on sound technical analysis to justify the change to those who will pay for any required system upgrades – the ratepayer. • The draft Implementation Plan for the BES definition states “Compliance obligations for Elements included by the definition shall begin 24 months after the applicable effective date of the definition.” We are concerned that the stated implementation period will give insufficient time to complete transition plans for newly identified BES Elements and Facilities, where those plans require approval, procurement, installation and commissioning of additional equipment. We believe a period of 60 months at a minimum is more appropriate. Finally, we believe that the SDT proposed approach for exception criteria is reasonable recognizing that one method/criteria can not be applicable to everyone and every situation within the ERO footprint. However, we believe that there is a huge gap and lack of any transparency on how the exception application will be evaluated and processed. We strongly suggest that the SDT develop a reference or a guidance document as part of the RoP that should provide guidance to Registered Entities, Regional Entities and the ERO on how an exception application should be processed. Else, (a) it will pose a challenge for each of the entities including ERO, and (b) may introduce Regional discretion and be perceived as having no transparency for the registered entities.

Individual

Steve Eldrige

Umatilla Electric Cooperative (UEC)

Yes

The Umatilla Electric Cooperative (UEC) believes the SDT continues to make substantial progress towards a clear and workable definition of the Bulk Electric System (“BES”) that markedly improves both the existing definition and the SDT’s previous proposal. UEC therefore supports the new definition, although our support is conditioned on: (1) a workable Exceptions process being developed in conjunction with the BES definition; and, (2) the SDT moving forward expeditiously on Phase II of the standards development process in accordance with the SAR recently put forward by the SDT, which would address a number of important technical issues that have been identified in the standards development process to date. UEC strongly supports the following elements of the revised BES definition: (1) Clarification of how lists of Inclusions and Exclusions applies: The revised core definition moves the phrase “Unless modified by the lists shown below” to the beginning of the definition. This change makes clear that the Inclusions and Exclusions apply to all Elements that would otherwise be included in or excluded from the core definition (i.e., “all Transmission Elements operated at 100kV or higher and Real Time and Reactive Power resources connected at 100kV or higher”) and eliminates a latent ambiguity in the first draft of the definition, discussed further in our comments on the first draft. (2) The exclusion for “facilities used in the local distribution of electric energy.” As the starting point for the BES definition, UEC supports the use of the phrase “all Transmission Elements” and the qualifying sentence: “This does not include facilities used in the local distribution of electric energy.” This language helps ensure that FERC, NERC, and the Regional Entities (“REs”) will act within the jurisdictional constraints Congress placed in Section 215 of the Federal Power Act (“FPA”). In Section 215(a)(1), Congress unequivocally excluded “facilities used in the local distribution of electric energy” from the keystone “bulk-power system” definition. 16 U.S.C. § 824o(a)(1). Including the same language in the definition helps ensure that entities involved in

enforcement of reliability standards will act within their statutory limits. In addition, as a practical matter, inclusion of the language will help focus both the industry and responsible agencies on the high-voltage interstate transmission system, where the reliability problems Congress intended to regulate – “instability, uncontrolled separation, [and] cascading failures,” 16 U.S.C. § 824o(a)(4) – will originate. At the same time, level-of-service issues arising in local distribution systems will be left to the authority of state and local regulatory agencies and governing bodies, just as Congress intended. 16 U.S.C. § 824o(i)(2) (reserving to state and local authorities enforcement of standards for adequacy of service). UEC thanks the SDT for the excellent work to include this sentence. For similar reasons, UEC believes the use of the phrase “Transmission Elements” as the starting point for the base definition is desirable because both “Transmission” and “Elements” are already defined in the NERC Glossary of Terms Used in NERC Reliability Standards, and the term “Transmission” makes clear that the BES includes only Elements used in Transmission and therefore excludes Elements used in local distribution of electric power. (3) Appropriate Generator Thresholds. In the standards development process, it has become apparent that the thresholds for classifying generators as BES in the current NERC Statement of Compliance Registry Criteria (“SCRC”) (20 MVA for individual generators, 75 MVA for multiple generators aggregated at a single site), which predate the adoption of FPA Section 215, were never the product of a careful analysis to determine whether generators of that size are necessary for operation of the interconnected bulk transmission system. Ideally, such an analysis would be conducted as part of the current standards development process. UEC recognizes that, given the deadlines imposed by FERC in Order No. 743, it will not be possible for the SDT to conduct such an analysis within the time available. Accordingly, UEC agrees with the approach taken by the SDT, which is to propose a Phase II of the standards development process that would address the generator threshold issue and several other technical issues that have arisen during the current process. As long as Phase II proceeds expeditiously, UEC is prepared to support the BES definition as proposed by the SDT. While UEC supports the overall approach adopted by the SDT and much of the specific language incorporated into the second draft of the BES definition, we believe the second draft would benefit from further clarification or modification in a number of respects, most of which are detailed in our subsequent answers. Further, we believe a workable Exclusion Process is essential for a BES Definition that will meet the legal requirements of FPA Section 215, especially for systems operating in the Western Interconnection. As detailed in our previous comments, UEC believes a 200kV threshold would be more appropriate for WECC than a 100kV threshold. In addition, a 200kV threshold for the West is backed by solid technical analysis conducted by the WECC Bulk Electric System Definition Task Force, and repeated claims that there is no technical analysis to support this view are therefore incorrect. That said, we raise the issue here to emphasize the importance of the Exclusions for Local Networks and Radial Systems and the Exceptions process. These Exclusions and the Exceptions are essential for a definition that works in the Western Interconnection because the core definition will be over-inclusive in our region. As long as those Exclusions and the Exceptions Process are retained in a form substantially equivalent to those produced by the SDT at this juncture, UEC will support the SDT’s proposal.

Yes

We support the SDT’s changes to the first Inclusion because it is more clear and simple than the initial approach. That being said, we suggest that an additional sentence of clarification would help avoid future controversy about the meaning of Inclusion 1. As we understand it, the BES intends to include transformers only if both the primary and secondary terminals operate at 100kV or above, which is why the definition uses the word “and” (“the primary and secondary terminals”). We support this approach since it would exclude transformers where the secondary terminals serve distribution loads, and which therefore function as distribution rather than transmission facilities. We believe the SDT’s intent would be clarified by adding a sentence at the end of Inclusion 1 that reads: “Transformers with either primary or secondary terminals, or both, that operate at or below 100kV are not part of the BES.” This language will help ensure that there is no controversy over whether the SDT’s use of the word “and” in the phrase “the primary and secondary terminals” was intentional. We also support the SDT’s proposal to develop detailed guidance concerning the point of demarcation between BES and non-BES elements in the Phase II SAR. In this regard, we note that, while Inclusion 1 at least implicitly suggests that the dividing line between BES and non-BES Elements should be at the transformer where transmission-level voltages are stepped down to distribution-level voltages, we believe further clarification of this point of demarcation between the BES and non-BES Elements is necessary. Many different configurations of transformers and other equipment that may lie at the juncture between the BES and non-BES systems. If the point of demarcation is designated at the

transformer without further elaboration, many entities that own equipment on the high side of a transformer will be swept into the BES, and thereby exposed to inappropriately stringent regulations and undue costs. For example, distribution-only utilities commonly own the switches, bus, and transformer protection devices on the high side of transformers where they take delivery from their transmission provider. Ownership of these protective devices and high-voltage bus on the high side of the transformer should not cause these entities to be classified as BES owners. As the Phase II process moves forward, we commend to the SDT the extensive work performed on the point of demarcation question by the WECC BESDTF. We also support the incorporation of language (“ . . . unless excluded under Exclusions E1 or E3”) making it clear that transformers that are operated as an integral part of a Radial System or Local Network should not be considered BES facilities, regardless of their operating voltage. Further clarification might be achieved by using the phrase “. . . unless the transformer is operated as part of a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2.”

Yes

UEC supports the changes made in Inclusion 2 and believes that the definition in its current form adds clarity. In particular, we support the SDT’s decision to collapse Inclusions 2 and 3 from the previous draft definition into a single Inclusion that addresses the treatment of generation for purposes of the BES definition. We also support the SDT’s proposal for a Phase II of the BES Definition process that would examine the technical justification for these thresholds and that would establish new thresholds based on a careful technical analysis. It is our understanding that the generator threshold issue will be vetted through the complete standards development process. We agree with this approach because if the generator threshold is treated as merely an element of NERC’s Rules of Procedure, it can be changed with considerably less process and industry input than the Standards Development Process. Compare NERC Rules of Procedure § 1400 (providing for changes to Rules of Procedure upon approval of the NERC board and FERC) with NERC Standards Process Manual (Sept. 3, 2010) (providing for, e.g., posting of SDT proposals for comment, successive balloting, and super-majority approval requirements). See also Order No. 743-A, 134 FERC ¶ 61,210 at P 4 (2011) (“Order No. 743 directed the ERO to revise the definition of ‘bulk electric system’ through the NERC Standards Development Process” (emph. added)). Addressing all aspects of Phase II through the Standards Development Process will improve the content of the definition by bringing to bear industry expertise on all aspects of the definition and will ensure that, once firm guidelines are established, they can be relied upon by both industry and regulators without threat that they will be changed with little notice and little process. UEC believes further clarification of the proposed language would be appropriate. The SDT proposes continued reliance upon the thresholds that are used in the NERC Statement of Compliance Registry Criteria for registration of Generation Owners and Generation Operators, which is currently 20 MVA for an individual generation unit and 75 MVA for multiple units on a single site. Conceptually, we are concerned about this approach because, as we understand it, the purpose of the Compliance Registry is to sweep in all generators that might be material to the reliable operation of the BES, and not to definitively determine whether a given generator is, in fact, material to the reliable operation of the BES. As the SCRC itself states, the SCRC is intended only to identify “candidates for registration.” SCRC at p.3, § 1 (emph. added). Accordingly, we believe that the generator threshold determined in Phase II should be incorporated directly into the BES Definition rather than being incorporated by reference from the SCRC. We also believe that the specific language proposed by the SDT could be further clarified. The SDT proposes that generation be included in the BES if the “Generation resource(s)” has a “nameplate rating per the ERO Statement of Compliance Registry.” We understand this language is intended to be a placeholder for the results of the technical analysis that would occur in Phase II but we believe simply stating that the threshold will be “per the ERO Statement of Compliance Registry” is ambiguous. Further, for the reasons noted above, we believe the threshold should be part of the BES Definition, and should not simply be a cross-reference to the SCRC (and, given the different purposes of the BES Definition and the SCRC, it is not clear that the same threshold should be used in both). We therefore propose that Inclusion 2 be rewritten to state: “Qualifying Individual Generation Resources or Qualifying Aggregate Resources connected at a voltage of 100kV or above.” Two definitions would then be added to the note at the end of the definition to read as follows: For purposes of this BES Definition, Qualifying Individual Generation Resources means an individual generating unit that meets the materiality threshold to be included in this definition or, in the absence of such a materiality threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of such a resource as a Generation Owner under the ERO Statement of Compliance Registry Criteria. For purposes of this BES

Definition, Qualifying Aggregate Generation Resources means any facility consisting of one or more generating units that are connected at a common bus that meets the materiality threshold to be included in this definition, or, in the absence of such a threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of multiple-unit generator as a Generation Owner under the ERO Statement of Compliance Registry Criteria. The "materiality threshold" is intended to refer to the generator threshold developed in Phase II. We suggest using definitions in this fashion for several reasons. First, we believe the language we suggest more clearly states the intention of the SDT, which we understand is to classify generation units as part of the BES if they are necessary for operation of the BES, but to exclude smaller generating units because they are not material to the operation of the interconnected transmission grid. Second, we believe use of the defined terms better reflects the intention of the SDT to reserve the specific question about generator thresholds to the technical analysis that will occur in Phase II without having to revise the BES Definition at the end of that process. That is, the definitions are designed to allow the SDT to include revised thresholds in the definition at the conclusion of the Phase II process based upon the technical analysis planned for Phase II, and the revised thresholds will be automatically incorporated into the BES Definition if the language we suggest is used. The thresholds used in the SCRC would only be a fall-back, to be used only until Phase II is completed. Third, the definitions can be incorporated into other parts of the BES Definition, which will add consistency and clarity. As noted in our answers to several of the questions below, the specific 75 MVA threshold is retained in several of the Exclusions and Inclusions, and we believe the industry would be better served if the revised thresholds arrived at after technical analysis in Phase II are automatically incorporated into all relevant provisions of the BES Definition. There is no reason for the SDT to continue to rely on the 75 MVA threshold once the analysis planned for Phase II on the threshold issue is completed. Fourth, the phrase "or that meets the materiality threshold to be included in this definition" is intended to preserve the SDT's flexibility to make a determination that generators below a specific threshold are not "necessary to" maintain the reliability of the interconnected transmission system, and to incorporate that finding as part of the definition itself, even if a different threshold is used in the SCRC to identify potential candidates for registration. Accordingly, our proposed language makes clear that a specific threshold in the definition controls over any threshold that might be included in the SCRC. For the reasons stated above, we believe it is highly desirable to include any material threshold in the BES Definition itself rather than relegating the threshold to the SCRC, which is merely a procedural rule rather than a full-fledged Reliability Standard. Finally, we agree with the SDT's decision to examine the question of where the line between BES and non-BES Elements should be drawn more closely in Phase II under the rubric of "contiguous vs. non-contiguous BES," and commend the work of the Project 2010-07 Standards Drafting Team and the GO-TO Team as a good starting point for the SDT's analysis on this issue. We understand Inclusion 2 would classify generators exceeding specific thresholds as part of the BES, but would not necessarily require facilities interconnecting such generators to be part of the BES. As discussed more fully in our answer to Question 9, based on extensive technical analysis that has already been performed by the NERC Project 2010-07 Standards Drafting Team and its predecessor, the NERC "GO-TO Team," regulating as part of the BES a dedicated interconnection facility connecting a BES generator to the interconnected bulk transmission grid will result in an unnecessary regulatory burden that produces considerable expense for the owner of the interconnection facility with little or no improvement in bulk system reliability. We also believe the clauses at the end of Inclusion 2 are somewhat confusing and that greater clarity would be achieved by changing ". . . including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100kV or above" so that the Inclusion covers transformers with terminals "connected at a voltage of 100kV or above, including the generator terminal(s) on the high side of the step-up transformer(s) if operated at a voltage of 100kV or above."

Yes

UEC supports the removal of the Cranking Path language in I3. As noted in our response to Question 9, there is no reason to classify as BES the facilities interconnecting a BES generator to the bulk interstate system. A Cranking Path is simply a specific type of such an interconnection facility.

Yes

UEC supports the revised language generally, but believes additional changes would make the language clearer. Specifically, we believe Inclusion 4 should not incorporate a hard 75 MVA generation threshold (i.e., "resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)"). Instead, we urge the SDT to replace this language with the defined term

"Qualifying Aggregate Generation Resources," which we discuss in more detail in our response to Question 3. This language will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. More generally, we are not certain what is accomplished by Inclusion 4 that is not already accomplished by Inclusion 2, which also addresses whether generation should be defined as BES. The SDT's stated concern is with variable generation units such as wind and solar plants. It is not clear to us why this concern is not fully addressed in Inclusion 2, which addresses multiple generation units connected at a common bus, the configuration of most variable generation plants with multiple units. We are also concerned that the language, as proposed, could have unintended consequences and improperly classify local distribution systems as BES in certain circumstances. This is because multiple distributed generation units could render a local distribution system a "collector system" and the entire system the equivalent of an aggregated generation unit, causing the local distribution system to be improperly denied status as a Local Network. If many different distributed generation units are connected to a local distribution system, it is very unlikely that more than a few of those units would fail simultaneously, and it is therefore unlikely that multiple generation units would produce a measureable impact on the interconnected bulk transmission system, especially if the units individually do not otherwise exceed the materiality threshold to be established by the SDT in Phase II. Further, we are concerned that, if small distributed generation units become the industry norm, Inclusion 4 could unintentionally sweep in local distribution systems, especially where local policies favor the growth of small solar or other renewable generation systems for public policy reasons. Finally, we suggest that the SDT add the phrase ". . . unless the dispersed power producing resources operate within a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2." This language, which parallels the language included at the end of Inclusion I1, would make clear that dispersed small-scale generators scattered throughout a Radial System or Local Network serving retail load would not convert the Radial System or Local Network into a BES system, even if the aggregate capacity of those small generators exceeds the relevant threshold.

No

UEC has several concerns about the new language in Inclusion 5. First, because Reactive Power devices produce power, they are "power producing resources" and we therefore believe Inclusion 5 is duplicative of Inclusion 4, which addresses "power producing devices." Second, there is no capacity threshold specified in Inclusion 5 for Reactive Power devices that would be considered part of the BES. This is inconsistent with the approach taken in the balance of the definition, where thresholds are specified for generators and other types of power producing devices. Third, UEC believes the appropriate threshold for inclusion or exclusion of Reactive Power devices from the BES should be subject to the same technical analysis that will cover generators in the Phase II process. Finally, UEC believes this issue should be addressed in Phase 2 since there is not technical justification or analysis done to determine the thresholds. UEC strongly believes that there should be technical justification for thresholds for this issue and all other issues.

Yes

UEC continues to strongly support the radial system exclusion, which is necessary as a legal matter, because, among other reasons, FERC in Orders No. 743 and 743-A has required that the existing radial exemption in the NERC Statement of Compliance Registry Criteria be maintained. As a practical matter, radial systems are used for service to retail loads, usually in remote or rural areas, and not for the transmission of bulk power. Hence, operation of the radials has little or nothing to do with the reliable operation of the interconnected bulk transmission network. We also support the inclusion of the note discussing normally open switches because this language provides needed clarity for a common radial system configuration. We also agree with the substantive thrust of this language, which is that a radial system should not be considered part of the BES if it is interconnected at a single point, even if there is an alternative point of delivery that is normally open. While we support the Exclusion for Radial Systems, we believe several clarifications and refinements are necessary. (1) The term "transmission Elements" in the initial paragraph should be changed to "Elements." Radial systems are not transmission systems and including the word "transmission" in the Radial System exclusion is therefore unnecessary and confusing. (2) Subparagraph (b) of Exclusion 1 refers to "generation resources . . . with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)". We urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," discussed in more detail in our response to Question 3. This language will

preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. (3) Subparagraph (b) also seems to assume that if a Radial System contains a generator exceeding the 75 MVA threshold, the Radial System itself must be included in the BES because it links the generator to the interconnected bulk transmission system. As discussed more fully in our response to Question 9, below, NERC's Project 2010-17 Standards Drafting Team and GO-TO Task Force have both concluded that this assumption is unwarranted. (4) The "Note" as drafted by the SDT indicates that "a normally open switching device between radial systems" will not serve to disqualify the Radial from exclusion under Exclusion 1. As discussed above, UEC strongly supports the note conceptually. However, we believe this language should be included in a separate subparagraph (d), rather than a note, because treatment as a "note" suggests it is less important than other portions of the Exclusion. We also suggest the language be changed to read: (d) Normally-open switching devices between radial elements as depicted and identified on system one-line diagrams does not affect this exclusion. This will make clear that a radial with more than one normally-open switch connecting it to another radial is still a radial. From the perspective of the BES Definition, the key question is whether switches operating between Radials are normally open, not whether there is more than one normally-open switch.

Yes

UEC supports the revised language. The language provides clarity regarding the BES status of customer-owned cogeneration facilities. However, UEC urges the SDT to remove the reference to the 75 MVA threshold and replace it with the defined term "Qualifying Aggregate Generation Resources" or some equivalent language for the reasons stated in our responses to Questions 3, 5, and 7. In addition, we are concerned that Exclusion 2 will place local distribution utilities in a difficult position because, under Exclusion 1 or Exclusion 3 as drafted, they could lose their status as a Radial System or a Local Network through the actions of a customer constructing behind-the-meter generation. With respect to Radial Systems, the appearance of behind-the-meter generators could cause the Radial System to exceed the thresholds specified in subparagraphs (b) and (c) of Exclusion 1 through no fault of the Radial System owner. Similar, a Local Network could lose its status because behind-the-meter generation could be of sufficient size that power moves into the interconnected grid in certain hours or under certain contingencies, rather than moving purely onto the Local Network, as required in subparagraph (b) of Exclusion 3. The Exclusions for Radial Systems and Local Networks should be made consistent with the Exclusion for behind-the-meter generation. There is no technical reason to believe the power flowing from a behind-the-meter customer-owned generator will have less impact on the bulk system than an equivalent-sized generator owned by a utility operating a Radial System or LN.

Yes

UEC strongly supports the exclusion of Local Networks ("LNs") from the BES. The conversion of radial systems to local networks should be encouraged because networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. If the BES definition were to provide an exclusion for radials without providing a similar exclusion for LNs, however, it would discourage networking local distribution systems because of the significantly increased regulatory burdens faced by the local distribution utility if it elected to network its radial facilities. By placing radial systems and LNs on the same regulatory footing, the proposed definition will ensure that decisions about whether to network radial systems are made on the basis of costs and benefits to the retail customers served by those radials, and not on the basis of disparate regulatory treatment. Consumers would ultimately benefit. UEC also supports specific refinements made to the LN exclusion by the SDT in the current draft of the BES definition. In particular, UEC supports the clarification of the purposes of a LN. The current draft states that LNs connect at multiple points to "improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system." UEC supports this change in language because it reflects the fundamental purposes of a LN and emphasizes one of the key distinctions between LNs and bulk transmission facilities, namely, that LNs are designed primarily to serve local retail load while bulk transmission facilities are designed primarily to move bulk power from a bulk source (generally either the point of interconnection of a wholesale generator or a the point of interconnection with another bulk transmission system) to one or more wholesale purchasers. UEC believes further improvement of the language could be achieved with additional modifications and clarifications. With respect to the core language of Exclusion 3, we believe the language making a "group of contiguous transmission

Elements operated at or above 100kV” the starting point for identifying a LN would be improved by deleting the term “transmission” from this phrase. This is so because LNs are not used for transmission and the use of the term “transmission Elements” is therefore both confusing and unnecessary. There would be no room for argument about what the SDT intended by including the word “transmission” if the word is deleted and the Exclusion applies to any “group of Elements operated at 100kV or above” that meets the remaining requirement of the Exclusion. Further, any definitional value that is added by using the term “transmission Elements” is accomplished by using that term in the core definition, and there is no reason to carry the term through in the Exclusions. UEC also believes that subparagraphs (a) and (b) are redundant, because whatever protection is offered by the generation limit in subparagraph (a) is duplicated by the limit in subparagraph (b) requiring no flow out of the LN. We believe the SDT can eliminate subparagraph (a) of Exclusion 3 and simply rely on subparagraph (b) because if power only flows into the LN even if it interconnects more than 75 MVA of generation, the interconnected generation interconnected will have no significant interaction with the interconnected bulk transmission system. It will only interact with the LN. And, with the advent of distributed generation, it is easy to foresee a situation in which a large number of very small distributed generators are interconnected into a LN, so that the aggregate capacity of these generators exceeds 75 MVA. However, because the generators are small and dispersed and, under the criterion in subparagraph (b), would be wholly absorbed within the LN rather than transmitting power onto the interconnected grid, those generators would not have a material impact on the grid. We also suggest that subparagraph (b) of Exclusion 3 could be more clearly drafted. Subparagraph (b), as part of the requirement that power flow into a LN rather than out of it, includes this description: “The LN does not transfer energy originating outside the LN for delivery through the LN.” We understand this language is intended to distinguish a LN from a link in the transmission system – power on a transmission link passes through the transmission link to a load located elsewhere, while power in a LN enters the LN and is consumed by retail load within the LN. While we agree with the concept proposed by the SDT, we believe the language would be clearer if it read: “The LN does not transfer energy originating outside the LN for delivery through the LN to loads located outside the LN.” We believe the italicized language is necessary to distinguish between a transmission system, where power that originates outside a system is delivered through the system and passes through the system to a sink located somewhere outside the system, from a LN, in which power originating outside the LN passes through the LN and is delivered to retail load within the LN. To put it another way, the italicized language helps distinguish a transmission system from an LN, in which the LN “transfers energy originating outside the LN for delivery through the LN to loads located within the LN.” We also believe the language of subparagraph (a) of Exclusion 3 could be improved. Subparagraph (d) would make LNs part of the BES if they interconnect “non-retail generation greater than 75 MVA (gross nameplate rating).” For the reasons stated in our responses to Questions 3, 5 and 7, we urge the SDT to replace the reference to a hard 75 MVA threshold with the defined term “Qualifying Aggregate Generation Resources” or some equivalent. We are also uncertain what is meant by the use of the term “non-retail generation” in subparagraph (a). From context, we believe the SDT considers “non-retail generation” to be the equivalent of generation that is located behind the retail meter, usually but not always owned by the customer and used to serve the customer’s own load. We therefore suggest that the SDT replace the term “non-retail generation” with “generation located behind the retail customer’s meter.” Similarly, we are unsure what is meant by the phrase “the LN and its underlying Elements.” We believe the phrase “and its underlying Elements” could simply be deleted from the definition without loss of meaning. In the alternative, the SDT might consider using the phrase “the LN, including all Elements located on the distribution side of any Automatic Fault Interrupting Devices (or other points of demarcation) separating the LN from the bulk interstate transmission system.” We believe this phrase more accurately reflects the SDT’s intent, which appears to be that generation exceeding 75 MVA in aggregate capacity interconnected anywhere within the LN disqualifies that LN from being excluded from the BES under Exclusion 3. UEC also believes that both subparagraphs (a) and (b) of Exclusion 3 could be safely eliminated as long as subparagraph (c) is retained. Subparagraph (c) makes a LN part of the BES if it is classified as a Flow Gate or Transfer Path. Flow Gates and Transfer Paths are, by definition, the key facilities that allow reliable transmission of bulk electric power on the interconnected grid. If a LN has not been identified as either a Flow Gate or a Transfer Path, it is unlikely the LN is necessary for the reliable transmission of electricity on the interconnected bulk system. Apart from these specific improvements that we believe could be achieved by modifying the language of Exclusion 3, we believe the SDT may need to re-examine certain assumptions that appear to underlie the current draft. Specifically, subparagraph

(a) suggests that if BES generation is embedded within a LN, the LN itself must also be BES. But two NERC bodies have already addressed similar questions and concluded there is no technical basis for such concerns. NERC's Standards Drafting Team for Project 2010-07 and its predecessor, the "GO-TO Task Force" were formed to address how the dedicated interconnection facilities linking a BES generator to high-voltage transmission facilities should be treated under the NERC standards. The GO-TO Team concluded that by complying with a handful of reliability standards, primarily related to vegetation management, reliable operation of the bulk interconnected system could be protected without unduly burdening the owners of such interconnection systems. Therefore, there is no reason, according to the GO-TO Team, that dedicated high-voltage interconnection facilities must be treated as "Transmission" and classified as part of the BES in order to make reliability standards effective. See Final Report from the NERC Ad Hoc Group for Generator Requirements at the Transmission Interface (Nov. 16, 2009) (paper written by the GO-TO Task Force). Similarly, the Project 2010-07 Team observed that interconnection facilities "are most often not part of the integrated bulk power system, and as such should not be subject to the same level of standards applicable to Transmission Owners and Transmission Operators who own and operate transmission Facilities and Elements that are part of the integrated bulk power system." White Paper Proposal for Information Comment, NERC Project 2010-07: Generator Requirements at the Transmission Interface, at 3 (March 2011). Requiring Generation Owners and Operators to comply with the same standards as BES Transmission Owners and Operators "would do little, if anything, to improve the reliability of the Bulk Electric System," especially "when compared to the operation of the equipment that actually produces electricity – the generation equipment itself." Id. We believe that interconnection of BES generators within a LN is analogous and that, based on the findings of the Project 2010-07 and GO-TO Teams, automatically classifying a LN as "BES" simply because a large generator is embedded in the LN will result in substantial overregulation and unnecessary expense with little gain for bulk system reliability. If anything, generation interconnected through a LN is less likely to produce material impacts on the interconnected bulk transmission system than the equivalent generator interconnected through a single dedicated line because an LN is interconnected to the bulk system at several points, so that if one interconnection goes down, power can still flow from the BES generator to the bulk system on other interconnection points. Where a dedicated interconnection facility is involved, by contrast, if the interconnection line fails, the generator is unavailable to the interconnected bulk system. Similarly, we suggest that the SDT re-examine the assumptions underlying subparagraph (b), which seems to suggest that a local distribution system cannot be classified as a Local Network if power flows out of that system at any time, even if the amount is de minimis, the outward flow is only for a few hours, a year, or the outward flow occurs only in an extreme contingency. Accordingly, we suggest that the initial clause of subparagraph (b) be revised to read: "Except in unusual circumstances, power flows only into the LN." Finally, we note that the LN exclusion must not operate in any way as a substitution for the statutory prohibition on including "facilities used in the local distribution of electric energy" in the BES. Therefore, even with the LN exclusion, the SDT must retain this statutory language in the core definition of the BES, as discussed in our answer to Question One. If a certain piece of equipment is a "facility used in the local distribution of electric energy," then it is not part of the BES in the first instance, and so consideration of the LN Exclusion, or of any other Exclusion, any Inclusion, or any Exception, would be both unnecessary and uncalled for.

Yes

UEC supports the revised language because retail reactive devices are used to address local customer or retail voltage issues, rather than voltage issues on the interconnected bulk grid, and such local devices should therefore be excluded from the BES definition.

No

UEC extends its thanks to the SDT and to the many industry entities that have actively participating in the Standards Development Process. UEC supports the current draft and believes, with certain refinements discussed in our comments, that the definition will serve the industry and reliability regulators well for many years to come. In addition, as noted earlier, UEC is encouraged that the 20/75 MVA generation thresholds referred to in the NERC Statement of Compliance Registry Criteria, which have been relied upon by the SDT largely as a matter of necessity, will be reviewed and a technical assessment will be performed to identify the appropriate generation unit and plant size threshold to ensure a reliable North America. Finally, we understand that the Rules of Procedure Team will continue to move forward with developing an Exceptions Process that will complement the BES Definition and ensure that, to the extent the BES Definition is over-inclusive, facilities that should not

be classified as BES will be excluded from the BES. Because the Exceptions Process is integral to a workable BES Definition, we support the current process for moving forward with the Exceptions Process and the BES Definition on parallel paths. We note that UEC specifically supports the changes made by the SDT in the "Effective Date" provision of the BES Definition, which shortens the effective date of the new definition to the beginning of the first calendar quarter after regulatory approval (as opposed to the first calendar quarter twenty-four months after regulatory approval), with a 24-month transition period. UEC supports this conclusion because it will allow entities seeking deregistration under the terms of the new BES definition to obtain the benefits of the new definition without an unreasonable wait, while allowing any entities that may be newly-classified as BES owners or operators sufficient time to come into compliance with newly-applicable Reliability Standards. UEC also supports the 24-month transition period for the reasons laid out by the SDT.

Steve Alexanderson

Central Lincoln

Yes

We agree with the changes. We must point out that the overall flow, or how one proceeds through the inclusions and exclusions is not clear. Can an item that meets an inclusion be subsequently excluded? If so, this needs to be explicitly stated. So far, we only have the flow chart produced by the ROP team that indicates otherwise ([http://www.nerc.com/docs/standards/sar/20110428\\_BES\\_Flowcharts.pdf](http://www.nerc.com/docs/standards/sar/20110428_BES_Flowcharts.pdf)). This was made evident by the question at the 9/28 webinar regarding an I5 capacitor on an E3 local network. The questioner thought the capacitor was BES per I5, but the answer was that it was excluded per E3. We can find no support for the answer given. The listing of specific exclusions within I1 (exception proves the rule) argues for questioner's stance that the capacitor is BES as written. Also, if included items could subsequently be excluded, they would be no different from any other item that met the voltage threshold of 100kV. There would be no need for any of the inclusions if all possible outputs from the inclusion tests go to the same exclusion test inputs. We strongly support the addition of the language regarding local distribution facilities, as it matches congressional intent to leave the regulation of these facilities to state and local authorities.

Yes

Central Lincoln strongly agrees with this inclusion as written. It is consistent with the recent PRC-004 and PRC-005 interpretation and the NERC definition of Transmission. We believe the recent changes to this inclusion add clarity.

No

Referencing the Criteria which in turn references the BES definition creates a circular definition. Central Lincoln encourages the adoption of specific thresholds that are technically justified. We also note that the Criteria and its revisions do not go through the standards development process, so that thresholds may change with little warning and without triggering an implementation plan for facilities that may be swept into the BES as a result.

Yes

We agree with the removal of the voltage language, since the inclusions and exclusions apply only to equipment over 100 kV.

Yes

Central Lincoln agrees both with the inclusion and with the revised language. The revised language removes the need to provide a separate definition for "Collector System".

No

While we agree that reactive devices of sizable capacity connected at 100 kV or higher are needed for BES reliability, Central Lincoln fails to see why this inclusion is needed as they are already captured by the 100 kV threshold. We would propose instead to eliminate this inclusion and substitute an exclusion for smaller capacity devices. If the SDT really believes an inclusion for reactive devices is needed, we suggest the SDT provide a technically justified capacity limit within the inclusion. In addition we suggest also including the phrase "...unless excluded under Exclusion E1, E2 or E4" similar to that in I1. Please see the answer to Q1 above Q10 below.

No

Central Lincoln notes that a new term has been introduced, "non-retail generation," with no definition

provided. The answer to the question on this during the 9/28 webinar indicated that non-retail generation was behind the retail customer's meter. We can see no reason why the net-metered PV systems should count toward the aggregate limit (exceeding the limit means no exclusion) while a non-blackstart thermal plant doesn't (the radial system is excluded if any amount of load is present). We have also heard the SDT meant just the opposite of what was stated in the webinar. We ask that a reasonable definition for non-retail be provided within the BES definition document. We strongly agree that radial systems should be excluded and that the presence of normally open switching devices between radial systems should not cause them to be considered non-radial. Such a result would cause the removal of these devices to the detriment of the local level of service. We note that the singular "A normally open switching device" is used and suggest that an allowance be made for the possibility of multiple devices. "Normally open switching devices..."

Yes

No

We strongly agree that local networks should be excluded, since they act much like the radial systems excluded in E1 while providing a higher level of service to customers. These networks should not be discouraged in the name of reliability. We again object to the introduction of the new confusing term "non-retail generation" with no definition provided.

No

Please see Central Lincoln's answers to Q1 and Q6. Any device that might be excluded under E4 has already been included per I5. Unless I5 is removed, or rewritten as suggested above; this exclusion will exclude nothing.

Yes

We note that the SAR for Phase II, like that for Phase I, does not include all entity types. We see no reason to maintain dual definitions for the different entity types, and the resulting confusion. In order to help meet the fast approaching January target date, Central Lincoln will be voting affirmative in this ballot, with the hope these comments will be addressed in Phase II. If the ballot should fail, please address these comments in this phase. Thanks to the team for their good work.

Yes

Yes

We believe further clarification is needed to limit BES transformers only to those serving the transmission system and not distribution loads, such as excluding transformers with one or both terminals operating below 100 kV.

Yes

We are in general agreement with this inclusion, except that there is no threshold for reactive resources as there is for generators and transformers. We recommend that a minimum level be established for this equipment, such as 100 MVAR, or that studies be conducted to determine an appropriate threshold.

Yes

Yes

Yes
HEC agrees with the changes by the SDT. Although HEC believes that there needs to be explicit language stating whether or not an item that meets inclusion can be overridden by an exclusion. An example of this was given during the Webinar on 9/28 regarding a Capacitor included under I5 yet excluded under E3 according to the NERC representative.
Yes
HEC agrees with the inclusions to I1 and believes that add clarity to the definition.
No
HEC would like to see the inclusion of specific thresholds that are technically justified.
Yes
HEC agrees with the inclusions to the core definition.
Yes
HEC agrees with the inclusions and revised language to the definition
No
HEC believes this inclusion should include a technically justified capacity limit on reactive resources to warrant inclusion.
Yes
HEC strongly agrees that radial systems should be excluded from the BES and that the presence of a normally open switching device between radial systems should not cause them to be considered non-radial
Yes
Yes
HEC believes that local networks should be excluded from the BES and agrees with exclusions to the definition.
Yes
HEC agrees with E4.
No

Braun Blasing McLaughlin, PC
Yes
In an effort to avoid potential confusion and provide clarity we believe the following sentence "This does not include facilities used in the local distribution of electric energy" more appropriately fits under the "exclusions," rather than "inclusions," section.
Yes
We believe additional clarification of transformers that are to be included may be achieved with respect to auto transformers, phase angle regulators and generator step-up transformers by adding the following recommended sentence: "All transformers (including autotransformers, voltage regulators, and phase angle regulators) with primary and secondary terminals operated at or above 100kV, unless excluded by E1 or E3."
No
We recommend removing the reference of the ERO Statement of Compliance Registry Criteria (Registry Criteria). The BES Definition should be the governing document and independent of ERO registration requirements. The definition should drive what appears in the Registry Criteria.

Additionally, we support using the BES Phase 2 technical analysis to identify and provide technical support for determining the appropriate minimum MVA rating that a single unit, or the aggregation of multiple units, must meet to be considered part of the BES.

Yes

We recommend rewording Inclusion I3 as follows: "Only Primary Blackstart resources designated as part of the Transmission Operator's restoration plan." We have concerns that making all Blackstart generation either primary or secondary BES elements will create an incentive to remove those secondary Blackstart capable units in order to avoid BES inclusion. Making the primary Blackstart unit the only BES element will remove this incentive. In so doing, this will allow the secondary Blackstart units to remain in the Transmission Operator's plan and training program as an alternate tool for the Transmission Operator to restore the system.

Yes

Yes

However, appropriate MVAR level should be established. Reactive resources should be treated similar to generation criteria and included in the technical studies associated with the Phase 2 technical analysis in order to establish the appropriate MVAR level included as BES.

Yes

For the E1 reference "Note," we would benefit from additional clarification identifying the treatment of a normally open switch and offer the following: "Radial systems shall be assessed with all normally open switching devices in their open positions." The wording in Exclusion 1-c should more clearly reflect what is intended by using the term "non-retail generation." Also, as with the technical justification for Inclusions I2 and I4, it is recommended that the generation threshold, i.e. gross nameplate values, be deferred to Phase 2.

Yes

It is preferred to hold reference to gross nameplate rating/threshold values until generation technical justification is completed as part of Phase 2; these studies should apply to any real or reactive power threshold reference. For Exclusion E3-b using the phrase "[p]ower flows only into the LN" is too restrictive. An allowable MW threshold of LN power producing resources should be deferred to the Phase 2 BES technical analysis. Where no generation is present in the LN, it is recommended that an allowance for residual flow through the LN.

Yes

Individual

Russell Noble

Cowlitz County PUD

Yes

Cowlitz County PUD No. 1 (Cowlitz) commends the SDT for the simplified concise core definition. However, Cowlitz believes that only Real and Reactive Power resources necessary for the support of the BES should be included. Therefore, Cowlitz suggests the core definition or the Inclusions section state this. This will allow basis for demonstrating resource Elements should be excluded from the BES through the Rules of Procedure exception process. This is not to say that owners of non-BES resource Elements should not be registered, as such entities may still have an obligation to contribute BES Reliability functions. Cowlitz votes affirmative and believes the above concern can be addressed in Phase II.

Yes

Cowlitz supports the SDT's efforts to simplify this inclusion. However, Cowlitz suggests the following change to clarify the inclusive nature of the use of "and:" Transformers with primary and secondary terminals both operated at 100 kV or higher...

Yes

Cowlitz also strongly supports Phase II to address the lack of technical justification of the MVA bright

line criteria.
Yes
Yes
However, Cowlitz suggests Inclusion 4 be made parallel with Inclusion 2: ...(greater than the gross aggregate name plate rating per the ERO Statement of Compliance Registry Criteria) utilizing...
No
Cowlitz has several concerns about the new language in Inclusion 5. First, because Reactive Power devices produce power, they are "power producing resources" and we therefore believe Inclusion 5 is duplicative of Inclusion 4, which addresses "power producing devices." Second, there is no capacity threshold specified in Inclusion 5 for Reactive Power devices that would be considered part of the BES. This is inconsistent with the approach taken in the balance of the definition, where thresholds are specified for generators and other types of power producing devices. Finally, Cowlitz believes the appropriate threshold for inclusion or exclusion of Reactive Power devices from the BES should be subject to the same technical analysis that will cover generators in the Phase II process.
Yes
Yes
Cowlitz is concerned that Exclusion 2 will place local distribution utilities in a difficult position; under Exclusion 1 or Exclusion 3 as drafted, they could lose their status as a Radial System or a Local Network through the actions of a customer constructing behind-the-meter generation. With respect to Radial Systems, the appearance of behind-the-meter generators could cause the Radial System to exceed the thresholds specified in subparagraphs (b) and (c) of Exclusion 1 through no fault of the Radial System owner. Similar, a Local Network could lose its status because behind-the-meter generation could be of sufficient size that power moves into the interconnected grid in certain hours or under certain contingencies, rather than moving purely onto the Local Network, as required in subparagraph (b) of Exclusion 3. The Exclusions for Radial Systems and Local Networks should be made consistent with the Exclusion for behind-the-meter generation. There is no technical reason to believe the power flowing from a behind-the-meter customer-owned generator will have less impact on the bulk system than an equivalent-sized generator owned by a utility operating a Radial System or LN. However, Cowlitz understands the difficulty of pressing the argument at this time for any generation that is connected directly through a dedicated step-up transformer to Elements at or greater than 100 kV.
Yes
Cowlitz strongly supports the categorical exclusion of Local Networks ("LNs") from the BES. This exclusion will allow conversion of radial systems to LNs without compliance impact, and should be encouraged rather than discouraged as networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. The decision of whether to network radial systems should be made on the basis of costs and benefits to the retail customers served by those radials, and not on the basis of disparate regulatory treatment. Consumers will ultimately benefit from the path chosen by the SDT. Cowlitz believes that the word "transmission" does not add clarity to the Exclusion; simply stating "Elements" is sufficient. This will allow for a gradual acceptance that transmission is not defined by a certain voltage, but more a medium in which electrical power is efficiently transported from power resources to load centers where it is distributed. The old convention of transmission versus distribution no longer fits in the current regulatory environment, and as such should be retired. Cowlitz also believes that subparagraphs (a) and (b) are redundant; subparagraph (a) is duplicated by the limit in subparagraph (b) requiring no flow out of the LN. However, Cowlitz also believes that removing (a) will complicate FERC's acceptance of this exclusion. Therefore this should be addressed in Phase II. Cowlitz is confused by the use of the term "non-retail generation" in subparagraph (a). From context, we believe the SDT considers "non-retail generation" to mean generation that is not connected through a dedicated step-up transformer to voltages at or above 100 kV, is consumed by the retail customer's load, or consumed within the LN rather than being physically exported and sold to markets outside the LN. Cowlitz suggests that the SDT rewrite subparagraph (a) to read "Limits on connected generation: The LN and its underlying Elements do not include generation resources identified in Inclusion I3 and does not have any generation net power flow greater than 75 MVA across any single retail revenue metering point into an Element operated at

or greater than 100 kV.”
Yes
No
Cowlitz appreciates the opportunity to comment, and the hard work of the SDT.

Utility Services, Inc.
Yes
Upon reflection of the core definition and BES Inclusion Designations, Utility Services believes that there is an unintended redundancy between the two. Utility Services would like to suggest that the portion of the core definition that refers to the Real and Reactive Power resources be removed from the core and to leave the Inclusions as is.
Yes
Utility Services supports the comments offered by other commenters who suggest that transformers and other related devices be mentioned in the inclusion.
Yes
Yes
Utility Services supports suggestions by others that request that the language of the Inclusion use the exact language of the SCRC III.3.c. Leaving the language as is will likely increase the number of black start facilities beyond those currently applicable.
Yes
Yes
Yes
Utility Services is very concerned that the "single point of connection" lacks clarity and applications need to be identified. Utility Services suggests that the SDT publish illustrative one-line diagrams to aid the industry in determining when the designations are best applied.
Yes
Utility Services supports the comments offered by others suggesting that the language be revised to be identical to the language in the SCRC.
Yes
Yes
Yes
Utility Services would like to raise the question of whether SCRC III.3.d (the so-called "Generator Materiality" clause) is incorporated within the BES Inclusion Designations. One theory suggests that given that I2 is designed to deal with III.3.a and III.3.b and I3 reflects the need to incorporate black start generation; then generators under the materiality clause are not identified with the inclusion criteria. However, the second theory suggests that resources identified through I2 reflect the entire III.c.1-4 language of the SCRC, then the generators in the material clause are captured under I2. But if this is the case, then I3 is redundant to I2 and does not need to be separately addressed.
Group
Jean Nitz
ACES Power Marketing
Yes
Yes

Yes
We'd prefer to see the language from the ERO Statement of Compliance Registry Criteria repeated within the BES Definition itself instead of referencing an outside document. As it stands right now, the Compliance Registry Criteria needs to stay intact for Phase I of this project. That makes the Compliance Registry Criteria reliant on the BES Definition and vice versa. We understand that the Statement of Compliance Registry Criteria may be reviewed/revised at the same time Phase 2 of this project is being developed, therefore we agree with Inclusion I2 of this draft.
No
Blackstart Resources can actually be on the distribution system. There is still the question of whether the distribution system would then be subjected to the enforceable standards. If so, there would most likely be a significant cost increase associated with tracking compliance for these distribution systems without a commensurate increase in reliability since Blackstart Resources are rarely used. This could very well cause entities to un-designate Blackstart Resources on distribution systems to avoid these distribution systems from becoming part of the BES. The same rationale that was used for eliminating cranking paths could also be applied to Blackstart Resources.
Yes
Further clarification on what "dispersed power" means would be helpful. How does it compare to distributed generation?
Yes
We understand the SDT's logic behind not setting any threshold values for reactive resources during Phase 1 of this project. Ample time and effort should be given to developing the technical justification behind such values. However, we encourage the SDT to consider adding threshold values in Phase 2 of the project to provide even more clarity to this inclusion.
Yes
The term "non-retail generation" used in Exclusion E1 (item c) and again in E3 (item a) should be clarified (see comments for question 8 below). The Note after item c should also be clarified to indicate that closing a normally open switch doesn't affect this exclusion.
Yes
"A generating unit or multiple generating units that serve all or part of retail customer Load with electric energy on the customer's side of the retail meter" sounds a lot like "non-retail generation" that is used in E1 and E3 which was described in the webinar as generation that resides on the customer side of the retail meter and is used to supply energy to that customer's load and is owned by the customer. Is E2 assuming that this generation is not owned by the customer? Also, part ii) adds to the confusion. Conceptually we agree with this exclusion but further clarification is preferred.
No
The term "non-retail generation" used in Exclusion E1 (item c) and again in E3 (item a) should be clarified. The following applies to E3 (item c): A flowgate should not be used to limit applicability of E3. First, there is no definition for what constitutes a permanent flowgate. Second, flowgates are often created for a myriad of reasons that have nothing to do with them being necessary to operate the BES. While section c) in E3 attempts to limit the applicability to permanent flowgates, there is no definition for what constitutes a permanent flowgate particularly since no flowgate is truly permanent. The NERC Glossary of Terms definition of flowgate includes flowgates in the IDC. This is a problem because flowgates are included in the IDC for many reasons not just because reliability issues are identified. Flowgates could be included to simply study the impact of schedules on a particular interface as an example. It does not mean the interface is critical. As an example, it could be used to generate evidence that there are no transactional impacts to support exclusion from the BES. Furthermore, the list of flowgates in the IDC is dynamic. The master list of IDC flowgates is updated monthly and IDC users can add temporary flowgates at anytime. While the "permanent" adjective applied to flowgates probably limits the applicability from the "temporary" flowgates, it is not clear which of the monthly flowgates would be included from the IDC since they might be added one month and removed another. Flowgates are created for many reasons that have nothing to do with them being necessary to operate the BES. First, flowgates are created to manage congestion. The IDC is more of a congestion management tool than a reliability tool. FERC recognized this in Order 693, when they directed NERC to make clear in IRO-006 that the IDC should not be relied upon to relieve

IROLs that have been violated. Rather, other actions such as re-dispatch must be used in conjunction. Second, flowgates are used as a convenient point to calculate flows to sell transmission service. The characteristics of the flowgate make it a good proxy for estimating how much contractual use has been sold not necessarily how much flow will actually occur. While some flowgates definitely are created for reliability issues such as IROLs, many simply are not.

Martyn Turner

LCRA Transmission Services Corporation

Yes

No

LCRA TSC supports the inclusion of transformers (with both the primary and secondary windings operated at 100-kV or higher) in the BES definition; however, additional clarification is suggested. The term transformers needs to be further defined with respect to function (auto transformers, phase angle regulators, generator step-up transformers, etc.). Similarly, a separate definition for "Transformer" could be developed and included in the NERC Glossary of Terms.

No

Yes

No

LCRA TSC suggests consistency between this inclusion criteria and the criteria used in I2 for "generation".

No

This inclusion conflicts with exclusion E4. Which one takes priority?

No

The current wording is unclear with respect to the treatment of normally open switching devices. LCRA TSC suggests the following language to replace the existing language on the note to E1: "Two radial systems connected by a normally open, manually operated switching device, as depicted on prints or one-line diagrams for example, may be considered as radial systems under this exclusion." The current wording is unclear with respect to "non-retail generation". The sudden loss of large, radial-supplied load may result in reliability deficiencies. LCRA TSC suggests stating a load level or a load capacity in the exclusion.

No

Yes

No

This exclusion conflicts with inclusion item I5. Which one takes priority?

Yes

LCRA TSC supports the direction the standards drafting team taking with this project on the BES Definition and encourages further clarification as noted in these comments for proper application.

Saurabh Saksena

National Grid

No

While we agree that the BES should not include facilities used in the local distribution of energy, we

feel that this is already captured in Exclusion E3. Stating it in the core definition is confusing, and should be eliminated. We suggest removing "This does not include facilities used in the distribution of electric energy" from the core definition.

Yes

Yes

Yes

Yes

We agree with Inclusion I4, however we feel that the inclusion could be interpreted in some different ways. This inclusion could be interpreted to exclude dispersed generation greater than 75 MVA if the first common point is less than 100 kV. To eliminate any confusion in the interpretation of this inclusion, we suggest this wording: Dispersed power producing resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating) connected to a Transmission Element at 100 kV or above, utilizing a system designed primarily for aggregating capacity which includes all transformers between the generator(s) and the Transmission Element.

No

We see some potential conflicts between this inclusion and the exclusions. Without some additional wording, it seems like some devices that are in a Local Distribution Network would be considered BES. In addition, reference to a transformer in Inclusion I1 is not necessary since the definition includes "all Transmission Elements operated at 100 kV", thus by definition and I5, those connected to 100 kV and higher are already included. We suggest: Static or dynamic devices dedicated to supplying or absorbing Reactive Power that are connected at 100kV or higher unless the device is in an area excluded from BES by Exclusion E1 or E3, or through a dedicated transformer with a high-side voltage of 100kV or higher, unless excluded by Exclusion E4.

Yes

Yes

We agree with this exclusion, but the intention of point (i), the net capacity provided to the BES does not exceed 75 MVA, is not clear. We suggest this wording: "the net capacity provided to the BES for 90% of the hours of the year does not exceed 75 MVA".

Yes

We agree with Exclusion E3 on local networks, however we suggest this clarification to the first sentence: A group of contiguous transmission Elements operated at or above 100kV but less than 300kV that distribute power to Load rather than transfer bulk power across the interconnected system under normal ("all-lines-in") configuration and conditions. We also suggest the following clarification to part c, so that the IROLs don't get overlooked: Not part of Flowgate, transfer path, or an Interconnected Reliability Operating Limit (IROL). The LN does not contain a monitored Facility of a permanent Flowgate in the Eastern Interconnection, a major transfer path within the Western Interconnection, or a comparable monitored Facility in the ERCOT or Quebec Interconnection, and is not a monitored Facility included in an IROL.

Yes

Yes

The proposed implementation period in the draft definition is too short. The new BES definition will likely result in increased operational costs during the implementation period that will ultimately be borne by customers. Implicit in the Commission's directive to change the BES definition is the Commission's determination that the benefits of this change, including consistency among the regions, outweigh the ratepayer impacts. However, National Grid remains concerned that the ratepayer impacts have not been fully taken into account. The implementation period is a tool that can allow NERC to meet the Commission's directive while softening any resulting ratepayer impacts. Implementation can and should be staged in order to mitigate and even out rate increases. National Grid suggests that the implementation period be flexible to allow entities who anticipate that large

and/or expensive upgrades to the BES will be necessary to meet compliance can submit an alternate implementation plan to spread compliance and the associated rate changes over a longer period; we would suggest a minimum of 7 years. This time period was also recognized as a reasonable implementation time period in the recent TPL-001-2 for those portions of the standard that would also result in plans that would require siting, permitting and construction activities. This BES definition is likely to have similar impacts for some entities and allowing for an implementation timeline with the definition change enables achievement of the goals while recognizing the realities of constructing facilities in today's environment.

EMP & NERC Compliance

Yes

Dominion agrees with the clarifying changes provided that the use of the capitalized terms "Transmission" and "Elements" mean that an Element that is radial is not part of the BES regardless of whether it is specifically included in the Exclusions (E1 through E4).

Yes

The proposed changes are much clearer than proposed language in the 1st draft of this BES definition.

Yes

Dominion interprets the revised language to exclude generating resources connected at less than 100 kV. If this interpretation is not accurate, then Dominion does not support the revised language.

Yes

Yes

No

The language in the last part of Inclusion 15 "...or through a transformer that is designated in Inclusion 11" introduces ambiguity. Specifically, it is not clear how implementation of this language would result in the inclusion of any Static or dynamic device that is not already included. Dominion suggests that the language in 15 be revised to read "Static or dynamic devices dedicated to supplying or absorbing Reactive Power that are connected at 100 kV or higher, or connected through a dedicated transformer with at least one terminal voltage of 100 kV or higher." Dominion understands that the SDT intended for this Inclusion to not address generators or power producing resources because they are covered elsewhere (I2 and I4) and requests that the SDT confirm this understanding.

No

Dominion does not agree that exclusion of a radial should be based upon the aggregate capacity of generation. A radial serving only generation should be excluded just as it is for load (as proposed by the SDT in 1a). No reliability gaps exist since the owner and/or operator of generation (with an individual with gross individual or gross aggregate nameplate rating per the ERO Statement of Compliance Registry Criteria) must comply with applicable reliability standards. Dominion requests that the SDT provide technical justification for E1a and E1b as it did for E3, and explain the intent of the footnote in E1.

No

Dominion supports exclusion for behind-the-meter generation, (if connected at >100 kV) if the load behind the meter (to which that generation is intended to support) does not rely on generation outside that metered point for purposes of back-up energy or any type of ancillary services at any time. The proposed language appears to suggest that standby, back-up, and maintenance power services are always required. There are alternative means to provide these services, such as reducing load to match 'reliability services' provided by the available behind-the-meter generation. Further, even if standby, back-up, and maintenance power services are always required, the exclusion criteria obligation should be placed on the retail load, not the generation outside the metered point

No

Dominion could support if E3a were eliminated.

Yes
Yes
<p>As a general policy, Dominion believes that attempting to precisely refine the definition of the BES may not be the best way to insure BES reliability. Instead, industry effort should be focused on developing specific reliability standard requirements targeted toward solving problems that need to be addressed. Stated differently, every Element that could have an impact on the BES does not need to be included in the definition of the BES. NERC's Functional Model addresses the broad range of functions performed by the electric utility industry. When reliability concerns are identified and can best be addressed via a standard, modifying the requirements in that standard as applicable to that functional model should occur rather than attempting to modify the BES definition. Effort spent on developing specific reliability standard requirements mentioned above is superior to the industry engaging in definitional debates that do not address to the underlying reliability drivers. It is not essential that each reliability standard explicitly apply to each registered entity. The existing reliability requirements, as applied to the various functional entities require communication of information necessary to insure there are no reliability gaps, either directly or indirectly among the various entities. The existing standards typically have a hierarchy wherein: • Planners (PA, TP) receive information predominately from the owners (GO, DP, TO) and those that represent end-use customers (LSE and PSE); • Reliability entities (BA, RC and TOP) receive information predominately from operating entities (GOP, TOP) and those that represent end-use customers (LSE and PSE); • Planners provide reliability assessments to Reliability entities (BA, RC and TOP) and receive feedback on these reliability assessments (including validity of assumptions and result); and • Reliability entities (BA, RC and TOP) give instructions (including when necessary directives) to operating entities (GOP, TOP) and those that represent end-use customers (LSE and PSE). This is how the industry has historically operated, how it operates today and why the standards in place today are structured as they are. Reliability is best served when the standards themselves contain the appropriate requirements and are applied to either an Element or Facility or to the appropriate functional entity (DP, GO, GOP, LSE, TO, TOP, etc.). Definitional boundaries can create the potential for false positives in reliability and, in fact, may be detrimental to reliability in the longer term if they impose additional compliance burdens without closing a reliability gap.</p>

<p>There is no established basis for the generation thresholds referenced through the ERO Statement of Compliance Registry Criteria in Appendix 5B and the specificity of 75 MVA in the proposed BES definition. The objectives identified in the Phase 2 SAR for the definition of the Bulk Electric System include establishing an engineering basis for the generation thresholds. Phase 2 will be critical in refining and improving the Bulk Electric System definition and bringing additional clarity to the definition.</p>
Yes
No
<p>Nameplate rating of the generator is not a reflection of what can be actually injected into the transmission system with resulting electrical impacts on transmission loading and behavior. Recommend the BES definition be based on a generators established net accredited generating capacity instead of what it could do by nameplate rating. In addition, many generators do not achieve their nameplate rating due to limitations imposed by the limitations and capabilities of their turbine/boiler capabilities. Using the nameplate rating will not allow the exclusion of some generators that should be excluded. Recommend the following language: Generating resource(s) with a net accredited capability per the ERO Statement of Compliance Registry Criteria and including the generator terminals through the high-side of the step-up transformer(s), connected at a voltage of 100 kV or above.</p>

We believe that the new definition is a good clarification.
Yes
No
1. The parenthetical phrase regarding the ERO SCRC is not clear. Is the intent that the inclusion applies to any generating resource that is required to register as a Generator or Generator Operator per the ERO SCRC? Or was a reference to the 75 MVA threshold inadvertently omitted? It also seems that it wouldn't need to be in parentheses, just make it a phrase in the sentence. 2. The wording of the sentence after the parenthetical phrase is also worded awkwardly. Suggest changing it to "including the generator terminals and all electrical equipment up to and including the high side of generator step up transformers, if they are connected at a voltage of 100 kV or higher.
Yes
Yes
No
There should be a limitation on what reactive components needs to be included. The limits could be based on capacity of the units or on the voltage step that occurs upon switching of the device.
Yes
Yes
No
1. b) should be reworded to "Normally there is power flow only into the LN: The LN is not normally used to transfer power originating outside of the LN for delivery through the LN." There could be conditions inside the LN, such as large loads shut down for maintenance, which would allow the parallel transmission Elements to allow power to flow through the LN. Those conditions would have no negative or adverse effect on the BES. 2. Capitalize "Network" at the beginning of the Exclusion.
Yes
No
Group
David Thorne
Pepco Holdings Inc
Yes
Yes

No
The definition should not reference the ERO Statement of Compliance Registry Criteria; rather the actual generation threshold criteria should be listed in the definition itself. This way the definition can stand on it's own without having to refer to another document for applicability. Also, the wording should be changed to read "including the generator terminals through the high side of any dedicated generator step-up transformer(s), connected at a voltage of 100kV or above." Otherwise, the present wording could ensnare distribution facilities (similar to the cranking path argument in I3) if a 21 MVA generator was connected on a distribution line with no dedicated generator step-up transformer. In that case the distribution line and substation feeder transformer might be construed to be in scope.
Yes
Agree with the SDT decision to delete the inclusion of Black Start Cranking Paths.
No
The SDT reworded Inclusion I4 to use the phrase "utilizing a system designed primarily for aggregating capacity". This was to address a concern that the previous definition could ensnare distributed generation or small generators in a distribution system. We agree with the intent of this modification. I4 was intended solely to address wind and solar farms that use a collector system to aggregate their capacity. Therefore, to provide better clarity on the intent of this Inclusion, perhaps it would be better to specifically mention these examples in the wording: "Dispersed power producing resources (such as wind and solar farms, etc.) which utilize a system designed primarily for aggregating capacity, where the capacity is greater than 75MVA (gross aggregate nameplate rating) and the facility is connected at a common point at a voltage of 100kV or above."
No
Agree in principle. However, the last phrase "or through a transformer that is designated in Inclusion I1" is unnecessary, since if the resource were connected through a transformer meeting Inclusion I1 it would by nature be connected at 100kV or higher.
No
1) Additional clarification is needed on whether certain bus sections supplying radial systems would be considered part of the BES. It is critical that the BES definition address this issue, since it will define what transmission Protection Systems fall in scope for PRC-004 & 005. One way to address this issue would be to add a qualifier to Exclusion E1 that states, "if a radial system is supplied from a bus section in a substation, then this bus section is considered part of the radial system and is not considered part of the BES if the tripping of this bus section does not result in an interruption to any BES facilities when the station is operating in its normal configuration." 2) Since the SDT deleted the inclusion of Black Start Cranking Paths in I3 then reference to I3 in criteria E1b and E1c should also be removed. Limits on connected generation should only be constrained by the 75MVA limit. In summary, delete the phrase "not identified in Inclusion I3" from both Exclusions E1b and E1c.
Yes
No
1) In the Drafting Teams Consideration of Comments on the previous version, it was stated, "...It is not the SDT's intent to specifically exclude any facilities in major metropolitan areas; it expects that the specific examples mentioned (NYC, Washington DC) would not qualify for exclusion under the revised Exclusion E3." The currently proposed E3 will result in specific exclusion of major local networks in major metropolitan areas. These major LNs qualify for exclusion under proposed E3, and its qualifiers, in that they distribute power to the local load rather than act as facilities to transfer bulk power across the interconnected system. However, the LNs that supply large amounts of load in very dense load areas should have some transmission reliability considerations. To capture the appropriate LNs in question, consideration should be given to limiting the amount of load supplied by a LN to some load level. For example if an LN has a peak load level of less than 1,000MVA it would qualify for LN exclusion and if it exceeds 1,000MVA it would not qualify for exclusion. There are certainly many LNs that supply relatively small amounts of load, just as radial facilities. They should be excluded. It is important to develop a load level that would provide the proper balance between the small LNs and the major LNs. 2) Since the SDT deleted the inclusion of Black Start Cranking Paths in I3 then reference to I3 in criteria E3a should also be removed. Limits on connected generation should only be

constrained by the 75MVA limit. Therefore E3a should then read "Limits on connected generation: The LN and its underlying Elements do not include generation resources with an aggregate capacity of non-retail generation greater than 75 MVA (gross nameplate rating):"

Yes

Yes

1) From the proposed BES definition and Exclusion E1 it is very clear that a 138-12kV distribution transformer serving radial load would not be considered part of the BES. However, suppose this transformer was connected to a position in a ring-bus or a breaker-and-a-half arrangement. Would the physical bus between the transformer high side terminals and the two breakers in the ring-bus, or breaker-and-a-half-bus, be considered part of the BES? They would be contiguous transmission elements (bus) operating at 138kV and supplying a radial distribution transformer. Also, tripping of this "radial" bus section would not interrupt any BES facilities, due to the station bus arrangement. As such, by definition and Exclusion E1 this 138kV bus section (element) would not be part of the BES, and no special exclusion filing would be required. Is this correct? However, take the same 138-12kV transformer but this time connected in a typical line-bus arrangement. The transformer by definition is not a BES element. As was the case above, the bus section between the transformer and the two breakers in the line-bus would be contiguous elements (bus) operating at 138kV and supplying a radial distribution transformer. Again, by definition and Exclusion E1 this bus section (element) would not be part of the BES. However, in this case tripping of the "radial" bus section would result in an interruption to the through path of the station, and could therefore interrupt the through flow on BES facilities. Does this make either the transformer, or its associated bus section, or both part of the BES? Based on the above examples, if the type of bus connection could influence whether an element is included in the BES or not, then additional language needs to be added to the definition (either as an Inclusion or Exclusion) to make this point clear. The BES definition needs to be specific enough to eliminate any confusion as to what is included, and what is not included, and thereby greatly minimize, if not eliminate, the need to request interpretations. A sample FAQ document, with examples, would be extremely helpful, but should not be a substitute for a BES description which leaves little room for interpretation. 2) As seen from the above attempt to describe issues that need clarification, without a diagram to show specific situations, it is difficult to fully explain the concerns on ensuring that the BES definition stands on its own. Since the commenting process does not accommodate diagrams, PHI is sending separately a white paper with diagrams in an attempt to clarify the definition and make it as unambiguous as possible, leaving little room for interpretation. This paper may be helpful in developing a FAQ document. 3) The definition should state that it applies to a system "normal" configuration. It does not include maintenance or N-1 or any abnormal configurations. 4) There was no place on the comment forms to comment on the proposed Implementation Plan for the BES definition. So comments are included here. The proposed plan states "compliance obligations for Elements included by the definition shall begin 24 months after the applicable effective date of the definition." This is fine for most applications; however, there is an effect with PRC-005 compliance. PRC-005 (Protection System Maintenance Standard) requires that evidence for the last two maintenance intervals, in order to demonstrate that you are following the prescribed intervals in your maintenance plan. If additional facilities are brought into scope by the new BES definition, and the protection systems associated with these facilities were not previously maintained on the same interval as other BES facilities, then it may not be possible within the allotted 24 months to demonstrate the facilities were maintained within the prescribed intervals for BES facilities. An implementation plan at least as long as one full maintenance cycle would be required to assure compliance. This issue needs to be addressed or coordinated with PRC-005.

Cynthia S. Bogorad

Transmission Access Policy Study Group (please see [www.tapsgroup.org](http://www.tapsgroup.org) for a list of TAPS' more than 40 members)

Yes

TAPS appreciates the SDT's work on this project. For the most part, TAPS supports what it believes to be the intent of the proposed language. The proposed specific exclusion of facilities used in the local distribution of electric energy is appropriate and consistent with Section 215 of the Federal Power Act. However, we have one suggestion to better carry out what we believe to be the SDT's intent. The SDT

proposes to change the core generation definition from the prior version's "...Real Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below," to "Unless modified by the lists shown below, ... Real Power and Reactive Power resources connected at 100 kV or higher...." Because of this change from "as described below... unless... modified by the list shown below" to simply "unless modified by the lists shown below," the proposed core definition now has the effect of including all generation, regardless of size, that is connected at over 100kV. We do not think this is the SDT's intent. For the same reason, the core definition now has the effect of including all Reactive Power resources connected at over 100kV, including generators; Inclusion I5, which includes "[s]tatic or dynamic devices dedicated to supplying or absorbing Reactive Power," does not alter the core definition's inclusion of all Reactive Power resources connected at over 100kV (whether "dedicated" or not). The most straightforward solution to this problem is to simply delete Real and Reactive Power resources from the core definition, so that such resources are instead handled entirely in the Inclusions. The core definition would thus read: "Unless modified by the lists shown below, all Transmission Elements operated at 100 kV or higher. This does not include facilities used in the local distribution of electric energy."

Yes

TAPS supports the intent of proposed Inclusion I2. For the sake of clarity, we suggest revising "per the ERO Statement of Compliance Registry Criteria" to "as described in the ERO Statement of Compliance Registry Criteria."

Yes

We recommend clarifying that the dispersed power resources covered by this inclusion do not include generators on the retail side of the retail meter. Specifically, we recommend that the Inclusion read: "Dispersed power producing resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating) utilizing a system designed primarily for aggregating capacity, connected at a common point at a voltage of 100kV or above, but not including generation on the retail side of the retail meter."

Yes

Yes

TAPS supports the exclusion of radial systems from the BES Definition. Such systems are generally not "necessary for operating an interconnected electric transmission network," the standard in Orders 743 and 743-A. We have several suggestions to clarify the proposed language for this Exclusion. Proposed Exclusion E1 refers to "[a] group of contiguous transmission Elements that emanates from a single point of connection of 100 kV or higher." We appreciate the SDT's clarification of the point of connection requirement, but the term "a single point of connection" should be further defined (more clearly than just by voltage), and should be generic enough to encompass the various bus configurations. It is not the case, for example, that each individual breaker position in a ring bus is a separate point of connection for this purpose; in that situation, a bus at one voltage level at one substation should be considered "a single point of connection." Some examples of configurations that should be considered a single point of connection for this purpose are at [https://www.frc.com/Standards/StandardDocs/BES/BESAppendixA\\_V4\\_clean.pdf](https://www.frc.com/Standards/StandardDocs/BES/BESAppendixA_V4_clean.pdf), Examples 1-6. Although the core definition (appropriately) refers to "Transmission Elements" (with a capital "T"), proposed Exclusion E1 refers to "transmission Elements" (with a lowercase "t"). To avoid confusion, either "Transmission" should be capitalized in both locations, or the word "transmission" should simply be deleted from Exclusion E1, leaving a "group of contiguous Elements." We understand that the lack of capitalization may have been a deliberate choice by the SDT in an attempt to avoid confusion that SDT members believe exists in the Glossary definition. If the Glossary definition of Transmission is unclear—which TAPS does not necessarily believe is the case—the answer is not to simply abandon the Glossary definition in favor of an entirely undefined term; it is to submit a SAR to improve the Glossary definition. Exclusion E1(c) refers to "an aggregate capacity of non-retail generation less than or equal to 75 MVA." "Non-retail generation" is potentially ambiguous, because it could be read as distinguishing between generation that will be sold at wholesale and generation that is used by the retail provider to meet retail load. On the understanding that the intent is in fact to

describe generation behind the end-user meter, sometimes referred to as "behind-the-second-meter generation," we suggest the following revision: "an aggregate generation capacity less than or equal to 75 MVA, not including generation on the retail customer's side of the retail meter." Exclusion E1 concludes with a "Note": "A normally open switching device between radial systems, as depicted on prints or one-line diagrams for example, does not affect this exclusion." The Note should not specify the types of evidence required to prove a normally open switch, and the phrase "as depicted on prints or one-line diagrams" should be deleted. This phrase is equivalent to a "Measure" in a standard and should not be embedded in the equivalent of a "Requirement." Since the phrase only gives an "example," it does not in fact add anything to the Note, but may lead to confusion over what sort of evidence is required. If the phrase remains in the Note, it should at minimum be better explained: "A normally open switching device between radial systems, as depicted on prints or one-line diagrams used in the normal course of business for example, does not affect this exclusion." In addition, while we believe the SDT's intent is that two otherwise radial lines connected to each other by a normally open breaker are both excluded, the statement that a normally open switching device "does not affect this exclusion" is unclear. We suggest that the note be modified to state that a normally open switching device "does not prevent this exclusion from applying," or words to that effect.

Yes

Yes

TAPS supports the exclusion of Local Networks from the BES. Such systems are generally not "necessary for operating an interconnected electric transmission network," the standard in Orders 743 and 743-A. We have several suggestions to clarify the proposed language for this Exclusion. TAPS' comments in response to Question 7 above regarding "points of connection at 100kV or higher" and "non-retail generation" are applicable to Exclusion E3 as well. The term "bulk power," which occurs twice in Exclusion E3, is vague and could be read incorrectly as a reference to the statutorily-defined "bulk-power system," which is not, we think, the SDT's intent. The word "bulk" should be deleted, so that the Exclusion simply refers to transferring "power" across the interconnected system. TAPS raised this concern in response to the last posting of the BES Definition. In response, the SDT removed some instances of "bulk power" but left the remaining two, stating that "the SDT believes it provides conceptual value to the exclusion principle." The SDT does not state what conceptual value the term is intended to provide; on the assumption that it relates to a distinction between transferring power from local generation to serve local load, and transferring power over longer distances, TAPS suggests, as an alternative to simply deleting the word "bulk," that the Exclusion be revised to refer to "transfers of power from non-LN generation to non-LN load." Exclusion E3(c) states: "Power flows only into the LN: The LN does not transfer energy originating outside the LN for delivery through the LN." This statement is unclear because the two parts mean different things. TAPS proposes rewriting this sentence to state: "Power flows only into the LN, that is, at each individual connection at 100 kV or higher, the pre-contingency flow of power is from outside the LN into the LN for all hours of the previous 2 years" to help clarify the intent. Two years is suggested because it is the time period set out in the draft exception application form for which an applicant should state whether power flows through an Element to the BES.

Yes

Individual

Joe Tarantino

Sacramento Municipal Utility District

Yes

In an effort to avoid potential confusion and provide clarity we believe the following sentence "This does not include facilities used in the local distribution of electric energy" more appropriately fits under the "exclusions," rather than "inclusions," section.

Yes

We believe additional clarification of transformers that are to be included may be achieved with respect to auto transformers, phase angle regulators and generator step-up transformers by adding the following recommended sentence: "All transformers (including autotransformers, voltage

regulators, and phase angle regulators) with primary and secondary terminals operated at or above 100kV, unless excluded by E1 or E3.”

No

We recommend removing the reference of the ERO Statement of Compliance Registry Criteria (Registry Criteria). The BES Definition should be the governing document and independent of ERO registration requirements. The definition should drive what appears in the Registry Criteria. Additionally, we support using the BES Phase 2 technical analysis to identify and provide technical support for determining the appropriate minimum MVA rating that a single unit, or the aggregation of multiple units, must meet to be considered part of the BES.

Yes

We recommend rewording Inclusion I3 as follows: “Only Primary Blackstart resources designated as part of the Transmission Operator’s restoration plan.” We have concerns that making all Blackstart generation either primary or secondary BES elements will create an incentive to remove those secondary Blackstart capable units in order to avoid BES inclusion. Making the primary Blackstart unit the only BES element will remove this incentive. In so doing, this will allow the secondary Blackstart units to remain in the Transmission Operator’s plan and training program as an alternate tool for the Transmission Operator to restore the system.

Yes

We support using the BES Phase 2 technical analysis to identify and provide technical support for determining the appropriate minimum MVA rating that the aggregation of multiple units must meet to be considered part of the BES. We also support using the Phase 2 studies to identify an appropriate minimum MVA level that a single unit of the aggregation of multiple units must be considered BES.

Yes

However, appropriate MVAR level should be established. Reactive resources should be treated similar to generation criteria and included in the technical studies associated with the Phase 2 technical analysis in order to establish the appropriate MVAR level included as BES.

Yes

For the E1 reference “Note,” we would benefit from additional clarification identifying the treatment of a normally open switch and offer the following: “Radial systems shall be assessed with all normally open switching devices in their open positions.” The wording in Exclusion 1-c should more clearly reflect what is intended by using the term “non-retail generation.” Also, as with the technical justification for Inclusions I2 and I4, it is recommended that the generation threshold, i.e. gross nameplate values, be deferred to Phase 2.

Yes

It is preferred to hold reference to gross nameplate rating/threshold values until generation technical justification is completed as part of Phase 2; these studies should apply to any real or reactive power threshold reference. For Exclusion E3-b using the phrase “[p]ower flows only into the LN” is too restrictive. An allowable MW threshold of LN power producing resources should be deferred to the Phase 2 BES technical analysis. Where no generation is present in the LN, it is recommended that an allowance for residual flow through the LN.

Yes

Group

John P. Hughes

Electricity Consumers Resource Council (ELCON)

Yes

However, one of the FERC directives in Order 743 charged NERC with delineating the difference between transmission and distribution. The Inclusions and Exclusions are a step in that direction, but this subject will need more consideration in Phase II.

Yes

No
Since an aggregate of 75 MVA is allowed at a single site, there is no basis for maintaining the 20 MVA for a single generator. The proposed MOD-026 assigns thresholds by region that are much higher than 20 MVA for modeling purposes. Since modeling generally would require more granularity than what is necessary for the reliable operation of the interconnected transmission system (BES), the SDT might want to review the threshold basis for NERC Project 2007-09 (Generator Verification). It is understood that the threshold will be reconsidered in Phase II of the BES Definition Project; however, a modest change from 20 to 75 MVA seems appropriate on an interim basis justified by the current 75 MVA aggregate per site. The following phrase should be added at the end "unless excluded under Exclusion E2."
Yes
Yes
The term "dispersed power" and "dispersed generation" are often synonymous with distributed generation, which includes behind-the-meter generation (CHP). The Inclusion should be clarified by specifically referencing wind and solar, or adopt the FERC term "Variable Energy Resources." Also, to distinguish this Inclusion from Inclusion I2, the SDT might want to clarify that the collection system (usually at voltage below 100 KV anyway) is not part of the BES—just the resources and any transformers included by I1, if this is indeed the intent of this Inclusion. The following phrase should be added at the end "unless excluded under Exclusion E2."
Yes
Yes
ELCON supports the changes made from the first posting for both E1 and E3 (which complements E1), as this will help maintain the status quo referred to in the introductory text. We seek one clarification: Some large industrial customers that operate in remote, rural locations provide distribution services to third parties (usually on a pro bono basis) where the local utility (LSE) is unable or unwilling to serve. These transactions, which are akin to "border-line sales" in utility parlance, are typically de minimis relative to the Load of the entity that delivers the power. While the distribution is at low voltages (less than 100 kV), the power may have been received by the entity at a higher voltage. We seek affirmation by the SDT that such situations are not precluded by Exclusion E1.
Yes
ELCON supports the proposed revisions to Exclusion E2.
Yes
This Exclusion and Exclusion E1 aid in the delineation of local distribution versus transmission. We suggest three clarifying revisions. First, the phrase "but less than 300 kV" should be deleted. Many large industrial facilities have on-site distribution systems that operate above 300 kV due solely to the capacity of the lines to supply power over the distance required at the manufacturing sites. Second, for the same reasons discussed above (in response to question #7), the phrase "do not have an aggregate capacity of non-retail generation greater than 75 MVA (gross nameplate rating)" in "a)" should be changed to "the net capacity provided to the transmission grid does not exceed 75 MVA." Third, the introductory phrase in "b)" -- "Power flows only into the LN" -- is inconsistent with the recognition in "a)" that power may flow out of an LN and into the transmission grid if there is generation connected to the LN and the 75 MVA limit is observed. We recommend either deleting the introductory clause or correcting it to read "Power is not transferred through the LN."
Yes
This is a needed exception to Inclusion I5 as these reactive power resources are used by retail customers for power factor correction at their own facilities in order avoid imposed power factor penalties.
No

Don Schmit
Nebraska Public Power District

Yes
The drafting team has done a great job of adding clarity and to improving the BES definition. Although more work is needed as noted in comments below, overall the drafting team is on the right track with the BES defintion.
Yes
No
Inclusion 2 does not take into consideration a later exclusion (Exclusion 3). At the end of Inclusion 2 after the words "...100 kV or above." Add the words ", unless excluded under Exclusion 3".
Yes
Yes
However the exclusion needs to be noted in I2, so as to non conflict with I2. (See comment on #2 above.)
No
In E3 (a): please define "non-retail generation" as used in E3(a). Also, what is the criterion that makes this generation BES generation? The MVA rating only, or is there other criteria? A generator may have a 75 MVA gross nameplate rating, but may be limited physically or electrically to below the 75 MVA. Is this a basis for exclusion for this generator?
Yes
Regarding the Local Network: Can there be some additional technical documents or examples provided for the most common configurations? The LN document is a good document to provide guidance, however the supply of common configuration examples would be very helpful in determining LN applicability. Examples where technical document with examples would be helpful: 1. If a breaker and a half source substation provides two parallel 115 kV lines feeding a load only substation from separate breaker and a half legs at the source substation, would the two parallel lines feeding the load be a LN distribution network feed since theyare from the same source substation? 2. if there is a radial feed from a ring bus or a breaker and a half configuration to a radial load on a single line can the portion of the ring bus or breaker and a half bus between the line breakers and the breakers themselves at the source substation be excluded from the BES? 3. Can some legs of a 115kV breaker and a half substation be disgnated BES and the other legs be non BES depending on how the BES lines and loads tie in to the breaker and half legs? 4. In determining if elements are BES is there any consideration to fault locations and if these faults would interrupt BES flow on ring bus or breaker and a half configurations to help determine what is BES? If so, how many contingencies would be considered to interrupt BES flow?

David M. Conroy
Central Maine Power Company
No
The second sentence, "This does not include facilities used in the local distribution of electric energy," is vague and not sufficiently clear for northeast industry expert colleagues to be certain of what is "not included." This sentence seems to apply only to distribution facilities that have already been classified based on the FERC "Seven Factor Test" in Order 888. If so, this sentence should be restated as follows for clarity: "This does not include facilities classified as distribution facilities." For US entities, this classification is clearly delineated in our annual FERC Form 1 filing.
Yes
We generally agree, but suggest modification to the language of Inclusion I1 to clarify its application for transformers with more than two windings: "Transformers with two or more terminals operated at 100 kV or higher, unless excluded under Exclusion E1 or E3." Based on this wording, transformer

tertiary windings would also be BES – is that the intent?
No
Inclusion I2 should remove the reference to the Statement of Compliance Registry Criteria. The definition should stand on its own. I2 should be revised to read: “Generators with a gross nameplate rating of 20 MVA or greater, or a generating plant/facility connected at a common bus, with a gross aggregate nameplate rating of 75 MVA or greater; and is directly connected at a voltage of 100 kV or above. BES includes the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100 kV or above.” This is consistent with the proposed I2 and the current Compliance Registry Criteria.
No
Inclusion I3 should be changed to include the phrase, “material to,” currently in the Statement of Compliance Registry Criteria (Section 3C3). Based on the definition wording, the Generator Step-Up transformer (GSU) would not be BES if the generator would not otherwise already be included as BES under another definition provision.
No
The term “common point” needs clarification and/or definition. (e.g., is it intended to apply to the risk of single mode failure, where all the resources could be lost for a single event?) Some northeast industry expert colleagues interpret I2 to mean the collector system itself needs to be 100 kV or above in order to be BES. I2 seems to not include the collector system itself in BES. I4 should be restated as follows: “Dispersed power producing resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating) utilizing a collector system connected at a common point. BES includes the interconnecting substation with the step-up transformer(s) connected at a voltage of 100 kV or above.” [alternatively, replace “interconnecting substation with” with, “generator terminals through the high-side of” if the entire collector system is intended to be BES] Also note that some wind collector systems require supplemental dynamic reactive resources or special control system to meet reliability standards. As written, these reactive resources or controls may not be considered to be BES.
Yes
There is no such thing as “supplying or absorbing Reactive Power” but the intended meaning is sufficiently clear since it is industry ‘shorthand’. We suggest an alternative wording of: “Static or dynamic Reactive Power resources that are connected at 100 kV or higher, or...”
No
E1 needs to be revised to make it less confusing. “Radial systems” leaves the impression that E1 is not simply a “radial line exclusion”, because of the plural and the word “systems.” Northeast industry expert colleagues are not clear what this sentence specifies: “A group of contiguous transmission Elements that emanates from a single point of connection of 100 kV or higher.” • Does E1 apply only to a single radial transmission line (and its associated “group of Elements”)? • Alternatively, does E1 apply to multiple radial lines “emanating from” the same substation regardless of the bus configuration – would a ring bus or a two-bus system that is connected with a tie breaker be considered as “a single point of connection”? • If the radial line is simply tapped off a BES line without any automatic interruption device, should not the radial line be included as part of the BES since a permanent fault on this radial line will take out the BES line it is tapping off of? If the radial line is defined as part of the BES, it could be subject to certain requirements such as vegetation management for overhead lines. • Should not the exclusion include some description of the operational requirements to help resolve the ambiguity? As it is, the exclusion is scenarios-based. When a specific scenario is overlooked, the oversight becomes a source of ambiguity. This definition is not clear. Clarity is imperative. E1(c) should define or replace the term “non-retail”. Industry needs clarity on exactly what generation this clause applies to, in order to properly apply this definition. The Note referring to the “Normally Open switch” needs further clarification. As written, it seems to conflict with FERC order 743, paragraph 55: “While commenters would like to expand the scope of the term “radial” to exclude certain transmission facilities such as tap lines and secondary feeds via a normally open line, we are not persuaded that such categorical exemption is warranted.” E1 should be restated as follows: “Radial systems: A single transmission line or transformer not otherwise identified in the Inclusions above, with a single point of connection of 100 kV or higher and: a) Only serves Load. Or, b) Only includes generation resources, not identified in the Inclusions above. Or, c) Both serves Load and only includes generation resources not identified in the Inclusions above.”

No

E2 should be consistent with the Statement of Compliance Registry Criteria. References to Balancing Authority, Generator Owner, and Generator Operator should not be included in the BES definition. "Net capacity" is unclear – must flow never exceed 75 MVA on an instantaneous or integrated hourly energy basis per either design or operating experience? There is a potential for hundreds of MW to be interconnected at a customer facility, with the "net capacity" (= flow into the transmission system? Instantaneous? Annual average? On an integrated hourly basis at any hour?) being less than 75 MVA – are hundreds of MW of generation "not material" to BES reliability? The conditions under which direction of flow (i.e., "net capacity") is assessed are critical, but E2(i) is silent on this. In E2(ii), the "and", "or", and "or" are not clear – what are the necessary terms of the referenced "binding obligation" and what is an "applicable regulatory authority"? Are "standby" and "back-up" and "maintenance" power services independently defined and provided by a GOP, GO, or BA? Northeast industry expert colleagues do not understand the relevance of E2(ii) to BES reliability. E2 should be restated as follows: "A generating unit or multiple generating units that serve all or part of retail customer Load with electric energy on the customer's side of the meter if the flow to or from the BES can never exceeds 75 MVA."

No

"Local Network" is capitalized (network not capitalized at the beginning of E3) throughout E3, yet it is not defined in the NERC Glossary. This exclusion is vague. This exclusion applies to a network with "multiple points of connection" with the purpose "to improve the level of service to retail customer load" – this phrase is intent-based and not reliability-based – most/all transmission "improves service" compared to it not being there. In essence, this exclusion can be obtained if a portion of the network: 1. Doesn't have significant generation (again, "non-retail" phrase is unclear) 2. Power only flows "into" this portion of the network, and not (ever? Even under any TPL design contingencies?) "out." Is this considering only pre-contingency steady state conditions? During contingency conditions and for the period following a contingency the LN could supply power to other parts of the network depending on the nature of the contingency. The conditions under which direction of flow is assessed are critical, but E3(b) is silent on this. 3. This portion of the network is not part of a monitored transmission interface This "Local Network Exclusion" is supported by a technical analysis which relied on transmission distribution factors (see [http://www.nerc.com/docs/standards/sar/bes\\_definition\\_technical\\_justification\\_local\\_network\\_20110819.pdf](http://www.nerc.com/docs/standards/sar/bes_definition_technical_justification_local_network_20110819.pdf) on the NERC BES Definition standard page [http://www.nerc.com/filez/standards/Project2010-17\\_BES.html](http://www.nerc.com/filez/standards/Project2010-17_BES.html) ). This transfer distribution factor (TDF) method was rejected by FERC in Order 743. Paragraph 85 of the Order states: "Given the questionable and inconsistent exclusions of facilities from the bulk electric system by the material impact assessment and the variable results of the Transmission Distribution Factor test proposed in NPCC's compliance filing in Docket No. RC09-3, there are no grounds on which to reasonably assume that the results of the material impact assessment are accurate, consistent, and comprehensive.<sup>93</sup> Additionally, we have noted how the results of multiple material impact tests can vary depending on how the test is implemented." The phrase "contiguous transmission elements" is also not clear, especially when qualified as not being part of a monitored transmission interface. Should the "contiguous transmission elements" comprise a complete and exhaustive set of contiguous elements? Or can they be a subset of a larger contiguous set in which the other elements of the larger set are actually part of a monitored interface? Unless E3 is made more specific and clear, it should be stricken.

No

Consider using other wording to replace "retail"

Yes

If the definition and inclusions and exclusions are not sufficiently specific and clear, stakeholders will flood NERC and RROs with interpretation requests and/or apply the definition and its inclusions or exclusions incorrectly. Explanatory figures with one-line diagrams should be developed and shared to illustrate the system configurations included and excluded in a BES Definition. This would be very helpful for definition clarity. This should be done as part of an "Application Guide" for the BES Definition – there is precedence for an "Application Guide" with graphical support in CIP-002 version 5. A sample set of one-line diagrams with interpretations based upon the inclusions and exclusions developed by Northeast Power Coordinating Council members for discussion purposes is available as an example, but note that there is not a uniform agreement on these diagrams based on the BES Definition as written, due to lack of clarity.

Yes
a)The general concept is sound, but the Inclusion and Exclusion sections create so many circular references it is virtually impossible to take a definitive stance on whether an asset is included or excluded to the BES definition. Please revise the inclusion and exclusion criteria to give pinpointed statements that are final and do not reference other criteria, that then again reference other criteria.b)We believe that 200kV and above is the appropriate bright line for the Bulk Electric System. c)In I5, only those Reactive Power devices applied for the purpose of BES support or BES voltage control should be included. A Reactive Power device connected at >100kV but used for the purpose of voltage support to local load should not be included. d)The core definition uses "Transmission Elements" while E1 uses "transmission Elements". What is the difference? If one or both terms are applicable, their definition should be included.
Yes
Agree in general, but have the following comments:a)We agree in general with the revisions to the specific inclusions for transformers in I1; however, we believe the transformer voltage level should be 200kV or above. b)The inclusion is unclear since it includes a certain voltage transformers, but excludes those that have E1 or E3 Exclusion criteria. Each exclusion criteria has multiple stipulations to its applicability, and then has a final inclusive reference to I3. Please make the wording exact and not dependent on clausal statements.
No
a)This definition becomes dependent on a document that can be changed without direct correlation to the BES definition. Remove the reference to the ERO Statement of Compliance Registry Criteria, and simply state the criteria as currently used. There is no need to look up another definition in another document to identify what is included in the BES definition. b)All MOD Standards' requirements for generators should also follow this definition.
Yes
a)The definition should include only those black start generators connected 100 kV and above and included in the restoration plan. b)We agree with the changes but believe clarity would be added by changing the word "identified" to "designated".
Yes
a)For a consistent application, we suggest that the definition of the terms "Dispersed power producing resources" is included. Consider including some examples also.
No
a)Only those Reactive Power devices applied for the purpose of BES support or BES voltage control should be included. A Reactive Power device connected at >100kV but used for the purpose of voltage support to local load and/or needed to support local networks should be excluded. b)We believe that this inclusion should be limited to dynamic devices with an aggregate capacity greater than 75 MVA (gross aggregate nameplate rating) connected through a common point. c)See the response to question 2: The inclusion is unclear since it includes a certain voltage transformers, but excludes those that have E1 or E3 Exclusion criteria. Each exclusion criteria has multiple stipulations to its applicability, and then has a final inclusive reference to I3. Please make the wording exact and not dependent on clausal statements.
Yes
a)We suggest the wording "non-retail generation" should be clarified with an explanation of why it is used in this exclusion. b)This exclusion criterion has multiple stipulations to its applicability, and also has a final inclusive reference to I3. Please make the wording exact and not dependent on clausal statements.
No
a)If retail generation fails to meet (i) or (ii) it appears that the retail generation would be included. The wording of (ii) is complex. Who will police this with retail behind-the-meter generators? b)Clarification needs to be provided for what is meant by E2 (ii), regarding generation on the customer's side of the retail meter; otherwise we have trouble developing a position on this question.

No
a) The exclusion should also be extended to reactive resources needed to support the local area network (see response to Q10). It is also suggested that "local network" be renamed to "local area network" to better describe or distinguish itself from a wide-area network such as the BES. b) We would agree with the exclusion if the wording of the exclusion includes the following phrase (in italics) added at the end of E3 b): Power flows only into the LN: The LN does not transfer energy originating outside the LN for delivery through the LN "under normal operating conditions".
No
a) Reactive Power devices connected 100 kV and above applied for the purpose of voltage support to local load and/or local area network should also be excluded.
Yes
a) We believe this revised definition is an improvement over the previous posting, a step in the right direction. b) The definition of the BES is referenced in several existing standards and the Statement of Compliance Registry Criteria. Our concern is how this revised definition will impact entity registration, i.e., how will the revised definition be integrated into the Compliance Registry Criteria. The implementation plan should include how the integration is going to occur. The Rules of Procedure exception process should be further defined or referenced in this definition. c) See Question 1 response: The general concept is sound, but the Inclusion and Exclusion sections create so many circular references it is virtually impossible to take a definitive stance on whether an asset is included or excluded to the BES definition. Please revise the inclusion and exclusion criteria to give pinpointed statements that are final and do not reference other criteria, that then again reference other criteria

William D Shultz
Southern Company Generation
No
We have two concerns with the changes that are proposed. First, the use of "effective dates" and "compliance obligations ... shall begin" in the implementation plan of the definition change is confusing. Effective date is usually used to indicate the mandatory and enforceable date of a new item. Second, a radial circuit from 100kV to a generating facility with two (2) 20 MVA generators seems to meet both the inclusion criteria (I2) and the exclusion criteria (E1). Which criteria is dominant, inclusion or exclusion?
Yes
Yes
Yes, provided that the minimum gross individual nameplate rating threshold is the same as the gross aggregate nameplate rating (currently > 75MVA). The MVA ratings are specified in many places in the BES definition, where a reference is made in I2 to using the Statement of Compliance Registry Criteria. We believe that the BES definition should point to the Statement of Compliance Registry Criteria and not include MVA values. We also believe individual units < 75MVA should be excluded unless they have been shown to be critical to BES reliability through a technical justification study performed by the transmission planning authority.
Yes
Yes
Yes
We believe that the size of the reactive power resource should be considered as a key factor to be part of BES. When considering generating resources, the size, e.g., greater than 75 MVA, was a key part of criteria to be included or excluded as BES. A similar approach should be applied when considering reactive power resources. Moreover, the language at the end of I5, "or through a transformer that is designated in Inclusion I1," appears to be redundant since the reactive power resources are connected to 100 kV or higher already without this additional language. The following language is suggested: I5 - Static or dynamic devices dedicated to supplying or absorbing Reactive Power that are connected at 100 kV or higher, or through a dedicated transformer with a high-side

voltage of 100 kV or higher, and with an aggregate continuous nameplate rating greater than 30 MVA.

No

Subpart (b) uses the term "generation resources" while subpart (c) uses the term "non-retail generation", why are these different terms used? Further, why is it important that the term "non-retail generation" is used in subpart (c)? In addition, the SDT needs to clarify what the term "non-retail generation" means. Is this what is commonly referred to as "customer owned" or "behind-the-meter" generation? The change in version 2 that removed the requirement that an excluded radial system have an automatic interruption device at the single point of connection to the rest of the BES creates a problem. Three-terminal circuits are common below 230 kV. The "tapped portion" should not be left out of the BES since a fault on that portion takes out the whole line. We propose this revised language in the first sentence on E1: "E1 - Radial systems: A group of contiguous transmission Elements that emanates from a single point of connection of 100 kV or higher, where the connection has an automatic interruption device,..." Exclusion E1, subpart (c) uses the phrase "an aggregate capacity of ... less than or equal to 75 MVA ...". Exclusion E3. subpart (a) provides that the local networks "do not have an aggregate capacity of ... greater than 75 MVA ...". Why are these phrases stated differently even though they appear to address the same resources?

Yes

Some editing is needed. The second part, (ii), of the and logic provided for the exclusion criteria E2 is confusing. The initial criteria, (i), seems to be adequate regarding impact to the BES. The criteria listed after "(ii)" does not seem to be relevant to the impact on the BES. What does it mean to provide standby, back-up, and maintenance power services to a generating unit or multiple generating units? It is unclear who is providing the power service. If this is needed, the statement needs to be simplified so it can be understood. What is the difference between the terms "retail Load" and "retail customer Load" as used in Exclusions E2 and E3?

Yes

What does the term "non-retail generation" mean? Can the term "non-retail generation" in E3a be changed to simply "generation."

Yes

Yes

1) On page 1, the year of the anticipated date for the BOT adoption is correctly 2012. 2) We believe that the last two sentences of the first paragraph of the Background Information section of the 2nd draft of the definition document is incorrect. The statements read: " It should be noted that the revised definition does not address functional entity registration or standards requirements applicability. Those are separate issues." The definition of the BES that is approved will govern the scope of the equipment that is relevant to many of the reliability standards. This issue cannot be separated from the applicability of the requirements of the reliability standards. What is the purpose of creating a continent wide definition of the BES if it is not to provide instruction the entities subject to the requirements of the standards? Refer to these sample standard requirements to see that this definition already plays a major part in the applicability of the requirements: EOP-005-2 R1, R4; EOP-006-2 R1; EOP-008-1 R1; FAC-008-1 R1.2; and PRC-005-1a for example - there are many others.

Item (b) is unclear: Although the first sentence says "Power flows only into the LN," which suggests there will be no exports, the second sentence says "The LN does not transfer energy originating outside the LN for delivery through the LN," which suggests it could deliver power originating within the LN. This would seem to be reasonable by comparison to E-2, so long as no more than 75 MVA is exported (which is indeed the limitation on the quantity of "non-retail generation" in the LN). On a related point, if the limit on connected generation is not intended to be a limit on possible exports, and therefore any power from interconnected non-retail generation must be sold within the LN, why does the limit need to be so low; why should the aggregate quantity of such internally-consumed generation be an issue? Also, is the "non-retail" designation intended to exclude customer-owned generation from the 75 MVA calculation?
Yes
No

No
Need to clarify the systems associated with this inclusion. The phrase "dispersed power producing resources" in inclusion (14) is confusing and does not clearly communicate the focus of this inclusion. Without reviewing the reference information provided in the 1st draft comment form, it's not clear that dispersed power producing resources refer to wind and solar resources. Recommendation: Include examples after phrase "dispersed power producing resources" for clarification to this inclusion. Change I4 to read - Dispersed power producing resources (i.e. wind and solar resources) with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating) utilizing a system designed primarily for aggregating capacity, connected at a common point at a voltage of 100 kV or above.
No
This inclusion should be worded to only include static or dynamic reactive devices which are necessary to meet the NERC Planning Criteria in terms of normal and post-disturbance voltage profiles. We shouldn't have to include smaller shunt cap banks and reactors which are used primarily for voltage support (not voltage collapse). Recommendation: Change I5 to read - Static or dynamic devices dedicated to supplying or absorbing Reactive Power which are necessary to meet the NERC Planning Criteria in terms of normal and post-disturbance voltage profiles that are connected at 100 kV or higher, or through a dedicated transformer with a high-side voltage of 100 kV or higher, or through a

transformer that is designated in Inclusion I1
Yes
Yes
Yes
Yes
Yes
Yes, the definition should also provide clarification on mobile equipment installed to support maintenance or equipment failures. Adding mobile equipment is a common practice for our industry and should be addressed in the definition to bring a general awareness and common understanding of the practice regarding the NERC standards. Recommendation: Add the following Exclusion to BES definition for mobile equipment. Exclude all mobile equipment on stand-by that has not been placed into service as well as all components of mobile equipment that does not meet the inclusion criteria for the primary function of the device being installed (e.g. ,battery bank on mobile transformer installed on radial feed would also be excluded)
Individual
Scott Miller
MEAG Power
Yes
MEAG agrees to the clarifying changes to the core definition in general, however, we maintain that 200kV and above is the correct bright line for the BES.
Yes
We agree in general with the revisions to the specific inclusions for transformers in I1; however, we believe the transformer voltage level should be 200kV or above.
Yes
We agree in general with the revisions to I2 for generation; however, we maintain that 200kV and above is the correct bright line for the Bulk Electric System.
No
We agree with the changes but believe clarity would be added by changing the word "identified" to "designated".
Yes
No
We feel that this inclusion should be limited to dynamic devices with an aggregate capacity greater than 75 MVA (gross aggregate nameplate rating) connected through a common point.
Yes
We suggest the wording "non-retail generation" should be clarified with an explanation of why it is used in this exclusion.
No
Clarification needs to be provided for what is meant by E2 (ii), regarding generation on the customer's side of the retail meter; otherwise we have trouble developing a position on this question.
No
We would agree with the exclusion if the wording of the exclusion includes the following phrase (in italics) added at the end of E3 b): Power flows only into the LN: The LN does not transfer energy originating outside the LN for delivery through the LN "under normal operating conditions".
Yes
Yes

The definition of the BES is referenced in several existing standards and the Statement of Compliance Registry Criteria. We are concerned how this revised definition will impact entity registration, i.e., how will the revised definition be integrated into the Compliance Registry Criteria. The implementation plan should include how the integration is going to occur.
Group
David Dockery or John Bussman
AECI
Yes
In general, we agree with this revision. We however believe the correct voltage thresholds to be, transformer primary voltage of 200 kV or higher and secondary voltage of 100 kV or higher.
No
"100 kV or above" should be modified to "200 kV or above with a registered rating of 150 MVA or greater."
Yes
The word "identified" should be replaced with "designated".
Yes
In general, we agree with this revision. However, the aggregate MVA threshold should be 150 MVA or greater, and threshold voltage level should be 200kV or higher.
Yes
This inclusion should be limited to reactive devices 150 MVAR or greater (gross aggregate nameplate rating) connected through a common point at the 200 kV level or higher level.
Yes
This inclusion should be limited to reactive devices 150 MVAR or greater (gross aggregate nameplate rating) connected through a common point at the 200 kV level or higher level.
Yes
Remove "non-retail" because it is irrelevant to reliability. In general, we agree with the remaining concepts. However transformer voltage threshold should be 200 kV or higher, the power thresholds should be 150 MVA or greater.
Yes
E2 "retail meter" should read "retail meter(s)". (i) Should be reworded as "the maximum net impact to the BES does not exceed 150 MVA, connected at 200 kV or higher." (ii) if we understand this clause correctly, we believe our proposed (i) wording will handle the issue. Also, all load's inclusion, within a BA, is dictated within the BAL standards and so remove entirely or additional clarification is needed.
Yes
We would agree in principle with the LN exclusion if the wording of the exclusion includes the following phrase (in italics) added at the end of E3 b): Power flows only into the LN: The LN does not transfer energy originating outside the LN for delivery through the LN "under normal operating conditions". Also, the correct BES threshold level should be 200 kV rather than 100 kV. Finally, the nomenclature of Flowgate (FG) components appears to be confused. AECI believes E3 c) should be changed to read "contingent Facility" rather than "monitored Facility". Although unspecified within the NERC Glossary, we believe FG monitored Facilities are typically the impacted facilities in danger of overload, while the contingent facilities are those which, if lost, would cause the monitored Facility to become overloaded. As currently written, a formerly qualified LN could later become disqualified due to an external entity's ill-designing a parallel EHV line, thereby causing one or more potential (N-1) overloaded Facility within that LN. Further, operational FG loading conditions are often relieved by opening-up LN elements near the monitored Facility, with little impact upon BES reliability, yet with lesser reliability to the underlying LN loads. This implies that the monitored elements of Flowgates are typically non-essential to the BES reliability. AECI can support "contingent" FG Facilities disqualifying a LN claim, but it cannot support "monitored" Facilities as disqualifying factors for rejecting a LN claim.
Yes
Ownership is irrelevant, so "owned and operated by the retail customer solely for its own use", should

be replaced by "owned and operated solely in conjunction with specific industrial customer loads."
Yes
: AECI supports the bright-line concept, but believes the SDT should adopt a core voltage threshold of "200 kV or higher", and MVA capacity of "150 MVA or greater". A proper threshold is critical, because an inappropriately low threshold will divert significant industry attention and resource away from what truly benefits the BES reliability. (The number of facilities tend to rise more geometrically than linearly as the voltage threshold drops.) We believe that an evaluation of the transmission-line Surge Impedance Loading (SIL), at various kV levels, could provide technical insight as to why many industry planning engineers believe sub-230kV Facilities, in general do not belong within the BES. AECI suggests that the SDT consider a more consistent bright-line facility threshold of 150 MVA capability for all equipment. This would include transmission lines as well, where an Surge Impedance Loading analysis demonstrates that lines below 230 kV, can support 150 MVA flow up to 280 miles (applying 1.1 p.u. line-loadability of SIL, IEEE Transactions on Power Apparatus and Systems, Vol.PAS-98, No.2 March/April 1979, p 609, Figure 7),without additional reactive compensation. In comparison, single-conductor 138 kV lines, in same table, can support 150 MVA transfers no more than 50 miles, while 345 kV lines are capable of supporting 150 MVA transfers well over 600 miles.

Northern Wasco County PUD
Yes
We agree with the changes. We must point out that the overall flow, or how one proceeds through the inclusions and exclusions is not clear. Can an item that meets an inclusion be subsequently excluded? If so, this needs to be explicitly stated. So far, we only have the flow chart produced by the ROP team that indicates otherwise ( <a href="http://www.nerc.com/docs/standards/sar/20110428_BES_Flowcharts.pdf">http://www.nerc.com/docs/standards/sar/20110428_BES_Flowcharts.pdf</a> ). This was made evident by the question at the 9/28 webinar regarding an I5 capacitor on an E3 local network. The questioner thought the capacitor was BES per I5, but the answer was that it was excluded per E3. We can find no support for the answer given. The listing of specific exclusions within I1 (exception proves the rule) argues for questioner's stance that the capacitor is BES as written. Also, if included items could subsequently be excluded, they would be no different from any other item that met the voltage threshold of 100kV. There would be no need for any of the inclusions if all possible outputs from the inclusion tests go to the same exclusion test inputs. We strongly support the addition of the language regarding local distribution facilities, as it matches congressional intent to leave the regulation of these facilities to state and local authorities.
Yes
Northern Wasco County PUD strongly agrees with this inclusion as written. It is consistent with the recent PRC-004 and PRC-005 interpretation and the NERC definition of Transmission. We believe the recent changes to this inclusion add clarity.
No
Referencing the Criteria which in turn references the BES definition creates a circular definition. Northern Wasco County PUD encourages the adoption of specific thresholds that are technically justified. We also note that the Criteria and its revisions do not go through the standards development process, so that thresholds may change with little warning and without triggering an implementation plan for facilities that may be swept into the BES as a result.
Yes
We agree with the removal of the voltage language, since the inclusions and exclusions apply only to equipment over 100 kV.
Yes
Northern Wasco County PUD agrees both with the inclusion and with the revised language. The revised language removes the need to provide a separate definition for "Collector System".
No
While we agree that reactive devices of sizable capacity connected at 100 kV or higher are needed for BES reliability, Northern Wasco County PUD fails to see why this inclusion is needed as they are already captured by the 100 kV threshold. We would propose instead to eliminate this inclusion and substitute an exclusion for smaller capacity devices. If the SDT really believes an inclusion for reactive

devices is needed, we suggest the SDT provide a technically justified capacity limit within the inclusion. In addition we suggest also including the phrase "...unless excluded under Exclusion E1, E2 or E4" similar to that in I1. Please see the answer to Q1 above Q10 below.

No

Northern Wasco County PUD notes that a new term has been introduced, "non-retail generation," with no definition provided. The answer to the question on this during the 9/28 webinar indicated that non-retail generation was behind the retail customer's meter. We can see no reason why the net-metered PV systems should count toward the aggregate limit (exceeding the limit means no exclusion) while a non-blackstart thermal plant doesn't (the radial system is excluded if any amount of load is present). We have also heard the SDT meant just the opposite of what was stated in the webinar. We ask that a reasonable definition for non-retail be provided within the BES definition document. We strongly agree that radial systems should be excluded and that the presence of normally open switching devices between radial systems should not cause them to be considered non-radial. Such a result would cause the removal of these devices to the detriment of the local level of service. We note that the singular "A normally open switching device" is used and suggest that an allowance be made for the possibility of multiple devices. "Normally open switching devices..."

Yes

No

We strongly agree that local networks should be excluded, since they act much like the radial systems excluded in E1 while providing a higher level of service to customers. These networks should not be discouraged in the name of reliability. We again object to the introduction of the new confusing term "non-retail generation" with no definition provided.

No

Please see Northern Wasco County PUD's answers to Q1 and Q6. Any device that might be excluded under E4 has already been included per I5. Unless I5 is removed, or rewritten as suggested above; this exclusion will exclude nothing.

Yes

In order to help meet the fast approaching target date, Northern Wasco County PUD will be voting affirmative in this ballot, with the hope these comments will be addressed in Phase II. If the ballot should fail, please address these comments in this phase. Thanks to the team for their good work.

Tri-State Generation and Transmission Assn., Inc., Energy Management

Yes

We believe that the new definition is a good clarification.

Yes

No

1. The parenthetical phrase regarding the ERO SCRC is not clear. Is the intent that the inclusion applies to any generating resource that is required to register as a Generator or Generator Operator per the ERO SCRC? Or was a reference to the 75 MVA threshold inadvertently omitted? It also seems that it wouldn't need to be in parentheses, just make it a phrase in the sentence. 2. The wording of the sentence after the parenthetical phrase is also worded awkwardly. Suggest changing it to "including the generator terminals and all electrical equipment up to and including the high side of generator step up transformers, if they are connected at a voltage of 100 kV or higher."

Yes

Yes

No

There should be a limitation on what reactive components needs to be included. The limits could be based on capacity of the units or on the voltage step that occurs upon switching of the device

Yes
Yes
No
1. b) should be reworded to "Normally there is power flow only into the LN: The LN is not normally used to transfer power originating outside of the LN for delivery through the LN." There could be conditions inside the LN, such as large loads shut down for maintenance, which would allow the parallel transmission Elements to allow power to flow through the LN. Those conditions would have no negative or adverse effect on the BES. 2. Capitalize "Network" at the beginning of the Exclusion

Linda Jacobson-Quinn

Farmington Electric Utility System

Yes

Yes

No

FEUS is concerned I2 is dependent on the Statement of Compliance Registry Criteria (SCRC). Modification of the SCRC is not required to go through the same process of modification of a Standard but section 1400 of the NERC Rules of Procedure. Section 1400 does allow for industry comment and requires multiple tiers of approval. However, it seems by changing the SCRC generating resources may be included or excluded from the BES – without requiring modification to the definition of the BES through the Standards Development Process. In addition, Page 4 Section I of the SCRC is dependent on the NERC definition of the BES. Logically, the SCRC should be dependent on the definition of the BES not the inverse.

Yes

No

FEUS feels additional clarity should be added to I4. It appears I4 is not intended to include each individual wind turbine generating unit in a wind farm as a BES element, but rather to include the point at which the aggregation becomes large enough to meet the aggregate capacity threshold of 75MVA.

No

I5 should be modified to identify a minimum Reactive Power threshold for static or dynamic devices. As drafted a 1 MVA device supplying or absorbing Reactive Power that is connected at 100 kV or higher would be included in the BES.

Yes

No

E2 should be modified to include a size and threshold for individual generating units, similar to that identified in I2. As currently worded E2 places the same threshold (75 MVA) on a single generating unit as is placed on multiple generating units.

Individual

Allen Rinard

South Houston Green Power, LLC

No

South Houston Green Power, LLC [SHGP], a registered generator owner in ERCOT, submits the following comments: Cogeneration facilities, some of which are well over 75 MW in size, are located at a number of industrial sites owned by SHGP and its affiliates. Some of these cogeneration facilities generate power that is distributed within the industrial site and used for manufacturing plant operations. In some instances, excess power not required for plant operations is delivered back into the electric transmission grid through the tie line(s) connecting the industrial site to the grid. While the tie lines and some of the internal lines at these industrial sites operate at 100kV or higher, they

do not perform anything that resembles a transmission function. Rather than transmit power long distances from generation to load centers, the tie lines and internal lines perform primarily an end user distribution function consisting of the distribution of power brought in from the grid or generated internally to different plants within each industrial site. In some cases, the facilities also perform an interconnection function to the extent they enable power from cogeneration facilities to be delivered into the grid. The voltage of the tie lines and internal lines at these industrial sites is dictated by the load and basic configuration of each site. Higher voltage lines are used when necessary to meet applicable load requirements or to reduce line losses. That does not mean that such lines perform a transmission function. SHGP would oppose any BES definition that would by default subject either the tie lines or the internal lines at such industrial sites to the mandatory reliability standards applicable to Transmission Owners and Transmission Operators when they more readily fit the Generation Owner / Generation Operator standards. Such an expanded BES definition would subject registered entities to substantial compliance costs and create potential exposure to penalties, but would not likely substantially enhance the reliability of the BES. Perhaps such costs and exposure could be justified in exceptional circumstances, if subjecting these facilities to compliance with reliability standards were to result in a material increase in reliability of the BES. There is reason to believe, however, that in many cases the additional reliability benefit would be minimal at best. The tie lines and internal lines at industrial sites owned by SHGP and its affiliates have been operated for years as end user distribution and interconnection facilities, and practices and procedures have developed over the years that have enabled such operations to achieve a high degree of reliability for such sites. Requiring these facilities to now operate in a different manner as transmission facilities may well result in a degradation of the reliability of the manufacturing plants located at such sites. For example, outages would have to be coordinated with the RTO, which may not be interested in coordinating such outages with scheduled manufacturing plant outages. In light of these considerations, SHGP agrees with the proposed revisions to the core definition, particularly the proposal to include a sentence expressly excluding facilities used in the local distribution of electric energy, provided it is understood that end user-owned delivery facilities located "behind-the-meter" are, regardless of voltage level, by default outside the scope of this definition.

Yes

No

SHGP agrees with the proposed revisions to Inclusion I2, but requests the following phrase added at the end "unless excluded under Exclusion E2".

Yes

No

Further clarification of "Dispersed power producing resources" is needed. Multiple small resources should not be included. The following phrase should be added at the end of Inclusion I4 "unless excluded under Exclusion E2".

No

The phrase should be added at the end "unless excluded under Exclusion E4".

No

SHGP generally supports with the proposed revisions to Exclusion E1, but suggests several additional clarifying revisions should be made. First, the phrase "a single point of connection" in the introductory sentence should be revised to read "a single point of connection (including multiple connections to the same ring bus or substation where the energy normally flows in the same direction)". This revision is intended to ensure that radial systems which involve multiple parallel lines and are designed to operate as a single radial system, but that nevertheless connect to the grid through more than line for reliability. Second, for this same reason, an additional (i.e., second) note should be added to the end of Exclusion E1 that reads as follows: "Note, a normally closed switching device that enables multiple lines emanating from the same grid ring bus or different grid buses to operate as a single radial system does not affect this exclusion." Third, the phrase "with an aggregate capacity of non-retail generation less than or equal to 75 MVA should be eliminated.

Yes

SHGP generally agrees with the proposed revisions to Exclusion E2, but believes that a clarifying

revision should be made. Substitute "transmission grid" for "BES" in the phrase "provided to the BES" to insure that the metering is to the grid.

SHGP would like to broaden the scope of Local Networks. If a Local Network does not allow transfer of Bulk Power across the Interconnected System, then the Local Network should be excluded regardless of the amount of generation behind the meter. Often, large industrial sites install large combined Heat & Power cogeneration units due to a hefty steam load. Subjecting industrial facilities to additional reporting and coordination efforts [other than those already required by the TO and RTO] may have little, if any, increase in grid reliability. The 75 MVA (gross nameplate rating) needs to be eliminated. To date, none of the Regional Entities has suggested that SHGP or its affiliates register as a Transmission Owner or Transmission Operator with respect to any SHGP or affiliated delivery facilities.

Yes

Group

William Bush

Holland Board of Public Works

Yes

Holland BPW believes that the proposed definition is an improvement to the status quo, but requires additional work. The thresholds for classifying generators as Bulk Electric System (BES) must be revised. There was little technical support for proposing the current thresholds. No greater evidence than that which was proffered for the initial thresholds should be required to modify those standards. Four years of compliance experience and industry feedback support increasing these thresholds. Holland BPW supports increasing the generation thresholds from 20 MVA (individual gross nameplate) and 75 MVA (aggregate gross nameplate) to not less than 100 MVA (individual gross nameplate) and 300 MVA (aggregate gross nameplate). Holland BPW recognizes that the SDT and NERC have committed to making these revisions as part of "Phase II", and are asking the industry to trust that such an initiative will not succumb to work on other initiatives. However, even if work on this initiative commences immediately, entities that should be removed from the Compliance Registry face costs of compliance or the risk of non-compliance penalties even though their facilities are not necessary for the reliable operation of the interconnected transmission system. That said, there are two significant improvements in the revised draft. First, it is essential to make clear that the "Inclusions" and "Exclusions" apply only to the first sentence of the core definition (i.e., "Transmission Elements"). The revised definition appears to address this. By placing "Unless modified by the lists shown below" at the beginning of the first sentence of the definition clarifies that the lists of Inclusions and Exclusions pertain only to "Transmission Elements" that would otherwise be included or excluded from the core definition. The revised definition and the lists of Inclusions and Exclusions do not and cannot be applied in a manner to pull in facilities used in the local distribution of electric energy as BES facilities because Congress, by statute, has already determined that such facilities are outside of NERC's reach, as recognized by the second sentence of the definition. Second, Holland BPW supports the addition of the second sentence of the core definition that states, "This does not include facilities used in the local distribution of electric energy." This language provides necessary recognition to the jurisdictional limitation provided for in Section 215 of the Federal Power Act, and as recognized by the FERC in Orders 743 and 743-A (see, e.g., ¶¶ 58-59 in 743-A). Finally, if the revised definition goes forward, it is imperative that the rules of procedure providing for an exception process be adopted at the same time.

No

It is essential that regional entities and NERC recognize that "facilities used in the local distribution of electric energy" are not included in the definition of BES, regardless of the gross individual or gross aggregate nameplate rating of generation resources. While the addition of the second sentence in the core definition makes this clarification, Holland BPW believes it is necessary that regional entities and NERC recognize that neither this Inclusion nor any of the Inclusions may be used as a basis to compel registration and compliance in such instances, regardless of the size of the generators. The statutory exemption of facilities used in the local distribution of electric energy is not limited by generator number or capability. NERC's definitions cannot impose limitations that are not set forth in the

statute. For purposes of the exclusion of facilities that might otherwise meet the definition of BES, the thresholds for determining what generating resources constitute BES facilities should be modified from the current levels (gross individual nameplate capacity of 20 MVA or gross aggregate nameplate rating of 75 MVA). Holland BPW supports modification of the thresholds to not less than 100 MVA (gross individual nameplate capacity) and 300 MVA (gross aggregate nameplate).

Yes

Holland BPW supports the exclusion of radial systems from the BES definition, but believes that further clarification is necessary. First, the deletion of “originating with an automatic interruption device” is a step in the right direction. However, “emanates from a single point of connection” could be too narrowly interpreted (i.e., multiple buses within a single substation could be viewed as multiple points of connection). Holland BPW proposes the following modification: “emanates from a single substation connected to the BES at 100 kV or higher...” Entities whose only connection emanates from a single substation and otherwise meet the BES definition should not be denied exclusion under E1 solely because they connect to multiple buses at that single substation. Additionally, adoption of “E3 – Local Networks” renders specious any argument that claims that connecting to multiple buses within a single substation makes a material difference for reliability purposes since local networks would have multiple connections anyway. Additionally, it is not clear why it is necessary to include the note at the end of the revised definition. (“A normally open switching device between radial systems, as depicted on prints or one-line diagrams for example, does not affect this exclusion.”) This raises questions as to what “normally open” means, and whether the only evidence demonstrating what “normally open” means will be prints or one-line diagrams. Further, it is not entirely clear what is meant by the language “does not affect this exclusion”. If the note remains, it should be modified to read something like, “a normally open switching device between radial systems does not prevent application of this exclusion.” Finally, the generation threshold limit in E1(b) and E1(c) should be revised as discussed in response to Q1. Specifically, the proposed threshold of 75 MVA for this exclusion should be raised to not less than 300 MVA in both E1(b) and E1(c).

Yes

Holland BPW supports the exclusion of Local Networks (LN) from the definition of BES. Such systems are generally not necessary for the reliable operation of the interconnected transmission network. However, some revisions are necessary. Holland BPW believes that E3(a) and E3(b) can and should be eliminated, provided E3(c) remains. E3(c) provides that an LN is BES if it is classified as a Flow Gate or Transfer Path. The bases for removing E3(a) and E3(b) are as follows: (1) Provision E3(a) establishes a 75 MVA limit on connected generation. This is inconsistent with the concept of a LN and should be removed. If not removed, it should be increased to not less than 300 MVA, consistent with the discussion in response to Q1. If an LN does not accommodate bulk power transfer across the interconnected system, the amount of generation that exists and is distributed within that system is immaterial for purposes of the reliable operation of the interconnected transmission system. During the NERC Webinar, NERC representatives suggested that placing an upper limit on generation within a LN might be desirable based upon an assumption that if that entity’s internal generation is lost, then replacement generation would have to come from the BES, and could therefore affect reliability. This assumption has not been substantiated. In most instances, generation resources are dispersed throughout the LN – it is unlikely an event would result in the loss in the amount of the aggregate generation. Additionally, LNs have local load shedding and system restoration plans for such contingencies. (2) E3(b) is unnecessary and should be removed. The proposed language in E3(b) appears to be concerned with flows originating from outside of the LN, coming into the LN, and then exiting the LN to loads outside of the LN. As noted above, E3(c) appears to address this concern. If E3(b) is maintained, then the introductory clause (“Power flows only into the LN:”) should be deleted, because it is inconsistent with the second clause (“The LN does not transfer energy originating outside the LN for delivery through then LN.”) If E3(b) is retained, Holland BPW supports the second clause (“The LN does not transfer energy originating outside the LN for delivery through then LN”) because it appears to be the portion of the provision that addresses the concern about flows into, through, and then out of, the LN. (3) E3(b) should also be removed or modified because it fails to recognize typical

municipal system operations. An LN may have internal generation that is less than its peak load but in excess of off-peak or holiday load levels. The language "Load flows only into the LN" does not recognize this situation and prevents an LN from making the most economic use of surplus generation. There are no reliability reasons to discourage such sales since with or without such transactions, this generation is not necessary for the reliable operation of the interconnected transmission system.

Andrews Kurth, LLP

Yes

Yes

Yes

The interplay between Inclusion I2, which references the Statement of Registry Compliance, and Exclusions E1-E3 is unclear. Under the Registry criteria, "a customer-owned or operated generator/generation that serves all or part of retail load with electric energy on the customer's side of the retail meter may be excluded as a candidate for registration ... if (i) the net capacity provided to the bulk power system does not exceed the criteria above." It appears that the SDT intended to invoke this provision by referencing the Statement of Registry Compliance, which counts only the "net" capacity provided, by referencing the Statement of Compliance Registry Criteria. However, Exclusions E1 and E3 exclude generation on the basis of "gross nameplate ratings." For customer-owned facilities, this treatment is inconsistent with netting treatment provided in the Statement of Registry Compliance. Exclusions E1-E3 should be revised to reference the Statement of Compliance Registry Criteria as well so that customer-owned generation is included or excluded based on its net capacity to the grid rather than its gross nameplate capacity. TIEC also supports revisiting and potentially raising the thresholds that trigger registration as a Generation Owner or Operator. TIEC understands that the SDT has decided to maintain the status quo as reflected in NERC's Registry Criteria at this time. TIEC looks forward to addressing potential modifications to the thresholds in the appropriate context.

Yes

Yes

Yes

Yes

As noted in response to Question 3, above, Exclusion E1 would only allow exclude radial systems with "aggregate capacity of non-retail generation less than or equal to 75 MVA (gross nameplate rating)." The reference to "non-retail" generation in subsection (c) indicates that the SDT may have intended to preserve the "netting" approach set forth in the Statement of Registry Compliance, but this should be made clearer. The description in subsection (c) should be revised to exclude "Where the radial system serves Load and includes generation resources not identified in Inclusions I2 or I3," and the remainder of that sentence referencing a 75 MVA gross nameplate rating should be removed. This will provide a reference back to the Statement of Registry Compliance and clarify that only net capacity is considered for customer-owned facilities.

Yes

Please see the response to Question 3, above. Unlike exclusions E1 and E3, this exclusion refers specifically to the "net capacity" provided, which is consistent with existing treatment for generation that is netted against internal load under the Statement of Registry Compliance.

Yes

As noted in response to Question 3, above, subsection (a) of Exclusion E3 would only exclude Local Networks with "aggregate capacity of non-retail generation less than or equal to 75 MVA (gross nameplate rating)." The reference to "non-retail" generation in subsection (a) indicates that the SDT may have intended to preserve the "netting" approach set forth in the Statement of Registry Compliance, but this should be made clearer. The description in subsection (a) should be revised to exclude "Where the radial system serves Load and includes generation resources not identified in Inclusions I2 or I3," and the remainder of that sentence referencing a 75 MVA gross nameplate rating should be removed. This will provide a reference back to the Statement of Registry Compliance and clarify that only net capacity is considered for customer-owned facilities. TIEC also disagrees with the 300 kV upper limitation on transmission elements within a Local Network. Consistent with TIEC's comments to FERC, if these facilities are serving a distribution function, their voltage level is irrelevant. The transmission versus distribution distinction should be based on function, not voltage level. The remainder of this exclusion clarifies what constitutes a distribution function, so the 300 kV limit is unnecessary and should be removed.

PGE requests additional clarity in the wording of Inclusion 4. Inclusion 4 is not intended to include each individual wind turbine generating unit in a wind farm as a BES element, but rather to include the point at which the aggregation becomes large enough to meet the aggregate capacity threshold of 75 MVA. However, the response to comments from the last comment posting and the current wording of Inclusion 4 does not provide sufficient clarity to answer this question.

Yes

Yes

Yes

Yes

PGE agrees with Exclusion E3, but believes additional clarification is necessary to facilitate a complete understanding and application of the exclusion criteria. First, there is no specific definition of "non-retail" generation provided. Additionally, E3 b) states "Power flows only into the LN: The LN does not transfer energy originating outside the LN for delivery through the LN." PGE believes that a local network should still qualify for the LN exclusion if power may flow out of the LN at a discrete point or certain discrete points during abnormal operating conditions, but power still flows into the LN on an aggregate basis during all operating conditions, and power flows only into the LN at all discrete points during normal operating conditions.

Andrew Gallo
City of Austin dba Austin Energy
Yes
In an effort to avoid potential confusion and provide clarity we believe the sentence, "This does not include facilities used in the local distribution of electric energy," more appropriately fits under the "exclusions" (rather "inclusions") section.
Yes
We believe additional clarification of transformers to be included may be achieved with respect to auto transformers, phase angle regulators and generator step-up transformers by adding the following sentence: All transformers (including autotransformers, voltage regulators, and phase angle regulators) with primary and secondary terminals operated at or above 100kV, unless excluded by E1 or E3.
No
We recommend removing the reference of the ERO Statement of Compliance Registry Criteria (Registry Criteria). The BES Definition should be the governing document and independent of ERO registration requirements. The definition should drive what appears in the Registry Criteria. Additionally, we support using the BES Phase 2 technical analysis to identify and provide technical support for determining the appropriate minimum MVA rating that a single unit, or the aggregation of multiple units, must meet to be part of the BES.
Yes
We recommend rewording Inclusion I3 as follows: "Only Primary Blackstart resources designated as part of the Transmission Operator's restoration plan." We have concerns that making all Blackstart generation either primary or secondary BES elements creates an incentive to remove those secondary Blackstart capable units in an effort to avoid BES inclusion. We believe that making the primary Blackstart unit the only BES element will remove this incentive. In so doing, this will allow the secondary Blackstart units to remain in the Transmission Operator's plan and training program as an alternate tool for the Transmission Operator to restore the system.
Yes
Yes
Appropriate MVar level should be established. Reactive resources should be treated similar to generation criteria and included in the technical studies associated with the Phase 2 technical analysis in order to establish the appropriate MVar level included as BES.
Yes
For the E1 reference "Note," we would benefit from additional clarification identifying the treatment of a normally open switch and offer the following: "Radial systems shall be assessed with all normally open switching devices in their open positions." The wording in Exclusion 1-c should more clearly reflect what is intended by using the term "non-retail generation." Also, as with the technical justification for Inclusions I2 and I4, we recommend that the generation threshold, i.e. gross nameplate values, be deferred to Phase 2.
Yes
Yes
We prefer to hold reference to gross nameplate rating/threshold values until generation technical justification is completed as part of Phase 2; these studies should apply to any real or reactive power threshold reference. For Exclusion E3-b using the phrase "[p]ower flows only into the Local Network" is too restrictive. An allowable MW threshold of Local Network power producing resources should be deferred to the Phase 2 BES technical analysis. Where no generation is present in the Local Network, it is recommended that an allowance for residual flow through the Local Network.
Yes

No
Individual
Martin Kaufman

Yes
However, in Order 743, FERC directed NERC to further delineate the differences between transmission systems (used to transfer electric power between regions) and distribution systems (used to deliver electric power locally). The inclusions and exclusions defined in the draft BES definition are a step in the right direction, but further work is necessary during Phase II to meet the intention of the order. Additionally, the SDT should consider defining terms, such as non-retail generation, or providing references (footnotes) that elaborate on the referenced concept.
Yes
The Inclusion I1 contains the phrase "unless excluded under Exclusion E1 or E3". While recognizing that this is a welcomed clarification on how I1 interacts with the Exclusion section, it is inconsistent with Inclusions I2 through I5. The BES SDT team should consider how to standardize the language around the interactions between the Inclusions and Exclusions (perhaps add an "unless" qualifier for each Inclusion).
No
The Inclusion I1 contains the phrase "unless excluded under Exclusion E1 or E3". While recognizing that this is a welcomed clarification on how I1 interacts with the Exclusion section, it is inconsistent with Inclusions I2 through I5. The BES SDT team should consider how to standardize the language around the interactions between the Inclusions and Exclusions (perhaps add an "unless" qualifier for each Inclusion).
Yes
Yes
The BES SDT should clarify the difference between "dispersed power producing resources" and "generation resources" in such a manner that it is clear that an industrial plant containing providing the BES with power from ten 7.5MVA machines connected at a common point at a voltage of 100 kV or higher meets the qualifications for generation resources and does not meet the qualifications for a "dispersed power producing resource".
No
The BES SDT should work on clarifying the differences between Inclusion I5 and Exclusion E4. The phrase "solely for its own use" in Exclusion E4 is vague and open to interpretation. It is unclear whether equipment, such as power factor correction facilities, surge capacitors located in motor terminal boxes and excitation capacitors installed for use by a motor located on the low side of a 138 kV primary transformer would be excluded from the BES. Is the intent of this requirement to capture "reactive resources" that provide VARs to the BES in regions that exhibit voltage stability issues?
Yes
The removal of the requirement for an automatic fault interrupting device from this requirement is a welcomed change from the first posting. This Exclusion helps preserve the current NERC Registry and explicitly excludes many facilities used in the distribution of electric power.
Yes
Yes
Exclusion E1 and E3 aid in the delineation of distribution and transmission facilities. However, we request that the BES SDT review paragraphs 108 and 109 of FERC Order 743. In order to meet reliability target requirements to safely and economically operate manufacturing and production facilities, many industrial facilities are fed by two or more utility transmission lines that originate at independently fed utility substations. Due to the magnitude of an industrial site's load, these transmission lines are typically designed to operate at levels in excess of 100 kV at the request of the

utility company. These transmission lines typically terminate into an interconnection facility, owned by the industrial facility, that spot networks the transmission lines via a ring buss or breaker and a half substation within the industrial facility's private use network in order to serve the load of the facility's private use network. These private use networks typically satisfy the requirements set forth in the definition of a Local Network (power flows in, not a flowgate, etc.); however, the term "non-retail generation" is not a term that is implicitly defined or consistent with this documents use of "net capacity provided..." phrasing in similar exclusions.

Yes

The BES SDT should work on clarifying the differences between Inclusion I5 and Exclusion E4. The phrase "solely for its own use" in Exclusion E4 is vague and open to interpretation. It is unclear whether equipment, such as power factor correction facilities, surge capacitors located in motor terminal boxes and excitation capacitors installed for use by a motor located on the low side of a 138 kV primary transformer would be excluded from the BES.

Yes

It would be worthwhile to explain the relationship (timeline) between the BES Definition implementation plan and the compliance implementation plan proposed in the BES RoP team's new Appendix 5C for the NERC Rules of Procedure.

Individual

Kootenai Electric Cooperative

Yes

Kootenai Electric Cooperative ("KEC") believes the SDT continues to make substantial progress towards a clear and workable definition of the Bulk Electric System ("BES") that markedly improves both the existing definition and the SDT's previous proposal. KEC therefore strongly supports the new definition, although our support is conditioned on: (1) a workable Exceptions process being developed in conjunction with the BES definition; and, (2) the SDT moving forward expeditiously on Phase II of the standards development process in accordance with the SAR recently put forward by the SDT, which would address a number of important technical issues that have been identified in the standards development process to date. KEC strongly supports the following elements of the revised BES definition: (1) Clarification of how lists of Inclusions and Exclusions applies: The revised core definition moves the phrase "Unless modified by the lists shown below" to the beginning of the definition. This change makes clear that the Inclusions and Exclusions apply to all Elements that would otherwise be included in or excluded from the core definition (i.e., "all Transmission Elements operated at 100 kV or higher and Real Time and Reactive Power resources connected at 100 kV or higher") and eliminates a latent ambiguity in the first draft of the definition, discussed further in our comments on the first draft. (2) The exclusion for Local Distribution Facilities. As the starting point for the BES definition, KEC supports use of the phrase "all Transmission Elements" and the qualifying sentence: "This does not include facilities used in the local distribution of electric energy." This language helps ensure that FERC, NERC, and the Regional Entities ("REs") will act within the jurisdictional constraints Congress placed in Section 215 of the Federal Power Act ("FPA"). In Section 215(a)(1), Congress unequivocally excluded "facilities used in the local distribution of electric energy" from the keystone "bulk-power system" definition. 16 U.S.C. § 824o(a)(1). Including the same language in the definition helps ensure that entities involved in enforcement of reliability standards will act within their statutory limits. In addition, as a practical matter, inclusion of the language will help focus both the industry and responsible agencies on the high-voltage interstate transmission system, where the reliability problems Congress intended to regulate – "instability, uncontrolled separation, [and] cascading failures," 16 U.S.C. § 824o(a)(4) – will originate. At the same time, level-of-service issues arising in local distribution systems will be left to the authority of state and local regulatory agencies and governing bodies, just as Congress intended. 16 U.S.C. § 824o(i)(2) (reserving to state and local authorities enforcement of standards for adequacy of service). For similar reasons, KEC believes use of the phrase "Transmission Elements" as the starting point for the base definition is desirable because both "Transmission" and "Elements" are already defined in the NERC Glossary of Terms Used, and the term "Transmission" makes clear that the BES includes only Elements used in Transmission and therefore excludes Elements used in local distribution of electric power. (3) Appropriate Generator Thresholds. In the standards development process, it has become apparent that the thresholds for classifying generators as BES in the current NERC Statement of

Compliance Registry Criteria (“SCRC”) (20 MVA for individual generators, 75 MVA for multiple generators aggregated at a single site), which predate the adoption of FPA Section 215, were never the product of a careful analysis to determine whether generators of that size are necessary for operation of the interconnected bulk transmission system. Ideally, such an analysis would be conducted as part of the current standards development process. KEC recognizes that, given the deadlines imposed by FERC in Order No. 743, it will not be possible for the SDT to conduct such an analysis within the time available. Accordingly, KEC agrees with the approach taken by the SDT, which is to propose a Phase II of the standards development process that would address the generator threshold issue and several other technical issues that have arisen during the current process. As long as Phase II proceeds expeditiously, KEC is prepared to support the BES definition as proposed by the SDT. While KEC strongly supports the overall approach adopted by the SDT and much of the specific language incorporated into the second draft of the BES definition, we believe the second draft would benefit from further clarification or modification in a number of respects, most of which are detailed in our subsequent answers. Our support for the definition is not contingent upon these changes being adopted. Further, we believe a workable Exclusion Process is essential for a BES Definition that will meet the legal requirements of FPA Section 215, especially for systems operating in the Western Interconnection. As detailed in our previous comments, KEC believes a 200-kV threshold would be more appropriate for WECC than a 100-kV threshold. In addition, a 200-kV threshold for the West is backed by solid technical analysis conducted by the WECC Bulk Electric System Definition Task Force, and repeated claims that there is no technical analysis to support this view is therefore incorrect. That being said, we raise the issue here to emphasize the importance of the Exclusions for Local Networks and Radial Systems and the Exceptions process. These Exclusions and the Exceptions are essential for a definition that works in the Western Interconnection because the core definition will be over-inclusive in our region. As long as those Exclusions and the Exceptions Process are retained in a form substantially equivalent to those produced by the SDT at this juncture, KEC will support the SDT’s proposal and will not further pursue its claims regarding the 200-kV threshold. Finally, we suggest that the SDT address the circumstance when an Element is covered by both an Inclusion and an Exclusion. We note that some of the inclusions already contain language addressing this question. For example, Inclusion 1 indicates that transformers falling within the specified parameters are part of the BES “. . . unless excluded under Exclusions E1 or E3.” Where it is not already included, similar language should be included in the other Inclusions and/or Exclusions to explain whether the SDT intends the Inclusions or the Exclusions to predominate in situations where facilities might be covered by both. We suggest clarifying language in our responses to Questions 2 and 5.

Yes

KEC supports the SDT’s changes to the first Inclusion because it is more clear and simple than the initial approach. That being said, we suggest that an additional sentence of clarification would help avoid future controversy about the meaning of Inclusion 1. As we understand it, the BES intends to include transformers only if both the primary and secondary terminals operate at 100 kV or above, which is why the definition uses the word “and” (“the primary and secondary terminals”). We support this approach since it would exclude transformers where the secondary terminals serve distribution loads, and which therefore function as distribution rather than transmission facilities. We believe the SDT’s intent would be clarified by adding a sentence at the end of Inclusion 1 that reads: “Transformers with either primary or secondary terminals, or both, that operate at or below 100 kV are not part of the BES.” This language will help ensure that there is no controversy over whether the SDT’s use of the word “and” in the phrase “the primary and secondary terminals” was intentional. We also support the SDT’s proposal to develop detailed guidance concerning the point of demarcation between BES and non-BES elements in the Phase II SAR. In this regard, we note that, while Inclusion 1 at least implicitly suggests that the dividing line between BES and non-BES Elements should be at the transformer where transmission-level voltages are stepped down to distribution-level voltages, we believe further clarification of this point of demarcation between the BES and non-BES Elements is necessary. Many different configurations of transformers and other equipment that may lie at the juncture between the BES and non-BES systems. If the point of demarcation is designated at the transformer without further elaboration, many entities that own equipment on the high side of a transformer will be swept into the BES, and thereby exposed to inappropriately stringent regulations and undue costs. For example, distribution-only utilities commonly own the switches, bus and transformer protection devices on the high side of transformers where they take delivery from their transmission provider. Ownership of these protective devices and high-voltage bus on the high side of

the transformer should not cause these entities to be classified as BES owners. As the Phase II process moves forward, we commend to the SDT the extensive work performed on the point of demarcation question by the WECC BESDTF. We also support the incorporation of language (“ . . . unless excluded under Exclusions E1 or E3”) making it clear that transformers that are operated as an integral part of a Radial System or Local Network should not be considered BES facilities, regardless of their operating voltage. Further clarification might be achieved by using the phrase “. . . unless the transformer is operated as part of a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2.”

Yes

KEC supports the changes made in Inclusion 2 and believe that the definition in its current form adds clarity. In particular, we support the SDT’s decision to collapse Inclusions 2 and 3 from the previous draft definition into a single Inclusion that addresses the treatment of generation for purposes of the BES definition. We also support the SDT’s proposal for a Phase II of the BES Definition process to examine the technical justification for these thresholds and to establish new thresholds based on a careful technical analysis. It is our understanding that the generator threshold issue will be vetted through the complete standards development process. We agree with this approach because if the generator threshold is treated as merely an element of NERC’s Rules of Procedure, it can be changed with considerably less due process and industry input than the Standards Development Process. Compare NERC Rules of Procedure § 1400 (providing for changes to Rules of Procedure upon approval of the NERC board and FERC) with NERC Standards Process Manual (Sept. 3, 2010) (providing for, e.g., posting of SDT proposals for comment, successive balloting, and super-majority approval requirements). See also Order No. 743-A, 134 FERC ¶ 61,210 at P 4 (2011) (“Order No. 743 directed the ERO to revise the definition of ‘bulk electric system’ through the NERC Standards Development Process” (emph. added)). Addressing all aspects of Phase II through the Standards Development Process will improve the content of the definition by bringing to bear industry expertise on all aspects of the definition and will ensure that, once firm guidelines are established, they can be relied upon by both industry and regulators without threat that they will be changed with little notice and little due process. KEC also believes further clarification of the proposed language would be appropriate. The SDT proposes continued reliance upon the thresholds that are used in the NERC Statement of Compliance Registry Criteria for registration of Generation Owners and Generation Operators, which is currently 20 MVA for an individual generation unit and 75 MVA for multiple units on a single site. Conceptually, we are concerned about this approach because, as we understand it, the purpose of the Compliance Registry is to sweep in all generators that might be material to the reliable operation of the BES, and not to definitively determine whether a given generator is, in fact, material to the reliable operation of the BES. As the SCRC itself states, the SCRC is intended only to identify “candidates for registration.” SCRC at p.3, § 1 (emph. added). Accordingly, we believe that the generator threshold determined in Phase II should be incorporated directly into the BES Definition rather than being incorporated by reference from the SCRC. We also believe that the specific language proposed by the SDT could be further clarified. The SDT proposes to include generation in the BES if the “Generation resource(s)” has a “nameplate rating per the ERO Statement of Compliance Registry.” We understand this language is intended to be a placeholder for the results of the technical analysis that would occur in Phase II but we believe simply stating that the threshold will be “per the ERO Statement of Compliance Registry” is ambiguous. Further, for the reasons noted above, we believe the threshold should be part of the BES Definition, and should not simply be a cross-reference to the SCRC (and, given the different purposes of the BES Definition and the SCRC, it is not clear that the same threshold should be used in both). We therefore propose that Inclusion 2 be rewritten to state: “Qualifying Individual Generation Resources or Qualifying Aggregate Resources connected at a voltage of 100 kV or above.” Two definitions would then be added to the note at the end of the definition to read as follows: For purposes of this BES Definition, Qualifying Individual Generation Resources means an individual generating unit that meets the materiality threshold to be included in this definition or, in the absence of such a materiality threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of such a resource as a Generation Owner under the ERO Statement of Compliance Registry Criteria. For purposes of this BES Definition, Qualifying Aggregate Generation Resources means any facility consisting of one or more generating units that are connected at a common bus that meets the materiality threshold to be included in this definition, or, in the absence of such a threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of multiple-unit generator as a Generation Owner under the ERO Statement of Compliance Registry Criteria. The “materiality

threshold" is intended to refer to the generator threshold developed in Phase II. We suggest using definitions in this fashion for several reasons. First, we believe the language we suggest more clearly states the intention of the SDT, which we understand is to classify generation units as part of the BES if they are necessary for operation of the BES, but to exclude smaller generating units because they are not material to the operation of the interconnected transmission grid. Second, we believe use of the defined terms better reflects the intention of the SDT to reserve the specific question about generator thresholds to the technical analysis that will occur in Phase II without having to revise the BES Definition at the end of that process. That is, the definitions are designed to allow the SDT to include revised thresholds in the definition at the conclusion of the Phase II process based upon the technical analysis planned for Phase II, and the revised thresholds will be automatically incorporated into the BES Definition if the language we suggest is used. The thresholds used in the SCRC would only be a fall-back, to be used only until Phase II is completed. Third, the definitions can be incorporated into other parts of the BES Definition, which will add consistency and clarity. As noted in our answers to several of the questions below, the specific 75 MVA threshold is retained in several of the Exclusions and Inclusions, and we believe the industry would be better served if the revised thresholds arrived at after technical analysis in Phase II are automatically incorporated into all relevant provisions of the BES Definition. There is no reason for the SDT to continue to rely on the 75 MVA threshold once the analysis planned for Phase II on the threshold issue is completed. Fourth, the phrase "or that meets the materiality threshold to be included in this definition" is intended to preserve the SDT's flexibility to make a determination that generators below a specific threshold are not "necessary to" maintain the reliability of the interconnected transmission system, and to incorporate that finding as part of the definition itself, even if a different threshold is used in the SCRC to identify potential candidates for registration. Accordingly, our proposed language makes clear that a specific threshold in the definition controls over any threshold that might be included in the SCRC. For the reasons stated above, we believe it is highly desirable to include any material threshold in the BES Definition itself rather than relegating the threshold to the SCRC, which is merely a procedural rule rather than a full-fledged Reliability Standard. Hence, we agree with the SDT's decision to examine the question of where the line between BES and non-BES Elements should be drawn more closely in Phase II under the rubric of "contiguous vs. non-contiguous BES," and commend the work of the Project 2010-07 Standards Drafting Team and the GO-TO Team as a good starting point for the SDT's analysis on this issue. We understand Inclusion 2 would classify generators exceeding specific thresholds as part of the BES, but would not necessarily require facilities interconnecting such generators to be part of the BES. As discussed more fully in our answer to Question 9, based on extensive technical analysis that has already been performed by the NERC Project 2010-07 Standards Drafting Team and its predecessor, the NERC "GO-TO Team," regulating as part of the BES a dedicated interconnection facility connecting a BES generator to the interconnected bulk transmission grid will result in an unnecessary regulatory burden that produces considerable expense for the owner of the interconnection facility with little or no improvement in bulk system reliability. We also believe the clauses at the end of Inclusion 2 are somewhat confusing and that greater clarity would be achieved by changing ". . . including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100 kV or above" so that the Inclusion covers transformers with terminals "connected at a voltage of 100 kV or above, including the generator terminal(s) on the high side of the step-up transformer(s) if operated at a voltage of 100 kV or above." Finally, as discussed further in our answer to Questions 5 and 6, KEC believes more clarity may be achieved by collapsing Inclusion 5, addressing Reactive Power resources, and Inclusion 4, which addresses dispersed renewable resources, into a single Inclusion that addresses "power producing resources" (the language used in current Inclusion 4).

Yes

KEC supports the changes made in Inclusion 3 and believe that the definition in its current form adds clarity. In particular, we support the SDT's decision to collapse Inclusions 2 and 3 from the previous draft definition into a single Inclusion that addresses the treatment of generation for purposes of the BES definition. We also support the SDT's proposal for a Phase II of the BES Definition process to examine the technical justification for these thresholds and to establish new thresholds based on a careful technical analysis. It is our understanding that the generator threshold issue will be vetted through the complete standards development process. We agree with this approach because if the generator threshold is treated as merely an element of NERC's Rules of Procedure, it can be changed with considerably less due process and industry input than the Standards Development Process. Compare NERC Rules of Procedure § 1400 (providing for changes to Rules of Procedure upon approval

of the NERC board and FERC) with NERC Standards Process Manual (Sept. 3, 2010) (providing for, e.g., posting of SDT proposals for comment, successive balloting, and super-majority approval requirements). See also Order No. 743-A, 134 FERC ¶ 61,210 at P 4 (2011) (“Order No. 743 directed the ERO to revise the definition of ‘bulk electric system’ through the NERC Standards Development Process” (emph. added)). Addressing all aspects of Phase II through the Standards Development Process will improve the content of the definition by bringing to bear industry expertise on all aspects of the definition and will ensure that, once firm guidelines are established, they can be relied upon by both industry and regulators without threat that they will be changed with little notice and little due process. KEC also believes further clarification of the proposed language would be appropriate. The SDT proposes continued reliance upon the thresholds that are used in the NERC Statement of Compliance Registry Criteria for registration of Generation Owners and Generation Operators, which is currently 20 MVA for an individual generation unit and 75 MVA for multiple units on a single site. Conceptually, we are concerned about this approach because, as we understand it, the purpose of the Compliance Registry is to sweep in all generators that might be material to the reliable operation of the BES, and not to definitively determine whether a given generator is, in fact, material to the reliable operation of the BES. As the SCRC itself states, the SCRC is intended only to identify “candidates for registration.” SCRC at p.3, § 1 (emph. added). Accordingly, we believe that the generator threshold determined in Phase II should be incorporated directly into the BES Definition rather than being incorporated by reference from the SCRC. We also believe that the specific language proposed by the SDT could be further clarified. The SDT proposes to include generation in the BES if the “Generation resource(s)” has a “nameplate rating per the ERO Statement of Compliance Registry.” We understand this language is intended to be a placeholder for the results of the technical analysis that would occur in Phase II but we believe simply stating that the threshold will be “per the ERO Statement of Compliance Registry” is ambiguous. Further, for the reasons noted above, we believe the threshold should be part of the BES Definition, and should not simply be a cross-reference to the SCRC (and, given the different purposes of the BES Definition and the SCRC, it is not clear that the same threshold should be used in both). We therefore propose that Inclusion 2 be rewritten to state: “Qualifying Individual Generation Resources or Qualifying Aggregate Resources connected at a voltage of 100 kV or above.” Two definitions would then be added to the note at the end of the definition to read as follows: For purposes of this BES Definition, Qualifying Individual Generation Resources means an individual generating unit that meets the materiality threshold to be included in this definition or, in the absence of such a materiality threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of such a resource as a Generation Owner under the ERO Statement of Compliance Registry Criteria. For purposes of this BES Definition, Qualifying Aggregate Generation Resources means any facility consisting of one or more generating units that are connected at a common bus that meets the materiality threshold to be included in this definition, or, in the absence of such a threshold, that meets the gross nameplate capacity voltage threshold requiring registration of the owner of multiple-unit generator as a Generation Owner under the ERO Statement of Compliance Registry Criteria. The “materiality threshold” is intended to refer to the generator threshold developed in Phase II. We suggest using definitions in this fashion for several reasons. First, we believe the language we suggest more clearly states the intention of the SDT, which we understand is to classify generation units as part of the BES if they are necessary for operation of the BES, but to exclude smaller generating units because they are not material to the operation of the interconnected transmission grid. Second, we believe use of the defined terms better reflects the intention of the SDT to reserve the specific question about generator thresholds to the technical analysis that will occur in Phase II without having to revise the BES Definition at the end of that process. That is, the definitions are designed to allow the SDT to include revised thresholds in the definition at the conclusion of the Phase II process based upon the technical analysis planned for Phase II, and the revised thresholds will be automatically incorporated into the BES Definition if the language we suggest is used. The thresholds used in the SCRC would only be a fall-back, to be used only until Phase II is completed. Third, the definitions can be incorporated into other parts of the BES Definition, which will add consistency and clarity. As noted in our answers to several of the questions below, the specific 75 MVA threshold is retained in several of the Exclusions and Inclusions, and we believe the industry would be better served if the revised thresholds arrived at after technical analysis in Phase II are automatically incorporated into all relevant provisions of the BES Definition. There is no reason for the SDT to continue to rely on the 75 MVA threshold once the analysis planned for Phase II on the threshold issue is completed. Fourth, the phrase “or that meets the materiality threshold to be included in this definition” is intended to

preserve the SDT's flexibility to make a determination that generators below a specific threshold are not "necessary to" maintain the reliability of the interconnected transmission system, and to incorporate that finding as part of the definition itself, even if a different threshold is used in the SCRC to identify potential candidates for registration. Accordingly, our proposed language makes clear that a specific threshold in the definition controls over any threshold that might be included in the SCRC. For the reasons stated above, we believe it is highly desirable to include any material threshold in the BES Definition itself rather than relegating the threshold to the SCRC, which is merely a procedural rule rather than a full-fledged Reliability Standard. Hence, we agree with the SDT's decision to examine the question of where the line between BES and non-BES Elements should be drawn more closely in Phase II under the rubric of "contiguous vs. non-contiguous BES," and commend the work of the Project 2010-07 Standards Drafting Team and the GO-TO Team as a good starting point for the SDT's analysis on this issue. We understand Inclusion 2 would classify generators exceeding specific thresholds as part of the BES, but would not necessarily require facilities interconnecting such generators to be part of the BES. As discussed more fully in our answer to Question 9, based on extensive technical analysis that has already been performed by the NERC Project 2010-07 Standards Drafting Team and its predecessor, the NERC "GO-TO Team," regulating as part of the BES a dedicated interconnection facility connecting a BES generator to the interconnected bulk transmission grid will result in an unnecessary regulatory burden that produces considerable expense for the owner of the interconnection facility with little or no improvement in bulk system reliability. We also believe the clauses at the end of Inclusion 2 are somewhat confusing and that greater clarity would be achieved by changing ". . . including the generator terminals through the high-side of the step-up transformer(s) connected at a voltage of 100 kV or above" so that the Inclusion covers transformers with terminals "connected at a voltage of 100 kV or above, including the generator terminal(s) on the high side of the step-up transformer(s) if operated at a voltage of 100 kV or above." Finally, as discussed further in our answer to Questions 5 and 6, KEC believes more clarity may be achieved by collapsing Inclusion 5, addressing Reactive Power resources, and Inclusion 4, which addresses dispersed renewable resources, into a single Inclusion that addresses "power producing resources" (the language used in current Inclusion 4).

Yes

KEC supports the revised language generally, but believes additional changes would make the language clearer. Specifically, we believe Inclusion 4 should not incorporate a hard 75 MVA generation threshold (i.e., "resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)"). Instead, we urge the SDT to replace this language with the defined term "Qualifying Aggregate Generation Resources," which is discussed in more detail in our response to Question 3. This language, or some equivalent, will preserve the SDT's ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. More generally, we are not certain what is accomplished by Inclusion 4 that is not already accomplished by Inclusion 2, which also addresses whether generation should be defined as BES. The SDT's stated concern is with variable generation units such as wind and solar plants. It is not clear to us why this concern is not fully addressed in Inclusion 2, which addresses multiple generation units connected at a common bus, the configuration of most variable generation plants with multiple units. We are also concerned that the language, as proposed, could have unintended consequences and improperly classify local distribution systems as BES in certain circumstances. This is because multiple distributed generation units could render a local distribution system a "collector system" and the entire system the equivalent of an aggregated generation unit, causing the local distribution system to be improperly denied status as a LN. If many different distributed generation units are connected to a local distribution system, it is very unlikely that more than a few of those units would fail simultaneously, and it is therefore unlikely that multiple generation units would produce a measureable impact on the interconnected bulk transmission system, especially if the units individually do not otherwise exceed the materiality threshold to be established by the SDT in Phase II. Further, we are concerned that, if small distributed generation units become the industry norm, Inclusion 4 could unintentionally sweep in local distribution systems, especially where local policies favor the growth of small solar or other renewable generation systems for public policy reasons. Finally, we suggest that the SDT add the phrase ". . . unless the dispersed power producing resources operate within a Radial System meeting the requirements of Exclusion E1 or a Local Network meeting the requirements of Exclusion E2." This language, which parallels the language included at the end of Inclusion 11, would make clear that dispersed small-scale generators scattered throughout a Radial System or Local Network serving retail load would not convert the

Radial System or Local Network into a BES system, even if the aggregate capacity of those small generators exceeds the relevant threshold.

No

KEC has several concerns about the new language in Inclusion 5. First, because Reactive Power devices produce power, they are “power producing resources” and we therefore believe Inclusion 5 is duplicative of Inclusion 4, which addresses “power producing devices.” Second, there is no capacity threshold specified in Inclusion 5 for Reactive Power devices that would be considered part of the BES. This is inconsistent with the approach taken in the balance of the definition, where thresholds are specified for generators and other types of power producing devices. Finally, KEC believes the appropriate threshold for inclusion or exclusion of Reactive Power devices from the BES should be subject to the same technical analysis that will cover generators in the Phase II process.

Yes

KEC continues to support the radial system exclusion, which is necessary as a legal matter, because, for example, FERC in Orders No. 743 and 743-A has required that the existing radial exemption in the NERC Statement of Compliance Registry Criteria be maintained. As a practical matter, radial systems are used for service to retail loads, usually in remote or rural areas, and not for the transmission of bulk power. Hence, operation of the radials has little or nothing to do with the reliable operation of the interconnected bulk transmission network. We also support the inclusion of the note discussing normally open switches because this language provides needed clarity for a common radial system configuration. We also agree with the substantive thrust of this language, which is that a radial system should not be considered part of the BES if it is interconnected at a single point, even if there is an alternative point of delivery that is normally open. While we support the Exclusion for Radial Systems, we believe several clarifications and refinements are necessary. (1) The term “transmission Elements” in the initial paragraph should be changed to “Elements.” Radial systems are not transmission systems and including the word “transmission” in the Radial System exclusion is therefore unnecessary and confusing. (2) Subparagraph (b) of Exclusion 1 refers to “generation resources . . . with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating)”. We urge the SDT to replace this language with the defined term “Qualifying Aggregate Generation Resources,” discussed in more detail in our response to Question 3. This language, or some equivalent, will preserve the SDT’s ability to revise the 75 MVA threshold in Phase II, with the result of Phase II included in the BES Definition by operation rather than requiring further revision of the Definition. (3) Subparagraph (b) also seems to assume that if a Radial System contains a generator exceeding the 75 MVA threshold, the Radial System itself must be included in the BES because it links the generator to the interconnected bulk transmission system. As discussed more fully in our response to Question 9, below, NERC’s Project 2010-17 Standards Drafting Team and GO-TO Task Force have both concluded that this assumption is unwarranted. (4) The “Note” as drafted by the SDT indicates that “a normally open switching device between radial systems” will not serve to disqualify the Radial from exclusion under Exclusion 1. As noted above, KEC strongly supports the note conceptually. However, we believe this language should be included in a separate subparagraph (d), rather than a note, because treatment as a “note” suggests it is less important than other portions of the Exclusion. We also suggest the language be changed to read: (d) Normally-open switching devices between radial elements as depicted and identified on system one-line diagrams does not affect this exclusion. This will make clear that a radial with more than one normally-open switch connecting it to another radial is still a radial. From the perspective of the BES Definition, the key question is whether switches operating between Radials are normally open, not whether there is more than one normally-open switch.

Yes

KEC supports the revised language. The language provides clarity regarding the BES status of customer-owned cogeneration facilities. However, KEC urges the SDT to remove the reference to the 75 MVA threshold and replace it with the defined term “Qualifying Aggregate Generation Resources” or some equivalent language for the reasons stated in our responses to Questions 3, 5, and 7. In addition, we are concerned that Exclusion 2 will place local distribution utilities in a difficult position because, under Exclusion 1 or Exclusion 3 as drafted, they could lose their status as a Radial System or a Local Network through the actions of a customer constructing behind-the-meter generation. With respect to Radial Systems, the appearance of behind-the-meter generators could cause the Radial System to exceed the thresholds specified in subparagraphs (b) and (c) of Exclusion 1 through no fault of the Radial System owner. Similarly, a Local Network could lose its status because behind-the-

meter generation could be of sufficient size that power moves into the interconnected grid in certain hours or under certain contingencies, rather than moving purely onto the Local Network, as required in subparagraph (b) of Exclusion 3. The Exclusions for Radial Systems and Local Networks should be made consistent with the Exclusion for behind-the-meter generation. There is no technical reason to believe the power flowing from a behind-the-meter customer-owned generator will have less impact on the bulk system than an equivalent-sized generator owned by a utility operating a Radial System or LN.

Yes

KEC strongly supports the categorical exclusion of Local Networks (“LNs”) from the BES. We believe the exclusion is necessary to ensure that the BES definition complies with the statutory requirement, discussed in our response to Question 1, to exclude all facilities used in the local distribution of electric power. LNs are, of course, probably the most common form of local distribution facility. Further, the conversion of radial systems to local distribution networks should be encouraged because networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. If the BES definition were to provide an exclusion for radials without providing a similar exclusion for LNs, however, it would discourage networking local distribution systems because of the significantly increased regulatory burdens faced by the local distribution utility if it elected to network its radial facilities. By placing radial systems and LNs on the same regulatory footing, the proposed definition will ensure that decisions about whether to network radial systems are made on the basis of costs and benefits to the retail customers served by those radials, and not on the basis of disparate regulatory treatment. Consumers will ultimately benefit from the path chosen by the SDT. KEC also supports specific refinements made to the LN exclusion by the SDT in the current draft of the BES definition. In particular, KEC supports the clarification of the purposes of a LN. The current draft states that LNs connect at multiple points to “improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system.” KEC supports this change in language because it reflects the fundamental purposes of a LN and emphasizes one of the key distinctions between LNs and bulk transmission facilities, namely, that LNs are designed primarily to serve local retail load while bulk transmission facilities are designed primarily to move bulk power from a bulk source (generally either the point of interconnection of a wholesale generator or a the point of interconnection with another bulk transmission system) to one or more wholesale purchasers. KEC believes further improvement of the language could be achieved with additional modifications and clarifications. With respect to the core language of Exclusion 3, we believe the language making a “group of contiguous transmission Elements operated at or above 100 kV” the starting point for identifying a LN would be improved by deleting the term “transmission” from this phrase. This is so because LNs are not used for transmission and the use of the term “transmission Elements” is therefore both confusing and unnecessary. There would be no room for argument about what the SDT intended by including the word “transmission” if the word is deleted and the Exclusion applies to any “group of Elements operated at 100 kV or above” that meets the remaining requirement of the Exclusion. Further, any definitional value that is added by using the term “transmission Elements” is accomplished by using that term in the core definition, and there is no reason to carry the term through in the Exclusions. KEC also believes that subparagraphs (a) and (b) are redundant in the sense that whatever protection is offered by the generation limit in subparagraph (a) is duplicated by the limit in subparagraph (b) requiring no flow out of the LN. We believe the SDT can eliminate subparagraph (a) of Exclusion 3 and simply rely on subparagraph (b) because if power only flows into the LN even if it interconnects more than 75 MVA of generation, the interconnected generation interconnected will have no significant interaction with the interconnected bulk transmission system. It will only interact with the LN. And, with the advent of distributed generation, it is easy to foresee a situation in which a large number of very small distributed generators are interconnected into a LDN, so that the aggregate capacity of these generators exceeds 75 MVA. However, because the generators are small and dispersed and, under the criterion in subparagraph (b), would be wholly absorbed within the LN rather than transmitting power onto the interconnected grid, those generators would not have a material impact on the grid. We also suggest that subparagraph (b) of Exclusion 3 could be more clearly drafted. Subparagraph (b), as part of the requirement that power flow into a LN rather than out of it, includes this description: “The LN does not transfer energy originating outside the LN for delivery through the LN.” We understand this language is intended to distinguish a LN from a link in the transmission system – power on a transmission link passes through the transmission link to a load located elsewhere, while power in a LN enters the LN and is consumed by retail load within the LN. While we agree with the concept

proposed by the SDT, we believe the language would be clearer if it read: "The LN does not transfer energy originating outside the LN for delivery through the LN to loads located outside the LN." We believe the italicized language is necessary to distinguish between a transmission system, where power that originates outside a system is delivered through the system and passes through the system to a sink located somewhere outside the system, from a LN, in which power originating outside the LN passes through the LN and is delivered to retail load within the LN. To put it another way, the italicized language helps distinguish a transmission system from an LN, in which the LN "transfers energy originating outside the LN for delivery through the LN to loads located within the LN." We also believe the language of subparagraph (a) of Exclusion 3 could be improved.

Subparagraph (d) would make LNs part of the BES if they interconnect "non-retail generation greater than 75 MVA (gross nameplate rating)." For the reasons stated in our responses to Questions 3, 5 and 7, we urge the SDT to replace the reference to a hard 75 MVA threshold with the defined term "Qualifying Aggregate Generation Resources" or some equivalent. We are also uncertain what is meant by the use of the term "non-retail generation" in subparagraph (a). From context, we believe the SDT considers "non-retail generation" to mean generation that is used by retail customers located within a LN rather than being exported and sold on wholesale markets outside the LN. We therefore suggest that the SDT replace the phrase "non-retail generation" with the phrase "generation sold in wholesale markets and transmitted outside the LN." Similarly, we are unsure what is meant by the phrase "the LN and its underlying Elements." We believe the phrase "and its underlying Elements" could simply be deleted from the definition without loss of meaning. In the alternative, the SDT might consider using the phrase "the LN, including all Elements located on the distribution side of any Automatic Fault Interrupting Devices (or other points of demarcation) separating the LN from the bulk interstate transmission system." We believe this phrase more accurately reflects the SDT's intent, which appears to be that generation exceeding 75 MVA in aggregate capacity interconnected anywhere within the LN disqualifies that LN from being excluded from the BES under Exclusion 3.

Finally, KEC believes that both subparagraphs (a) and (b) of Exclusion 3 could be safely eliminated as long as subparagraph (c) is retained. Subparagraph (c) makes a LN part of the BES if it is classified as a Flow Gate or Transfer Path. Flow Gates and Transfer Paths are, by definition, the key facilities that allow reliable transmission of bulk electric power on the interconnected grid. If a LN has not been identified as either a Flow Gate or a Transfer Path, it is unlikely the LN is necessary for the reliable transmission of electricity on the interconnected bulk system. Apart from these specific improvements that we believe could be achieved by modifying the language of Exclusion 3, we believe the SDT may need to re-examine certain assumptions that appear to underlie the current draft. Specifically, subparagraph (a) suggests that if BES generation is embedded within a LN, the LN itself must also be BES. But two NERC bodies have already addressed similar questions and concluded there is no technical basis for such concerns. NERC's Standards Drafting Team for Project 2010-07 and its predecessor, the "GO-TO Task Force" were formed to address how the dedicated interconnection facilities linking a BES generator to high-voltage transmission facilities should be treated under the NERC standards. The GO-TO Team concluded that by complying with a handful of reliability standards, primarily related to vegetation management, reliable operation of the bulk interconnected system could be protected without unduly burdening the owners of such interconnection systems. Therefore, there is no reason, according to the GO-TO Team, that dedicated high-voltage interconnection facilities must be treated as "Transmission" and classified as part of the BES in order to make reliability standards effective. See Final Report from the NERC Ad Hoc Group for Generator Requirements at the Transmission Interface (Nov. 16, 2009) (paper written by the GO-TO Task Force). Similarly, the Project 2010-07 Team observed that interconnection facilities "are most often not part of the integrated bulk power system, and as such should not be subject to the same level of standards applicable to Transmission Owners and Transmission Operators who own and operate transmission Facilities and Elements that are part of the integrated bulk power system." White Paper Proposal for Information Comment, NERC Project 2010-07: Generator Requirements at the Transmission Interface, at 3 (March 2011). Requiring Generation Owners and Operators to comply with the same standards as BES Transmission Owners and Operators "would do little, if anything, to improve the reliability of the Bulk Electric System," especially "when compared to the operation of the equipment that actually produces electricity – the generation equipment itself." Id. We believe that interconnection of BES generators within a LN is analogous and that, based on the findings of the Project 2010-07 and GO-TO Teams, automatically classifying a LN as "BES" simply because a large generator is embedded in the LN will result in substantial overregulation and unnecessary expense with little gain for bulk system reliability. If anything, generation interconnected through a LN is less

likely to produce material impacts on the interconnected bulk transmission system than the equivalent generator interconnected through a single dedicated line because an LN is interconnected to the bulk system at several points, so that if one interconnection goes down, power can still flow from the BES generator to the bulk system on other interconnection points. Where a dedicated interconnection facility is involved, by contrast, if the interconnection line fails, the generator is unavailable to the interconnected bulk system. Similarly, we suggest that the SDT re-examine the assumptions underlying subparagraph (b), which seems to suggest that a local distribution system cannot be classified as a Local Network if power flows out of that system at any time, even if the amount is de minimis, the outward flow is only for a few hours a year, or the outward flow occurs only in an extreme contingency. Accordingly, we suggest that the initial clause of subparagraph (b) be revised to read: "Except in unusual circumstances, power flows only into the LN."

Yes

KEC supports the revised language because retail reactive devices are used to address local customer or retail voltage issues, rather than voltage issues on the interconnected bulk grid, and such local devices should therefore be excluded from the BES definition.

No

KEC extends its thanks to the SDT and to the many industry entities that have actively participating in the Standards Development Process. KEC strongly supports the current draft and believes, with certain refinements discussed in our comments, that the definition will serve the industry and reliability regulators well for many years to come. In addition, as noted earlier, KEC is encouraged that the 20/75 MVA generation thresholds referred to in the NERC Statement of Compliance Registry Criteria, which have been relied upon by the SDT largely as a matter of necessity, will be reviewed and a technical assessment will be performed to identify the appropriate generation unit and plant size threshold to ensure a reliable North America. Finally, we understand that the Rules of Procedure Team will continue to move forward with developing an Exceptions Process that will complement the BES Definition and ensure that, to the extent the BES Definition is over-inclusive, facilities that should not be classified as BES will be excluded from the BES. Because the Exceptions Process is integral to a workable BES Definition, we support the current process for moving forward with the Exceptions Process and the BES Definition on parallel paths. We note that KEC specifically supports the changes made by the SDT in the "Effective Date" provision of the BES Definition, which shortens the effective date of the new definition to the beginning of the first calendar quarter after regulatory approval (as opposed to the first calendar quarter twenty-four months after regulatory approval), with a 24-month transition period. KEC supports this conclusion because it will allow entities seeking deregistration under the terms of the new BES definition to obtain the benefits of the new definition without an unreasonable wait, while allowing any entities that may be newly-classified as BES owners or operators sufficient time to come into compliance with newly-applicable Reliability Standards. KEC also supports the 24-month transition period for the reasons laid out by the SDT.

ATC LLC

Yes

Yes

Yes

Yes

Yes

No

ATC agrees with the inclusion provided the last clause is removed, as noted below. The BES definition is intended to establish a bright line BES definition. The clause "dedicated transformer" is undefined and unclear. Inclusion I5 –Static or dynamic devices dedicated to supplying or absorbing Reactive

Power that are connected at 100 kV or higher (deletion of remainder of clause).
Yes
Unless there is a specific reason to the contrary, ATC suggests that Exclusion E1b include the qualification of "aggregate capacity of non-retail generation less than or equal to 75 MVA" to be consistent with the wording in E1c.
Yes
No
ATC agrees in general with the exclusions for E3 pending the following changes: Power flows only into the LN: The LN does not transfer energy originating outside the LN for delivery through the LN under normal operating conditions (n-0 contingency); and ATC suggests considering a different approach for the power flow criteria in Exclusion E3b: Inclusion E3b - No Firm Power Transfers are scheduled to flow out of, or through, the LN in the operating horizon [for BES designations applicable to the operating horizon] and no Firm Power Transfers are reserved to flow out of, or through, the LN in the planning horizon [for BES designations applicable to the planning horizon].
Yes
No
Group
Sandra Shaffer
PacifiCorp
Yes
PacifiCorp believes the SDT continues to make substantial progress towards a clear and workable definition of the Bulk Electric System ("BES") that markedly improves both the existing definition and the SDT's previous proposal. PacifiCorp strongly supports the new definition, conditioned on: (1) a workable Exceptions process being developed in conjunction with the BES definition; and, (2) the SDT moving forward expeditiously on Phase II of the standards development process in accordance with the SAR recently put forward by the SDT.
Yes
PacifiCorp suggests a clarification to I1 to provide as follows: "Transformers with either primary or secondary terminals, or both, that operate at or below 100 kV are not part of the BES."
No
Requiring owners of single generators (20 MVA – 75 MVA) to meet reliability standards that owners of distributed power producing resources (See 14) do not have to meet is discriminatory. The limit for a single unit should be set to 75 MVA until such time as a technical review can determine the appropriate levels for all generation resources. However, even with this concern, PacifiCorp supports the entire BES definition in its current form based on the timeframe under which the SDT is operating and with an emphasis based on a phase II SAR to address PacifiCorp's objections regarding generation levels.
Yes
PacifiCorp supports the removal of reference to Cranking Paths in I3. There is no reason to classify as BES the facilities interconnecting a BES generator to the interconnected transmission system.
No
Setting a dispersed power producing resource limit to 75 MVA at a common point discriminates against single generator owners who own generators between 20 MVA and 75 MVA (inclusion I1), typically connected at a common point and requires such owners to be subject to additional standards that dispersed power producing owners are not required. However, even with this concern, PacifiCorp supports the entire BES definition in its current form based on the timeframe under which the SDT is operating and with an emphasis based on a phase II SAR to address PacifiCorp's objections regarding generation levels. Under the attached scenario, please identify which elements would be considered BES: This response included a drawing. This format will not allow the submission of the drawing. The drawing will be sent separately in an email. Reference "Proj 2010-17 PAC Drawing".

No
PacifiCorp recommends the addition of the phrase "...unless excluded under E1 or E3." Otherwise, PacifiCorp believes that I5 is currently acceptable. However, phase II should identify limits and technically justify the appropriate limit(s).
Yes
: The note in E1 as written is ambiguous and requires clarification. PacifiCorp assumes the note means that two radial systems separated by a normally open switching device allows for the exclusion of both radial systems. PacifiCorp recommends that the SDT revise the note to serve as a paragraph clarifying E1 that, "Radial systems separated by normally open switching device(s) as depicted on prints or one-line diagrams for example, and operated in the normally open position, except during abnormal operating conditions, qualifies both radial systems under this exclusion."
Yes
Yes
PacifiCorp strongly supports the categorical exclusion of Local Networks ("LNs") from the BES. PacifiCorp believes the exclusion is necessary to ensure that the BES definition complies with FERC's statutory jurisdictional requirements. PacifiCorp recommends the following modifications: • Change "contiguous transmission Elements" to "contiguous Elements". • Modify item b to state, "Power flows only into the LN during normal operating conditions: The LN does not transfer energy originating outside the LN for delivery to loads located outside the LN..." • Add an item (may be included in item b) to provide as follows: "The LN is not critical (or is not relied upon) to maintain the reliability of the interconnected system during abnormal operating conditions."
Yes
No
It is absolutely imperative that phase II continue as proposed by the STD. If phase II was not proposed PacifiCorp would vote no on this proposal.

NESCOE
No
The New England States Committee on Electricity ("NESCOE") appreciates the opportunity to provide comments on the revised BES definition. NESCOE is New England's Regional State Committee and represents the collective views of the six New England states. Please consider this submission to reflect the views of the States of Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island and Vermont. Some of these states may submit separate comments in addition to this joint filing. NESCOE does not believe that the proposed changes address our fundamental concerns. As NESCOE pointed out in its comments on the previous draft, the definition's reliance on a 100 kV "bright line" threshold may impose substantial costs on New England ratepayers without achieving meaningful reliability benefits. NERC and the drafting team have not provided any technical justification for imposing the 100 kV test, despite its potential for over-inclusiveness and significant costs. NESCOE believes that the Federal Energy Regulatory Commission ("FERC" or "the Commission") recognizes the need to avoid this result. As the Commission pointed out in Order 743A, Order 743 does not mandate the application of a 100 kV threshold, and NERC is free to propose alternatives. Unless and until NERC provides a technical justification for its approach, the Standard should use the 100 kV threshold concept in a way that is consistent with the Commission's guidance. Specifically, the Standard should make clear that the 100 kV threshold is an "initial line of demarcation," and not the end of the analysis. According to Order 743A, the two criteria that bound the BES definition are (1) the statutory exclusion of facilities used in local distribution, and (2) the requirement that the facilities included be "necessary for reliable operation" of the interconnected transmission system. A definition that recognizes these limits, coupled with an efficient and transparent exceptions process, would meet FERC's expectations. The proposed definition does not meet this standard. For these reasons, absent a technical justification for imposing a 100 kV threshold, NESCOE suggests the following revised core definition: "All Transmission Elements operated at 100 kV or higher and Real Power and Reactive Power resources connected at 100 kV or higher that are necessary for the reliable operation of the

interconnected transmission network, including but not limited to the facilities listed below as Inclusions, and excluding (1) facilities that are used in the local distribution of electric energy, and (2) the facilities and systems listed below as Exclusions. Other Elements may be included or excluded on a case-by-case basis through the Rules of Procedure exception process." Where FERC had concerns that the existing definitions for the bulk power system were under-inclusive, the proposed Standard risks erring in the opposite direction. Because the definition of the BES is critical to NERC's role as ERO and will have a significant impact on ratepayers, NESCOE believes the drafting team should track FERC's guidelines as closely as possible, or provide a specific technical justification for relying on the 100 kV bright line threshold.

No

NESCOE supports the revised Inclusion I1 language that treats Exclusions E1 and E3 as alternative exclusions, either of which may qualify as an exclusion. However, specificity is needed regarding what equipment is included in I1 (e.g., autotransformers, PARs, primary, secondary, tertiary windings).

No

Failing to establish a known MVA rating at this stage is problematic. The BES definition cannot be considered in a vacuum, and adjusting or establishing thresholds such as MVA ratings will create regulatory uncertainty and may result in additional costs and unnecessary system upgrades. Additionally, Inclusion I2 should remove the reference to the Statement of Compliance Registry Criteria. The definition should be the governing document regarding generation that is included in the BES.

No

While NESCOE appreciates that cranking paths were excluded in response to industry comments, as we stated in comments to the prior posting of the BES definition, blackstart units should be excluded from the BES. Such units are appropriately covered under regional restoration procedures and applicable NERC standards (see for example, Emergency Operating Procedure EOP-005-2). However, should blackstart units be included in subsequent postings of the definition, we suggest that the language be revised to state that only those units "material to" the BES are included.

No

NESCOE continues to disagree with this proposed inclusion. NESCOE is concerned with the potential adverse impact this may have on the development of renewable generation resources. In addition, NESCOE suggests that the aggregate 75 MVA of connected generation is too low and is not adequately supported by technical analysis. The threshold value should be related to the largest contingency the applicable control area is designed to operate to. A level of 300 MVA would be appropriate. Finally, the inclusion needs to be clarified in order that entities have clear guidance on what is meant by "common point of interconnection."

No

NESCOE believes that inclusion of all devices that supply reactive power to the BES is unnecessary and will result in transferring unjustified costs to the ratepayer. Static devices (fixed capacitors) should remain excluded from the BES as they are dispatched by operations personnel, and if one fixed capacitor bank fails, the operator can replace its impact by switching in another fixed bank. This represents routine operation of the system. On the other hand, dynamic devices may be important to maintaining voltage stability of the system. These installations typically are rated to supply or absorb 75 MVA or more to or from the BES. Therefore, NESCOE suggests that dynamic reactive power devices rated at 75 MVA or more be included in the BES. Further, revised inclusion I5 is a new inclusion that lacks definition (and appears to be redundant with the general BES definition). NERC should provide additional technical justification for the additional language under Inclusion I5.

Yes

NESCOE suggests that the aggregate 75 MVA of connected generation is too low and would benefit from additional technical justification. The threshold value should be related to the largest contingency to which the applicable control area is designed to operate. A level of 300 MVA would be appropriate. This 300 MVA limit represents 25% of the 1200 MVA loss of source that is typically assumed for operation of the Northeast portion of the Eastern Interconnection. Depending on system conditions, this number may be as high as 1500 MVA. Therefore, the suggested value of 300 MVA has a technical basis and falls well within typical loss of source expectations for the Northeast.

Yes

While NESCOE generally supports Exclusion E2, no information has been provided by NERC demonstrating that the 75 MVA rating is based on any sound technical analysis.

Yes

NESCOE generally supports this exclusion but believes it is too narrow. As noted in the response to question 7, Exclusion E3 should allow a higher level of aggregate generation MVA on a Local Network (at least 300 MVA). In addition, NESCOE believes that local networks should not necessarily be ineligible for Exclusion E3 simply because an amount of power may transfer out of the network at times. NERC's draft technical network exclusions document should be amended such that local networks would be permitted to qualify for network exclusions under E3 if power flowing out of the network is minimal and would not likely adversely impact the BES. For example, transfers of less than or equal to 100 MVA should not have any adverse impact on the BES. The draft technical network exclusions document should be amended to state that transfers of 100 MVA into the BES from the local distribution network are acceptable. The 100 MVA limit suggested here represents 25% of the rated value of a typical 345/115 substation (typically on the order of 400 MVA). Rarely does more than a fraction of the rated MVA flow from the low voltage side to the high voltage side. An allowance of 100 MVA represents a flow level will have no significant impact to the interconnected bulk power network.

Yes

While we are generally supportive of this exclusion, the term "retail" needs to be clarified (i.e., are retail customers of all sizes intended to be excluded?).

Yes

NESCOE offers the following additional comments: 1) Phased Approach. While well-intentioned, separating the BES definition project into two separate phases is problematic from both a procedural and substantive perspective. While we recognize that the filing due date is rapidly approaching, the BES definition cannot be considered in a vacuum, divorced from the concerns raised by a number of parties in response to past postings of the BES definition. The issues NERC has identified for consideration during the proposed "Phase 2" are inseparable from the development of the BES definition and should be squarely addressed before a definition is adopted. In particular, the development of criteria for determining what facilities are "necessary for the reliable operation" of the interconnected system cannot be put off for a second phase. Contrary to FERC's direction, NERC's proposal will force ratepayers to incur costs related to compliance with mandates that may or may not be revised through the second phase of the project. The importance of considering and resolving such concerns before adopting a definition is heightened by the proposed two-year implementation requirement. This short implementation period almost guarantees that entities will commit resources shortly after adoption of the definition to ensure compliance within the mandated period. In other words, ratepayers will bear costs related to compliance irrespective of any change resulting from the Phase 2 process or the exception process. Expediency, while understandable given the filing deadline, must be balanced against the risk that a multi-phased approach could lead to significant consumer costs without attendant meaningful reliability benefits. 2) Cost-Benefit Analysis. A cost impact analysis should be performed as part of developing any reliability standard. However, the development of the BES definition has failed to consider the cost impacts of the definition (and its inclusions and exclusions) and weigh these impacts against identified benefits that the definition would achieve. NESCOE stated in its May 21, 2011 comments on the last posting of the BES definition that "any new costs a revised definition imposes – which fall ultimately on consumers – should provide meaningful reliability benefits." A cost-benefit analysis should be integral to the development of a BES definition and, indeed, any reliability standard. This analysis should include a probabilistic risk assessment examining the likelihood of an event and the costs and risks resulting from such event, which should be weighed against the costs of complying with the proposed reliability measures. 3) Technical Justification. In addition to performing a cost-benefit analysis, a technical basis must be provided to justify a proposed reliability standard. However, as we state above, the proposed BES definition does not provide a technical justification for the 100 kV threshold. Nor does it provide a technical justification for the threshold for generation resources or other elements of the definition. As stated above, while well-intentioned and understandable, deferring this technical justification to a later and separate phase of the project is a flawed and potentially costly approach. Providing a technical justification for a reliability standard is a core function of standards development and should be addressed at the forefront of the process rather than relegated to a separate phase largely undertaken after a standard is filed.

No
The last sentence of the core part of the definition states that no distribution facilities will be included, but we feel that some of these facilities could be included due to also being blackstart resources. We agree with the idea of removing distribution facilities, but would like to see some clarification or a qualifier with regards to blackstart resources.
Yes
Yes
Yes
No
We believe that the removal of the wording "single site" in I2 would eliminate the need to include dispersed power producing resources in I4. We feel that I4 should be removed to reduce redundancy in the definition, unless there is some other reason to include it. Also, we understand that 75 MVA is retained in I4 because there is no direct link to the ERO Statement of Compliance Registry Criteria, but we have concerns that this number could change in phase two of the project, creating unnecessary work in the future.
No
We understand that I5 is being used to capture those devices other than generation resources, but the language used leads us to believe that it could include all generators that supply or absorb reactive power. We also believe the language should be changed to be consistent with I1. We suggest that I5 be changed to read: "Static or dynamic devices specifically used for supplying or absorbing Reactive Power that are connected at 100 kV or higher, or through a dedicated transformer with a high-side terminal operated at 100 kV or higher, or through a transformer that is designated in Inclusion I1."
Yes
No
As expressed in our comment to question 5, we have concerns that the 75 MVA number could change in phase two of the project, creating unnecessary work in the future.
Yes
No
This particular Exclusion doesn't address the qualifier as to the impact to the BES. We believe the qualification language in E2, in regards to behind the meter generation, should also be included in Exclusion E4 for clarification purposes.
Yes
We believe a reference should be made to the ROP changes which also provide a mechanism whereby Elements may be excluded or included in the BES. Without that reference, the proposed definition is not all inclusive of all means for exclusions or inclusions. We would suggest the definition be expanded to say "Unless modified by the lists shown below or as provided by Appendix 5C of the NERC Rules of Procedure, all Transmission..." This comment was submitted in response to the original posting and the response received was that it was inadvertently left out and that it would be placed back in, but we don't see the reference in this draft of the definition.

Paul Cummings
City of Redding
Yes
Redding is concerned that NERC has a predetermined definition of Distribution Facilities and will not evaluate networked distribution facilities fairly. NERC stated their predetermined position in their "MOTION TO INTERVENE AND COMMENTS OF THE NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION" filed in the case of the City of Holland, Michigan (Docket No. RC11-5-000). On page 10 and 11 of this motion, under the section labeled "A. Holland's 138 kV lines are transmission rather than local distribution facilities" NERC states "Distribution facilities generally are characterized as elements that are designed and can carry electric energy (Watts/MW) in one direction only at any given time from a single source point (distribution substation) to final load centers." NERC is clearly states that only radial facilities are considered distribution facilities and are unwilling to consider that network facilities over 100Kv could be classified as Distribution Facilities. Holland's claim of NERC over reaching their authority appears to have credibility. In conclusion, Redding supports the addition of Distribution Facilities as an exclusion but believes that the BES Definition phase 2 needs to clearly define the difference between Distribution and Transmission Facilities by identifying the equipment "necessary for the Reliable Operation of the interconnected bulk power transmission system".
Yes
Yes
Redding believes that the definition should drive what appears in the Registry Criteria, therefore we

only support this on a temporary basis based on the premise that the BES Phase 2 technical analysis will identify and provide technical support for determining the appropriate minimum MVA rating for a single unit or the aggregation of multiple units.

Yes

Redding recommends the following rewording: "The Primary Blackstart resources designated in the Transmission Operator's restoration plan." We believe it reduces reliability if all Blackstart generation either primary or secondary are required to be BES. Requiring all Blackstart capable units to be BES creates an incentive to leave certain blackstart units out of restoration plans in order to avoid BES inclusion. By making only the primary Blackstart unit a BES element then Transmission Operators will be more willing to include ALL Blackstart units in their plan thus creating a complete procedure for the Transmission Operator to restore the system.

Yes

Yes

Redding believes that an appropriate MVAr level should be established in during Phase 2.

Yes

Yes

Yes

Yes

Yes

Redding is concerned that phase 2 will not produce significant rules or criteria that further define the BES; the desire to dedicate adequate resources is currently high since FERC has a looming deadline upon NERC, however without deadlines Redding believes that NERC will find it difficult to find the expertise or desire to finish the Project.

Individual

Keith Morisette

Tacoma Power

Yes

Tacoma Power supports the core definition as currently written.

Yes

Tacoma Power supports Inclusion I1 as currently written.

Yes

Tacoma Power generally supports Inclusion I2 and deferring the appropriate quantitative thresholds to those that will be determined in Phase 2. However, the term "gross individual" and "gross aggregate" nameplate rating, although industry used terms, are not industry defined or uniformly understood and applied. Nameplate ratings are determined from discussions and negotiations between the designer, supplier and the owner and it is the owner that makes the final determination of the generating station equipment nameplate ratings. Nameplate ratings for thermal or hydro plants may be based on such things as: fuel mix (best, worst and average), fuel delivery capacity, reservoir level, best efficiency point, normal operating point, ancillary equipment capacities, emissions and discharge restrictions, continuous versus peak output and designed versus installed and tested capacities. It would be more uniform to establish new or use existing criteria to define "gross individual" and "gross aggregate" nameplate ratings, such as that used in the Code of Federal Regulations CFR 18, Part 11.1, "Authorized Installed Capacity" for hydraulic units and CFR 18, Part 287.101, "Determination of Powerplant Design Capacity" for steam electric, combustion turbine and combined cycle units.

Yes

Tacoma Power generally support Inclusion I3 as written. We continue to believe the BES should only

include the Blackstart Resources that support a regional recovery. We propose changing Inclusion I3 to read, "Blackstart Resources identified in the Transmission Operator's restoration plan and included in a regional restoration plan."

Yes

Tacoma Power generally supports the Inclusion I4 as currently written. However, we support further refinement of the aggregate nameplate rating definition and support deferring the appropriate quantitative thresholds to those that will be determined in Phase 2.

No

Tacoma Power generally supports the intent of Inclusion I5 as currently written. However, we believe the definition of the MVAR threshold level must be included in the Phase 2 evaluation and should be determined in a similar manner to the generator threshold that will be determined for I2.

Yes

Tacoma Power generally supports the Exclusion E1 as currently written. However, the "note" at the end of E1 is confusing and can be interpreted inconsistently. We recommend moving the language from the "note" to part of the exclusion as its own section, as follows: (d) Normally-open switching devices between radial elements as depicted and properly identified on system one-line diagrams should not be used to deny this exclusion. Additionally, we believe it is not appropriate for E1 to state an MVA threshold in Section b) when determining such thresholds is the purpose for Phase 2. We urge the SDT to defer the determination of a MVA threshold in E1 to Phase 2.

Yes

Tacoma Power supports the Exclusion E2 as currently written.

No

Tacoma Power does not support the Exclusion E3 as currently written. We strongly believe that Section c) of E3 must replace the term "transfer path" with "Major Transfer Path" to distinguish these paths from any common ATC path. This revision is consistent with the existing language used in the form, Detailed Information to Support an Exception Request. Additionally, we believe it is not appropriate for E3 to state an MVA threshold in Section a) when determining such thresholds is the purpose for Phase 2. We urge the SDT to defer the determination of a MVA threshold in E3 to Phase 2. Finally, the term "non-retail generation" is not a universally understood term in the industry. We suggest that the SDT replace the phrase "non-retail generation" with "generation located on the retail customer's side of the meter."

Yes

Tacoma Power supports the Exclusion E4 as currently written.

No

Tacoma Power does not have any other concerns at this time. Thank you for consideration of our comments.

As acknowledged in the response to Question 12 comments on the previous BES definition, the BES definition is expansive compared to the definition of the BPS in the FPA Section 215. The inclusion of the limited Exclusions is an attempt to remedy the situation. However, the Exclusions need to include a fifth one that if, based on studies or other assessments, it can be shown that any transmission or generator element otherwise identified as part of the BES is not important to the reliability of the BPS, then that element should be excluded from the mandatory standards program. There has never been a study to show that elements, such as a 20 MW wind farm, 60 MW merchant generator (which operates infrequently in the depressed market) in a large BA (eg NYISO) or a radial transmission line connecting a small generator are important to the reliability of the BPS. They are covered by the mandatory standards program through the registration criteria. The BES Definition is the opportunity to permit an entity to demonstrate that an element is unimportant to reliability of the BPS. The SDT has identified a small subset of elements that it is willing to exclude. By their very nature, these exclusions dim the bright line that is the stated goal of this project. However, the SDT's foresight seems limited in its selections. Analytical studies are used to evaluate contingencies that could lead to

the Big Three (cascading outages, instability or voltage collapse). Such a study showing that a transmission or generation element is bounded by the N-1 or N-2 contingency would exclude it from the BES definition. For example, in a BA with a NERC definition Reportable Disturbance of approximately 400 MW (eg NYISO), a 20 MW wind farm, 60 MW merchant generator or numerous other smaller facilities would be bounded by larger contingencies. It would take more than six 60 MW merchant generators with close location and common mode failure to even be a Reportable Disturbance, much less become the N-1 contingency for the Big Three. Exclusion E5 should be "E5 - Any facility that can be demonstrated to the Regional Entity by analytical study or other assessment to be unimportant to the reliability of the BPS (with periodic reports by the Regional Entity to NERC of any such assessments)."

Yes

As acknowledged in the response to Question 12 comments on the previous BES definition, the BES definition is expansive compared to the definition of the BPS in the FPA Section 215. The inclusion of the limited Exclusions is an attempt to remedy the situation. We agree with the changes but believe clarity would be added by changing the word "identified" to "designated".
Yes
No
We believe that the size of the reactive power resource should be considered as a key factor to be part of BES. When considering generating resources, the size, e.g., greater than 75 MVA, was a key part of criteria to be included or excluded as BES. A similar approach should be applied when considering reactive power resources. We also suggest the removal of static reactive resources from this inclusion.
No
Subpart (b) uses the term "generation resources" while subpart (c) uses the term "non-retail generation", why are these different terms used? Further, why is it important that the term "non-retail generation" is used in subpart (c)? In addition, the SDT needs to clarify what the term "non-retail generation" means. Is this what is commonly referred to as "customer owned" or "behind-the-meter" generation? The change in version 2 that removed the requirement that an excluded radial system have an automatic interruption device at the single point of connection to the rest of the BES creates a problem. Three-terminal circuits are common below 230 kV. The "tapped portion" should not be left out of the BES since a fault on that portion takes out the whole line. We propose this revised language in the first sentence on E1: "E1 - Radial systems: A group of contiguous transmission Elements that emanates from a single point of connection of 100 kV or higher, where the connection has an automatic interruption device,..." Exclusion E1, subpart (c) uses the phrase "an aggregate capacity of ... less than or equal to 75 MVA ...". Exclusion E3, subpart (a) provides that the local networks "do not have an aggregate capacity of ... greater than 75 MVA ...". Why are these phrases stated differently even though they appear to address the same resources?
No
We suggest that clarification is needed for what is meant by E2 (ii), regarding generation on the customer's side of the retail meter. Also, we would like for a clarification of the difference between the terms "retail load" and "retail customer load" as used in exclusions E2 and E3.
No
We would agree with the exclusion if the wording of the exclusion includes the following phrase (in italics) added at the end of E3 b): "Power flows only into the LN: The LN does not transfer energy originating outside the LN for delivery through the LN "under normal operating conditions". What does the term "non-retail generation" mean? Can the term "non-retail generation in E3a be changed to simply "generation"?"
Yes
Yes
The definition of the BES is referenced in several existing standards and the Statement of Compliance Registry Criteria. Southern Companies are concerned how this revised definition will impact entity registration, i.e., how will the revised definition be integrated into the Compliance Registry Criteria. The implementation plan should include how the integration is going to occur. The Rules of Procedure exception process should be further defined or referenced in this definition.
Group
AI DiCaprio
PJM
No
While we agree with the changes to the definition, we do not understand the purpose of the final sentence "This does not include facilities used in the local distribution of electric energy." Since the issue of local (distribution) networks is addressed under Exclusion E3, we do not see the added benefit of the referenced text.
Yes

Yes
No
We support the SDT's decision to exclude the cranking paths from the BES definition since testing and verification of the use of facilities in the cranking path is already covered by the appropriate EOP standards. This inclusion is extraneous given there is already a designation specific for system restoration covered by an existing standard to recognize their reliability impacts and to ensure their expected performance. NERC Standards EOP-005-2 stipulates the requirements for testing blackstart resource and cranking paths. This testing requirement suffices to ensure that the facilities critical to system restoration are functional when needed, which meets the intent of identifying their criticality to reliability. We therefore suggest removing Inclusion I3.
Yes
The revised Inclusion I4 does clarify that there is no requirement for a contiguous BES path from the dispersed generation resources to the point of interconnection to the BES.
Yes
No
While we support the provisions of E1 in principle, we are seeking clarification to the following issues. Does the connection voltage of generation referred to in E1.b affect whether a radial system could be excluded under E1? Please clarify the meaning of "non-retail" generation used in E1.c.
Yes
Yes
Yes
Yes
Yes
(1) We support a phased approach proposed in the draft supplemental SAR. Development of the revised BES definition is an important and complex undertaking. The product of this work is fundamental to establishing the applicability of NERC Reliability Standards. The issues identified for attention in Phase 2 of this project warrant careful investigation and as such allowing additional time to properly research and provide for stakeholders to vet them is justified. Specific to the assessment of raising the generator rating threshold from 20 MVA to 75 MVA per unit, we would point out that this needs to be looked at from a different perspective. Industry debates so far have been on the apparent lack of reliability contribution and economic benefits for keeping the threshold at 20 MVA. The former point implies that any negative reliability impact that could be contributed by a generator higher than 20 MVA but lower than 75 MVA could be negligible. Some examples of the standards that the 20-75 MVA units may need to comply with to ensure reliability are: • Voltage and frequency ride through capability • Voltage control (AVR, etc.) • Underfrequency trip setting • Protection relay setting coordination • Data submission for modeling; verification of capability and model A Venn diagram developed by an industry group shows that generators at 20 to 74.99 MVA account for about 13.8% of the total installed capacity in the US. Out of this, 3.0% are currently deemed non-BES whereas the other 10.8% are BES. We do not know how the BES reliability may be affected if these 10.8% generators are no longer deemed BES facilities (after an increase of threshold to 75 MVA) and subject to compliance with NERC standards, including those mentioned above. An assessment from both a positive contribution and a negative impact viewpoints are thus required to aid the determination of the merit of raising the rating threshold. (2) The draft Implementation Plan for the BES definition states "Compliance obligations for Elements included by the definition shall begin 24 months after the applicable effective date of the definition." We are concerned that the stated implementation period may be insufficient time to complete transition plans for newly identified BES Elements and Facilities, where those plans require procurement, installation and commissioning of additional equipment. We believe a period of 24 months may be more appropriate.

During the previous comment period, BGE asked for clarification regarding the exclusion of "radial facilities". The particular example configuration in question involved two 115 kV lines emanating from two different points of connection and "tied" on the "low side" at 34.5 kV. The SDT responded that this was not a radial facility but would be excluded under the E3-Local Network exclusion. BGE believes that this particular configuration should be excluded under the E1-Radial Systems exclusion. BGE does not believe that two otherwise radial lines are made "non-radial" because they are tied at a voltage lower than 100 kV.

The Industrial Customers of Northwest Utilities ("ICNU") submits the following comments regarding the North American Electric Reliability Corporation's ("NERC") proposal for defining the Bulk Electric System ("BES"). ICNU is an incorporated, non-profit association of large end-use electric customers in the Pacific Northwest, with offices in Portland, Oregon. ICNU previously submitted comments in the Western Electricity Coordinating Council's ("WECC") process for defining the BES. ICNU's members are not electric utilities, but some ICNU members own substations that are interconnected to utility transmission systems and utility distribution systems. In addition, in some cases, ICNU members operate local distribution facilities behind their substations to serve their end-use loads. In some cases, the ICNU member's interconnection to the utility-owned transmission system or distribution system is via a utility-owned radial line; and, in others, the ICNU member's distribution system is looped into the utility's transmission system for reliability purposes. Finally, some ICNU members have local distribution systems that include the ICNU member's backup generating facilities. ICNU is submitting comments, because these facilities arguably could fall within NERC's proposed definition of BES. ICNU appreciates the work that NERC has done to date, and encourages NERC to develop a rule that recognizes the unique aspects of the Pacific Northwest transmission system and the particular needs of end-use customers. Given the arbitrary requirements and limitations imposed by the Federal Energy Regulatory Commission, ICNU supports NERC's overall approach to defining the BES. NERC has proposed a bright line rule in which all transmission elements operated 100 kV or higher will be included in the definition, subject to certain inclusions and exclusions. ICNU supports NERC's goal of

excluding facilities in the local distribution of electric energy. NERC proposes three general classes of exclusions, which includes certain radial systems, generating units that serve all or part of retail customer's load, and local networks. Specifically, NERC proposes that: 1) radial systems 100 kV and higher shall be excluded if they only serve load, or only include certain generation resources less than 75 MVA; 2) generating units that serve customer load on the customer meter are excluded if the net capacity provided to the BES does not exceed 75 MVA and standby, back up and maintenance power services are provided; 3) local networks operated less than 300 kV that distribute power to load rather than transfer bulk power across the interconnected system; and 4) reactive power owned and operated by a retail customer solely for its own benefit. ICNU supports these exclusions; however, ICNU is concerned that certain end-use retail customer facilities that do not impact the BES may still be inappropriately included. NERC appears to recognize this possibility and includes an exception process to include or exclude facilities on a case-by-case basis. ICNU urges NERC to develop this exception process, and to review the work by WECC regarding how to structure an appropriate exception. At a minimum, the exception process should not require end-use customers to perform costly and complex studies, but should instead require utilities or regional organizations that have the relevant expertise to conduct the necessary studies to determine if a specific facility should be removed or included in the BES. ICNU is also concerned about the term "non-retail generation," which does not appear to have a corresponding definition. ICNU understands that non-retail generation is intended to apply to generation behind the retail customer's meter. ICNU recommends that net metered systems should not count towards the generation limits for radial and local network systems.

**Additional Comments Submitted:**

**Salt River Project:**

Definition of Bulk Electric System (BES):

The Blackstart "Cranking Path" has been deleted from Inclusion 3 of the BES definition. However, NERC Standards EOP-005 and CIP-002, R1.2.4, require documenting the Cranking Path. In addition, CIP-002-4 identifies the Cranking Path as a Critical Asset in Attachment 1. Compliance to the NERC Standards needs to be an exact science whenever possible. SRP does not argue the inclusion or exclusion of Cranking Path. However, if it is excluded, guidance must be provided on whether or not a Cranking Path is subject to the previously mentioned Standards.

**Additional Comments Submitted:**

PacifiCorp

5. The SDT has revised the specific inclusions to the core definition in response to industry comments. Do you agree with Inclusion 14 (dispersed power)? If you do not support this change or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments.

Yes:

No: X

Comments: Setting a dispersed power producing resource limit to 75 MVA at a common point discriminates against single generator owners who own generators between 20 MVA and 75 MVA (inclusion I1), typically connected at a common point and requires such owners to be subject to additional standards that dispersed power producing owners are not required.

However, even with this concern, PacifiCorp supports the entire BES definition in its current form based on the timeframe under which the SDT is operating and with an emphasis based on a phase II SAR to address PacifiCorp's objections regarding generation levels.

Under the attached scenario, please identify which elements would be considered BES:

## Additional Comments Submitted

RFC Staff:

**Bulk Electric System (BES):** Unless modified by the lists shown below, all Transmission Elements operated at 100 kV or higher and Real Power and Reactive Power resources connected at 100 kV or higher. ~~This does not include facilities used in the local distribution of electric energy.~~ The BES includes:

### **Inclusions:**

- I1 - Transformers with primary and secondary terminals operated at 100 kV or higher, ~~unless excluded under Exclusion E1 or E3 for local distribution or retail customers.~~
- I2 - Generating resources as described in the ERO Statement of Compliance Registry Criteria including the generator terminals through the high-side of the step-up transformer(s), connected at a voltage of 100 kV or above.
- I3 - Blackstart Resources and associated designated blackstart Cranking Paths operated at 100 kV or higher, identified in the Transmission Operator's restoration plan, ~~regardless of voltage level.~~
- ~~I4 - Dispersed power producing resources as described in the ERO Statement of Compliance Registry Criteria utilizing a system designed primarily for aggregating capacity, connected at common point at a voltage of 100 kV or above.~~
- **I45** - Static or dynamic devices dedicated to supplying or absorbing Reactive Power that are connected at 100 kV or higher, or through a dedicated transformer with a high-side voltage of 100 kV or higher, or through a transformer that is designated in ~~Inclusion I1.~~

This definition does not include facilities used in the local distribution of electric energy or retail customers, which are:- **Exclusions:**

- E1 - Radial systems: A group of contiguous transmission Elements that emanates from a single point of connection of 100 kV or higher from a single Transmission source originating with a single automatic interruption device and:
  - a) Only serves Load. Or,
  - b) Only includes generation resources not identified in ~~Inclusion I3~~, with an aggregate capacity less than or equal to 75 MVA (gross nameplate rating). Or,
  - c) Where the radial system serves Load and includes generation resources, not identified in ~~Inclusion I3~~, - with an aggregate capacity of non-retail generation less than or equal to 75 MVA (gross nameplate rating).Note - A normally open switching device between radial systems, as depicted on prints or one-line diagrams for example, does not affect this exclusion.
- ~~E2~~ - A generating unit or multiple generating units that serve all or part of retail customer Load with electric energy on the customer's side of the retail meter if:
  - (i) the net capacity provided to the BES does not exceed 75 MVA, and
  - (ii) standby, back-up, and maintenance power services are provided to the generating unit or multiple generating units or to the retail Load by a Balancing Authority, or provided pursuant to a binding obligation with a Generator Owner or Generator Operator, or under terms approved by the applicable regulatory authority.
- E3 - Local Network (LN): A group of contiguous transmission Elements operated at or above 100 kV but less than 300 kV that distribute power to Load rather than transfer bulk power across the interconnected system. LN's emanate from multiple points of connection at 100 kV or higher to improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system. The LN is characterized by all of the following:

- a) Limits on connected generation: The LN and its underlying Elements do not include generation resources identified in ~~Inclusion~~-I3 and do not have an aggregate capacity of non-retail generation greater than 75 MVA (gross nameplate rating);
  - b) Power flows only into the LN: The LN does not transfer energy originating outside the LN for delivery through the LN; and;
  - c) Not part of a Flowgate or transfer path: The LN does not contain a monitored Facility of a permanent Flowgate in the Eastern Interconnection, a major transfer path within the Western Interconnection, or a comparable monitored Facility in the ERCOT or Quebec Interconnections, and is not a monitored Facility included in an Interconnection Reliability Operating Limit (IROL).
- **E4** – Reactive Power devices owned and operated by the retail customer solely for its own use.

Note - Elements may be included or excluded on a case-by-case basis through the Rules of Procedure exception process.

## Consideration of Comments on Initial Ballot — Definition of BES (Project 2010-17)

Date of Initial Ballot: September 30, 2011 - October 10, 2011

**Summary Consideration:** Many commenters followed instructions and cast their ballot while simply pointing to their detailed comments in the posted comment report. The SDT thanks those commenters as this greatly reduces the administrative workload on the SDT. Those who decided to place comments in the ballot report for the most part echoed comments that had already been seen by the SDT in the posted comment report which was administered first by the SDT. As a result, there were no changes to the definition due to comments received in the ballot report. However, for ease of reference, the changes to the definition made as a result of those comments are repeated here.

The SDT made the following changes to the definition due to industry comments received:

- Clarified the wording in Inclusion I1 to indicate that at least one secondary terminal must be at 100 kV or higher to accommodate multiple terminal transformers.
- Removed the reference to the ERO Statement of Compliance Registry Criteria in Inclusion I2 so that there is no chance of the registry values being changed and affecting the definition prior to resolution of threshold values in Phase II of this project.
- Clarified that generators were not part of Inclusion I5 to avoid improperly pulling in small generators.
- Clarified the language of Exclusion E2 by re-ordering the text as suggested.
- Clarified the language of Exclusion E3.b as suggested.

The SDT feels that it is important to remind the industry that Phase II of this project will begin immediately after the conclusion of Phase I as SDT resources clear up. The same SDT will follow through with Phase II.

The SDT is recommending that this project be moved forward to the recirculation ballot stage.

There were two comments that were repeated multiple times throughout the various documents. The first topic was about how to sort through the definition inclusions and exclusions, i.e., which takes precedence. The SDT offers this guidance on that issue:

The application of the draft 'bright-line' BES definition is a three (3) step process that when appropriately applied will identify the vast majority of BES Elements in a consistent manner that can be applied on a continent-wide basis.

Initially, the BES 'core' definition is used to establish the bright-line of 100 kV, which is the overall demarcation point between BES and non-BES Elements. Additionally, the 'core' definition identifies the Real Power and Reactive Power resources connected at 100 kV or higher as included in the BES. To fully appreciate the scope of the 'core' definition an understanding of the term Element is needed. Element is defined in the NERC Glossary of Terms as:

“Any electrical device with terminals that may be connected to other electrical devices such as a generator, transformer, circuit breaker, bus section, or transmission line. An element may be comprised of one or more components. “

Element is basically any electrical device that is associated with the transmission or the generation (generating resources) of electric energy.

Step two (2) provides additional clarification for the purposes of identifying specific Elements that are included through the application of the ‘core’ definition. The Inclusions address transmission Elements and Real Power and Reactive Power resources with specific criteria to provide for a consistent determination of whether an Element is classified as BES or non-BES.

Step three (3) is to evaluate specific situations for potential exclusion from the BES (classification as non-BES Elements). The exclusion language is written to specifically identify Elements or groups of Elements for potential exclusion from the BES.

Exclusion E1 provides for the exclusion of ‘transmission Elements’ from radial systems that meet the specific criteria identified in the exclusion language. This does not include the exclusion of Real Power and Reactive Power resources captured by Inclusions I2 – I5. The exclusion (E1) only speaks to the transmission component of the radial system. Similarly, Exclusion E3 (local networks) should be applied in the same manner. Therefore, the only inclusion that Exclusions E1 and E3 supersede is Inclusion I1.

Exclusion E2 provides for the exclusion of the Real Power resources that reside behind the retail meter (on the customer’s side) and supersedes inclusion I2.

Exclusion E4 provides for the exclusion of retail customer owned and operated Reactive Power devices and supersedes Inclusion I5.

In the event that the BES definition incorrectly designates an Element as BES that is not necessary for the reliable operation of the interconnected transmission network or an Element as non-BES that is necessary for the reliable operation of the interconnected transmission network, the Rules of Procedure exception process may be utilized on a case-by-case basis to either include or exclude an Element.

The second item is about providing specific guidance on how the information on the exception request form will be used in making decisions on inclusions/exclusions in the exception process. While not technically part of this document which is about the definition, since the question did come up in these comments, the SDT provides the following information:

The SDT understands the concerns raised by the commenters in not receiving hard and fast guidance on this issue. The SDT would like nothing better than to be able to provide a simple continent-wide resolution to this matter. However, after many hours of discussion and an initial attempt at doing so, it has become obvious to the SDT that the simple answer that so many desire is not achievable. If the SDT could have come up with the simple answer, it would have been supplied within the bright-line. The SDT would also like to point out to the commenters that it directly solicited assistance in this matter in the first posting of the criteria and received very little in the form of substantive comments.

There are so many individual variables that will apply to specific cases that there is no way to cover everything up front. There are always going to be extenuating circumstances that will influence decisions on individual cases. One could take this statement to say that the regional discretion hasn't been removed from the process as dictated in the Order. However, the SDT disagrees with this position. The exception request form has to be taken in concert with the changes to the ERO Rules of Procedure and looked at as a single package. When one looks at the rules being formulated for the exception process, it becomes clear that the role of the Regional Entity has been drastically reduced in the proposed revision. The role of the Regional Entity is now one of reviewing the submittal for completion and making a recommendation to the ERO Panel, not to make the final determination. The Regional Entity plays no role in actually approving or rejecting the submittal. It simply acts as an intermediary. One can counter that this places the Regional Entity in a position to effectively block a submittal by being arbitrary as to what information needs to be supplied. In addition, the SDT believes that the visibility of the process would belie such an action by the Regional Entity and also believes that one has to have faith in the integrity of the Regional Entity in such a process. Moreover, Appendix 5C of the proposed NERC Rules of Procedure, Sections 5.1.5, 5.3, and 5.2.4, provide an added level of protection requiring an independent Technical Review Panel assessment where a Regional Entity decides to reject or disapprove an exception request. This panel's findings become part of the exception request record submitted to NERC. Appendix 5C of the proposed NERC Rules of Procedure, Section 7.0, provides NERC the option to remand the request to the Regional Entity with the mandate to process the exception if it finds the Regional Entity erred in rejecting or disapproving the exception request. On the other side of this equation, one could make an argument that the Regional Entity has no basis for what constitutes an acceptable submittal. Commenters point out that the explicit types of studies to be provided and how to interpret the information aren't shown in the request process. The SDT again points to the variations that will abound in the requests as negating any hard and fast rules in this regard. However, one is not dealing with amateurs here. This is not something that hasn't been handled before by either party and there is a great deal of professional experience involved on both the submitter's and the Regional Entity's side of this equation. Having viewed the request details, the SDT believes that both sides can quickly arrive at a resolution as to what information needs to be supplied for the submittal to travel upward to the ERO Panel for adjudication.

Now, the commenters could point to lack of direction being supplied to the ERO Panel as to specific guidelines for them to follow in making their decision. The SDT re-iterates the problem with providing such hard and fast rules. There are just too many variables to take into account. Providing concrete guidelines is going to tie the hands of the ERO Panel and inevitably result in bad decisions being made. The SDT also refers the commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.1 where the basic premise on evaluating an exception request must be based on whether the Elements are necessary for the reliable operation of the interconnected transmission system. Further, reliable operation is defined in the Rules of Procedure as operating the elements of the bulk power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cyber security incident, or unanticipated failure of system elements. The SDT firmly believes that the technical prowess of the ERO Panel, the visibility of the process, and the experience gained by having this same panel review multiple requests will result in an equitable, transparent, and consistent approach to the problem. The SDT would also point out that there are options for a submitting entity to pursue that are outlined in the proposed ERO Rules of Procedure changes if they feel that an improper decision has been made on their submittal.

Some commenters have asked whether a single 'yes' or 'no' response to an item on the exception request form will mandate a negative response to the request. To that item, the SDT refers commenters to Appendix 5C of the proposed NERC Rules of Procedure, Section 3.2 of the proposed Rules of

Procedure that states “No single piece of evidence provided as part of an Exception Request or response to a question will be solely dispositive in the determination of whether an Exception Request shall be approved or disapproved.”

The SDT would like to point out several changes made to the specific items in the form that were made in response to industry comments. The SDT believes that these clarifications will make the process tighter and easier to follow and improve the quality of the submittals.

Finally, the SDT would point to the draft SAR for Phase II of this project that calls for a review of the process after 12 months of experience. The SDT believes that this time period will allow industry to see if the process is working correctly and to suggest changes to the process based on actual real-world experience and not just on suppositions of what may occur in the future. Given the complexity of the technical aspects of this problem and the filing deadline that the SDT is working under for Phase I of this project, the SDT believes that it has developed a fair and equitable method of approaching this difficult problem. The SDT asks the commenter to consider all of these facts in making your decision and casting your ballot and hopes that these changes will result in a favorable outcome.

If you feel that the drafting team overlooked your comments, please let us know immediately. Our goal is to give every comment serious consideration in this process. If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herb Schrayshuen, at 404-446-2560 or at [herb.schrayshuen@nerc.net](mailto:herb.schrayshuen@nerc.net). In addition, there is a NERC Reliability Standards Appeals Process.<sup>1</sup>

Voter	Entity	Segment	Vote	Comment
Kirit Shah	Ameren Services	1	Negative	Please refer to Ameren comments submitted using the Comment Form.
Andrew Z Puztai	American Transmission Company, LLC	1	Negative	Comments submitted.
John Bussman	Associated Electric Cooperative, Inc.	1	Negative	comments posted on comment form
Michael S Crowley	Dominion Virginia Power	1	Negative	Please see Dominion's submitted comments

<sup>1</sup> The appeals process is in the Standards Processes Manual: [http://www.nerc.com/docs/standards/sc/Standard\\_Processes\\_Manual\\_Approved\\_May\\_2010.pdf](http://www.nerc.com/docs/standards/sc/Standard_Processes_Manual_Approved_May_2010.pdf).

Voter	Entity	Segment	Vote	Comment
Bernard Pelletier	Hydro-Quebec TransEnergie	1	Negative	Please see our comments on the BES Definition
Terry Harbour	MidAmerican Energy Co.	1	Negative	See the MidAmerican submitted comments. The BES definition needs additional specific inclusion or exclusion provisions that clearly exclude variable resource generation collector circuits rated below 100 kV and generators less than 20 MVA connected to those collector circuits in accordance with the registration criteria.
Tracy Sliman	Tri-State G & T Association, Inc.	1	Negative	Comments submitted by electronic form.
Kathleen Goodman	ISO New England, Inc.	2	Negative	please refer to detailed comments submitted for this project.
Charles Yeung	Southwest Power Pool, Inc.	2	Negative	SPP's comments on this concurrent ballot/comment period have been submitted and provide support for our Negative vote. In addition, SPP is a member of the IRC SRC and is in support of those comments on this standard. Please refer to these sets of comments for our recommendations.
Chris W Bolick	Associated Electric Cooperative, Inc.	3	Negative	Please see comments of AECI.
Linda Jacobson	City of Farmington	3	Negative	FEUS appreciates the SDT work in defining the BES. While the proposed definition is an improvement over the current definition, FEUS feels there is some additional clarification necessary before approval. Seperate comments have been submitted.
Richard Blumenstock	Consumers Energy	3	Negative	See Consumers Energy's comments on the official submittal form.
Michael F. Gildea	Dominion Resources Services	3	Negative	See Dominion's submitted comments.
David Kiguel	Hydro One Networks, Inc.	3	Negative	After careful analysis of the proposed documents, Hydro One Networks Inc. is casting a negative vote. We commend the SDT for the effort in facing the challenge. However, we believe that the proposed definition and the exception request criteria still need further work. Some issues need to be resolved before a

				final approval is granted. Please see our detailed comments as provided in the on-line system.
Tony Eddleman	Nebraska Public Power District	3	Negative	Comments were submitted through the Nebraska Public Power District comment form.
Janelle Marriott	Tri-State G & T Association, Inc.	3	Negative	Tri-State G&T Load Serving Entity comments were submitted via electronic comment process.
David Frank Ronk	Consumers Energy	4	Negative	See Comments provided by Consumers Energy Company
Brock Ondayko	AEP Service Corp.	5	Negative	AEP believes the drafting team is on the correct path, and the concepts expressed appear to be appropriate. However, AEP has a number of questions and recommended refinements that if addressed by the drafting team, will make the definition more clear to industry. These comments are being submitted via electronic form by Thad Ness on behalf of American Electric Power.
Francis J. Halpin	Bonneville Power Administration	5	Negative	Please refer to formal BPA Comments submitted on 10/7/2011.
David C Greyerbiehl	Consumers Energy Company	5	Negative	See Consumers Energy's comments on the official comment submittal forms.
Mike Garton	Dominion Resources, Inc.	5	Negative	See comments filed on this project.
Dan Roethemeyer	Dynegy Inc.	5	Negative	Comments will be included with those to be submitted with the SERC OC Standards Review Group.
Christopher Schneider	MidAmerican Energy Co.	5	Negative	See the MidAmerican submitted comments. The BES definition needs additional specific inclusion or exclusion provisions that clearly exclude variable resource generation collector circuits rated below 100 kV and generators less than 20 MVA connected to those collector circuits in accordance with the registration criteria.
