Texas Industrial Energy Consumers (TIEC)	Yes	<p>Proposed exclusion E3 should be revised to categorically exclude all facilities that are part of a local distribution network (LDN), regardless of the specifics of the LDN's interconnection with the Bulk Electric System. As currently drafted, Exclusion 3 places a number of inappropriate limits on a whether a local distribution system is excluded from the Bulk Electric System definition. As recognized by the Commission in Order No. 743-A, Section 215 of the Federal Power Act categorically excludes local distribution systems from the Bulk Power System definition without qualification. As a result, LDNs are outside the FERC's jurisdiction and are outside the scope of this rulemaking. The SDT should revise the approach to Exclusion 3 to exclude all facilities that are part of a LDN, regardless of how the LDN is interconnected to the grid. Specifically, making exclusion of an LDN contingent upon the LDN being connected through automatic fault-interrupting devices is inappropriate. Similar to the concerns TIEC expressed in response to Question 7, above, if there are concerns about LDNs impacting the Bulk Electric System, then it is the responsibility of the transmission provider serving the LDN to ensure that systems and facilities are in place to protect the grid. The specifics of an LDN's interconnection to the grid should not dictate whether it is subject to regulation. TIEC would therefore recommend removing proposed qualification (a) to the LDN exclusion.</p> <p>Further, the requirement that generation in the LDN can never exceed demand is inappropriate. As the SDT</p>

Organization	Yes or No	Question 9 Comment
		<p>properly recognized in Exclusion 2, as long as the generation within an LDN does not trigger registration requirements, the LDN should be able to export power to the grid without subjecting itself to regulation. Many LDNs export small amount of power intermittently to balance the flow within the LDN. Subjecting these networks to regulation as a result of this balancing activity is inconsistent with the existing generation registration requirements and would exceed the scope of this rulemaking. The existing generation registration requirements exempt customer-owned generation that serves retail load from generation registration requirements as long as the net capacity provided to the bulk power system does not exceed the nameplate requirements for stand-alone generators. Consistent with this approach, an LDN should not have to be registered as long as its net exports to the grid do not exceed the generation registration requirements. TIEC accordingly requests that proposed LDN characteristics (c) and (d) be removed as qualifications to the LDN exclusion, and that the exclusion be revised to allow generation output to the grid as long the net export to the grid does not exceed the threshold levels for registration as a generator owner/operator.</p>
<p><b>Response:</b> One of the objectives of the revised definition of the BES is to provide a deterministic method of identifying and excluding facilities that are used for distribution, and Exclusion E3 is one of the mechanisms by which the SDT proposes to accomplish this. The SDT has revised the Exclusion E3 local network in a way that removes the mention of automatic fault interrupting devices which the SDT believes addresses the concern about the apparent disconnect between Section 215 and the prior proposal.</p> <p>The SDT believes that generation connected within a network that would otherwise be a distribution system, can change the functionality of that network to one that serves transmission functions; hence, the SDT believes that some limit on connected generation must continue to exist in this exclusion principle.</p> <p><b>E3 - Local <del>Distribution</del> Networks (LDN):</b> <del>A G</del>groups of <u>contiguous transmission</u> Elements operated <u>at or above 100 kV but less than 300 kV</u> that distribute power to Load rather than transfer bulk power across the <del>h</del>interconnected <del>S</del>system. LDN's <u>emanate from multiple points of connection at 100 kV or higher are connected to the Bulk Electric System (BES) at more than one location solely</u> to improve the level of service to retail customer Load <u>and not to accommodate bulk power transfer across the interconnected system</u>. The LDN is characterized by all of the following:</p> <p><del>Separable by automatic fault interrupting devices: Wherever connected to the BES, the LDN must be connected through automatic fault interrupting devices;</del></p> <ul style="list-style-type: none"> <li>a) Limits on connected generation: <del>Neither t</del>The LDN, <del>nor</del>and its underlying Elements <u>do not include generation resources identified in Inclusion I3, and do not have an aggregate capacity of non-retail generation greater than 75 MVA (gross nameplate rating) (in aggregate), includes more than 75 MVA generation;</u></li> <li>b) Power flows only into the <del>Local Distribution Network</del>LDN: <del>The generation within the LDN shall not exceed the electric Demand within the LDN. The LN does not transfer energy originating outside the LN for delivery through the LN; and</del> <u>Not used to transfer bulk power: The LDN is not used to transfer energy originating outside the LDN for delivery through the LDN; and</u></li> <li>c) Not part of a Flowgate or <del>F</del>transfer <del>P</del>path: The LDN does not contain a monitored Facility of a permanent <del>f</del>lowgate in the Eastern Interconnection, a major transfer path within the Western Interconnection <del>as defined by the Regional Entity</del>, or a comparable monitored Facility in the <u>ERCOT or Quebec</u></li> </ul>		

Organization	Yes or No	Question 9 Comment
		Interconnections, and is not a monitored Facility included in an Interconnection Reliability Operating Limit (IROL).
PacifiCorp	Yes	PacifiCorp believes this meets FERC’s intent in Order Nos. 743 and 743A, however additional clarification may be added particularly around items b and c. Regardless of the generation level (item b), if the power only flows into the Local Distribution Network (“LDN”) (item c) then the the level of generation is not material and should have no impact on the reliable operation of the BES.
<p><b>Response:</b> The primary goal of the SDT in the revision of the definition of the BES is to improve clarity in the current language and to provide as much certainty as possible in the identification of BES and non-BES Elements. The Commission provided guidance within Order Nos. 743 &amp; 743a which identified the current application of the existing BES definition was essentially correct for the majority of the continent and directed clarification of the existing language to support consistent application across all regions. Additional guidance from the Commission spoke to significant changes in the scope of the definition with an expectation that the revision to the definition would not significantly expand or contract what is currently considered to be the BES. Therefore the SDT disagrees with removal of all limits on connected generation, but it has made this provision somewhat less restrictive as shown in the revised item E3.a.</p> <p><b>E3 - Local <del>Distribution</del> Networks (LDN):</b> <u>A Groups of contiguous transmission Elements operated at or above 100 kV but less than 300 kV that distribute power to Load rather than transfer bulk power across the interconnected system. LDN’s emanate from multiple points of connection at 100 kV or higher are connected to the Bulk Electric System (BES) at more than one location solely to improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system.</u> The LDN is characterized by all of the following:</p> <p><del>Separable by automatic fault interrupting devices: Wherever connected to the BES, the LDN must be connected through automatic fault interrupting devices;</del></p> <p>a) Limits on connected generation: <del>Neither the LDN, nor and its underlying Elements do not include generation resources identified in Inclusion I3, and do not have an aggregate capacity of non-retail generation greater than 75 MVA (gross nameplate rating) (in aggregate), includes more than 75-MVA generation;</del></p> <p>b) Power flows only into the <del>Local Distribution Network</del>LDN: <del>The generation within the LDN shall not exceed the electric Demand within the LDN. The LN does not transfer energy originating outside the LN for delivery through the LN; and</del></p> <p><del>Not used to transfer bulk power: The LDN is not used to transfer energy originating outside the LDN for delivery through the LDN; and</del></p> <p>c) Not part of a Flowgate or <del>Transfer Path</del> Path: The LDN does not contain a monitored Facility of a permanent <del>Flowgate</del> Flowgate in the Eastern Interconnection, a major transfer path within the Western Interconnection <del>as defined by the Regional Entity</del>, or a comparable monitored Facility in the <u>ERCOT or Quebec Interconnections</u>, and is not a monitored Facility included in an Interconnection Reliability Operating Limit (IROL).</p>		
Intellibind	Yes	This does address some of my concerns on small radial transmission systems. I think that there will be confusion when small entities try and apply both E3 and E1 to their particular situations. The ambiguity will cause more questions than it is trying to answer.
<p><b>Response:</b> The revisions to Exclusion E3 are intended to bring more clarity and consistency to the application of this exclusion principle. The SDT believes this</p>		

Organization	Yes or No	Question 9 Comment

<p>Blachly Lane Electric Cooperative                      Central Electric Cooperative                      Clearwater Power Company                      Consumers Power Inc                      Coos-Curry Electric Cooperative                      Douglas Electric Cooperative                      Fall River Electric Cooperative                      Lane Electric Cooperative                      Lincoln Electric Cooperative                      Lost River Electric Cooperative                      Northern Lights Inc</p>	<p>Yes</p>	<p>We strongly support the categorical exclusion of Local Distribution Networks from the BES. For reasons discussed at length in our answer to Question 1, we believe the exclusion is necessary to ensure that the BES definition complies with the statutory requirement to exclude all facilities used in the local distribution of electric power. LDNs are likely the most common kind of local distribution facility. Further, the conversion of radial systems to local distribution networks should be encouraged because networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. We also support, with the reservations discussed below, the LDN exclusion as drafted by the SDT. We believe the SDT has identified the key characteristics that separate LDNs from facilities that are part of the bulk transmission system and therefore should be classified as BES. Hence, LDNs can be excluded from the BES based on the characteristics identified by the SDT without compromising the reliability of the interconnected bulk transmission system. However, for the reasons stated in our answers to Questions 3 and 4, we believe the SDT's wholesale adoption of the 20 MVA and 75 MVA thresholds from the NERC Statement of Compliance Registry lacks adequate technical justification. The SDT repeats that error here by incorporating those thresholds into the LDN exception. The 100 MVA threshold seems more in alignment with technical standards such as Power System Stabilizer requirements.</p>

Okanogan Electric Cooperative PNGC Power Raft River Rural Electric Cooperative Salmon River Electric Cooperative Umatilla Electric Cooperative West Oregon Electric Cooperative		
<p><b>Response:</b> The SDT has revised the Exclusion E3 Local Network in a way that removes the mention of automatic fault interrupting devices, which the SDT believes addresses the concern about the apparent disconnect between Section 215 and the prior proposal.</p> <p>The limits on connected generation, now described in item E3.a, have been revised, resulting in a less restrictive exclusion characteristic. The SDT notes, however, that the responses to the comments in the first posting of the BES Definition did not yield any technically-based alternatives to the generation thresholds of the ERO Statement of Compliance Registry Criteria (SCRC), and as such, the SDT has no technical rationale to deviate from the SCRC. After consulting with the NERC Board of Trustees and the NERC Standards Committee, the SDT has decided to forgo any attempt at changing generation thresholds at this time. There simply isn't enough time or resources to do that topic justice with the mandated schedule. Therefore, the primary focus of the SDT efforts will be to address the directives in Orders 743 and 743a. However, this does not mean that the other issues will be dropped. Both the NERC Board of Trustees and the NERC Standards Committee have endorsed the idea that the Project 2010-17 SDT take a phased approach to this project with a new Standards Authorization Request (SAR) to address generation thresholds as well as several other issues that have arisen from SDT deliberations.</p> <p><b>E3 - Local <del>Distribution</del> Networks (LDN):</b> <del>A Group</del> of <u>contiguous transmission</u> Elements operated <u>at or above 100 kV but less than 300 kV</u> that distribute power to Load rather than transfer bulk power across the <del>interconnected</del> <u>system</u>. <del>LDN's emanate from multiple points of connection at 100 kV or higher are connected to the Bulk Electric System (BES) at more than one location solely</del> to improve the level of service to retail customer Load <u>and not to accommodate bulk power transfer across the interconnected system</u>. Clallam County PUD No.1	Yes	<p>Clallam strongly supports the categorical exclusion of Local Distribution Networks from the BES. In fact, for reasons discussed at length in our answer to Question 1, we believe the exclusion is necessary to ensure that the BES definition complies with the statutory requirement to exclude all facilities used in the local distribution of electric power. LDNs are, of course, probably the most common kind of local distribution facility. Further, the conversion of radial systems to local distribution networks should be encouraged because networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. Clallam also supports, with the reservations discussed below, the LDN exclusion as drafted by the SDT. At least conceptually, we believe the SDT has identified the key characteristics that separate LDNs from facilities that are part of the bulk transmission system and therefore should be classified as BES. Hence, LDNs can be excluded from the BES based on the characteristics identified by the SDT without compromising the reliability of the interconnected bulk transmission system. Although Clallam supports the LDN exclusion, we believe the exclusion should be refined in the following respects:</p> <ul style="list-style-type: none"> <li>o The SDT’s draft states that: “LDN’s are connected to the Bulk Electric System (BES) at more than one location solely to improve the level of service to retail customer Load.” (emphasis added) We are concerned that the use of the term “solely” implies the need for an examination of the motives of a local distribution utility in connecting to the BES at more than one location. This result is problematic because it defeats the purpose of the exclusion, which is to allow LDNs to be excluded from the BES without an in-depth and expensive inquiry into the exact nature of the LDN. In addition, the local utility may have a number of motives for connecting to the BES at more than one location, but the local utility’s motives have nothing to do with how the LDN interacts with the interconnected bulk system, which should be the key determinant in including or excluding any Element from the BES. With these concerns in mind, we therefore recommend that the SDT revise the sentence quoted above as follows: “LDN’s are connected to the Bulk Electric System (BES) at more than one location solely to improve the level of service to retail customer Load and not to accommodate</li> </ul>

Organization	Yes or No	Question 9 Comment
		<p>bulk transfers of power across the interconnected bulk system.” By instituting this suggestion, the SDT would emphasize the key difference between an LDN, which is designed to reliably serve local, end-use retail customers, and the BES, which is designed to accommodate bulk transfer of power at wholesale over long distances.</p> <p>o We believe the characteristics specified by the LDN in subsections (b) and (c) of the exclusion are redundant. Subsection b specifies that the LDN would not interconnect more than 75 MVA of generation in aggregate. Subpart c specifies that power flows only into the LDN. We believe the SDT can eliminate subpart b of the definition and simply rely on subpart c because if power only flows into the LDN even if it interconnects more than 75 MVA of generation, the interconnected generation interconnected will have no significant interaction with the interconnected bulk transmission system, only with the LDN. Further, with the advent of distributed generation, it is easy to foresee a situation in which a large number of very small distributed generators are interconnected into a LDN, so that the aggregate capacity of these generators exceeds 75 MVA. However, because the generators are small and dispersed and, under the subpart c criteria, would be wholly absorbed within the LDN rather than transmitting power onto the interconnected grid, those generators would not have a material impact on the grid. In addition, the 75 MVA criterion would make an LDN interconnecting more than 75 MVA part of the BES. For the reasons set forth by the Project 2010-07 SDT, we are concerned the result will be the local utility being improperly classified as a Transmission Owner and Transmission Operator, which would subject the local utility to a number of reliability standards that would significantly increase its compliance burden without substantially improving bulk system reliability. In fact, in the LDN situation, there is even less reason to impose these burdens on the local utility than in the situation addressed by the Project 2010-07 team, where generators are interconnected to the BES by dedicated interconnection facilities. Because the LDN is interconnected at multiple points, the generators interconnected to the LDN could continue to operate even if one or two interconnection points are out of service. On the other hand, in the situation addressed by the Project 2010-07 team, if the dedicated interconnection facility is out of service, the generation is unavailable because there is no alternative route to deliver it to load.</p> <p>Finally, for the reasons stated in our answers to Questions 3 and 4, we believe the SDT’s wholesale adoption of the 20 MVA and 75 MVA thresholds from the NERC Statement of Compliance Registry lacks adequate technical justification. The SDT repeats that error here by incorporating those thresholds into the LDN exception.</p>
<p><b>Response:</b> The SDT has made changes to the introductory paragraph in Exclusion E3, which the SDT believes clarifies the intent of the local network; however, the SDT believes that the descriptive language adds necessary context to the entire exclusion principle and therefore should be retained.</p> <p>The SDT has determined that a generation limit is appropriate from a bright-line perspective to qualify these local networks as distribution; however, in the revised Exclusion E3, the limits on connected generation have been made somewhat less restrictive as indicated in E3.a. Also, the revised Exclusion E3 now</p>		

Organization	Yes or No	Question 9 Comment
		<p>specifically excludes from consideration the “behind the meter” generation in the limits on connected generation. Entities that own/operate facilities that are not necessarily captured for exclusion by Exclusion E3 can still pursue exclusion through the RoP Exception Process.</p> <p>The SDT notes that the responses to the comments in the first posting of the BES Definition did not yield any technically-based alternatives to the generation thresholds of the ERO Statement of Compliance Registry Criteria (SCRC), and as such, the SDT has no technical rationale to deviate from the SCRC. After consulting with the NERC Board of Trustees and the NERC Standards Committee, the SDT has decided to forgo any attempt at changing generation thresholds at this time. There simply isn’t enough time or resources to do that topic justice with the mandated schedule. Therefore, the primary focus of the SDT efforts will be to address the directives in Orders 743 and 743a. However, this does not mean that the other issues will be dropped. Both the NERC Board of Trustees and the NERC Standards Committee have endorsed the idea that the Project 2010-17 SDT take a phased approach to this project with a new Standards Authorization Request (SAR) to address generation thresholds as well as several other issues that have arisen from SDT deliberations.</p> <p><b>E3</b> - Local <del>Distribution</del>-Networks (LDN): <del>A G</del>groups of <u>contiguous transmission</u> Elements operated <u>at or above 100 kV but less than 300 kV</u> that distribute power to Load rather than transfer bulk power across the <del>h</del>interconnected <del>S</del>system. LDN’s <u>emanate from multiple points of connection at 100 kV or higher are connected to the Bulk Electric System (BES) at more than one location solely</u> to improve the level of service to retail customer Load <u>and not to accommodate bulk power transfer across the interconnected system</u>. The LDN is characterized by all of the following:</p> <p><del>Separable by automatic fault interrupting devices: Wherever connected to the BES, the LDN must be connected through automatic fault interrupting devices;</del></p> <p>a) Limits on connected generation: <del>Neither t</del>The LDN, <del>nor and</del> its underlying Elements <u>do not include generation resources identified in Inclusion I3, and do not have an aggregate capacity of non-retail generation greater than 75 MVA (gross nameplate rating) (in aggregate), includes more than 75 MVA generation;</u></p> <p>b) Power flows only into the <u>Local Distribution Network</u><del>LN</del>: <del>The generation within the LDN shall not exceed the electric Demand within the LDN. The LN does not transfer energy originating outside the LN for delivery through the LN; and</del></p> <p><del>Not used to transfer bulk power: The LDN is not used to transfer energy originating outside the LDN for delivery through the LDN; and</del></p> <p>c) Not part of a Flowgate or <del>T</del>transfer <del>P</del>path: The LDN does not contain a monitored Facility of a permanent <del>f</del>Flowgate in the Eastern Interconnection, a major transfer path within the Western Interconnection <del>as defined by the Regional Entity</del>, or a comparable monitored Facility in the <u>ERCOT or Quebec Interconnections</u>, and is not a monitored Facility included in an Interconnection Reliability Operating Limit (IROL).</p>
FortisBC	Yes	<p>We agree with this concept as part of establishing a bright-line definition along with this clarifying exclusion in the revised BES definition. However, requirements in Exclusion E3 are restrictive and we do not agree to the limits on connected generation for Local Distribution Networks (LDN), described in part (b). The development and implementation of distributed generation will grow considerably in the future and will operate together with conventional sources of energy. The real net aggregated power of distributed generation seen by the bulk power system at the interconnection may be larger than past experience; hence it requires to be reassessed based on technical studies with respect to the future integration of DG’s. (Please refer to comments in questions: 3 &amp; 4)</p>

Organization	Yes or No	Question 9 Comment
		<p>Also, we suggest combining exception E3 (c) and (d) as follows:“(c) Power is intended to flows only into the LDN: The generation within the LDN shall not exceed the electric Demand within the LDN; The LDN is intended to deliver power to load and not be used to transfer bulk power between different locations in the BES. It is recognized that under specified system conditions, bulk power transfers may take place between different points of the BES via the LDN. However, for these conditions BES reliability is not dependent on the existence of these power flows through the LDN.”Finally, we suggest and urge the SDT to carefully craft the exception criteria &amp; procedure that is flexible and technically sound to adequately allow entities to present their case, and/or unique characteristics of the elements under exception to the ERO for exclusion</p>
<p><b>Response:</b> The SDT has determined that a generation limit is essential to qualify these local networks as distribution; however, in the revised Exclusion E3, the limits on connected generation have been made somewhat less restrictive as indicated in E3.a. Also, the revised Exclusion E3 now specifically excludes from consideration the “behind the meter” generation in the limits on connected generation.</p> <p>The revised Exclusion E3 now combines the prior items E3.c and E3.d into a revised item E3.b.</p> <p><b>E3 - Local <del>Distribution</del> Networks (LDN):</b> <del>A G</del>groups of <u>contiguous transmission</u> Elements operated <u>at or above 100 kV but less than 300 kV</u> that distribute power to Load rather than transfer bulk power across the <del>h</del>interconnected <del>S</del>system. 		<p><del>accommodate bulk power transfer across the interconnected system.</del> The LDN is characterized by all of the following:</p> <p><del>Separable by automatic fault interrupting devices: Wherever connected to the BES, the LDN must be connected through automatic fault interrupting devices;</del></p> <p>a) Limits on connected generation: <del>Neither the LDN, nor</del> and its underlying Elements <u>do not include generation resources identified in Inclusion I3, and do not have an aggregate capacity of non-retail generation greater than 75 MVA (gross nameplate rating) (in aggregate), includes more than 75 MVA generation;</u></p> <p>b) Power flows only into the <u>Local Distribution Network</u><del>LN</del>: <del>The generation within the LDN shall not exceed the electric Demand within the LDN.</del> <u>The LN does not transfer energy originating outside the LN for delivery through the LN; and</u></p> <p><del>Not used to transfer bulk power: The LDN is not used to transfer energy originating outside the LDN for delivery through the LDN; and</del></p> <p>c) Not part of a Flowgate or <del>T</del>transfer <del>P</del>path: The LDN does not contain a monitored Facility of a permanent <del>f</del>lowgate in the Eastern Interconnection, a major transfer path within the Western Interconnection <del>as defined by the Regional Entity</del>, or a comparable monitored Facility in the <u>ERCOT or Quebec Interconnections</u>, and is not a monitored Facility included in an Interconnection Reliability Operating Limit (IROL).</p>
Clark Public Utilities	Yes	<p>Clark strongly supports the categorical exclusion of Local Distribution Networks from the BES. Clark also believes that adopting a 200 kV bright-line threshold will result in most, if not all, LDN being exempted from the BES without any need to analyze or self-certify an LDN. This is another case where a higher threshold (with an appropriate inclusion process) will have no affect on BES reliability but will focus resources on investigation low voltage facilities that truly have an impact on interconnected system operations. Clark does recommend a revision to the LDN exclusion language. E3 - Local distribution networks (LDNs): Groups of Elements operated above 100 kV that distribute power to Load rather than transfer bulk power across the interconnected System. LDN's are connected to the Bulk Electric System (BES) at more than one location solely to improve the level of service to retail customer Load and not to accommodate bulk transfers of power across the interconnected bulk system. The LDN is characterized by all of the following:</p>
<p><b>Response:</b> The SDT has not uncovered nor been presented with any technical rationale for deviating from the voltage threshold of 100 kV in the definition of BES; however, the SDT believes that the revised definition speaks to, and sufficiently identifies, the exclusion of the facilities used for distribution functions.</p> <p>The SDT has made changes to the introductory paragraph in Exclusion E3, which the SDT believes clarifies the intent of the local network.</p> <p><u>E3 - Local <del>Distribution</del> Networks (LDN): A Groups of contiguous transmission Elements operated at or above 100 kV but less than 300 kV that distribute power to Load rather than transfer bulk power across the <del>h</del>interconnected <del>S</del>system. Modern Electric Water Company	Yes	<p>Similar to our Question #7 comments regarding radial exclusions in E1, a usable BES definition excluding local distribution networks (LDNs) is needed to allow this industry to focus on and conduct business in a</p>

Organization	Yes or No	Question 9 Comment
		<p>fashion that promotes reliable and efficient system operation. In line with a 1/18/2011 Executive Order directing federal regulatory agencies to base their practices on science and to consider costs, excluding LDNs from the BES definition would achieve that aim on a national scale. While differing only in connectivity, LDNs operate and function exactly as radial systems. We suggest modifying the second and third sentences of E3 as “LDNs are normally operated such that they are connected to the BES through more than one AFID simultaneously, and exist to promote the level of service to Loads as commonly defined by states’ utility commissions. For a System to be characterized as an LDN, it must meet all of the following:” Sub-bullet E3-c should be clarified to indicate conditions, timeframes and metrics used to demonstrate power flow direction. We support the intent of the remaining sub-bullets.</p>
<p><b>Response:</b> The SDT has made changes to the introductory paragraph in Exclusion E3, which the SDT believes clarifies the intent of the local network. The SDT has revised the Exclusion E3 local network in a way that removes the mention of automatic fault interrupting devices.</p> <p><b>E3 - Local Distribution Networks (LDN):</b> A group of contiguous transmission Elements operated at or above 100 kV but less than 300 kV that distribute power to Load rather than transfer bulk power across the interconnected system. LDN’s emanate from multiple points of connection at 100 kV or higher are connected to the Bulk Electric System (BES) at more than one location solely to improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system. Michigan Public Power Agency	Yes	<p>I question the technical justification for the 75 MVA and the 100 KV as pointed out in my comments above. But given those points addressed above I would suggest the following clarification be considered.</p> <p>The exclusion refers to groups of Elements that “distribute power to Load rather than transfer bulk power across the interconnected system.” The use of the term “bulk power” is vague and could be read incorrectly as a reference to the “bulk-power system,” which is defined in the Federal Power Act but is not a NERC</p>

Organization	Yes or No	Question 9 Comment
		<p>defined term.</p> <p>If the LDN is connected to the BES at more than one location, there will by definition be some loop flow. We recommend below that Exclusion 3(d) be revised to quantify the amount of loop flow that is permissible in an excluded LDN.</p> <p>In the context of the first sentence of Exclusion E3, less specificity is needed, and the sentence should only be revised for the sake of accuracy to state: “Groups of Elements operated above 100 kV that are primarily intended to distribute power to load rather than to transfer power across the interconnected System.”</p> <p>The exclusion’s reference to connection “at more than one location” is vague. The sentence should be revised to read “connected to the Bulk Electric System (BES) from more than one Transmission source solely to improve the level of service to retail customer Load,” and “Transmission source” should have the same meaning that it does in E1.</p> <p>E3(a) should require that there be switching devices between the LDN and the BES, not specifically automatic fault-interrupting devices. The term “separable by” in “Separable by automatic fault interrupting devices” is unclear and should be reworded.</p> <p>E3(b) To avoid pulling an LDN into the BES based on very small customer-owned generation (such as rooftop photovoltaics and hospital backup diesel generators) that the utility does not consider or rely on, or necessarily even know about, the item should be reworded: “Limits on connected generation: Neither the LDN, nor its underlying Elements (in aggregate), includes more than 75 MVA of generation used to meet the resource -adequacy requirements of electric utilities.”</p> <p>E3(d) states “Not used to transfer bulk power.” As noted above, “bulk power” is a vague term. There will necessarily be some loop flow on a system that is connected to the BES at more than one location. The amount of permissible loop flow for this purpose needs to be determined and stated in this item.</p>
<p><b>Response:</b> The SDT has not uncovered nor been presented with any technical rationale for deviating from the voltage threshold of 100 kV or 75 MVA in the definition of BES; however, the SDT believes that the revised definition speaks to, and sufficiently identifies, the exclusion of the facilities used for distribution functions. After consulting with the NERC Board of Trustees and the NERC Standards Committee, the SDT has decided to forgo any attempt at changing generation thresholds at this time. There simply isn’t enough time or resources to do that topic justice with the mandated schedule. Therefore, the primary focus of the SDT efforts will be to address the directives in Orders 743 and 743a. However, this does not mean that the other issues will be dropped. Both the NERC Board of Trustees and the NERC Standards Committee have endorsed the idea that the Project 2010-17 SDT take a phased approach to this project with a new Standards Authorization Request (SAR) to address generation thresholds as well as several other issues that have arisen from SDT deliberations.</p> <p>The SDT has modified the definition such that the term “bulk power” is no longer used in the characteristics, specifically new item E3.b. The term “bulk power” was retained in the paragraph E3, as the SDT believes it provides conceptual value to the exclusion principle.</p>		

Organization	Yes or No	Question 9 Comment
		<p>The SDT has revised the Exclusion E3 Local Network in a way that removes the mention of automatic fault interrupting devices.</p> <p>The SDT has made changes to the introductory paragraph in Exclusion E3, which the SDT believes clarifies the intent of the local network.</p> <p>After consideration of the establishment of limits on flow-through, the SDT has elected to make modifications to the local network characteristics to preclude the scheduled use of the network for flow-through rather than establishing a MW limit or transfer distribution factor. The SDT has determined that this is appropriate from a bright-line perspective to qualify these local networks as distribution; Entities that own/operate facilities that are not necessarily captured for exclusion by Exclusion E3 can still pursue exclusion through the RoP Exception Process.</p> <p>The revised Exclusion E3 now specifically excludes from consideration the “behind the meter” generation in the limits on connected generation.</p> <p><b>E3 - Local <del>Distribution</del>-Networks (LDN):</b> <del>A Groups of contiguous transmission Elements operated at or above 100 kV but less than 300 kV that distribute power to Load rather than transfer bulk power across the interconnected system. LDN’s emanate from multiple points of connection at 100 kV or higher are connected to the Bulk Electric System (BES) at more than one location solely to improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system.</del> The LDN is characterized by all of the following:</p> <p><del>Separable by automatic fault interrupting devices: Wherever connected to the BES, the LDN must be connected through automatic fault interrupting devices;</del></p> <p>a) Limits on connected generation: <del>Neither the LDN, nor and its underlying Elements do not include generation resources identified in Inclusion I3, and do not have an aggregate capacity of non-retail generation greater than 75 MVA (gross nameplate rating) (in aggregate), includes more than 75 MVA generation;</del></p> <p>b) Power flows only into the <del>Local Distribution Network</del>LDN: <del>The generation within the LDN shall not exceed the electric Demand within the LDN. The LN does not transfer energy originating outside the LN for delivery through the LN; and</del>  <del>Not used to transfer bulk power: The LDN is not used to transfer energy originating outside the LDN for delivery through the LDN; and</del></p> <p>c) Not part of a Flowgate or <del>Transfer Path</del>: The LDN does not contain a monitored Facility of a permanent <del>Flowgate</del> in the Eastern Interconnection, a major transfer path within the Western Interconnection <del>as defined by the Regional Entity</del>, or a comparable monitored Facility in the <del>ERCOT or</del> Quebec Interconnections, and is not a monitored Facility included in an Interconnection Reliability Operating Limit (IROL).</p>
Utility System Efficiencies, Inc.	Yes	<p>USE agrees in concept with this Exclusion. However, in sub-bullet b), as noted in our response to Question 4, there is no technical justification for the 75 MVA threshold on connected generation.</p> <p>In sub-bullet c), it should be clarified whether this requirement is at any time or is for hourly integrated values.</p> <p>Also in sub-bullet e), the use of the term “major transfer paths” should be modified to be “major transfer paths in the Table titled Major WECC Transfer Paths in the Bulk Electric System.” Finally, the reference to “above 100 kV” should be “at or above 100 kV” for consistency with the rest of the definition.</p>
<b>Response:</b> See response to Q4.		

Organization	Yes or No	Question 9 Comment
		<p>The SDT has determined that a generation limit is appropriate from a bright-line perspective to qualify these local networks as distribution; however, in the revised Exclusion E3, the limits on connected generation have been made somewhat less restrictive as indicated in E3.a. Also, the revised Exclusion E3 now specifically excludes from consideration the “behind the meter” generation in the limits on connected generation. Entities that own/operate facilities that are not necessarily captured for exclusion by Exclusion E3 can still pursue exclusion through the RoP Exception Process.</p> <p>The revised version of the Exclusion E3 language removes the comparison of connected generation to network demand.</p> <p>The new item E3.c clarifies the language regarding WECC major paths.</p> <p><b>E3 - Local <del>Distribution</del>-Networks (LDN):</b> <del>A</del> <u>Groups</u> of <u>contiguous transmission</u> Elements operated <u>at or above 100 kV but less than 300 kV</u> that distribute power to Load rather than transfer bulk power across the <del>interconnected</del> <u>system</u>. LDN's <u>emanate from multiple points of connection at 100 kV or higher are connected to the Bulk Electric System (BES) at more than one location solely</u> to improve the level of service to retail customer Load <u>and not to accommodate bulk power transfer across the interconnected system</u>. The LDN is characterized by all of the following:</p> <p><del>Separable by automatic fault interrupting devices: Wherever connected to the BES, the LDN must be connected through automatic fault interrupting devices;</del></p> <p>a) Limits on connected generation: <del>Neither the LDN, nor</del> <u>and its underlying Elements do not include generation resources identified in Inclusion I3, and do not have an aggregate capacity of non-retail generation greater than 75 MVA (gross nameplate rating) (in aggregate), includes more than 75 MVA generation;</u></p> <p>b) Power flows only into the <del>Local Distribution Network</del> <u>LDN</u>: <del>The generation within the LDN shall not exceed the electric Demand within the LDN. The LN does not transfer energy originating outside the LN for delivery through the LN; and</del></p> <p><del>Not used to transfer bulk power: The LDN is not used to transfer energy originating outside the LDN for delivery through the LDN; and</del></p> <p>c) Not part of a Flowgate or <del>Transfer</del> <u>Path</u>: The LDN does not contain a monitored Facility of a permanent <del>Flowgate</del> in the Eastern Interconnection, a major transfer path within the Western Interconnection <del>as defined by the Regional Entity</del>, or a comparable monitored Facility in the <u>ERCOT or Quebec Interconnections</u>, and is not a monitored Facility included in an Interconnection Reliability Operating Limit (IROL).</p>
Cowlitz County PUD	Yes	<p>Cowlitz strongly supports the categorical exclusion of Local Distribution Networks from the BES. In fact, for reasons discussed at length in our answer to Question 1, we believe the exclusion is necessary to ensure that the BES definition complies with the statutory requirement to exclude all facilities used in the local distribution of electric power. LDNs are, of course, probably the most common kind of local distribution facility. Further, the conversion of radial systems to local distribution networks should be encouraged because networked systems generally reduce losses, increase system efficiency, and increase the level of service to retail customers. Cowlitz supports the LDN exclusion, but we believe the exclusion should be refined in the following respects:</p> <ul style="list-style-type: none"> <li>o The SDT's draft states that: "LDN's are connected to the Bulk Electric System (BES) at more than one location solely to improve the level of service to retail customer Load." (emphasis added) We recommend that the SDT revise the sentence quoted above as follows: "LDN's are connected to the Bulk Electric System (BES) at more than one location solely to improve the level of service</li> </ul>

Organization	Yes or No	Question 9 Comment
		<p>to retail customer Load and not to accommodate bulk transfers of power across the interconnected bulk system.” By instituting this suggestion, the SDT would emphasize the key difference between an LDN, which is designed to reliably serve local, end-use retail customers, and the BES, which is designed to accommodate bulk transfer of power at wholesale over long distances. We propose that a reliable BES will help insure a reliable LDN. If the LDN is not reliable, it should then be an issue to be resolved by the local authorities. If the BES is not reliable, the local authorities lack the tools to remedy the situation.</p>
<p><b>Response:</b> The introductory paragraph in Exclusion E3 has been revised to eliminate the term “solely” and to explain that the local network does not accommodate bulk transfer across the interconnected system.</p> <p><b>E3 - Local <del>Distribution</del> Networks (LDN):</b> <del>A G</del>groups of <u>contiguous transmission</u> Elements operated <u>at or above 100 kV but less than 300 kV</u> that distribute power to Load rather than transfer bulk power across the <del>h</del>interconnected <del>S</del>system. LDN's <u>emanate from multiple points of connection at 100 kV or higher are connected to the Bulk Electric System (BES) at more than one location solely</u> to improve the level of service to retail customer Load <u>and not to accommodate bulk power transfer across the interconnected system</u>. The LDN is characterized by all of the following:</p> <p><del>Separable by automatic fault interrupting devices: Wherever connected to the BES, the LDN must be connected through automatic fault-interrupting devices;</del></p> <p>a) Limits on connected generation: <del>Neither t</del>The LDN, <del>nor</del>and its underlying Elements <u>do not include generation resources identified in Inclusion I3, and do not have an aggregate capacity of non-retail generation greater than 75 MVA (gross nameplate rating) (in aggregate), includes more than 75 MVA generation;</u></p> <p>b) Power flows only into the <del>Local Distribution Network</del>LDN: <del>The generation within the LDN shall not exceed the electric Demand within the LDN</del>The LN <u>does not transfer energy originating outside the LN for delivery through the LN; and</u></p> <p><del>Not used to transfer bulk power: The LDN is not used to transfer energy originating outside the LDN for delivery through the LDN; and</del></p> <p>c) Not part of a Flowgate or <del>T</del>transfer <del>P</del>path: The LDN does not contain a monitored Facility of a permanent <del>f</del>lowgate in the Eastern Interconnection, a major transfer path within the Western Interconnection <del>as defined by the Regional Entity</del>, or a comparable monitored Facility in the <u>ERCOT or</u> Quebec Interconnections, and is not a monitored Facility included in an Interconnection Reliability Operating Limit (IROL).</p>		
New England States Committee on Electricity	Yes	NESCOE believes that this language appropriately excludes facilities that serve local distribution loads from the BES.
Public Utilities Commission of Ohio	Yes	Exclusion 3 is appropriate. This reflects the reality that local distribution can be at any level. As a reminder the Commission proposed seven indicators of local distribution to be evaluated on a case-by-case basis:(1) Local distribution facilities are normally in close proximity to retail customers.(2) Local distribution facilities are primarily radial in character.(3) Power flows into local distribution systems; it rarely, if ever, flows out.(4) When power enters a local distribution system, it is not reconsigned or transported on to some other market.(5) Power entering a local distribution system is consumed in a comparatively restricted geographical

**Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17**

Organization	Yes or No	Question 9 Comment
		area.(6) Meters are based at the transmission/local distribution interface to measure flows into the local distribution system.(7) Local distribution systems will be of reduced voltage.This test clearly indicates that not all radial circuit lines are the same. This exclusion would not only appropriately apply the seven factor test, but also comply with the Federal Power Act regarding appropriate authority.
New York State Dept of Public Service	Yes	This exclusion properly recognizes that local distribution facilities can be at any voltage level. It also properly recognizes that reliable service to load often requires parallel circuits. As written, the exclusion respects FERC’s concern that major generation facilities should not be part of the LDN, by limiting the exclusion to generation of 75 MVA or less, and to only facilities that move energy down to the LDN.
BGE and on behalf of Constellation NewEnergy, Constellation Commodities Group and Constellation Control and Dispatch	Yes	No comment.
Oregon Public Utility Commission Staff	Yes	Exclusion E3 is absolutely necessary for excluding local distribution elements from the interconnected bulk transmission system as required by Section 215 of the FPA of 2005. This exclusion mirrors the Seven Factor Test (established in FERC Order 888), which sets sound overarching principles for differentiating local distribution elements from bulk transmission elements. Also, the conversion of radial systems to local distribution networks is generally implemented by a distribution provider to improve the level of service to local retail customers, not to accommodate bulk transfer of wholesale power.Retaining Exclusion E3 is absolutely crucial for maintaining the 100 kV brightline in the core BES definition. Without the distribution network E3 exclusion, the voltage threshold in the core BES definition would need to be changed to the 200 kV level. Otherwise, NERC and Regional Entities will have to deal with endless exception applications and evaluations associated with the removal of local distribution elements that have no impact on the reliable operation of the interconnected bulk transmission system.
National Association of Regulatory Utility Commissioners	Yes	Exclusion 3 is essential for the standard to conform to Federal Power Act Section 215 that clearly excludes local distribution from FERC and NERC jurisdiction. The exclusion properly recognizes that local distribution can operate at above 100 kV. This exclusion seems to reflect the essence of the Seven Factor test from FERC’s Order 888. Although FERC Order 743A did not bind NERC to the Seven Factor test, it makes sense to pursue consistency between these tests.
Michigan Public Service Commission(MPSC)	Yes	MPSC Staff Comments: The MPSC strongly supports this exclusion because it should exclude a large number of subtransmission facilities that are used for the distribution of local load. Also, this exclusion

Organization	Yes or No	Question 9 Comment
		together with E1 parallels the seven-factor technical-functional test for classifying transmission and distribution. The problem with the seven-factor test is that it does not provide an on-going clear bright line for BES determination. For example, an engineer cannot apply the seven-factor test using a one-line diagram of an electric power network and determine - without supplemental evidence - that an element is classified as distribution or not.

<p><b>Response:</b> Thank you for your support. Based on stakeholder comments, the SDT modified the local network exclusion in the following manner:</p> <p>Elimination of the term “Distribution” in the label of this exclusion, making it a “local network”.</p> <p>Changes were made to the introductory paragraph in Exclusion E3, which the SDT believes clarifies the intent of the local network, including a statement that the local network does not accommodate bulk transfer across the interconnected system.</p> <p>Eliminated the provision in Exclusion E3.a which referred to automatic fault interrupting devices, and changed wording to clarify the connection point of the local network.</p> <p>Please see the revised definition.</p>		

10. The SDT is discussing an exclusion from the Bulk Electric System (BES) for small utilities based on statements in Order No. 743 that FERC does not believe its suggested approach to the BES definition and exemption process will have a significant economic impact on a substantial number of small entities and that small entities will not adversely impact the reliability of the Bulk Electric System. The SDT has been made aware that organizations that are not presently required to be registered by the NERC Statement of Compliance Registry Criteria would meet the requirements to be registered as Transmission Owners given the current proposed BES definition. These small utilities could use the Rules of Procedure (ROP) exception process but this may be an issue that could be handled more appropriately through the BES definition. This would alleviate the paperwork burden for these small utilities and also avoid a possibly unnecessary and significant impact on the administration of the ROP exception process during the transition period to the revised BES definition. The proposed exclusion language is:

**Exclusion E4: Transmission Elements, from a single Transmission source connected at a voltage of 100 kV or greater, owned by a small utility whose connection to the BES is solely through this single Transmission source, and without interconnected generation as recognized in the BES Designation Inclusion Items I2, I3, I4, or I5. A small utility is recognized as an entity that performs a Distribution Provider or Load Serving Entity function but is not required to register as a Distribution Provider or Load Serving Entity by the ERO.**

**Do you agree with this approach and the proposed language? If not, please be specific in your response with a technical reason for your disagreement and, if appropriate, suggested language for such an exclusion if you agree in general but feel that alternative language would be more appropriate.**

**Summary Consideration:** The basis for the additional exclusion was predicated by the circumstances of radial systems and the demarcation of the automatic interrupting device. With the change of the demarcation point back to the point where the tap line intersects with the transmission line; this proposed exclusion is unnecessary. The SDT will drop consideration for this proposed exclusion given the change to radial systems. This shall serve as a single response to all comments submitted in response to this question.

Organization	Yes or No	Question 10 Comment
Northeast Power Coordinating Council Hydro One Networks Inc	No	Small utility or distribution provider is a relative term. A distribution provider may have an impact on the transmission network based on its design, configuration, connection point, and protection. Such an exception should apply regardless of the size of an entity. The concept discussed here is to define a radial system and not a small utility, as mentioned in the FERC Order. We do not believe that the SDT had sufficient discussions while crafting the proposed exclusion in regards to small utilities. The language used in the proposed clause

**Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17**

Organization	Yes or No	Question 10 Comment
		<p>is only appropriate to establish a bright-line definition for a radial system. Many small utilities (and individual load customers or generation connections) have more than a single transmission source with a solid tap and, at the same time, be adequately protected and effectively isolated without any adverse impact on the transmission network. Such a practice and design is widely used across North America. Hence, we do not agree that this exclusion is an attempt to address the issue of small utilities. The definition and inclusions will force many small entities, load customers and generation unit owners to act and register as Transmission Owners. This may be in conflict with state or provincial regulatory act, Codes and Licenses. Consistent with the FERC Order, the ERO and the SDT should be aware of these conflicts and should not ignore them. The ERO and the SDT address this by providing explicit but simple provisions in the exception procedure by considering sound technical exception criteria that is flexible based on demonstration of evidence to justify the element's necessity for operation. Regulatory Acts and Rules will always overrule NERC requirements and the only evidence that should be required of small utilities/entities is:</p> <ul style="list-style-type: none"> <li>o Regulatory evidence</li> <li>o Evidence demonstrating that NO adverse reliability impact is afflicted on the interconnected BES because of their connection.</li> </ul>
Tri-State Generation and Transmission Association, Inc.	No	We disagree with adding E4. This issue should be resolved by enhancing the NERC Statement of Compliance Registry Criteria, not by integrating registration exemptions in NERC definitions.
NERC Staff Technical Review	No	The basis for exclusion must be based on system reliability. The need for an interrupting device between the BES and excluded radial Elements is necessary for system reliability independent of ownership of the excluded radial Elements.
Dominion	No	It is Dominion's position that, all things being equal a generator or a load have similar, but typically inverse impacts of the bulk power system. The burden for small entities is similar, whether that entity is a LSE, DP, GO or GOP.
SPP Standards Review Group	No	<p>What's the difference between the proposed E4 and E1(a)? Wouldn't they be the same?</p> <p>Would it be more appropriate to use single point of Transmission interconnection rather than single Transmission source in E1 and E4?</p>
SERC Planning Standards Subcommittee	No	This seems to be covered by E1.
South Carolina Electric and Gas	No	This seems to be covered by E1.

**Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17**

Organization	Yes or No	Question 10 Comment
Michigan Public Service Commission(MPSC)	No	MPSC Staff Comments: The BES definition proposed by the SDT should not use the term “transmission”. BES should not equal transmission. A system element defined as BES should not determine jurisdiction, ownership, or require duplicative NERC registration.
SERC OC Standards Review Group	No	We suggest that our comments to Question 3 and Question 4 be incorporated. We also question whether this is going to have an unintended consequence of requiring Distribution Providers to register that otherwise wouldn't have to register because some technical aspect has not been included in this exception.
Idaho Falls Power	No	Just as 100kv is an arbitrary number, so is 20MVA. We appreciate the NERC efforts made to define transmission material to the BES, and likewise feel the same efforts should be applied to small generation resources. There exists a large number of utilities with small generation serving local load on an LDN that will be possibly drawn into TO/TOP standard's compliance by the language in this draft.We hope the drafting team will define BES generation beyond a brightline criteria, as 20MVA lends no more clarity as to what is a BES asset than does 100kV.We believe it should be demonstrated as to why 20MVA is deemed a generation threshold of materiality to the BES. The opportunity now exists to address thresholds, not just the 100kV.
Western Electricity Coordinating Council	No	As written, it is unclear how this exclusion differs from the Radial exclusion. The term “single Transmission source” needs to be clarified - it could be read to be a single line or a single entity, which would change the meaning of this exclusion. It is also improper to include registration criteria in a definition. Furthermore, “small utility” needs to be defined more clearly. The last sentence appears circular because ownership of a transmission element would draw the owner into registration.
ReliabilityFirst	No	it needs to be clear that "all" items must be met to be excluded in E4, E4b seems to conflict with I2 that states it needs included, E4a should state a single source unless LDNs are allowed multiple sources and then could be considered networked, E4c needs to define who make a the determination on flow and under all system configurations
Southern Company	No	This seems to be covered by Exclusions E1 and E3.
Electricity Consumers Resource	No	We support the concept and intent of the exclusion but it should apply equally to similarly situated loads such as manufacturing facilities that have loads comparable to small municipalities or rural cooperative utilities.

**Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17**

Organization	Yes or No	Question 10 Comment
Council (ELCON)		Thus the language should be amended as noted below:"Exclusion E4: Transmission Elements, from a single Transmission source connected at a voltage of 100 kV or greater, owned by a small utility or similarly situated load whose connection to the BES is solely through this single Transmission source, and without interconnected generation as recognized in the BES Designation Inclusion Items I2, I3, I4, or I5. A small utility or similarly situated load is recognized as an entity that performs a Distribution Provider or Load Serving Entity function but is not required to register as a Distribution Provider or Load Serving Entity by the ERO."
Central Maine Power Company New York State Electric & Gas and Rochester Gas & Electric	No	This exclusion E4 seems to already be covered under the E1 "radial" exclusion.
Intellibind	No	This does not address the full concerns of these small entities. In on case I am familiar with the entity has a switchyard over 100KV and it was convenient for the interconnected utility to utilize the location of the switchyard to add a line for the Transmission Operators purpose, however now that there are two lines into the switchyard it has affected the small utility and they will not have exemption as described in Question 10. The financial burden is very high for these entities when not exempted. In this particular case noted above, the entity is planning to eventually decommission its system, but is caught in having to bear the cost of operating a transmission system even though it is only one substation that is immediatly stepped down to 13.8Kv and feeding a small distributed load. The proposed exemption will still not allow this entity to be exempt.The ROP process does not serve these small utilities well as an alternative and the Drafting Team should resolve these issues in the definition of the BES if possible.
Hydro-Quebec TransEnergie	No	The case of small Utility is covered through other exclusions. However, the Facilities owned by small utility should have protection requirement applied.
US Bureau of Reclamation	No	The small entities can seek exclusion using the BES Exception Process developed under this project.
Grand Haven Board of Light and Power	No	We agree with addition of Exclusion E4, except that it should apply to small load serving distribution utilities even if they are required to register as a Distribution Provider and Load Serving Entity. In our last fiscal year, July 2009 through June 2010, the Grand Haven Board of Light and Power served 262,847 MWh and peaked at 54 MW. Even though we are required to register as DP/LSE, we are still a small utility. Please revise the definition of a small entity for the purpose of this exception to use more reasonable criteria.
South Texas Electric Cooperative, Inc.	No	I agree with everything up to "...but is not required to register...by the ERO". There are many small utilities that fit into the scope and spirit of the exclusion BUT were required to register as DP and/or LSE by their ERO. This has generally been on the interpretation of "better safe". Please remove the language which gives

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 10 Comment
		this discretion to the ERO and insert language allowing already registered small utilities with have their registrations revoked or surrendered.
National Grid	No	This exclusion is not necessary. Many small utilities (and individual load customers or generation connections) have more than a single transmission source with a solid tap and, at the same time, be adequately protected and effectively isolated without any adverse impact on the transmission network. Such a practice and design is widely used across North America. Hence, we do not agree that this exclusion is an attempt to address the issue of small utilities. The definition and inclusions will force many small entities, load customers and generation unit owners to act and register as Transmission Owners. This may be in conflict with state or provincial regulatory act, Codes and Licenses, and may lead to jurisdictional challenges that could cause uncertainty and delay in implementing the new BES definition. Consistent with the FERC Order, the ERO and the SDT should be aware of these conflicts and should not ignore themThe ERO and the SDT address this by providing explicit but simple provisions in the exception procedure by considering sound technical exception criteria that is flexible based on demonstration of evidence to justify the element’s necessity for operation. The only evidence that should be required of small utilities/entities is: <ul style="list-style-type: none"> <li>o Regulatory evidence.</li> <li>o Evidence demonstrating that NO adverse reliability impact is afflicted on the interconnected BES because of their connection.</li> </ul>
Electric Reliability Council of Texas, Inc.	No	These entities should be subject to the exception process. They may warrant “first instance” exclusion in that process, but any such action should occur there, as opposed to the definition of BES. ERCOT ISO believes this is more consistent with FERC’s position that BES should reflect an objective threshold, with exceptions being subject to review by the ERO and FERC, as applicable. Accordingly, ERCOT ISO suggests that this issue be raised in the concurrent BES exception proceeding and ERCOT ISO reserves its right to comment on the substance in that proceeding.
ExxonMobil Research and Engineering	No	While the exclusion for a small utility makes sense, the exclusion should not be limited to a utility company. The SDT should extended the exclusion to similarly situated facilities or organizations with other primary business functions, such as industrial companies.
FortisBC	No	Small utility or distribution provider is a relative term. A smaller distribution provider may have an impact on the transmission network while a large one may not; this is based on their design, configuration and protection. Hence, such an exception should apply regardless of the size of an entity. Having said that, the concept discussed here is to define a radial system and not a small utility, as mentioned in the FERC Order. We do not believe that the SDT had sufficient discussions while crafting the proposed exclusion in regards to small utilities. The language used in the proposed clause is only appropriate to establish a bright-line definition for a radial system.It is worth noting that many small utilities (and individual load customers or generation connections) would have more than a single transmission source with a solid tap and, at the same

Organization	Yes or No	Question 10 Comment
		<p>time, be adequately protected and effectively isolated without any adverse impact on the transmission network. Such a practice and design is widely used across North America. Hence, we do not agree that this exclusion is an attempt to address the issue of small utilities. The definition and inclusions will force many small entities, load customers and generation unit owners to act and register as Transmission Owners. In some parts of the continent this would be in conflict with state or provincial regulatory act, Codes and Licenses. Consistent with the FERC Order, the ERO and the SDT should be aware of these conflicts and should not ignore them for later. Hence, we suggest the ERO and the SDT address this by providing explicit but simple provisions in the exception procedure by considering sound technical exception criteria that is flexible based on demonstration of evidence to justify the element's necessity for operation. Regulatory Acts and Rules will always trump NERC requirements and hence we suggest that the only evidence that should be required of small utilities/entities is:</p> <ul style="list-style-type: none"> <li>o Regulatory evidence</li> <li>o Evidence demonstrating that NO adverse reliability impact is afflicted on the interconnected BES because of their connection.</li> </ul>
American Transmission Company, LLC	No	ATC believes that small utilities have interfacing responsibilities, and should not be exempt if they own elements (e.g. CTs, batteries, etc.) that are part of a protection scheme that protects the BES Elements.
Occidental Energy Ventures Corp. (answers include all various Oxy affiliates)	No	<p>There is no legal basis to distinguish between "small utilities" and other similarly situated entities. Thus, to avoid unlawful discrimination, Exclusion E4 should be revised as follows:(Deleted language denoted by empty brackets: [ ].) Exclusion E4: Transmission Elements, from a single Transmission source connected at a voltage of 100 kV or greater [ ] whose connection to the BES is solely through this single Transmission source, and without interconnected generation as recognized in the BES Designation Inclusion Items I2, I3, I4, or I5. [ ]</p>
BGE and on behalf of Constellation NewEnergy, Constellation Commodities Group and Constellation Control and Dispatch	No	An automatic interruption device should be required as in exclusion E1.
City of St. George	No	<p>Is the transmission source a single line, a single substation? This needs to be defined.</p> <p>What is a small utility? This needs to be defined.</p> <p>Generation limits should also be revisited, see previous comments.</p>
Southern California Edison Company	No	Small utilities should not be automatically excluded from the BES if the BES Definition continues to focus on the size of interconnecting generators to determine what facilities are included in the BES. Instead, small

**Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17**

Organization	Yes or No	Question 10 Comment
		utilities should be required to justify their exclusion using the exemption procedure and the Technical Principles for Demonstrating BES Exceptions. This would provide the necessary oversight to ensure these smaller systems continued to stay under the thresholds stipulated in the BES definition. In many areas, it is both faster and less expensive for renewable generators to interconnect with these systems, thus potentially allowing for the addition of large amounts of generation totaling more than the draft BES allowances within a relatively short period of time.
Idaho Power	No	As written, it is unclear how this exclusion differs from the Radial exclusion. The term “single Transmission source” needs to be clarified - it could be read to be a single line or a single entity, which would change the meaning of this exclusion. It is also improper to include registration criteria in a definition. Furthermore, “small utility” needs to be defined more clearly. The last sentence appears circular because ownership of a transmission element would draw the owner into registration.
Cogentrix Energy, LLC	No	We suggest that our comments to Question 3 and Question 4 be incorporated.  We also question whether this is going to have an unintended consequence of requiring Distribution Providers to register that otherwise wouldn't have to register because some technical aspect has not been included in this exception.
Clark Public Utilities	No	This proposed exclusion has no affect or benefit. If an entity is not required to register as a DP or LSE why do they then need to be exempted from a standard that does not apply to the entity. The Commission was obviously focusing on a small utility with facilities greater than 100 kV making that entity a Transmission Owner. A 100 kV facility owned by a utility with a small amount of load is either material or immaterial to the reliability of the BES irrespective of the amount of load that entity serves. Therefore the term ‘small utility’ must refer to some other measure of size. This may be size of load, but also may include circuit miles of transmission greater than 100 kV, capacity of largest line greater than 100 kV line, and possible other measures of “smallness.”
The Dow Chemical Company	No	If this is adopted, it should apply to industrial sites as well as small utilities.
PJM	No	There is no technical justification to include/exclude elements based on the asset size of the owning company. The exclusion should be based on the technical merits.
New England States Committee on Electricity	No	This appears overly restrictive in that it only includes networks connected at a single source. Please see comments under 7 above.

**Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17**

Organization	Yes or No	Question 10 Comment
Southwest Power Pool	No	These entities should be subject to the exception process within the exclusion criteria. They warrant a “first instance” exclusion in that process, but any such action should occur there, as opposed to the definition of BES. SPP believes this is more consistent with FERC’s position that BES should reflect an objective threshold, with exceptions being subject to review by the ERO and FERC, as applicable. It may prove through that process that these entities receive the presumption of exclusion, but that should take part in that process as opposed to being granted a de jure exemption from the definition. Accordingly, SPP suggests that this issue be raised in the concurrent BES exception proceeding as an exclusion criterion, and SPP reserves its right to comment on the substance in that proceeding.
Manitoba Hydro	No	Small utilities should be excluded under the definition of the BES without requiring an additional and specific exclusion.
ISO New England, Inc.	No	This exclusion would not be required if the automatic disconnect requirement was removed from E1. If E1 is not modified as proposed herein then a MW threshold might have to be considered for this E4 definition. E4 should have also been included in the draft definition as well as this comment form.
Xcel Energy	No	There seems to be an implication that if a facility is determined to be BES, registration is required. Yet, the registration criteria already includes exclusion of users, owners and operators of the BES from registration, if they do not meet all the criteria. So, we fail to see why a special exclusion is necessary.
Independent Electricity System Operator	No	Small utilities may be impactive to the bulk power system and as such should not be subject to a carte-blanche exemption but should be subject to assessment and if necessary exclusions after going through the exception process. The outcome of the exception process may well be that such small utilities can be excluded but this cannot be determined a priori.  In addition, Exclusion E4 is worded very similarly to Exclusion E1. It is not clear what additional facilities will be excluded by E4 that are not already excluded by E1.
Golden Spread Electric Cooperative, Inc.	No	Suggested revision: Transmission Elements, from a single Transmission source connected at a voltage of 100 kV or greater, owned by a small utility whose connection(s) to the BES is(are) solely through this(these) single Transmission source(s), and without interconnected generation as recognized in the BES Designation Inclusion Items I2, I3, I4, or I5. The intent of the revision is to exlude a small utility with multiple radial connections to BES elements owned by others.
AltaLink	No	Small utility or distribution provider is a relative term. A smaller distribution provider may have an impact on the transmission network while a large one may not; this is based on their design, configuration and

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 10 Comment
		<p>protection. Hence, such an exception should apply regardless of the size of an entity. Having said that, the concept discussed here is to define a radial system and not a small utility, as mentioned in the FERC Order. We do not believe that the SDT had sufficient discussions while crafting the proposed exclusion in regards to small utilities. The language used in the proposed clause is only appropriate to establish a bright-line definition for a radial system. It is worth noting that many small utilities (and individual load customers or generation connections) would have more than a single transmission source with a solid tap and, at the same time, be adequately protected and effectively isolated without any adverse impact on the transmission network. Such a practice and design is widely used across North America. Hence, we do not agree that this exclusion is an attempt to address the issue of small utilities. The definition and inclusions will force many small entities, load customers and generation unit owners to act and register as Transmission Owners. In some parts of the continent this would be in conflict with state or provincial regulatory act, Codes and Licenses. Consistent with the FERC Order, the ERO and the SDT should be aware of these conflicts and should not ignore them for later. Hence, we suggest the ERO and the SDT address this by providing explicit but simple provisions in the exception procedure by considering sound technical exception criteria that is flexible based on demonstration of evidence to justify the element's necessity for operation. Regulatory Acts and Rules will always trump NERC requirements and hence we suggest that the only evidence that should be required of small utilities/entities is:</p> <ul style="list-style-type: none"> <li>o Regulatory evidence</li> <li>o Evidence demonstrating that NO adverse reliability impact is afflicted on the interconnected BES because of their connection.</li> </ul>
Modern Electric Water Company	No	<p>The BES definition has already had a significant economic (and operational) impact on a substantial number of small entities and those small entities have not adversely impacted the reliability of the BES. The Commission (and the SDT) should also consider the other side of the coin - an improved BES definition could have a positive impact on a significantly greater number of small entities than it will negatively impact small entities otherwise not currently registered. Crafting exclusions properly with industry suggestions should limit the small number affected by this proposed definition.</p> <p>Additionally, we point out that in one instance the SDT states that the BES definition does not address registration or the applicability of standards, yet in another instance is concerned what impact the definition will have on an entity's possible registration status. We don't believe you can have it both ways or continue to keep one's proverbial head in the sand any longer.</p> <p>We understand the SDTs scope is to provide a USABLE definition of the BES, but also understand that its intent is two-fold: 1) to correct what the Commission believes is a gap in reliability due to regional discretion, and 2) to remove ambiguity in what constitutes the BES so that industry can focus on and conduct business in a fashion that promotes reliable and efficient system operation and so that the RROs can implement their CMEPs. This second point is absolutely related to registration and the applicability of standards, and shouldn't be ignored.</p>

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 10 Comment
		<p>As drafted, Exclusion E4 still would not allow for the exclusion of ALL small utilities that may inadvertently be included in the BES based on the currently-drafted definition, even though they are, indeed, small utilities that should be excluded from the BES. It appears that the SDT is struggling with the idea that the BES definition should properly evaluate every single element in North America by itself. We believe this is why the term “generally” was used in NERC’s Statement of Compliance Registry Criteria (SCRC), and why the issue of the BES definition presently in front of the SDT cannot be entirely separated from registration and applicability of standards.</p> <p>If the SCRC will not be examined and modified similarly as the NERCs Rules of Procedure, then the BES definition must include some “grey area deference” for small utilities such as is the intent of E4. If it is the intent of the definition to exclude most small utilities from the BES, then exclusions should be granted based entirely on the definition. Otherwise, as the SDT correctly states, the RoP-based exclusion process will be flooded and ineffectual. As stated in the SCRC, the definition will initially identify those necessary, but still allows for refinements later. The SCRC utilizes NERC’s approved definition of the BES, and will be “improved” by this BES definition. Therefore, craft E4 with language that does not limit its intent to exclude small utilities from the BES. Do not use metrics already used in other exclusions. Do not reference registration requirements in exclusions that comprise the definition of the BES - the BES should not be defined in terms of registration criteria. In Order 743, FERC defines a small utility in terms of an entity’s annual MWhs sold. Consider aligning NERC’s and FERC’s definitions similarly.</p>
City of Redding	No	<p>Redding in theory supports this concept however the language proposed does little to improve the current LDN and Radial exemptions. Redding would like the SDT to continue exploring the issue however we have no suggestions for the definition level at this time. Redding does suggest that a viable alternative is to target this issue via the exception process by allowing a exception method to use system or entity “characteristics” as proof for an exception. This would allow a shorter and less burdensome exception process for small entities.</p>
Tacoma Power		<p>Tacoma Power supports the SDT’s thoughtful approach to minimizing impacts to small entities. They have no measureable impact to the BES and should not be burdened with the exemption process.</p>
Vermont Transco		<p>The exclusion wording is difficult to understand and apply. Are their voltage levels where this would not apply (ex. 230 kV) or load levels that would be seen as too high? Cannot agree or disagree due to the wording</p>
Exelon		<p>Exelon is abstaining from voting on this item. How would this exclusion be different from E1? Furthermore, Exelon suggests that a definition of “Small Utility” would need to be developed.</p>
BPA	Yes	<p>Generally agree BPA would like to provide an exclusion for a small utility with multiple connections to a single Transmission source connected at a voltage of 100 kV or greater. An example would be a single long 115 kV</p>

**Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17**

Organization	Yes or No	Question 10 Comment
		transmission line passing through a rural area where a small utility utilizes multiple taps to the 115 kV line to serve several radial systems
Cowlitz County PUD Cowlitz County PUD	Yes	Cowlitz supports the SDT in its efforts to avoid unintended consequences from changes to the BES definition, especially for small entities that can ill afford the substantial costs that accompany imposition of mandatory compliance with reliability standards. Further, we agree that the small utilities covered by the exemption will have no measurable impact on the operation of the interconnected BES. In the Pacific Northwest, many small entities were required to register by virtue of owning a very small portion of the region's 115-kV system. These utilities have faced substantial compliance burdens even though their operations are simply not material to the interconnected bulk grid in our region, and the investment of resources in compliance therefore will have no measurable effect in improving the reliability of the interconnected grid. Further, the such resources used to comply with the reliability efforts unjustly take away from necessary resources needed for local quality of service efforts.
Small Entity Working Group (SEWG)	Yes	Yes, with some clarifying edits. The final sentence should be revised as follows: "For purposes of this exclusion, a 'small utility' is an entity that performs a distribution provider or load serving entity function but is not required to register as a Distribution Provider or Load Serving Entity by the ERO."
Florida Municipal Power Agency Transmission Access Policy Study Group Northern California Power Agency	Yes	FMPA supports this exclusion. For the sake of clarity, the final sentence should be revised to read as follows: "For purposes of this exclusion, a "small utility" is an entity that performs a Distribution Provider or Load Serving Entity function but is not required to register as a Distribution Provider or Load Serving Entity by the ERO."
American Municipal Power and Members	Yes	For the sake of clarity, the final sentence should be revised to read as follows: "For purposes of this exclusion, a "small utility" is an entity that benefits from the utility of the BES, but does not meet the registry criteria to perform functions in the BES."
National Rural Electric Cooperative Association (NRECA)	Yes	NRECA agrees with this approach, but also believes this could be addressed in the Statement of Compliance Registry Criteria document.
Overton Power District No. 5	Yes	We support exclusion E4, for small utilities, but we are unclear how small utilities are defined in the exclusion language presented here.

**Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17**

Organization	Yes or No	Question 10 Comment
PacifiCorp	Yes	PacifiCorp believes this concept is appropriate with the following concern: Essentially the only difference between this proposed exclusion and E1a is this proposed exclusion does not include “an automatic interruption device”. So if the proposed E4 is left as a stand-alone exclusion it should also require “an automatic interrupting device” qualifier. Technical justification for requiring an interrupting device is the same justification used by the SDT in E1.
FHEC	Yes	this begs the question of the Statement of Compliance Registry Criteria being updated also.
South Texas Electric Cooperative, Inc.	Yes	There are many small utilities that fit into the scope and spirit of the exclusion BUT are currently registered as a DP and/or LSE. Will this exclusion remove them from registration OR should language be inserted that automatically revokes the NERC registrations of “already registered” small utilities. I recommend that any such revocation be handled by NERC and NOT by the various EROs for the sake of consistency.
Sacramento Municipal Utility District (SMUD)	Yes	As written, it is unclear how this exclusion differs from the Radial exclusion. Furthermore, “small utility” needs to be defined more clearly. The last sentence appears circular because ownership of a transmission element would draw the owner into registration. Small entities have no measurable impact to the BES and should not be burdened with the exemption process.
Illinois Municipal Electric Agency	Yes	With the following clarifying edits. The final sentence should be revised as follows: “For purposes of this exclusion, a ‘small utility’ is an entity that performs a distribution provider or load serving entity function but is not required to register as a Distribution Provider or Load Serving Entity by the ERO.”
Michigan Public Power Agency	Yes	But I question if the "Small Entity definition" as indicated in Order 743 language "we certify that this Final Rule will not have a significant economic impact on a substantial number of small entities." has been appropriately addressed.
Public Utilities Commission of Ohio	Yes	It appears this could be applied consistently with other exclusions.
New York State Dept of Public Service	Yes	This exclusion is consistent with E1 and E2. There should not be discrimination against similarly situated loads.
Springfield Utility Board	Yes	Springfield Utility Board supports the SDT in its efforts to avoid unintended consequences from changes to

**Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17**

		<p>the BES definition, especially for small entities that cannot afford the substantial costs that accompany imposition of mandatory compliance with Reliability Standards. Further, we agree that the small utilities covered by the exemption will have no measureable impact on the operation of the interconnected BES. In the Pacific Northwest, many small entities were required to register by virtue of owning a very small portion of the region's 115 kV system. These utilities have faced substantial compliance burdens even though their operations are simply not material to the interconnected bulk grid in our region, and the investment of resources in compliance, therefore, will have no measurable effect in improving the reliability of the interconnected Grid.</p>
Springfield Utility Board	Yes	<p>These comments are supplemental to Springfield Utility Board's comments provided to NERC on May 26, 2011 filed by Tracy Richardson. Please see the May 26 comments. This supplemental comment deals with the concept of "serving only load" and the classification of what types of generation are incorporated into the definition of generation for purposes of BES inclusion or exclusion. SUB's comment is that generation normally operated as backup generation for retail load is not counted as generation for purposes of determining generation thresholds for inclusion or exclusion from the BES. For purposes of BES inclusion or exclusion, a system with load and generation normally operated as backup generation for retail load is considered "serving only load" when using generation normally operated as backup generation for retail load (See Inclusions I2, I3, I5, and Exclusions E1, E2, E3). The rationale is that backup generation for retail load is normally used during a localized outage and for testing for reliability during a localized outage event. Including backup generation for retail load in generation thresholds (e.g. 75MVA) would not reflect generation used for restoration or reliability of the BES. Including backup generation for retail load in generation threshold calculations would cause an inappropriate inclusion of elements and devices, accelerate the triggering of inclusion (and may make exclusion provisions meaningless), and push more activity of excluding smaller systems from the BES into the exception process.</p>
American Electric Power	Yes	<p>AEP agrees with the proposed exclusion to the extent that such excluded small utilities would continue to provide any needed information the registered entities have requested from the excluded small utilities to ensure the reliability compliance of those registered entities.</p>
MidAmerican Energy Company	Yes	<p>Arbitrarily excluding small entities could affect reliability depending on the specific transmission facilities the entity owns and/or operates.</p>
Western Area Power Administration	Yes	<p>As discussed in the Applicability of Federal Power Act Section 215 to Qualifying Small Power Production and Cogeneration Facilities document, the concerns regarding the Regulatory Flexibility Act Analysis of 1980 stated in section VII does not define the phrase a 'significant economic impact' from the perspective of a small entity. A small entity may have staffed maintenance personnel, to accomplish its' own maintenance but now prefers to transfer by written agreement with another entity based upon NERC's compliance registry criteria,</p>

<p><b>Response:</b> The basis for the additional exclusion was predicated by the circumstances of radial systems and the demarcation of the automatic interrupting device. With the change of the demarcation point back to the point where the tap line intersects with the transmission line; this proposed exclusion is unnecessary. The SDT will drop consideration for this proposed exclusion given the change to radial systems.</p>		

11. In Order No. 743, the Commission addressed the need to differentiate between Transmission and distribution in the revised definition of the Bulk Electric System (BES). Specifically, the Commission stated that local distribution facilities are to be excluded from the BES. The SDT believes that it has excluded local distribution facilities through the revised bright-line core definition and specific inclusions and exclusions. Do you agree with this position? If not, please provide specific comments and suggestions on what else needs to be addressed or added.

**Summary Consideration:** The SDT made a number of clarifying changes to the draft BES definition that it believes provides a greater distinction between transmission and distribution facilities. The SDT has also included in the definition a statement that excludes facilities used in local distribution of electric energy. The SDT believes that the revised Exclusions E1 (radial exclusion) and E3 (Local Network exclusion) provide appropriate opportunities to exclude distribution facilities above 100 kV. In addition, the “cranking path” and “automatic interrupting devices” language have been removed from the draft BES definition.

**Bulk Electric System (BES):** ~~Unless modified by the lists shown below, All~~ Transmission Elements operated at 100 kV or higher, ~~and~~ Real Power ~~and Reactive Power~~ resources ~~as described below, and Reactive Power resources~~ connected at 100 kV or higher ~~unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.~~

**I32** - ~~Generating units resource(s) located at a single site with aggregate capacity greater than 75 MVA (with gross individual or gross aggregate nameplate rating) per the ERO Statement of Compliance Registry Criteria~~ including the generator terminals through the ~~high-side of the step-up GSU transformer(s),~~ connected ~~through a common bus operated~~ at a voltage of 100 kV or above.

**I43** - Blackstart Resources ~~and the designated blackstart Cranking Paths~~ identified in the Transmission Operator’s restoration plan ~~regardless of voltage.~~

**E1** - ~~Any radial systems: which is described as connected~~ A group of contiguous transmission Elements emanating from a single point of connection of 100 kV or higher from a single Transmission source originating with an automatic interruption device and:

- a) Only ~~servingserves~~ Load. ~~A normally open switching device between radial systems may operate in a ‘make before break’ fashion to allow for reliable system reconfiguration to maintain continuity of electrical service.~~ Or,
- b) Only ~~includingincludes~~ generation resources not identified in Inclusions ~~I2, I3, I4 and I5~~ with an aggregate capacity less than or equal to 75 MVA (gross nameplate rating). Or,
- c) ~~Is a combination of items (a.) and (b.) w~~Where the radial system serves Load and includes generation resources not identified in Inclusions ~~I2, I3, I4 and I5.~~ with an aggregate capacity of non-retail generation less than or equal to 75 MVA (gross nameplate rating).

Note – A normally open switching device between radial systems, as depicted on prints or one-line diagrams for example, does not affect this exclusion.

**E3** - Local ~~Distribution~~ Networks (LDN): ~~A Groups of contiguous transmission Elements operated at or above 100 kV but less than 300 kV that distribute power to Load rather than transfer bulk power across the interconnected Ssystem. LDN's emanate from multiple points of connection at 100 kV or higher are connected to the Bulk Electric System (BES) at more than one location solely to improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system. The LDN is characterized by all of the following: Separable by automatic fault interrupting devices: Wherever connected to the BES, the LDN must be connected through automatic fault-interrupting devices;~~

**E3a.** Limits on connected generation: ~~Neither tThe LDN, nor and its underlying Elements do not include generation resources identified in Inclusion I3, and do not have an aggregate capacity of non-retail generation greater than 75 MVA (gross nameplate rating) (in aggregate), includes more than 75 MVA generation;~~

**E3b.** Power flows only into the ~~Local Distribution Network~~LDN: ~~The generation within the LDN shall not exceed the electric Demand within the LDN. The LN does not transfer energy originating outside the LN for delivery through the LN; and~~

~~Not used to transfer bulk power: The LDN is not used to transfer energy originating outside the LDN for delivery through the LDN; and~~

**E3c.** Not part of a Flowgate or ~~T~~transfer ~~P~~path: The LDN does not contain a monitored Facility of a permanent ~~f~~lowgate in the Eastern Interconnection, a major transfer path within the Western Interconnection ~~as defined by the Regional Entity~~, or a comparable monitored Facility in the Quebec Interconnection, and is not a monitored Facility included in an Interconnection Reliability Operating Limit (IROL).

Organization	Yes or No	Question 11 Comment
Northeast Power Coordinating Council	No	<p>The current definition drafted by the SDT has not differentiated between Transmission and Distribution, nor excluded distribution facilities from the BES, nor addressed the issue of local distribution facilities above 100kV. It is important for the ERO and the SDT to understand and be consistent with the FERC Order for these important but complex issues. Many parts of the continent could be in conflict with state or provincial regulatory act, Codes, and Licenses. The ERO and SDT and RoP teams be aware of these conflicts and not disregard them, as they will pose many implementation complexities and confusion within the industry. Regulatory Acts and Rules will always supersede NERC requirements and hence it is important that ERO should neither be caught in regulatory conflict nor put entities in these situations. As responded to in Question 10, the ERO and SDT can address this by providing explicit but simple provisions in the exception criteria (to be used by exception procedure) by putting forward required technical assessments , which are based on a demonstration of evidence to justify the element's necessity for operation.</p> <p>For example, suggest that for local distribution, the evidence that should be required is:</p> <ul style="list-style-type: none"> <li>o Regulatory evidence</li> <li>o Evidence demonstrating that NO adverse reliability impact is afflicted on the interconnected BES because of</li> </ul>

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 11 Comment
		<p>their connection</p> <p>Some of the other key attributes of such an exception criteria should be:</p> <ul style="list-style-type: none"> <li>o Elements are not to be part of interconnection between two balancing authority or contribute to IROs</li> <li>o Entire system cannot be classified as contiguous</li> <li>o Entity to justify whether or not the elements are necessary for the operation of the interconnected transmission network</li> <li>o Distinguish if the element in question supplies load centers, major cities, serves the national interest and/or possibly impact national commerce or national security, or is identified by the relevant regulatory authority</li> </ul> <p>Accordingly, the exception criteria should ONLY list a menu of items and a prescribed report template that should be assessed and presented by an entity as their evidence and justification for exception to a RE, the ERO and any relevant regulatory authority. This evidence and justification would be used by the ERO as part of its decision making process.</p>
Hydro One Networks Inc	No	<p>We commend the SDT for their concept in putting forward a 100kV BES bright-line definition. However, we do not believe that the current definition drafted by the SDT has differentiated between Transmission and Distribution or excluded distribution facilities from the BES, or addressed the issue of local distribution facilities above 100kV. It is worth noting that different jurisdictions may use different terminology for “distribution” or non transmission facilities or elements. For example, some jurisdictions label certain facilities as distribution which connect and are owned and operated by the distribution utility, customer or a generator customer while other label them as connection facility or elements.(See Q10 response)</p>
<p><b>Response:</b> The SDT made a number of clarifying changes to the draft BES definition that it believes provides a greater distinction between transmission and distribution facilities. The SDT has also included in the definition a statement that excludes facilities used in local distribution of electric energy. The SDT believes that revised Exclusions E1 (radial exclusion) and E3 (Local Network exclusion) provide appropriate opportunity to exclude distribution facilities above 100 kV.</p> <p><b>Bulk Electric System (BES):</b> <del>Unless modified by the lists shown below, All</del> Transmission Elements operated at 100 kV or higher, <del>and</del> Real Power <del>and</del> Reactive Power resources <del>as described below, and Reactive Power resources</del> connected at 100 kV or higher <del>unless such designation is modified by the list shown below.</del> <u>This does not include facilities used in the local distribution of electric energy.</u></p>

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 11 Comment
<p><b>Response:</b> Thank you for your response. In the future please provide more information to let us know more specifically what you disagree with.</p>		
<p>Tri-State Generation and Transmission Association, Inc.</p>	<p>No</p>	<p>See the comments to Question 7.</p>
<p><b>Response:</b> See the response to Q7.</p>		
<p>Dominion</p>	<p>No</p>	<p>Dominion believes the core BES definition should include any non-radial Element or Facility operated at 100 Kv or higher and should exclude any radial Element or Facility (regardless of operating voltage) as well as non-radial Element or Facility operated below 100 kV. The core definition should also include defined criteria that are applied to an Element or Facility to determine whether or not it meets the intent of the Section 215 of Federal Power Act Section 215 defines the bulk power system as (1) facilities and control systems necessary for operating an interconnected electric energy transmission network; and (2) electric energy from generation facilities needed to maintain transmission system reliability. (3) However, Section 215 excludes facilities used in the local distribution of electric energy From the definition of the bulk power system. An Element or Facility should be included where the Element or Facility is necessary for operating an interconnected electric energy transmission network or is needed to maintain transmission system reliability. Likewise an Element or Facility should be excluded where the Element or Facility is not necessary for operating an interconnected electric energy transmission network or is needed to maintain transmission system reliability. Dominion agrees that the BES definition should exclude local distribution facilities under state jurisdiction. In specific instances (including UFLS programs and transmission protection systems that are implemented on distribution elements or radial transmission) local distribution facilities can be included in approved NERC reliability standards following under explicit standards dedicated to their explicit mission without their automatic inclusion in a definition of BES that could infringe on state jurisdiction.</p>
<p><b>Response:</b> The SDT made a number of clarifying changes to the draft BES definition that it believes provides a greater distinction between transmission and distribution facilities. The SDT has also included in the definition a statement that excludes facilities used in local distribution of electric energy. NERC Reliability Standards can apply to non-BES Facilities and compliance can be enforced for those entities in the NERC Compliance Registry.</p> <p><b>Bulk Electric System (BES):</b> <u>Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</u></p>		
<p>SPP Standards Review Group</p>	<p>No</p>	<p>The inclusion of Cranking Paths into the BES without regard to voltage level has the potential to pull distribution facilities into the BES. (See Question 5)</p>

Organization	Yes or No	Question 11 Comment
<p><b>Response:</b> The SDT removed Cranking Paths from the BES definition.</p> <p><b>43</b> - Blackstart Resources <del>and the designated blackstart Cranking Paths</del> identified in the Transmission Operator’s restoration plan <del>regardless of voltage</del>.</p>		
Michigan Public Service Commission(MPSC)	No	MPSC Staff Comments: The intent of the updated BES definition should be to classify facilities required to meet mandatory NERC reliability standards. Unnecessary and costly duplication of standards work should be avoided.
<p><b>Response:</b> The SDT is revising the BES definition to meet the FERC directives in Order Nos. 743 and 743-A. The SDT does not believe it is contributing to any unnecessary and costly duplication of standards work. No change made.</p>		
National Rural Electric Cooperative Association (NRECA)	No	NRECA believes the definition should explicitly state that facilities used in local distribution are excluded from the BES.
United Illuminating	No	The core definition should state that local distribution facilities are not included.
<p><b>Response:</b> The SDT included in the definition a statement that excludes facilities used in local distribution of electric energy.</p> <p><b>Bulk Electric System (BES):</b> <u>Unless modified by the lists shown below, A</u>ll Transmission Elements operated at 100 kV or higher, <u>and</u> Real Power <u>and</u> <u>Reactive Power</u> resources <del>as described below, and Reactive Power resources</del> connected at 100 kV or higher <del>unless such designation is modified by the list shown below.</del> <u>This does not include facilities used in the local distribution of electric energy as established by applicable regulatory authorities.</u></p>		
Idaho Falls Power	No	In the exclusions, we feel there has not been given enough clarification of generation assets on a LDN, specifically, is a single generation resource >20MVA but <75 MVA excluded? This does not seem clear because of the seeming inconsistencies of E2(i) and E3(b).Further, we believe generation on an LDN serving local load wherein the net flow is into the LDN should be excluded.
<p><b>Response:</b> The SDT made changes to the LDN, now LN, to address your comment and the comments of others. Specifically, LNs are permitted to have generating resources that in the aggregate do not exceed 75 MVA, and such generating resources are not already included under I3 of the BES definition. The SDT believes these changes clarify the amount of generation permitted in the LN.</p> <p><b>E3a.</b> Limits on connected generation: <del>Neither t</del>The LDN, <del>nor</del>and its underlying Elements <u>do not include generation resources identified in Inclusion I3 and do not have an aggregate capacity of non-retail generation greater than 75 MVA (gross nameplate rating) (in aggregate), includes more than 75 MVA generation;</u></p>		

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 11 Comment
Overton Power District No. 5	No	Facilities used in local distribution should not be swept up into the BES
Western Montana Electric Generating and Transmission Cooperative	No	While WMG&T agrees that the approach adopted by the SDT -- a core definition coupled with specific inclusions and exclusions - will be effective in removing most local distribution facilities from the BES, it will not remove all such facilities. For the reasons discussed at greater length in our answer to Question 1, WMG&T believes that the proposed definition is over-inclusive and is likely to sweep up certain facilities used in local distribution that should not be classified as BES. As discussed in our answer to Question 3, WMG&T notes that exclusion of facilities from the BES does not mean that owners of those facilities are entirely exempt from reliability standards. On the contrary, the statute provides that “users” of the BES can be subject to reliability regulation. Hence, even where an entity does not own BES assets, it could be required to, for example, provide necessary information to the applicable Reliability Coordinator and to participate in the regional Under-Frequency Load Shedding program by setting the UFLS relays in its Local Distribution Network at the appropriate settings. We note that participants in the WECC BESDTF Task Force generally agreed that appropriate information should be provided by non-BES entities, although there was considerable concern related to ensuring that the provision of information was not unduly burdensome.
Texas Industrial Energy Consumers (TIEC)	No	TIEC appreciates the SDT’s effort to identify situations where facilities rated above 100 kV should still be categorically excluded from the BES definition. This recognition is consistent with the concerns raised by TIEC and many of its individual members in comments to the FERC in Docket RM09-18-000. However, TIEC submits that the SDT’s approach to these exclusions should be revised to meet FERC’s express recognition in Order No. 743-A that “facilities used for local distribution are excluded from the Bulk-Power System definition under section 215, and thus are excluded from the bulk electric system.” Order No. 743-A at ¶58. It is crucial that the BES definition is drafted in a way that recognizes that it is the transmission provider’s responsibility to ensure that equipment is in place to protect the BES from the operations of excluded facilities, not the responsibility of a person owning facilities involved in the local distribution of electricity. These issues are addressed in further detail in response to the specific exclusions.
Electricity Consumers Resource Council (ELCON)	No	Section 215 of the Federal Power Act denies FERC jurisdiction over facilities used in the local distribution of electric energy. FERC has recognized that since facilities used in the local distribution of electric energy “are exempted from the Bulk-Power System, they also are excluded from the bulk electric system.” Section 215 of the Federal Power Act does not qualify the exclusion from FERC jurisdiction of “facilities used in the local distribution of electric energy.” For example, Section 215 does not state that:--The term “bulk power system” “does not include facilities used in the local distribution of electric energy [unless needed for reliability purposes];” or --The term “bulk power system” “does not include facilities [with automatic interruption devices] used in the local distribution of electric energy.” Any definition of the bulk electric system that does not exclude all “facilities used in the local distribution of electric energy” is unlawful.

Organization	Yes or No	Question 11 Comment
		<p>Further, the definition of the bulk electric system must recognize that Section 215 of the Federal Power Act does not allow the potential reliability impact of a facility to determine whether the facility is local distribution or transmission. By excluding all facilities used in the local distribution of electric energy from the definition of the Bulk-Power System in Section 215, Congress recognized that while facilities used in the local distribution of electric energy may be part of the Bulk-Power System, they are, nonetheless, not FERC jurisdictional. Thus, “facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof)” that are used in the local distribution of electric energy are not FERC jurisdictional regardless of the potential reliability impact of the facilities.</p>
<p><b>Response:</b> The SDT made a number of clarifying changes to the draft BES definition that it believes provides a greater distinction between transmission and distribution facilities. The SDT also included in the definition a statement that excludes facilities used in local distribution of electric energy.</p> <p><b>Bulk Electric System (BES):</b> <del>Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</del></p>		
Tennessee Valley Authority	No	<p>We cannot be certain of the effect of the BES definition on distribution facilities until our comments to the inclusions and exclusions above are considered.</p>
<p><b>Response:</b> The SDT made a number of clarifying changes to the draft BES definition that it believes provides a greater distinction between transmission and distribution facilities. The SDT also included in the definition a statement that excludes facilities used in local distribution of electric energy. The SDT believes these changes address your concerns.</p> <p><b>Bulk Electric System (BES):</b> <del>Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</del></p>		
Alabama Public Service Commission	No	<p>In drafting the inclusions and exclusions that accompany the core BES definition, the SDT needs to be very careful in considering jurisdictional issues. FERC has recognized in its recent orders regarding the BES definition that local distribution facilities are not subject to its jurisdiction under Section 215 of the Federal Power Act. As the SDT considers the scope of the inclusions and exclusions from the BES Definition, it needs to consider whether the proposed provisions only include: 1) facilities or control systems that are “necessary” for operating an interconnected electric transmission network and 2) whether they involve generation facilities that are “needed” to maintain transmission system reliability. If the proposed inclusions and exclusions result in the BES definition applying to facilities beyond this “necessary” and “needed” scope (such as local distribution facilities), then the definition would be inconsistent with Section 215 and could improperly make those facilities subject to “reliability standards” contrary to the Federal Power Act.</p>

Organization	Yes or No	Question 11 Comment
		<p>The APSC generally supports the BES Core Definition and all three Exclusions proposed by the SDT.</p> <p>The APSC strongly supports Exclusion E3 for local distribution networks and Exclusion E1 for radial systems (subject to the concerns below). Exclusion E3 will ensure State jurisdiction over facilities that are used in the local distribution of electric energy.</p> <p>The APSC does not support Inclusion I2 for individual generating units greater than 20 MVA. Inclusion I2 should be eliminated entirely because it will result in too many radial sub-transmission load serving facilities losing their non-BES status, when those facilities are not “necessary” for bulk power system reliability.</p> <p>The APSC supports Inclusion I3 (75MVA) as a sufficient generating unit threshold for purposes of this definition. If Inclusion I2 is eliminated, then the reference to Inclusion I2 within Exclusion E1 should also be eliminated.</p>
<p><b>Response:</b> The SDT made a number of clarifying changes to the draft BES definition that it believes provides a greater distinction between transmission and distribution facilities. The SDT also included in the definition a statement that excludes facilities used in local distribution of electric energy.</p> <p><b>Bulk Electric System (BES):</b> <u>Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</u></p> <p>After consulting with the NERC Board of Trustees and the NERC Standards Committee, the SDT has decided to forgo any attempt at changing generation thresholds at this time. There simply isn’t enough time or resources to do that topic justice with the mandated schedule. Therefore, the primary focus of the SDT efforts will be to address the directives in Orders 743 and 743a. However, this does not mean that the other issues will be dropped. Both the NERC Board of Trustees and the NERC Standards Committee have endorsed the idea that the Project 2010-17 SDT take a phased approach to this project with a new Standards Authorization Request (SAR) to address generation thresholds as well as several other issues that have arisen from SDT deliberations.</p> <p><b>32 -</b> <u>Generating units/resource(s) located at a single site with aggregate capacity greater than 75 MVA (with gross individual or gross aggregate nameplate rating) per the ERO Statement of Compliance Registry Criteria) including the generator terminals through the high-side of the step-up GSU transformer(s), connected through a common bus operated at a voltage of 100 kV or above.</u></p>		
ReliabilityFirst	No	we feel that BES elements have been included in teh exclusions
PJM	No	The bright line exclusion includes facilities that would normally be BES facilities but are excluded based on the asset size of the owner.
<p><b>Response:</b> The SDT does not believe it has excluded BES Elements in the draft BES definition. The SDT made a number of clarifying changes to the draft BES</p>		

Organization	Yes or No	Question 11 Comment
<p>definition that it believes provides a greater distinction between transmission and distribution facilities. The SDT also included in the definition a statement that excludes facilities used in local distribution of electric energy.</p> <p><b>Bulk Electric System (BES):</b> <u>Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</u></p>		
<p>Central Maine Power Company New York State Electric &amp; Gas and Rochester Gas &amp; Electric</p>	<p>No</p>	<p>Transmission and distribution facilities are already mutually exclusive and are already classified and reported in FERC Form 1. The SDT definition may have rolled in considerable portions of the distribution system for consideration as BES. A small generator that is entered into the black start program would make the complete cranking path BES. As documented previously this inclusion of immaterial generators and subsequently their distribution cranking paths is at odds with the Compliance Registry.</p>
<p>Exelon</p>	<p>No</p>	<p>As highlighted in the answers to Questions 5 and 7, Exelon does not believe that facilities used in local distribution of electric energy have been fully excluded in the draft BES definition. For example, there are many examples of black start cranking path facilities that are &lt;100kV and that are currently defined as facilities used in the “local distribution of electric energy”.</p>
<p><b>Response:</b> The SDT removed Cranking Paths from the BES definition. The SDT made a number of clarifying changes to the draft BES definition that it believes provides a greater distinction between transmission and distribution facilities. The SDT also included in the definition a statement that excludes facilities used in local distribution of electric energy.</p> <p><b>Bulk Electric System (BES):</b> <u>Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</u></p> <p><b>I 43</b> - Blackstart Resources <del>and the designated blackstart Cranking Paths</del> identified in the Transmission Operator’s restoration plan <del>regardless of voltage.</del></p>		
<p>Western Area Power Administration</p>	<p>No</p>	<p>Numerous distribution lines in the western US are 115kV, and some are being upgraded from 115kV to 230kV.</p>
<p>Intellibind</p>	<p>No</p>	<p>Due to the voltage bright line of 100kV there is still a question of what makes up sub-transmission. Many rural companies with large geographic areas use the 115kV system internally as sub transmission, but because of the bright line it is considered part of the transmission system. This is not its purpose, or how it is operated. There are no commercial paths, and no transmission flow through. On the other hand there are significant generation resources (significantly over 20MVA) that are interconnected directly through the sub transmission system to the BES, and by definition, since they are not interconnected at 100kV, they are</p>

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 11 Comment
		exempted from BES status. Some of these facilities do have direct impact on the BES.
Public Utility District No. 1 of Snohomish County, Washington	No	<p>While Snohomish County PUD agrees that the approach adopted by the SDT -- a core definition coupled with specific inclusions and exclusions - will be effective in removing most local distribution facilities from the BES, it will not remove all such facilities. For the reasons discussed at greater length in our answer to Question 1, Snohomish believes that the proposed definition is over-inclusive and is likely to sweep up certain facilities used in local distribution that should not be classified as BES. To give a further example, assume that a local distribution utility operates a distribution network that currently would be excluded from the SDT's definition, but that a cogeneration facility with a capacity of 30 MVA and average production of 15 MW is constructed in one of the industrial areas served by local distribution facility and the output is purchased by one of the industrial customers. Because of inclusion I2, the local utility would now be classified as owning BES facilities, even though the output of the generator rarely exceeds 20 MW in practice and the output is, as a matter of physics, absorbed by the surrounding industrial loads rather than being transmitting onto the interconnected grid. Further, the fundamental nature of the local distribution facilities has not changed. They are still used to deliver electric power to the utility's end-use customers, not to deliver power on the wholesale market across the interconnected bulk grid. Hence, the result of the SDT's definition is to include "facilities used on the local distribution of electric energy" in contravention of FPA Section 215(a)(1), 16 U.S.C. Â§ 8240(a)(1). The practical result of the improper classification would be that the local utility would be required to register as a Transmission Owner and Transmission Operator, and would incur substantial costs to comply with requirements that are designed to ensure the reliable operation of transmission lines that are part of the interconnected grid, not local distribution facilities. For the reasons explained in the papers published by the Project 2010-07 Task Force, the result is substantially increased compliance costs that produce little or no improvement in the reliability of the interconnected bulk system. Accordingly, if viewed in isolation, the SDT's core definitions and list of inclusions/exclusions do not comply with the statute or produce optimum benefits for bulk system reliability. Whether the SDT's approach complies with the statute can only be determined by examining the Exception process now under development, in conjunction with the SDT's definition. If the Exception process results in the exclusion of facilities that are improperly swept into the BES by the bright-line thresholds included in the SDT's definition, and the Exception can be attained at a reasonable cost to the involved entities, then the SDT will have achieved a result that complies with the statute. But this conclusion can be reached only upon review of the entire package, not just the core definition and list of inclusions/exclusions. In this regard, as discussed in our answer to Question 3, Snohomish notes that exclusion of facilities from the BES does not mean that owners of those facilities are entirely exempt from reliability standards. On the contrary, the statute provides that "users" of the BES can be subject to reliability regulation. 16 U.S.C. Â§ 8240(b). Hence, even where an entity does not own BES assets, it could be required to, for example, provide necessary information to the applicable Reliability Coordinator and to participate in the regional Under-Frequency Load Shedding program by setting the UFLS relays in its Local Distribution Network at the appropriate settings. We note that participants in the WECC BES Task Force</p>

		<p>conclusion can be reached only upon review of the entire package, not just the core definition and list of inclusions/exclusions. In this regard, as discussed in our answer to Question 3, Clallam notes that exclusion of facilities from the BES does not mean that owners of those facilities are entirely exempt from reliability standards. On the contrary, the statute provides that “users” of the BES can be subject to reliability regulation. 16 U.S.C. Â§ 824o(b). Hence, even where an entity does not own BES assets, it could be required to, for example, provide necessary information to the applicable Reliability Coordinator and to participate in the regional Under-Frequency Load Shedding program by setting the UFLS relays in its Local Distribution Network at the appropriate settings. We note that participants in the WECC BES Task Force generally agreed that appropriate information should be provided by non-BES entities, although there was considerable concern related to ensuring that the provision of information was not unduly burdensome.</p>
Electric Reliability Council of Texas, Inc.	No	<p>See response to question 1 - ERCOT ISO agrees that distribution facilities should be excluded, and such facilities are generally excluded in ERCOT ISO’s proposed alternative definition. However, FERC stated in 743 and 743-A that it has the right to determine if facilities are distribution or transmission. Accordingly, to respect the FPA explicit exclusion of distribution facilities and FERC’s authority to determine if a facility is transmission or distribution, ERCOT ISO position is that the general exemption should be in the BES definition, but any such exemptions must be subject to the exemption process to facilitate FERC’s authority to make the relevant determination. With respect to that process, it may provide for a presumptive exclusion with additional at FERC’s discretion. ERCOT ISO reserves its rights to comment on the criteria for exclusion/exemption/inclusion in that proceeding. In addition, the exception process should provide for the ability to include certain distribution facilities if the inclusion criteria of the exception process indicate such action is appropriate.</p>
MidAmerican Energy Company	No	<p>We disagree that the SDT has appropriately excluded local distribution facilities through the revised bright-line core definition and specific inclusions and exclusions. A similar bright line criterion excluding facilities below 100 kV would be better. The intent is to clearly define facilities below 100kV (exclusive of resources added under criterion I4) as local distribution (excluded from FERC jurisdiction in accordance with the Federal Power Act). Critical facilities below 100 kV would be brought back in under the provisions of inclusion exception criteria of the Technical Principles for Demonstrating BES Exceptions procedure.</p>
Springfield Utility Board	No	<p>While SUB agrees that the approach adopted by the SDT, a core definition, couple with specific inclusions and exclusions, will be effective in removing most local distribution facilities from the BES, it will not remove all such facilities. SUB believes that the proposed definition is over-inclusive and is likely to sweep up certain facilities used in local distribution that should not be classified as BES. SUB notes that exclusion of facilities from the BES does not mean that owners of those facilities are entirely exempt.</p>

**Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17**

Organization	Yes or No	Question 11 Comment
Springfield Utility Board	No	<p>These comments are supplemental to Springfield Utility Board's comments provided to NERC on May 26, 2011 filed by Tracy Richardson. Please see the May 26 comments. This supplemental comment deals with the concept of "serving only load" and the classification of what types of generation are incorporated into the definition of generation for purposes of BES inclusion or exclusion. SUB's comment is that generation normally operated as backup generation for retail load is not counted as generation for purposes of determining generation thresholds for inclusion or exclusion from the BES. For purposes of BES inclusion or exclusion, a system with load and generation normally operated as backup generation for retail load is considered "serving only load" when using generation normally operated as backup generation for retail load (See Inclusions I2, I3, I5, and Exclusions E1, E2, E3). The rationale is that backup generation for retail load is normally used during a localized outage and for testing for reliability during a localized outage event. Including backup generation for retail load in generation thresholds (e.g. 75MVA) would not reflect generation used for restoration or reliability of the BES. Including backup generation for retail load in generation threshold calculations would cause an inappropriate inclusion of elements and devices, accelerate the triggering of inclusion (and may make exclusion provisions meaningless), and push more activity of excluding smaller systems from the BES into the exception process.</p>
Midstate Electric Cooperative	No	<p>While MSEC agrees that the approach adopted by the SDT -- a core definition coupled with specific inclusions and exclusions - will be effective in removing most local distribution facilities from the BES, it will not remove all such facilities. For the reasons discussed at greater length in our answer to Question 1, MSEC believes that the proposed definition is over-inclusive and is likely to sweep up certain facilities used in local distribution that should not be classified as BES.</p> <p>As discussed in our answer to Question 3, MSEC notes that exclusion of facilities from the BES does not mean that owners of those facilities are entirely exempt from reliability standards. On the contrary, the statute provides that "users" of the BES can be subject to reliability regulation. Hence, even where an entity does not own BES assets, it could be required to, for example, provide necessary information to the applicable Reliability Coordinator and to participate in the regional Under-Frequency Load Shedding program by setting the UFLS relays in its Local Distribution Network at the appropriate settings. We note that participants in the WECC BESDTF Task Force generally agreed that appropriate information should be provided by non-BES entities, although there was considerable concern related to ensuring that the provision of information was not unduly burdensome.</p>
Public Utilities Commission of Ohio	No	<p>While it appears there was an attempt to draft the standard to comply with the Federal Power Act, the issues outlined throughout the questions above raise concerns that local distribution could easily get captured in NERC and FERC reliability standards needlessly and inappropriately.</p>

**Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17**

Organization	Yes or No	Question 11 Comment
New England States Committee on Electricity	No	As stated in 1 above, NESCOE is concerned that the proposed definition may unintentionally incorporate facilities into the BES that do not have a direct impact on the reliability of the system, potentially imposing significant costs without meaningful reliability benefits.
AltaLink	No	We commend the SDT for their concept in putting forward a 100kV BES bright-line definition. However, we do not believe that the current definition drafted by the SDT has differentiated between Transmission and Distribution or excluded distribution facilities from the BES, or addressed the issue of local distribution facilities above 100kV. We believe that the ERO and SDT can address this by providing explicit but simple provisions in the exception criteria (to be used by exception procedure) by putting forward a menu of key technical assessments, which are based on demonstration of evidence to justify the element's necessity for operation. For example, we suggest that for local distribution, the evidence that should be required is: <ul style="list-style-type: none"> <li>o Regulatory evidence</li> <li>o Evidence demonstrating that NO adverse reliability impact is afflicted on the interconnected BES because of their connection</li> </ul> We suggest that the exception criteria should ONLY list a menu of items and a prescribed report template that should be assessed and presented by an entity as their evidence and justification for exception to a RE, the ERO and any relevant regulatory authority. This evidence and justification would be used by the ERO as part of its decision making process.
Modern Electric Water Company	No	The proposed definition continues to inject ambiguity in that it introduces the use of the separately-defined capitalized term "Transmission". In NERC's Glossary of Terms (May 24, 2011), "Transmission" is defined in terms of function rather than voltage. As it should, the core definition implies that only Elements used for the transfer of energy to points where it is transformed for delivery to customers as well as certain resources are considered to be included in the BES. However, it also uses voltage, and we do not believe that the proposed definition goes far enough to distinguish between T and D. Under the language of the core definition, there exists a two-stage qualifier for non-resource Elements - namely that it must first be used for Transmission and not for "Distribution", and secondly, that it be operated above 100kV. Rather, the BES cannot contain Elements used for "Distribution" (a term not explicitly defined, but extrapolated from other NERC glossary terms to mean the "wires" between the transmission system and the end-use customer, and NOT defined by voltage). While the Exclusions detail characteristics of specific distribution-like Elements, we suggest that the core BES definition contain language explicitly excluding Distribution (there are Elements that are neither qualifying radials as defined in E1 nor local distribution networks as defined in E3). Section 215(a)(1) contains specific language that could be used in the core definition in this instance.
Michigan Public Power Agency	No	As I have indicated in my comments above the "small entity definition" is not being used when the 100 KV, 20 MVA, and 75 MVA aggregate are being used only. A unit with a long start up time and a low capacity factor and/or availability factor and connected to a local distribution system is interconnected to the BES has little opportunity to be counted on to support the BES during a critical event. With the environmental issues out

Organization	Yes or No	Question 11 Comment
		there it could be expected that owners of these types of units may well decide on economics of the issue and retire such units. How would the reliability of the BES be served then?
City of Redding	No	<p>Redding agrees that addressing Radial's and LDN's in the core definition is a great first step in identifying distribution facilities, however there will still be a sizeable amount of elements operated over 100 kV that will not be identified as distribution facilities through the efforts of the brightline. Additionally, as noted in question #1, in the Western Interconnect the majority of 100 kV elements are used as Distribution facilities. Therefore, the exclusions E1 &amp; E2 will help ease the burden of NERC and the Regional Entity in the West by reducing the number of Exception Process applications.</p> <p>Also, Redding believes the SDT needs to take a more literal approach to FERC's Orders and define the term "necessary for operating the interconnected transmission network" and clearly "establish whether a particular facility is local distribution or transmission". Without a clear distinction of these two foundational principles it will be difficult to remove the confusion between the Regulators and Entities as to the term "necessary".</p>
<p><b>Response:</b> The SDT made a number of clarifying changes to the draft BES definition that it believes provides a greater distinction between transmission and distribution facilities. The SDT also included in the definition a statement that excludes facilities used in local distribution of electric energy. The SDT believes that revised Exclusions E1 (radial exclusion) and E3 (Local Network exclusion) provide appropriate opportunity to exclude distribution facilities above 100 kV.</p> <p><b>Bulk Electric System (BES):</b> <del>Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</del></p>		
Hydro-Quebec TransEnergie	No	See comments on E3 (Q.9)
<p><b>Response:</b> See response to Q9.</p>		
Oregon Public Utility Commission Staff	No	<p>Without BES "demarcation" and "contiguous" principles being addressed in the proposed BES definition, this question is difficult to answer. NERC Staff has submitted written comments to this project stating that the BES "must be contiguous." Instituting a contiguous BES with Inclusion I2, for example, would result in a substantially over-inclusive BES definition. The adoption of a "contiguous" BES is therefore likely to result in imposition of reliability standards on a substantial number of distribution elements that nothing to do with improving or protecting the reliability of bulk transmission system. There is no compelling reason to adopt a "contiguous" BES down into local distribution systems. Section 215 of the FPA of 2005 gives FERC jurisdictional authority over "users" as well as "owners" and "operators" of the bulk power system. Consequently, FERC has the jurisdictional authority to require generation and other entities in the Compliance Registry to comply with applicable NERC requirements. Hence, even where an entity does not own or</p>

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 11 Comment
		operate BES assets, it could still be required, for example, to provide necessary information to the applicable Reliability Coordinator or Planning Coordinator and to participate in programs to prevent instability, uncontrolled separation, or cascading outages to the bulk transmission system. This approach would fully achieve the goals of bulk transmission system reliability without imposing the full BES regulatory compliance burden on local distribution elements.
National Association of Regulatory Utility Commissioners		The standard as currently written seems to exempt most local distribution from NERC and FERC reliability standards. Section 215 of the Federal Power Act requires such exemptions. There remain some outstanding concerns, however. For example, earlier comments from NERC staff have suggested that the BES needs to be contiguous. If the definition were to require continuity, it would likely sweep in many local distribution facilities that should not (and cannot under the statute) be included in the BES definition.
<p><b>Response:</b> The SDT did not adopt a “contiguous” BES down into the local distribution systems. The SDT made a number of clarifying changes to the draft BES definition that it believes provides a greater distinction between transmission and distribution facilities. The SDT also included in the definition a statement that excludes facilities used in local distribution of electric energy. The SDT believes that revised Exclusions E1 (radial exclusion) and E3 (Local Network exclusion) provide appropriate opportunity to exclude distribution facilities above 100 kV.</p> <p><b>Bulk Electric System (BES):</b> <u>Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</u></p>		
Grand Haven Board of Light and Power	No	The exclusions do not properly address the exclusion of single automatic interrupting device that serves a radial, load serving system and, through its operation, does not affect the BES.
<p><b>Response:</b> The SDT removed the requirement for an automatic interrupting device for radial exclusions.</p> <p><b>E1 - <del>Any radial systems; which is described as connected</del> A group of contiguous transmission Elements emanating from a single point of connection of 100 kV or higher from a single Transmission source originating with an automatic interruption device</b> and:</p>		
FHEC	No	Not until the Statement of Compliance Registry Criteria is conformed to this proposed definition.
South Texas Electric Cooperative, Inc.	Yes	I agree, but believe that those distribution companies that were forced to register as LSEs under FERC interpretation should be excluded as well.
South Texas Electric Cooperative, Inc.	Yes	I agree, but believe that those local distribution companies operating below the bright-line that were forced to register as LSEs under FERC Order on Compliance Filing (October 16, 2008) should be excluded as well. For example, BAL-005-0.1b, CIP-001-1a, EOP-002-3 and others do not apply to DPs but affect small local

Organization	Yes or No	Question 11 Comment
		<p>utilities as LSEs. If, according to FERC Order 743 a small local distribution utility would be rightly excluded from DP standards, then, by the same logic and as a distribution-level LSE, they should be excluded from LSE standards as well. If an operating system voltage below 100kV is too low to affect the BES/BPS, then it stands to reason that their connected load is too small as well. If not - then another bright-line should be established in the spirit of FERC Order 743 to differentiate between power flow across the BES/BPS and power flow to end-use consumers.</p>
<p><b>Response:</b> The SDT was assigned the job of revising the BES definition as required by FERC Order Nos. 743 and 743-A. Any changes to the ERO Statement of Compliance Registry Criteria are outside the scope of the SDT's assigned work. No change made.</p>		
Vermont Transco	No	<p>The inclusion of all black start units "regardless of voltage", the unclear definition of "automatic interruption device" and "common bus" could lead to local distribution company facilities being included in the definition of BES.</p>
ISO New England, Inc.	No	<p>The SDT definition will unnecessarily roll in portions of the distribution system for consideration as BES. A small generator that is entered into the black start program would make the complete cranking path BES. As documented previously this inclusion of immaterial generators and subsequently their distribution cranking paths is at odds with the Compliance Registry.</p>
<p><b>Response:</b> The SDT removed the requirement for (1) an automatic interrupting device for radial exclusions and (2) all Cranking Paths regardless of voltage from the draft BES definition. In addition, the "common bus" language has been deleted from the draft BES definition.</p> <p><del>E1 - Any radial systems: which is described as connected- A group of contiguous transmission Elements emanating from a single point of connection of 100 kV or higher from a single Transmission source originating with an automatic interruption device and:</del></p> <p><del>43 - Blackstart Resources and the designated blackstart Cranking Paths identified in the Transmission Operator's restoration plan regardless of voltage.</del></p>		
National Grid	No	<p>We don't believe the bright-line core definition and specific inclusions and exclusions prevent distribution from being considered as BES. Actually, it seems like a lot of distribution will be considered BES according to the inclusions and exclusions. (E1 may be interpreted to include step downs if they don't have automatic interruption devices and possibly the tied through distribution system to the other step-down transformer that doesn't have an automatic interruption device from the same Transmission source) If the definition is not revised to exclude more distribution, we are concerned about how the distribution elements that will be considered BES under the new definition will be classified. The BES definition should not be used to differentiate between transmission and distribution. It is important for the ERO and the SDT to understand and be consistent with the FERC Order for these important but complex issues. There could be conflicts with state or provincial jurisdictions. The ERO and SDT and RoP teams should be aware of these conflicts and not</p>

Organization	Yes or No	Question 11 Comment
		<p>disregard them, as they will pose many implementation complexities and confusion within the industry, and may lead to jurisdictional challenges that could cause uncertainty and delay in implementation of the new BES definition. It is important for the ERO to not put entities in situations where there is some confusion or conflict. Removing I4, the inclusion regarding blackstart resources and cranking paths, will prevent distribution from being considered as BES.</p> <p>Also, clarification that step downs which have one winding which is less than 100 kV but are tapped off of the BES system without an automatic interruption device are not BES could also prevent distribution from being considered as BES.</p>
<p><b>Response:</b> The SDT made a number of clarifying changes to the draft BES definition that it believes provides a greater distinction between transmission and distribution facilities. The SDT also included in the definition a statement that excludes facilities used in local distribution of electric energy. The SDT believes that revised Exclusions E1 (radial exclusion) and E3 (Local Network exclusion) provide appropriate opportunity to exclude distribution facilities above 100 kV. In addition, the Cranking Path and automatic interruption device language has been removed from the draft BES definition.</p> <p><b>Bulk Electric System (BES):</b> <del>Unless modified by the lists shown below, All</del> Transmission Elements operated at 100 kV or higher, <del>and</del> Real Power <del>and</del> Reactive Power resources <del>as described below, and Reactive Power resources</del> connected at 100 kV or higher <del>unless such designation is modified by the list shown below.</del> <u>This does not include facilities used in the local distribution of electric energy.</u></p> <p><del>I43</del> - Blackstart Resources <del>and the designated blackstart Cranking Paths</del> identified in the Transmission Operator's restoration plan <del>regardless of voltage.</del></p> <p><del>E1</del> - <del>Any radial systems: which is described as connected-</del> <u>A group of contiguous transmission Elements emanating from a single point of connection of 100 kV or higher from a single Transmission source originating with an automatic interruption device and:</u></p>		
ExxonMobil Research and Engineering	No	<p>The SDT has defined a specific type of local distribution facility in their bright-line definition of the bulk electric system. The SDT's definition focuses on a specific type of local distribution system that has a minimum impact on an interconnected transmission system when that interconnected transmission system does not include the facilities necessary to properly protect itself from faults originating on its boundary. Section 215 of the Federal Power Act does not qualify the type of local distribution facility that should be excluded. It exempts ALL facilities used in the local distribution of electric energy, regardless of whether the owners and operators of the interconnected transmission system have installed facilities that are necessary to secure the reliability of the interconnected transmission system from incidents originating at its boundaries. Additionally, the SDT should consider making its definition of a local distribution network consistent with exclusion E2. If a generation facility with a net aggregate rating less than 75 MVA or single unit with a net export capacity below 20 MVA is not a part of the bulk electric system, what is the technical justification of including a local distribution network that exports less than 75 MVA in the bulk electric system when it is not used to transmit electric energy between geographic regions? Many QFs and large industrial facilities may fall under the description of local distribution network due to the breadth of their private use network, connection to multiple</p>

Organization	Yes or No	Question 11 Comment
		<p>138 kV / 230 kV substations (done to improve reliability in order to provide safer operation of the industrial process), and possible cyclical generation exports (sometimes exporting / sometimes importing).</p>
<p><b>Response:</b> The SDT made a number of clarifying changes to the draft BES definition that it believes provides a greater distinction between transmission and distribution facilities. The SDT also included in the definition a statement that excludes facilities used in local distribution of electric energy. The SDT believes that revised Exclusions E1 (radial exclusion) and E3 (Local Network exclusion) provide appropriate opportunity to exclude distribution facilities above 100 kV.</p> <p><b>Bulk Electric System (BES):</b> <u>Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy as established by applicable regulatory authorities.</u></p> <p>After consulting with the NERC Board of Trustees and the NERC Standards Committee, the SDT has decided to forgo any attempt at changing generation thresholds at this time. There simply isn't enough time or resources to do that topic justice with the mandated schedule. Therefore, the primary focus of the SDT efforts will be to address the directives in Orders 743 and 743a. However, this does not mean that the other issues will be dropped. Both the NERC Board of Trustees and the NERC Standards Committee have endorsed the idea that the Project 2010-17 SDT take a phased approach to this project with a new Standards Authorization Request (SAR) to address generation thresholds as well as several other issues that have arisen from SDT deliberations.</p>		
FortisBC	No	<p>We commend the SDT for their concept in putting forward a 100kV BES bright-line definition. However, we do not believe that the current definition drafted by the SDT has differentiated between Transmission and Distribution or excluded distribution facilities from the BES, or addressed the issue of local distribution facilities above 100kV. It is important for the ERO and the SDT to understand and be consistent with the FERC Order for these important but complex issues. Otherwise, many parts of the continent could be in conflict with state or provincial regulatory act, Codes, and Licenses. We urge the ERO and SDT and RoP teams be aware of these conflicts and not disregard them, as they will pose many implementation complexities and confusion within the industry. Regulatory Acts and Rules will always trump NERC requirements and hence it is important that ERO should neither be caught in regulatory conflict nor put entities in these situations. It is worth noting that different jurisdictions may use different terminology for "distribution" or non transmission facilities or elements. For example, some jurisdictions label certain facilities as distribution which connect and are owned and operated by the distribution utility, customer or a generator customer while other label them as connection facility or elements. As stated earlier (Q10), we believe that the ERO and SDT can address this by providing explicit but simple provisions in the exception criteria (to be used by exception procedure) by putting forward a menu of key technical assessments, which are based on demonstration of evidence to justify the element's necessity for operation. For example, we suggest that for local distribution, the evidence that should be required is:</p> <ul style="list-style-type: none"> <li>o Regulatory evidence.</li> <li>o Evidence demonstrating that NO adverse reliability impact is afflicted on the interconnected BES because of their connection.</li> </ul> <p>Some of the other key attributes of such an exception criteria should be:</p> <ul style="list-style-type: none"> <li>o Elements are not to be part of interconnection between two balancing authority or contribute to IROLs</li> <li>o Entire system cannot</li> </ul>

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 11 Comment
		<p>be classified as contiguous o BESS Elements within exclusion can still be subject to relevant NERC Standards o Entity to justify whether or not the elements are necessary for the operation of the interconnected transmission network o Distinguish if the element in question supplies load centers, major cities, serves the national interest and/or possibly impact national commerce or national security, or is identified by the relevant regulatory authority. Accordingly, we suggest that the exception criteria should ONLY list a menu of items and a prescribed report template that should be assessed and presented by an entity as their evidence and justification for exception to a RE, the ERO and any relevant regulatory authority. This evidence and justification would be used by the ERO as part of its decision making process.</p>
<p><b>Response:</b> The SDT made a number of clarifying changes to the draft BES definition that it believes provides a greater distinction between transmission and distribution facilities. The SDT also included in the definition a statement that excludes facilities used in local distribution of electric energy. The SDT believes that revised Exclusions E1 (radial exclusion) and E3 (Local Network exclusion) provide appropriate opportunity to exclude distribution facilities above 100 kV. Your comments regarding the exception process criteria will be addressed separately in the response to the exception process comments.</p> <p><b>Bulk Electric System (BES):</b> <u>Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</u></p>		
Consumers Energy Company	No	<p>The proposed definition appears to treat “BES” and “Transmission” synonymously, and this is highly likely to have a significant effect on registration, even if this is not intended. To support consistency between reliability and tariffs, we recommend that more direct consideration be given to the FERC 7-factor test that has been consistently used to delineate transmission facilities for tariff purposes, and to discriminate between registration requirements for TO and DP based on this delineation. Further, reliability gaps will not be created (or can be addressed by minor changes to the applicable standards) if this recommendation is adopted because all aspects of the applicable standards/requirements are (or will be) captured by the current registration process.</p>
<p><b>Response:</b> The SDT reviewed and considered the FERC 7-factor test and has included some concepts of that test in the LN portion of the draft BES definition. No change made.</p>		
Occidental Energy Ventures Corp. (answers include all various Oxy affiliates)	No	<p>Local distribution facilities have not been excluded from the proposed definition of the BES. As FERC recognized in Order No. 743-A in directing NERC to exclude local distribution facilities from the revised definition of the BES, any definition that does not exclude all “facilities used in the local distribution of electric energy” is unlawful. FERC, as well as federal courts, have repeatedly stated that whether a facility is used in local distribution must be determined on a “case-specific” basis (see, e.g., Order No. 888 at 31,980-81). As a threshold matter, before devoting any additional time and resources to developing a definition of the BES, there must be a clear understanding of the factors to consider when determining whether a facility is either a</p>

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 11 Comment
		<p>local distribution facility or a transmission facility. Currently, such a determination is made by considering a “seven-factor test” that FERC has adopted, and the U.S. Supreme Court has upheld. The “seven-factor test,” of which no one factor is determinative, evaluates the following indicators: (1) Local distribution facilities are normally in close proximity to retail customers.(2) Local distribution facilities are primarily radial in character.(3) Power flows into local distribution systems; it rarely, if ever, flows out.(4) When power enters a local distribution system, it is not reconsigned or transported on to some other market. (5) Power entering a local distribution system is consumed in a comparatively restricted geographical area. (6) Meters are based at the transmission/local distribution interface to measure flows into the local distribution system.(7) Local distribution systems will be of reduced voltage (Order No. 888 at 31,981). The seven-factor test, which recognizes that a bright-line between transmission and distribution is a not a workable approach, is designed to ensure FERC does not impermissibly usurp state and local regulation of local distribution facilities. There is no evidence that the seven-factor test was considered in drafting the proposed definition of the BES.</p> <p>Please see further discussion in response to Question 12.</p>
Central Lincoln	No	<p>We believe the SDT has excluded most distribution facilities, but not all. The remaining distribution facilities will find it necessary to go through a lengthy exception process. As stated in Q1, we support the PNGC comments stating that local distribution as determined by the seven factor test should be excluded by definition. We note that the SDT has also developed a technical principal document that uses language similar to the seven factor test. To use it, though, an entity must apply for exception first. We believe the seven factors or technical principles should be part of the definition in order to avoid numerous exception applications and resulting delays.</p>
City of Anaheim	No	<p>A functional test, similar to the seven factor test used for FERC Order 888, should be used to identify transmission network facilities independent of voltage. All other electrical facilities not identified as transmission network facilities should be deemed local distribution facilities, and should be excluded from the Bulk Electric System pursuant to the statutory Bulk Power System definition provided under federal law (18 CFR 39.1, Title 18, Chapter I, Subchapter B, Part 39)i.e. “facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof), and electric energy from generating facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy.” Please note that the statute does not reference any voltage level, therefore both transmission network and local distribution facilities each can operate at voltages higher or lower than 100 kV. The radial (E1) and local distribution network (E3)exclusions are a good starting point under the definition, but the exception procedure should have a functional exception for local distribution facilities independent of voltage level.</p>
<p><b>Response:</b> The SDT made a number of clarifying changes to the draft BES definition that it believes provides a greater distinction between transmission and</p>		

Organization	Yes or No	Question 11 Comment
		<p>distribution facilities. The SDT also included in the definition a statement that excludes facilities used in local distribution of electric energy. The SDT believes that revised Exclusions E1 (radial exclusion) and E3 (Local Network exclusion) provide appropriate opportunity to exclude distribution facilities above 100 kV. In addition, the SDT reviewed and considered the FERC 7-factor test and has included some concepts of that test in the LN portion of the draft BES definition. However, the 7-factor test, in and of itself, has been cited by FERC as insufficient to prove a facility is distribution. The SDT has attempted to provide additional tests that will hopefully pass FERC scrutiny.</p> <p><b>Bulk Electric System (BES):</b> <u>Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</u></p>
<p>BGE and on behalf of Constellation NewEnergy, Constellation Commodities Group and Constellation Control and Dispatch</p>	<p>No</p>	<p>BGE votes “NO” due to the lack of clarity in exclusion E1.</p>
		<p><b>Response:</b> The SDT made significant revisions to Exclusion E1 and hopes that addresses the lack of clarity referred to in your comment.</p> <p><b>E1 - <del>Any radial systems: which is described as connected to a single point of connection of 100 kV or higher from a single Transmission source originating with an automatic interruption device</del> and:</b></p> <ul style="list-style-type: none"> <li>a) Only <del>servingserves</del> Load. <del>A normally open switching device between radial systems may operate in a ‘make-before-break’ fashion to allow for reliable system reconfiguration to maintain continuity of electrical service.</del> Or,</li> <li>b) Only <del>includingincludes</del> generation resources not identified in Inclusions <del>12, 13, 14 and 15</del> <u>with an aggregate capacity less than or equal to 75 MVA (gross nameplate rating).</u> Or,</li> <li>c) <del>Is a combination of items (a.) and (b.) where</del> the radial system serves Load and includes generation resources not identified in Inclusions <del>12, 13, 14 and 15.</del> <u>with an aggregate capacity of non-retail generation less than or equal to 75 MVA (gross nameplate rating).</u></li> </ul> <p><u>Note – A normally open switching device between radial systems, as depicted on prints or one-line diagrams for example, does not affect this exclusion.</u></p>
<p>City of St. George</p>	<p>No</p>	<p>The way the definition is currently written it will include many entities with lines, generation and other facilities whose only purpose is for the local generation and distribution of energy to local customers. The generation restrictions and other language in the proposed definition will add additional registrations (i.e. TO/TOP) to many smaller entities which will have a significant economic impact to those utilities with little or no benefit to</p>

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 11 Comment
		<p>the main bulk system. The problems may stem more from the “one size fits all” approach to the standards requirements, with the TO/TOP requirements being the most onerous and difficult to comply with especially for smaller entities. Allowed generation levels and the actual use of the transmission and generation facilities should be considered in what is and is not included in the BES. As the proposed definition stands now along with the current reliability standards a small utility with a few segments of 115 kV or 138 kV lines and with some generation to serve local load must comply with the same requirements as a very large utility with hundreds of miles of 345 kV or 500 kV lines and 1,000’s of MVA of generation. The use of applying small, medium and large criteria to many of the standard requirements, similar to what is being considered for the CIP standards with low, medium and high requirements should be considered.</p>
<p><b>Response:</b> The SDT made a number of clarifying changes to the draft BES definition that it believes provides a greater distinction between transmission and distribution facilities. The SDT also included in the definition a statement that excludes facilities used in local distribution of electric energy. The SDT believes that revised Exclusions E1 (radial exclusion) and E3 (Local Network exclusion) provide appropriate opportunity to exclude distribution facilities above 100 kV. The SDT is focused solely on revisions to the BES definition, and changes to specific standards are outside the scope of this project.</p> <p><b>Bulk Electric System (BES):</b> <del>Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</del></p>		
Puget Sound Energy	No	The language on total aggregate load served by LDN should be added for the exclusion list.
<p><b>Response:</b> The SDT did not see a need to provide an aggregate Load limitation on any of the draft BES definition exclusions. No change made.</p>		
Southern California Edison Company	No	SCE believes that the BES Definition, as currently proposed, relies too heavily on the characterization of interconnected generation in its “Inclusion” criteria.
<p><b>Response:</b> The SDT made significant revisions to the draft BES definition, including changes to the inclusion and exclusion portions to address your concerns and those of others.</p>		
GTC	No	Since distribution facilities are to be excluded can the drafting team clarify if the automatic interrupting protective device (breaker or circuit switcher) operating at 100kV or above and protecting an excluded transformer (non-BES) should be excluded with the excluded transformer? Perhaps an additional separate exclusion could eliminate any uncertainty.
<p><b>Response:</b> The SDT removed the automatic interrupting device language from the draft BES definition.</p> <p><b>E1 - Any radial systems; which is described as connected- A group of contiguous transmission Elements emanating from a single point of connection of</b></p>

<p><del>100 kV or higher from a single Transmission source originating with an automatic interruption device</del> and:</p>		
New York State Dept of Public Service	No	See comments under question 1.
<p><b>Response:</b> See response to Q1.</p>		
Long Island Power Authority	No	We don't believe the bright-line definition and specific inclusions and exclusions prevents distribution from being considered as BES. It seems like the intent to exclude non bulk distribution systems would still be included because of E3b. We don't believe that the SDT has fully excluded local distribution facilities as required by the FERC Order. Specifically E3b should be eliminated. The other remaining items a,c,d,e adequately define the LDN.
Independent Electricity System Operator	No	The existing definition and the associated inclusions and exclusions do not exclude local distribution facilities because the 75 MVA limit on generation within LDNs in E3 (b) will result in portions of the power system that are serving a distribution function being classified as BES. As stated before, we suggest subjecting the LDNs to assessment to determine their impact on the BES and including them if impactful by using the Exception Process.
<p><b>Response:</b> The SDT made a number of clarifying changes to the draft BES definition that it believes provides a greater distinction between transmission and distribution facilities. The SDT also included in the definition a statement that excludes facilities used in local distribution of electric energy. The SDT believes that revised Exclusions E1 (radial exclusion) and E3 (Local Network exclusion) provide appropriate opportunity to exclude distribution facilities above 100 kV. In addition, item E3b) was revised to provide further clarity.</p> <p><b>Bulk Electric System (BES):</b> <del>Unless modified by the lists shown below, All</del> Transmission Elements operated at 100 kV or higher, <del>and</del> Real Power <del>and</del> Reactive Power resources <del>as described below, and Reactive Power resources</del> connected at 100 kV or higher <del>unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</del></p> <p><b>E3b)</b> Only <del>including</del>includes generation resources not identified in Inclusions <del>I2, I3, I4 and I5</del> with an aggregate capacity less than or equal to 75 MVA (gross nameplate rating).</p>		
The Dow Chemical Company	No	The Dow Chemical Company ("Dow) is an international chemical and plastics manufacturing firm and a leader in science and technology, providing chemical, plastic, and agricultural products and services to many essential consumer markets throughout the world. Dow and certain of its worldwide affiliates and subsidiaries, including Union Carbide Corporation, own and operate electrical facilities at a number of industrial sites within the U.S., principally, in Texas and Louisiana. The electrical facilities at these various industrial sites are configured similarly and perform similar functions. In most cases, a tie line or lines connect

Organization	Yes or No	Question 11 Comment
		<p>the industrial site to the electric transmission grid. Power is delivered from the electric transmission grid to the industrial site through the tie line(s). Lines within the industrial site then deliver power to individual manufacturing plants within the site. Additionally, cogeneration facilities are located at a number of industrial sites owned by Dow and its subsidiaries. These cogeneration facilities generate power that is distributed within the industrial site and used for manufacturing plant operations. In some instances, excess power not required for plant operations is delivered back into the electric transmission grid through the tie line(s) connecting the industrial site to the grid. Under all circumstances, electricity is not flowing into and out of such industrial sites at the same time. While the tie lines and some of the internal lines at these industrial sites operate at 100kV or higher, they do not perform anything that resembles a transmission function. Rather than transmit power long distances from generation to load centers, the tie lines and internal lines perform primarily a local distribution function consisting of the distribution of power brought in from the grid or generated internally to different plants within each industrial site. In some cases, the facilities also perform an interconnection function to the extent they enable power from cogeneration facilities to be delivered into the grid. The voltage of the tie lines and internal lines at these industrial sites is dictated by the load and basic configuration of each site. Higher voltage lines are used when necessary to meet applicable load requirements or to reduce line losses. That does not mean that such lines perform a transmission function. At some sites, Dow is registered as a Generation Owner and Generation Operator. At other sites, the applicable Regional Entity has found that such registration is not required because of the relatively small amount of power supplied to the grid from the applicable cogeneration resources, even though those cogeneration resources have an aggregate capacity greater than 75 MVA (gross aggregate nameplate rating). Tie lines (to the grid) and internal lines at an industrial site that operate at 100kV or higher should be excluded from the BES definition if, due to the relatively small amount of power supplied to the grid from the generation resources at the site, the owner of those generation resources is not required to be registered as a Generation Owner and the operator of those generation resources is not required to be registered as a Generation Operator. At sites where the owner of the generation resources is registered as a Generation Owner and the operator of those generation resources is registered as a Generation Operator, the internal lines (between the generation resources and the manufacturing plants) that operate at 100kV or higher should be excluded from the BES definition, because they are distribution and not transmission facilities. The lines interconnecting the generation resources at such sites to the transmission grid should be included in the BES definition, but the owner and operator of such interconnection lines should not be registered as a Transmission Owner or Transmission Operator. In no instance has a Regional Entity determined that Dow or any subsidiary should be registered as a Transmission Owner or Transmission Operator. Instead, such interconnection lines should be considered as part of the generation resource and Generation Owners and Generation Operators should be subject to reliability standards specifically developed for such interconnection lines. Dow is strongly opposed to any BES definition that would result in either the tie lines or the internal lines at industrial sites being subject to the mandatory reliability standards applicable to Transmission Owners and Transmission Operators. Complying with reliability standards would cause Dow and its subsidiaries to incur</p>

Organization	Yes or No	Question 11 Comment
		<p>substantial compliance costs and create potential exposure to penalties in the future for noncompliance. Perhaps such costs and exposure could be justified if subjecting these facilities to compliance with reliability standards resulted in a material increase in reliability of the BES, but there is no reason to believe that will be the case. In fact, the opposite might be true. The tie lines and internal lines at industrial sites owned by Dow and its subsidiaries have been operated for decades as distribution and interconnection facilities, and practices and procedures have developed over the years that have enabled such operations to achieve a high degree of reliability for such sites. Requiring these facilities to now operate in a different manner as transmission facilities may well result in a degradation of the reliability of the manufacturing plants located at such sites. For example, outages would have to be coordinated with the RTO, which may not be interested in coordinating such outages with scheduled manufacturing plant outages. Dow recommends that a separate exclusion be added to the BES definition to address industrial distribution facilities. Proposed exclusion E-3 for local distribution networks is not sufficient to ensure that all industrial distribution facilities are excluded. For example, criteria b), entitled "Limits on connected generation" states that "Neither the LDN, nor its underlying Elements (in aggregate), includes more than 75 MVA generation". This criteria makes no sense for an industrial site with on-site electricity generation and a number of manufacturing plants that has internal power lines and lines interconnecting with the transmission grid that operate at 100 kV or higher where the owner and operator of the on-site electricity generation facilities are not registered as a Generation Owner and a Generation Operator because only a small amount of electricity is ever exported from the on-site electricity generation facilities to the transmission grid. This criteria also makes no sense with respect to internal electric lines (operated at 100 kV or higher) at such industrial sites even where the owner and operator of the on-site electricity generation facilities are registered as a Generation Owner and a Generation Operator. Criteria c) also causes proposed exclusion E-3 not to be sufficient to ensure that all industrial distribution facilities are excluded where the owner and operator of the on-site electricity generation facilities are not registered as a Generation Owner and a Generation Operator because only a small amount of electricity is ever exported from the on-site electricity generation facilities to the transmission grid. Criteria c), entitled "Power flows only into the LDN", states: "The generation within the LDN shall not exceed the electric Demand within the LDN."</p> <p>Criteria c) also makes no sense with respect to internal lines at such industrial sites even where the owner and operator of the on-site electricity generation facilities are registered as a Generation Owner and a Generation Operator.</p>
<p><b>Response:</b> The SDT made a number of clarifying changes to the draft BES definition that it believes provides a greater distinction between transmission and distribution facilities. The SDT also included in the definition a statement that excludes facilities used in local distribution of electric energy. The SDT believes that revised Exclusions E1 (radial exclusion) and E3 (Local Network exclusion) provide appropriate opportunity to exclude distribution facilities above 100 kV. In addition, the SDT made extensive changes to Exclusion E3 to address your concerns and those of others.</p>		

Organization	Yes or No	Question 11 Comment
		<p><b>Bulk Electric System (BES):</b> <u>Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</u></p> <p><b>E3 - Local Distribution Networks (LDN):</b> <u>A Groups of contiguous transmission Elements operated at or above 100 kV but less than 300 kV that distribute power to Load rather than transfer bulk power across the interconnected system. LDN's emanate from multiple points of connection at 100 kV or higher are connected to the Bulk Electric System (BES) at more than one location solely to improve the level of service to retail customer Load and not to accommodate bulk power transfer across the interconnected system.</u> The LDN is characterized by all of the following:</p> <p><u>Separable by automatic fault interrupting devices: Wherever connected to the BES, the LDN must be connected through automatic fault interrupting devices;</u></p> <p><b>E3a.</b> <u>Limits on connected generation: Neither the LDN, nor and its underlying Elements do not include generation resources identified in Inclusion 13, and do not have an aggregate capacity of non-retail generation greater than 75 MVA (gross nameplate rating) (in aggregate), includes more than 75 MVA generation;</u></p> <p><b>E3b.</b> <u>Power flows only into the Local Distribution NetworkLN: The generation within the LDN shall not exceed the electric Demand within the LDN. The LN does not transfer energy originating outside the LN for delivery through the LN; and</u></p> <p><u>Not used to transfer bulk power: The LDN is not used to transfer energy originating outside the LDN for delivery through the LDN; and</u></p> <p><b>E3c.</b> <u>Not part of a Flowgate or transfer Path: The LDN does not contain a monitored Facility of a permanent flowgate in the Eastern Interconnection, a major transfer path within the Western Interconnection as defined by the Regional Entity, or a comparable monitored Facility in the Quebec Interconnection, and is not a monitored Facility included in an Interconnection Reliability Operating Limit (IROL).</u></p>
Southwest Power Pool	No	See response to question 1 - SPP does not necessarily disagree with the characterization of excluded distribution facilities, but believes that issue should be addressed in the concurrent BES exemption proceeding for the reasons described in question 1. SPP reserves its rights to comment on the criteria for exclusion/inclusion in that proceeding.
		<p><b>Response:</b> The SDT believes it is appropriate to exclude Facilities used in the local distribution of electric energy in the BES definition.</p> <p><b>Bulk Electric System (BES):</b> <u>Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. Organization	Yes or No	Question 11 Comment
Quebec Interconnection, and is not a monitored Facility included in an Interconnection Reliability Operating Limit (IROL).		
SERC OC Standards Review Group	Yes	Exception E4 potentially does have issues - see our response to Question 10.
<b>Response:</b> See response to Q10.		
Colorado Springs Utilities	Yes	Please refer to comments on question 9 - Exclusion 3
<b>Response:</b> See response to Q9.		
Alliant Energy	Yes	In general we believe that the bright line has been created. There should however be one additional exclusion - Distribution Protection Systems designed specifically to protect Distribution System assets should not be considered part of the BES, even if they open an element of the BES (ie; Distribution Breaker Failure Relaying), as long as the action is to protect the Distribution System and not the BES.
<b>Response:</b> The SDT does not see a need to add the exclusion you requested since distribution protection systems that protect distribution systems are not determined to be BES under the draft BES definition. No change made.		
Illinois Municipal Electric Agency	Yes	Please see comments under Question 13.
<b>Response:</b> See response to Q13.		
Sacramento Municipal Utility District (SMUD)	Yes	SMUD does agree that the differentiation is established between the transmission & distribution systems. Although there is concern that the general “Bright-line” is not definitive and could afford additional value through incorporating clarifying language.
Sierra Pacific Power Co d/b/a NV Energy	Yes	Through the radial exclusion and the LDN exclusion (E1 and E3), the definition has made a delineation between distribution and bulk transmission. In this exclusion language, the definition as proposed addresses the quantifiable parameters from the FERC 7-factor transmission test.
American Transmission Company, LLC	Yes	ATC agrees that the revised bright-line core definition and associated inclusion and exclusion criteria excludes distribution, however, recognizes that there are protection elements that may be owned by distribution which may trip a BES Element. (Covered by NERC Standard PRC-005)

**Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17**

Organization	Yes or No	Question 11 Comment
PUD No. 2 of Grant County, Washington	Yes	Grant supports the concepts as presented in the draft. Exclusion of facilities from the BES does not mean that owners of those facilities are entirely exempt from reliability standards. The statutes provide that “users” of the BES can be subject to reliability regulation. Hence, even where an entity does not own BES assets, it could be required to, for example, provide necessary information to the applicable Reliability Coordinator and to participate in the regional Under-Frequency Load Shedding program by setting the UFLS relays in its Local Distribution Network at the appropriate settings. We note that participants in the WECC BESDTF Task Force generally agreed that appropriate information should be provided by non-BES entities, although there was considerable concern related to ensuring that the provision of information was not unduly burdensome.
Glacier Electric Cooperative	Yes	I do believe that the language in its plain sense does exclude local distribution systems, but I do see the possibility of differing interpretations of the language across the regions again. Perhaps adding some example system diagrams showing what would and would not be included in the BES would help alleviate any possible ambiguity and increase consistency across the regions.
PacifiCorp	Yes	PacifiCorp understands that no single bright line can accommodate all the various scenarios of local distribution. The proposed definition appears to capture a high percentage of LDNs. Additional LDNs can be addressed through the exemption process. Also, please refer to additional comments in question 13 regarding a contiguous BES.
Santee Cooper	Yes	The commission should remain open to future modifications of the bright-line core definition and specific inclusion and exclusions.

<p><b>Response:</b> Thank you for your support. Several stakeholders made suggestions for clarifying changes to the draft BES definition that were adopted to provide a greater distinction between transmission and distribution facilities. Please see the revised definition.</p>		

**12. Are you aware of any conflicts between the proposed definition and any regulatory function, rule order, tariff, rate schedule, legislative requirement or agreement, or jurisdictional issue? If so, please identify them here and provide suggested language changes that may clarify the issue.**

**Summary Consideration:** The task of the SDT is to put forward a 100 kV bright-line for the BES definition. The SDT has modified the definition and distribution facilities are now specifically excluded from the BES. However, the SDT acknowledges that there may still be regulatory conflicts as many of the commenters have voiced. The definition is neither intended to nor can it supersede any regulatory orders and/or rulings by relevant Federal, State, or Provincial Authorities. Although the SDT can not resolve all regulatory conflicts, it believes that a) proposed revisions to the definition should address many of these concerns; and b) remaining issues may be effectively addressed by the Rules of Procedure exception procedure currently under development.

Changes to the definition due to industry comments are as follows:

**Bulk Electric System (BES):** ~~Unless modified by the lists shown below, A~~ all Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources ~~as described below, and Reactive Power resources~~ connected at 100 kV or higher ~~unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.~~

**I32 -** ~~Generating units resource(s) located at a single site with aggregate capacity greater than 75 MVA (with gross individual or gross aggregate nameplate rating) per the ERO Statement of Compliance Registry Criteria~~ including the generator terminals through the high-side of the step-up GSU transformer(s), connected through a common bus operated ~~at a voltage of 100 kV or above.~~

**I43 -** ~~Blackstart Resources and the designated blackstart Cranking Paths~~ identified in the Transmission Operator's restoration plan ~~regardless of voltage.~~

**E1 -** ~~Any radial systems: which is described as connected~~ A group of contiguous transmission Elements emanating from a single point of connection of 100 kV or higher from a single Transmission source originating with an automatic interruption device ~~and:~~

**Note -** Elements may be included or excluded on a case-by-case basis through the Rules of Procedure exception process.

Organization	Yes or No	Question 12 Comment
AltaLink	Yes	
East Kentucky Power Cooperative, Inc.	Yes	

Organization	Yes or No	Question 12 Comment
<p><u>Response:</u> Without any details the SDT is unable to respond.</p>		
BPA	Yes	<p>The Low Voltage Ride Through standard is a U.S. industry standard via FERC Order 611A and applies to wind generation without regard to size. The I2 definition appears to be in conflict with the LVRT set by Order 611A. Request NERC clarification including when it will be issuing a LVRT reliability standard.</p> <p>DGF supports Rebecca Berdahl Comment 2, as discussed below.</p>
<p><u>Response:</u> Inclusion I2 has been modified by the SDT in the revised BES definition to address your concerns and those of others.</p>		
<p><del>I 32 - Generating units/resource(s) located at a single site with aggregate capacity greater than 75 MVA (with gross individual or gross aggregate nameplate rating) per the ERO Statement of Compliance Registry Criteria</del> including the generator terminals through the <del>high-side of the step-up GSU transformer(s)</del>, connected <del>through a common bus operated</del> at a voltage of 100 kV or above.</p>		
Northeast Power Coordinating Council	Yes	<p>The proposed definition will have a direct impact on entities not under FERC jurisdiction, and may be in conflict with regulatory requirements with which those entities must comply.</p>
Dominion	Yes	<p>The inclusion of an element or facility that is not integral to the reliable operation of the integrated bulk power system is in conflict with the intent of Section 215 of the FPA . This is especially true for radial facilities, whether used to connect generators or load to the bulk power system.</p>
Michigan Public Service Commission(MPSC)	Yes	<p>MPSC Staff Comments: The proposed BES definition creates friction with Order 888's seven-factor technical-functional test as implemented by state regulatory agencies. The resulting inconsistent treatment is likely to result in challenges by entities with FERC-defined distribution assets being now considered as transmission assets as inconsistent with the FPA. FERC's Order 888 discusses the two components of an unbundled transaction in interstate commerce has "for jurisdictional purposes -- a transmission component and a local distribution component." p 439 The Order also states that the Commission "will defer to recommendations by state regulatory authorities concerning where to draw the jurisdictional line under FERC's technical test for local distribution facilities" p 437, also known as the seven-factor technical-functional test. This test was applied by Michigan utilities, filed with the Michigan Public Service Commission in contested case-specific dockets, and after deliberation approved. These state-approved jurisdictional bright-line determinations were subsequently filed with and approved by FERC.</p>
Hydro-Quebec TransEnergie	Yes	<p>There appears to be a conflict between the proposed definition and the regulatory framework applicable in Quebec or at least there are some important differences between both.NERC's proposed definition of Bulk Electric System ("BES") is made in response to FERC's Order 743. FERC is looking to remove regional discretion, and in some cases to make sure BES includes the most important national load centers.As for</p>

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 12 Comment
		<p>HQT's System, the BES definition shall meet the expectations of Quebec's regulator, the Régie de l'Énergie du Québec, (Quebec Energy Board) which has the responsibility to ensure that electric power transmission in Québec is carried out according to the reliability standards it adopts. In a recent order (D-2011-068), the Régie de l'Énergie du Québec has recognized several level of application for the Reliability Standards in Québec. It stated specifically that most reliability standards in Québec shall be applied to the Main Transmission System (MTS). One other level of application recognised by this decision is the NPCC Bulk Power System (BPS) to which the standards related to the protection system (PRC-004-1 and PRC-005-1) and those related to the design of the transmission system (TPL 001-0 to TPL-004-0) will be applicable. The Main Transmission System definition is somewhat different than the Bulk Electric System definition. The Main Transmission System includes elements that impact the reliability of the grid, supply-demand balance and interchanges. It can be described as follows :The transmission system comprised of equipments and lines generally carrying large quantities of energy and of generating facilities of 50 MVA or more controlling reliability parameters:</p> <ul style="list-style-type: none"> <li>o Generation/load balancing</li> <li>o Frequency control</li> <li>o Level of operating reserves</li> <li>o Voltage control of the system and tie lines</li> <li>o Power flows within operating limits</li> <li>o Coordination and monitoring of interchange transactions</li> <li>o Monitoring of special protection systems</li> <li>o System restoration</li> </ul> <p>Therefore, it will be necessary to accommodate NERC's proposed definition of BES or the exception process with the Québec situation where Entities are under a different jurisdiction. These differences include more than one level of application for the reliability standards, the Main Transmission System definition being the main one to which most reliability standards apply.</p>
Hydro One Networks Inc		<p>See earlier comments and suggestions. NERC's revised definition will have a direct impact on many entities across North America and could also be in conflict with regulatory requirements, Codes, and Licenses, which non FERC jurisdictional must comply. It would be hard if not impossible to identify the conflicts. For example: in one of the the provincial energy acts, NERC Standards maycan only apply to generation over 50 MVA which will cause one or more of the requirements to be in conflict and /or what constitutes distribution and what is not considered transmission (such as connection facility to a load or generation and owned by the proponent). However, we agree to establish a 100kV BES bright-line definition and we believe that the best venue to address avoiding compliance conflicts is through the exception criteria and the exception procedure. The benefits of such an approach are:</p> <ul style="list-style-type: none"> <li>o Establishment of a continent wide bright line definition</li> <li>o Avoidance of regulatory conflicts and legal complexities</li> <li>o Assurance of the reliability of the interconnected transmission network</li> </ul>
Public Utility District No. 1 of	Yes	<p>As noted in our responses to Question 1 and Question 11, we believe the SDT proposal is potentially in conflict with the limitations of the Federal Power Act, and in particular the statutory exclusion for facilities used</p>

**Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17**

Organization	Yes or No	Question 12 Comment
Snohomish County, Washington		in the local distribution of electric energy. Unless the SDT adopts some approach other than a core definition with inclusions and exclusions based on brightline thresholds, the SDT's approach can meet the statutory requirements only if the Exception process currently under development results in facilities that are not properly classified as BES being exempted from regulation as BES facilities.

Chelan PUD – CHPD Kootenai Electric Cooperative Public Utility District No. 1 of Franklin County Midstate Electric Cooperative Northwest Requirements Utilities Big Bend Electric Cooperative, Inc		the Exception process currently under development results in facilities that are not properly classified as BES being exempted from regulation as BES facilities.
PUD No. 2 of Grant County, Washington	Yes	The Exceptions process is a necessary part of making this proposal compliant with the Federal Power Act. The SDT's approach can meet the statutory requirements only if the Exception process currently under development results in facilities that are not properly classified as BES being exempted from regulation as BES facilities.
ExxonMobil Research and Engineering	Yes	Section 215 of the Federal Power Act excludes facilities used in the local distribution of electric energy without any qualifications of the type of local distribution facility.
FortisBC	Yes	See earlier comments and suggestions. NERC's revised definition will have a direct impact on many entities across North America and could also be in conflict with regulatory requirements, Codes, and Licenses, which non FERC jurisdictional must comply. It would be impossible to identify each of these conflicts. For example: in one of the energy acts, NERC Standards can only apply to generation over 50 MVA which will cause one or more of the requirements to be in conflict and /or what constitutes distribution and what is not considered transmission (such as connection facility to a load or generation and owned by the proponent). However, we agree to establish a 100kV BES bright-line definition and we believe that the best venue to address avoiding compliance conflicts is through the exception criteria and the exception process. The benefits of such an approach are: <ul style="list-style-type: none"> <li>o Establishment of a continent wide bright line definition</li> <li>o Avoidance of regulatory conflicts and legal complexities</li> <li>o Assurance of the reliability of the interconnected transmission network</li> </ul>
Consumers Energy Company	Yes	The proposed definition creates a tension between FERC Order 888 and the resulting 7-factor test as applied for tariff purposes, and the registry criteria for registration of Transmission Owners and Transmission Operators. Entities with assets defined by FERC as Distribution might challenge any rules that treat Distribution assets as Transmission as not being consistent with the Federal Power Act of 2005.

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 12 Comment
Exelon	Yes	To the extent facilities used in local distribution of electric energy may be included in the definition of BES, the proposed definition is in conflict with the Federal Power Act.
Springfield Utility Board	Yes	The exceptions process is a necessary part of making this proposal compliant with the Federal Power Act. As noted in responses to Questions 1 and 11, SUB believes the basic SDT proposal is potentially in conflict with the limitations of the Federal Power Act, and in particular the statutory exclusion for facilities used in the local distribution of electric energy. The SDT's approach can meet the statutory requirements only if the Exception process currently under development results in facilities that are not properly classified as BES being exempted from regulation as BES facilities.
New York State Dept of Public Service	Yes	As expressed in comments under question 1, we believe that use of a 100 kV brightline definition is an overreach of authority and that any definition must respect the limitations itemized in FPA 215. The FPA recognizes that only a subset of the electric system facilities have the capacity to impact multi-state portions of the electric system and rise to the level of federal attention. As a practical matter, however, the electric system is a continuous machine and efforts to maintain reliability on both the transmission and local distribution portions of the electric system must be compatible. That is the key role that the regional entities play and that role should be maintained and respected by NERC efforts. The time and effort it takes to draft standards to address issues on the bulk system is directly attributable to the many different options to design and operate transmission facilities, and options to ensure reliability are different for each design and mode of operation. Multiply that a hundred fold to the different approaches there are to design, operate and to ensure reliability on the local distribution system. Attempts at the federal level to design uniform standards to apply at lower and lower levels of the system are doomed to failure given the nuances of each local system. These attempts will only lead to needless complications and the actual undermining of the reliability on the local distribution system. NERC staff comments seeking to sweep into NERC standards behind the meter generation, meters and relays located deep within the distribution system, etc. and then insist that the bulk system be contiguous is a phenomenal overreach and an intrusion on the design and functioning of the distribution system which will a) complicate efforts to maintain a reliable distribution system; and 2) will needlessly incur costs on ratepayers. NERC needs to stay focused on the authorities extended to it in the FPA. Leave it to the regions to interface locally with utilities, state authorities and other stakeholders to shape seamless reliability protocols that will benefit us all. The question asks if there are orders that relate to this effort. In 1997, the New York Public Service Commission held a proceeding Case No. 97-E-0251 that supplemented the FERC Seven Factor Test with three additional factors to be used in New York to distinguish between transmission and local distribution. This order can be found at the following link: <a href="http://documents.dps.state.ny.us/public/Common/ViewDoc.aspx?DocRefId={3C7602E0-62E0-4831-82B6-8C34A72934F4}">http://documents.dps.state.ny.us/public/Common/ViewDoc.aspx?DocRefId={3C7602E0-62E0-4831-82B6-8C34A72934F4}</a>

**Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17**

Organization	Yes or No	Question 12 Comment
Midstate Electric CooperativePublic Utilities Commission of Ohio	Yes	See concerns above with exceeding authority under the Federal Power Act Section 215. State Utility Commissions are charged with assuring safe, reliable service to their customers. We are in a much better situated position than FERC or NERC to provide any necessary regulation and oversight of the local distribution system.
The Dow Chemical Company	Yes	Comments: Section 215 of the Federal Power Act denies FERC jurisdiction over facilities used in the local distribution of electric energy. FERC has recognized that since facilities used in the local distribution of electric energy “are exempted from the Bulk-Power System, they also are excluded from the bulk electric system.” Section 215 of the Federal Power Act does not qualify the exclusion from FERC jurisdiction of “facilities used in the local distribution of electric energy.” For example, Section 215 does not state that:“i,§ The term “bulk power system” “does not include facilities used in the local distribution of electric energy [unless needed for reliability purposes];” or i,§ The term “bulk power system” “does not include facilities [with automatic interruption devices] used in the local distribution of electric energy.”Any definition of the bulk electric system that does not exclude all “facilities used in the local distribution of electric energy” is unlawful.Further, the definition of the bulk electric system must recognize that Section 215 of the Federal Power Act does not allow the potential reliability impact of a facility to determine whether the facility is local distribution or transmission. By excluding all facilities used in the local distribution of electric energy from the definition of the Bulk-Power System in Section 215, Congress recognized that while facilities used in the local distribution of electric energy may be part of the Bulk-Power System, they are, nonetheless, not FERC jurisdictional. Thus, “facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof)” that are used in the local distribution of electric energy are not FERC jurisdictional regardless of the potential reliability impact of the facilities.
Central Lincoln	Yes	Improper classification of local distribution facilities, even if only for the duration of the exceptions process; puts these facilities under the regulatory jurisdiction of NERC contrary to the Federal Power Act when they should be under the exclusive jurisdiction of state utility commissions or local utility boards.
Cowlitz County PUD	Yes	The Exceptions process is a necessary part of making this proposal compliant with the Federal Power Act. As noted in our responses to Question 1 and Question 11, we believe the basic SDT proposal is potentially in conflict with the limitations of the Federal Power Act, and in particular the statutory exclusion for facilities used in the local distribution of electric energy. The SDT’s approach can meet the statutory requirements only if the Exception process currently under development results in facilities that are not properly classified as BES being exempted from regulation as BES facilities. Cowlitz understands the difficulty in demonstrating what is and is not distribution to FERC due to the vague statute language. Cowlitz will work to help provide technical arguments which will buttress the BES definition in the future.

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 12 Comment
<p><b>Response:</b> The definition is neither intended to nor can it supersede any regulatory orders and/or rulings by relevant Federal, State, or Provincial Authorities. Although the SDT can not resolve all regulatory conflicts, it believes that a) proposed revisions to the definition should address many of these concerns; and b) remaining issues may be effectively addressed by the Rules of Procedure exception procedure currently under development. Specifically, the SDT added a sentence to the core definition to address concerns about local distribution.</p> <p><b>Bulk Electric System (BES):</b> <del>Unless modified by the lists shown below, All</del> Transmission Elements operated at 100 kV or higher, <del>and</del> Real Power <del>and</del> Reactive Power resources <del>as described below, and Reactive Power resources</del> connected at 100 kV or higher <del>unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</del></p>		
SPP Standards Review Group	Yes	See our responses to Questions 5 and 11 regarding the issue of distribution facilities and Cranking Paths.
<p><b>Response:</b> See responses to Q5 and Q11.</p>		
Idaho Falls Power	Yes	It is unclear how the reliability standards will be applied to registered entities should some assets be deemed not to be a part of the BES. As an example; will a an LSE with >25MW of load connected at 161kv be responsible for relay maintenance under PRC-005-1 if the 161 kv is exempted as a local distribution network? Clarification of this issue may be beyond the scope of the BES definition effort, however guidance in this area should accompany this effort.
<p><b>Response:</b> The application of Reliability Standards is not based solely on registration or an Element being classified as BES or not. There are several standards that are currently mandatory for Elements that are non-BES and they will continue to apply if those Elements are considered necessary for the operation of BES, such as UFLS. No change made.</p>		
Alabama Public Service Commission	Yes	See comments in response to Question 11 above.
<p><b>Response:</b> See response to Q11.</p>		
Western Montana Electric Generating and Transmission Cooperative	Yes	The Exceptions process is a necessary part of making this proposal compliant with the Federal Power Act. As noted in our responses to Question 1 and Question 11, we believe the basic SDT proposal is potentially in conflict with the limitations of the Federal Power Act, and in particular the statutory exclusion for facilities used in the local distribution of electric energy. The SDT's approach can meet the statutory requirements only if the Exception process currently under development results in facilities that are not properly classified as BES being exempted from regulation as BES facilities.

Organization	Yes or No	Question 12 Comment
Electricity Consumers Resource Council (ELCON)	Yes	See response to question 11 above. The definition of “local distribution” should be as defined and practiced in each state (US only) under state laws and regulations, and similarly by the Canadian provincial governments.
MRO's NERC Standards Review Forum	Yes	Within the Commission’s definition of BPS, it is clearly stated that BPS does not include facilities used in the local distribution of electrical energy.
<p><b>Response:</b> The SDT made a number of clarifying changes to the draft BES definition that it believes provides a greater distinction between transmission and distribution facilities. The SDT also included in the definition a statement that excludes facilities used in local distribution of electric energy</p> <p><b>Bulk Electric System (BES):</b> <del>Unless modified by the lists shown below, All</del> Transmission Elements operated at 100 kV or higher, <del>and</del> Real Power <del>and</del> Reactive Power resources <del>as described below, and Reactive Power resources</del> connected at 100 kV or higher <del>unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</del></p>		
PacifiCorp	Yes	<p>The SDT proposal combined with the ROP may be in conflict with Section 215 of the Federal Power Act (“FPA”) which excludes “facilities used in the local distribution of electric energy” from the definition of “bulk-power system.”</p> <p>As identified in other responses, without a technical reason for setting the generation limit to 20 MVA and even 75 MVA and/or requiring a contiguous BES to include such generators may be over-inclusive and by default require several elements which are not required for the reliable operation of the BES to be included in the BES definition.</p>
<p><b>Response:</b> The definition is neither intended to nor can it supersede any regulatory orders and/or rulings by relevant Federal, State, or Provincial Authorities. Although the SDT can not resolve all regulatory conflicts, it believes that a) proposed revisions to the definition should address many of these concerns; and b) remaining issues may be effectively addressed by the Rules of Procedure exception procedure currently under development.</p> <p>The SDT did not adopt a “contiguous” BES. After consulting with the NERC Board of Trustees and the NERC Standards Committee, the SDT has decided to forgo any attempt at changing generation thresholds at this time. There simply isn’t enough time or resources to do that topic justice with the mandated schedule. Therefore, the primary focus of the SDT efforts will be to address the directives in Orders 743 and 743a. However, this does not mean that the other issues will be dropped. Both the NERC Board of Trustees and the NERC Standards Committee have endorsed the idea that the Project 2010-17 SDT take a phased approach to this project with a new Standards Authorization Request (SAR) to address generation thresholds as well as several other issues that have arisen from SDT deliberations.</p> <p><b>32 -</b> <del>Generating units/resource(s) located at a single site with aggregate capacity greater than 75 MVA (with gross individual or gross aggregate nameplate rating) per the ERO Statement of Compliance Registry Criteria</del> including the generator terminals through the <del>high-side of the step-up GSU transformer(s),</del> connected <del>through a common bus operated</del> at a voltage of 100 kV or above.</p>		

Organization	Yes or No	Question 12 Comment
Grand Haven Board of Light and Power	Yes	This current definition does not comply with FERC Order No. 743 (and 743a) by not addressing the exclusion of a single automatic interrupting device that serves a radial, load serving system.
<p><b>Response:</b> The SDT revised Exclusion E1 to address your concern and those of others.</p> <p><del>E1 - Any radial systems: which is described as connected- A group of contiguous transmission Elements emanating from a single point of connection of 100 kV or higher from a single Transmission source originating with an automatic interruption device and:</del></p>		
National Grid	Yes	There could be some conflicts with the ISO-NE Pool Transmission Facility (PTF) definition. If something is considered non-PTF, but is considered BES with this new definition, it could lead to confusion about which criteria should be applied to these entities and potentially which tariff (non-PTF or PTF) is truly the correct tariff. We believe adding more clarity as previously mentioned in the other questions to the definition and excluding I4 and clarifying E1 will minimize these issues.
<p><b>Response:</b> The task of SDT is to put forward a 100 kV bright-line definition for BES. The SDT acknowledges that there may be regulatory conflicts but believes that many of these concerns may be addressed by the revised BES definition and exception procedure currently under development. SDT has made some changes to Inclusion I4 (now Inclusion I3) and Exclusion E1 that may address your concerns.</p> <p><del>I43 - Blackstart Resources and the designated blackstart Cranking Paths identified in the Transmission Operator's restoration plan regardless of voltage.</del></p> <p><del>E1 - Any radial systems: which is described as connected- A group of contiguous transmission Elements emanating from a single point of connection of 100 kV or higher from a single Transmission source originating with an automatic interruption device and:</del></p>		
Electric Reliability Council of Texas, Inc.	Yes	See response to question 1 - ERCOT ISO believes defining BES in terms of the relevant exclusions may be contrary to FERC's suggested approach in 743 and 743-A. While FERC did not mandate a particular approach, and gave the ERO the opportunity to propose an alternative to its suggested approach, it stated that any alternative must be equal to or greater than its suggested approach in terms of remedying the identified flaws associated with the current definition. Part of the remedy envisioned by FERC included the removal of subjectivity in defining BES and the ability of the ERO and FERC to review any proposed exemptions from the bright line definition. Although the exclusions strive to apply objective criteria, it is arguable that any such circumstances may not be that clear and may require some level of subjective judgment as to whether elements deemed to be distribution according to the exclusion criteria actually are distribution, as opposed to transmission. In addition, FERC expressly stated that it reserved the right to make that determination in the first instance. This approach takes that away from FERC.
Southwest Power Pool	Yes	See SPP's response to question 1 - SPP believes defining BES in terms of the relevant exclusions may be contrary to FERC's suggested approach in 743 and 743-A. While FERC did not mandate a particular

Organization	Yes or No	Question 12 Comment
		<p>approach, and gave the ERO the opportunity to propose an alternative to its suggested approach, it stated that any alternative must be equal to or greater than its suggested approach in terms of remedying the identified flaws associated with the current definition. Part of the remedy envisioned by FERC included the removal of subjectivity in defining BES and the ability of the ERO and FERC to review any proposed exemptions from the bright line definition. Although the exclusions strive to apply objective criteria, it is arguable that any such circumstances may not be that clear and may require some level of subjective judgment as to whether elements deemed to be distribution according to the exclusion criteria actually are distribution, as opposed to transmission. In addition, FERC expressly stated that it reserved the right to make that determination in the first instance. This approach takes that away from FERC.</p>
Alberta Electric System Operator	Yes	<p>Comments: Alberta’s legislation enables reliability standards, but prevents the AESO from developing rules related to reliability standards. The AESO therefore would like to see retention of the following clause from the NERC “Statement of Compliance Registry Criteria (revision 5) included in the list of inclusions as well as identifying the authority that determines what generators are material to reliability:III.c.4 Any generator, regardless of size, that is material to the reliability of the bulk power system. The wording should reflect that, for example, in the case of Alberta, that the AESO has the authority to make this determination.</p>
<p><b>Response:</b> The SDT made a number of clarifying changes to the draft BES definition that it believes provides a greater distinction between transmission and distribution facilities. The SDT also included in the definition a statement that excludes facilities used in local distribution of electric energy. The SDT believes that revised Exclusions E1 (radial exclusion) and E3 (Local Network exclusion) provide appropriate opportunity to exclude distribution facilities above 100 kV. The definition is neither intended to nor can it supersede any regulatory orders and/or rulings by relevant Federal, State, or Provincial Authorities. Although the SDT can not resolve all regulatory conflicts, it believes that a) proposed revisions to the definition should address many of these concerns; and b) remaining issues may be effectively addressed by the Rules of Procedure exception procedure currently under development.</p> <p><b>Bulk Electric System (BES):</b> <u>Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</u></p>		
Occidental Energy Ventures Corp. (answers include all various Oxy affiliates)	Yes	<p>The proposed definition conflicts with Section 215 of the FPA and case law because it ignores years of precedent regarding what constitutes “facilities used in local distribution” and defines the BES in such a way as to possibly cover local distribution facilities as well as transmission facilities. Specifically, FERC has jurisdiction over “all users, owners and operators of the bulk-power system” under Section 215 of the FPA (16 U.S.C. Â§ 824o(b)(1)). The bulk-power system is defined as:“(A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy” (Id. at Â§ 824o(a)(1)).By the plain language of Section 215 of the FPA, FERC’s jurisdiction over the Bulk Power System cannot include any “facilities used in</p>

Organization	Yes or No	Question 12 Comment
		<p>the local distribution of electric energy.” FERC has recognized that “[s]ince such facilities are exempted from the Bulk-Power System, they also are excluded from the bulk electric system” (Order No. 743-A at P 25). Congress specifically recognized that while facilities used in the local distribution of electric energy may be part of the Bulk-Power System, they are not FERC jurisdictional. Thus, “facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof)” that are used in the local distribution of electric energy are not jurisdictional regardless of the potential reliability impact of the facilities. The proposed definition of the BES would rewrite Section 215 of the FPA to exclude only “facilities used in local distribution of electric energy [unless needed for reliability purposes].” As the DC Court of Appeals stated in <i>Detroit Edison Co. v. FERC</i>: “[s]uch an interpretation would eviscerate state jurisdiction over numerous local facilities, in direct contravention of Congress’ intent” (<i>Detroit Edison Co. v. FERC</i>, 334 F.3d 48, 54 (U.S. App. D.C. 2003) (citation omitted)). In <i>Detroit Edison Co. v. FERC</i>, the DC Court of Appeals rejected FERC’s proposed definition of a “FERC-jurisdictional distribution facility” as any distribution facility that is not “used exclusively to provide service to unbundled retail customers” (Id.). The Court stated: “FERC’s position contradicts the plain language of the FPA,” and further that “FERC would rewrite the statute to exclude only ‘facilities used exclusively in local distribution’” (Id.). The exclusion of facilities used in the local distribution of electric energy from the definition of the BES does not mean that NERC lacks the ability to maintain the reliability of the BES. For example, if NERC determined that a retail customer’s self-provided “hard-tapped” radial line that is located behind the retail delivery point created a reliability issue, NERC could require that the transmission facilities be equipped with automatic fault-interruption devices. NERC could not, however, define the BES to include such local distribution facilities, which is the result of the proposed bright-line core definition and specific inclusions and exclusions. While FERC “granted NERC discretion” in developing the revised definition of the BES because FERC wanted to give NERC “the greatest amount of flexibility to utilize its technical expertise” (Order No. 743-A at PP 0-71), NERC’s discretion is not unbounded. Moreover, while FERC stated that it “will evaluate whether the [BES definition] proposal results in any conflicts with the statutory language” (Id. at P 72), it is imperative that NERC work within the statutory limitations of Section 215 of the FPA as to prevent submitting a proposal to FERC that is fundamentally unlawful. It would be a colossal waste of government and industry resources to develop and advance a definition that cannot withstand basic legal review. As provided above, the following are suggested language changes that may clarify the issue:</p> <p>Exclusion E1 - Any radial system which is described as connected from a single Transmission source [ ] and: a) Only serving Load. [ ] Or, b) Only including generation resources not identified in Inclusions I2, I3, I4 and I5. Or, c) Is a combination of items (a.) and (b.) where the radial system serves Load and includes generation resources not identified in Inclusions I2, I3, I4 and I5.</p> <p>Exclusion E3 - [All facilities used in the distribution of electric energy] (“[L]ocal [D]istribution [N]etworks, [“ or “[LDNs[“]): Groups of Elements operated above 100 kV that distribute power to Load rather than transfer bulk power across the interconnected System. LDN[s] are [normally] connected to the Bulk Electric System (BES) at more than one location solely to improve the level of service to retail customer Load. The LDN is characterized by all of the following: a) [ ] b) Limits on connected generation: [Generally], neither</p>

**Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17**

Organization	Yes or No	Question 12 Comment
		<p>the LDN, nor its underlying Elements (in aggregate), includes more than 75 MVA generation;c) Power flows only into the LDN: The generation within the LDN [normally does] [ ] not exceed the electric Demand within the LDN;d) Not used to transfer bulk power: The LDN is [generally] not used to transfer energy originating outside the LDN for delivery through the LDN; ande) Not part of a Flowgate or transfer path: The LDN normally does not contain a monitored Facility of a permanent flowgate in the Eastern Interconnection, a major transfer path within the Western Interconnection as defined by the Regional Entity, or a comparable monitored Facility in the Quebec Interconnection, and is not a monitored Facility included in an Interconnection Reliability Operating Limit (IROL).Exclusion E4 - Transmission Elements, from a single Transmission source connected at a voltage of 100 kV or greater [ ] whose connection to the BES is solely through this single Transmission source, and without interconnected generation as recognized in the BES Designation Inclusion Items I2, I3, I4, or I5. [ ]</p>
<p><b>Response:</b> The SDT made a number of clarifying changes to the draft BES definition that it believes provides a greater distinction between transmission and distribution facilities. The SDT also included in the definition a statement that excludes facilities used in local distribution of electric energy. The SDT believes that revised Exclusions E1 (radial exclusion) and E3 (Local Network exclusion) provide appropriate opportunity to exclude distribution facilities above 100 kV.</p>		
Muscatine Power and Water	Yes	<p>Within FERC’s definition of Bulk Power System, it is plainly stated that BPS does not include facilities used in the local distribution of electrical energy. Does this support or contradict the SDT’s concept of Local Distribution Network?</p>
<p><b>Response:</b> The LDN (now referred to as LN) is a unique case due to the multiple connections to the BES and as such the SDT believes it deserves a specific exclusion but it supports the SDT’s concept.</p>		
Southern California Edison Company	Yes	<p>For participants in an ISO/RTO, such as the CAISO, the final BES Definition may change the party who will control system facilities, even if they are distribution or radial in nature, based on the amount or size of interconnected generation. Generally, within the CAISO, facilities that are included in the BES Definition are under CAISO’s direct control, while radial and distribution facilities are not.</p>
<p><b>Response:</b> Control of system facilities is not within the scope of the SDT and must be worked out locally.</p>		
Clark Public Utilities	Yes	<p>The BES Definition does not have any reference to the exception process being developed. Both the exclusion and inclusion sections of the BES Definition should have a reference to the process where “BES Definition included” Transmission Elements may be excluded and “BES Definition excluded” Transmission Elements may be included.</p>

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 12 Comment
<p><b>Response:</b> The reference to the exception process was inadvertently left off the posting.</p> <p><b>Note -</b> Elements may be included or excluded on a case-by-case basis through the Rules of Procedure exception process.</p>		
New England States Committee on Electricity	Yes	A possible conflict exists with respect to state renewable resource objectives. Please refer to number 4 above regarding renewable energy objectives, which includes state legislation regarding renewable portfolio standards.
<p><b>Response:</b> The task of SDT is to put forward a 100 kV bright-line definition for BES. The definition is neither intended to nor can it supersede any regulatory orders and/or rulings by relevant Federal, State, or Provincial Authorities. Although the SDT can not resolve all regulatory conflicts, it believes that a) proposed revisions to the definition should address many of these concerns; and b) remaining issues may be effectively addressed by the Rules of Procedure exception procedure currently under development.</p>		
PPL Energy Plus and PPL Generation	Yes	See comments in Question 13.
Edison Electric Institute		See comments to Question 13.
<p><b>Response:</b> See response to Q13.</p>		
Manitoba Hydro	Yes	Canadian Entities are not under FERC jurisdiction, so the revised BES Definition may not apply. A number of Canadian Entities have the BES defined within their provincial legislation. This may introduce differences and even contradictions between elements that are included in the BES according to provincial legislation and the NERC definition.
<p><b>Response:</b> The definition is neither intended to nor can it supersede any regulatory orders and/or rulings by relevant Federal, State, or Provincial Authorities. Although the SDT can not resolve all regulatory conflicts, it believes that a) proposed revisions to the definition should address many of these concerns; and b) remaining issues may be effectively addressed by the Rules of Procedure exception procedure currently under development. Regional difference (vs. regional discretion), under the purview of the ERO, is acceptable methodology that will be consistently applied as a result of the definition and exception process.</p>		
ISO New England, Inc.	Yes	The proposal to include all Blackstart units' cranking paths has the potential to roll into the BES facilities distribution level circuits. Inclusion of those circuits would appear to conflict with statutory exclusion of set out in Section 215(a)(1) of the Federal Power Act, which states that the term "bulk power system": "does not include facilities used in the local distribution of electric energy." Section 215 sets the limits on what may be included within the bulk electric system, and thus subject to regulation by the ERO and FERC under the

Organization	Yes or No	Question 12 Comment
		reliability standards regime.
<p><b>Response:</b> The SDT has eliminated Cranking Path from the definition.</p> <p><b>43</b> - Blackstart Resources <del>and the designated blackstart Cranking Paths</del> identified in the Transmission Operator’s restoration plan <del>regardless of voltage</del>.</p>		
Consolidated Edison Co. of NY, Inc.	Yes	As FERC stated in Order 743-A “... the Commission uses the term “exclusion” herein when discussing facilities expressly excluded by the statute (i.e., local distribution) and the term “exemption” when referring to the exemption process NERC will develop for use with facilities other than local distribution that may be exempted from compliance with the mandatory Reliability Standards for other reasons.” (Footnote 82)Thereby, the Commission clearly established its preferred terminology; “exclusion” for local distribution and “exemption” for exceptions allowed under the NERC designations and Exception Process. The BES Definition and Designations do not fully utilize this FERC wording convention.
<p><b>Response:</b> The SDT and the corresponding Rules of Procedure team have created a set of terminology that is consistent across the two projects and in line with what they believe is the intent of FERC. No change made.</p>		
Modern Electric Water Company	Yes	Exclusion E1 and WECC Compliance Bulletin #4 (April 15, 2011) conflict. We support the intent of E1 and have provided suggested language modifications to it in Question #7 herein.Link - <a href="http://compliance.wecc.biz/Documents/2%20-%20WECC%20-%20Compliance%20Bulletins/01.04%20-%20Compliance%20Bulletin%20-%2004%20Interpretation%20PRC-004,%20PRC-005%20-%20April%2015,%202011.pdf">http://compliance.wecc.biz/Documents/2%20-%20WECC%20-%20Compliance%20Bulletins/01.04%20-%20Compliance%20Bulletin%20-%2004%20Interpretation%20PRC-004,%20PRC-005%20-%20April%2015,%202011.pdf</a>
<p><b>Response:</b> Exclusion E1 has been modified under the revised BES definition to address your concerns and those of others.</p> <p><b>E1</b> - <del>Any radial systems: which is described as connected</del> <u>A group of contiguous transmission Elements emanating from a single point of connection of 100 kV or higher from a single Transmission source originating with an automatic interruption device</u> and:</p>		
American Municipal Power and Members	No	In Ohio, 50 MW is the threshold for siting. Although 20 MW has recently been the criteria for the BES, if there is no technical justification (a study of some kind) then we highly recommend raising the threshold for generators to 50 MVA for a single unit. In our experience, registered generators, even those that have had severe violations, have been routinely classified as not having an impact on the BES in the enforcement process. Due to this truth, we can not understand the justification for keeping such a low threshold. We suggest raising the threshold to 50 MVA for single units, unless a technical study justifies inclusion.
<p><b>Response:</b> After consulting with the NERC Board of Trustees and the NERC Standards Committee, the SDT has decided to forgo any attempt at changing generation thresholds at this time. There simply isn’t enough time or resources to do that topic justice with the mandated schedule. Therefore, the primary focus</p>

<p>of the SDT efforts will be to address the directives in Orders 743 and 743a. However, this does not mean that the other issues will be dropped. Both the NERC Board of Trustees and the NERC Standards Committee have endorsed the idea that the Project 2010-17 SDT take a phased approach to this project with a new Standards Authorization Request (SAR) to address generation thresholds as well as several other issues that have arisen from SDT deliberations.</p> <p><del>32 - Generating units/resource(s) located at a single site with aggregate capacity greater than 75 MVA (with gross individual or gross aggregate nameplate rating) per the ERO Statement of Compliance Registry Criteria</del> including the generator terminals through the <del>high-side of the step-up_GSUtransformer(s)</del>, connected <del>through a common bus operated</del> at a voltage of 100 kV or above.</p>		
Tacoma Power		Tacoma Power is not aware of any conflicts at this time.
Independent Electricity System Operator	No	At this point, we are not aware of conflicts for our own jurisdiction. However, NERC must exercise caution while developing the exception criteria and the associated processes as these may result in jurisdictional issues between state/provincial and federal entities. We repeat our earlier point that the BES definition and TPC must be developed and approved simultaneously to provide assurances that mechanisms are in place to exclude those Facilities from BES classification that are not impactive on the BES.
BGE and on behalf of Constellation NewEnergy, Constellation Commodities Group and Constellation Control and Dispatch	No	We are not currently aware of any conflict, but have not had a chance to thoroughly consider the potential conflicts.
American Electric Power	No	AEP is not aware of any conflicts involving the proposed definition and any regulatory function, rule order, tariff, rate schedule, legislative requirement or agreement, or jurisdictional issue.

<u>Response:</u> Thank you for your response.		

**13.Are there any other concerns with this definition that haven’t been covered in previous questions and comments?**

**Summary Consideration:** Comments received for Question 13 were mostly re-statements of comments expressed in the previous question. No changes were made to the core definition or Inclusions or Exclusions based solely on question 13 comments. However, changes were made to the Implementation Plan to clarify the effective date of the revised definition.

Organization	Yes or No	Question 13 Comment
Northeast Power Coordinating Council		<p>Currently, the posted exception criterion is only a concept with many gaps and TBD, as posted details are later to follow. The exception criteria should be a menu of technical items (load flows, stability analysis etc) and non technical items (type of loads such as distribution companies versus major city center, national security, etc). Entities should be required to assess and provide their own justification under each category with a conclusion that takes into account all of the relevant items for element(s) under exception, in a consistent template and table of contents. Suggest the SDT to avoid specification of any parameters as they would differ under different design concepts, system configurations, system characteristics and regulatory requirements. The comments herein reflect thoughts on the document posted. An “all encompassing” comment is that the definition is too lengthy. The importance of the BES definition is recognized throughout the industry for its importance, and as such it should be simple, clear, and straightforward. The first draft definition posted was more along this line. I2, I3, and I5, being very similar, can they be combined into an encompassing generator inclusion criteria?</p>
<p><b>Response:</b> Comments concerning the Technical Principles (Exception Criteria) associated with the RoP Exception Process will be addressed through the dedicated responses developed by the SDT and published in the specific Consideration of Comments document associated with that portion of the overall project.</p> <p>The primary goal of the SDT in the revision of the definition of the BES is to improve clarity in the language and to provide as much certainty as possible in the identification of Bulk Electric System (BES) and non-BES Elements. Although the clarifications added to the core definition and the inclusions and exclusions have lengthened the definition as a whole, the SDT feels that the improvements in clarity and the increased ability to apply the definition to achieve consistent results justify the overall length of the definition.</p> <p>After consulting with the NERC Board of Trustees and the NERC Standards Committee, the SDT has decided to forgo any attempt at changing generation thresholds at this time. There simply isn’t enough time or resources to do that topic justice with the mandated schedule. Therefore, the primary focus of the SDT efforts will be to address the directives in Orders 743 and 743a. However, this does not mean that the other issues will be dropped. Both the NERC Board of Trustees and the NERC Standards Committee have endorsed the idea that the Project 2010-17 SDT take a phased approach to this project with a new Standards</p>		

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 13 Comment
<p>Authorization Request (SAR) to address generation thresholds as well as several other issues that have arisen from SDT deliberations.</p> <p><del>I 32 - Generating units resource(s) located at a single site with aggregate capacity greater than 75 MVA (with gross individual or gross aggregate nameplate rating) per the ERO Statement of Compliance Registry Criteria including the generator terminals through the high-side of the step-up GSU transformer(s), connected through a common bus operated at a voltage of 100 kV or above.</del></p>		
<p>Tri-State Generation and Transmission Association, Inc.</p>		<p>We believe that this definition is not consistent with the response from the SPCS in Project 2009-17, “Interpretation of PRC-004-1 and PRC-005-1 for Y-W Electric and Tri-State” and could change its intent. Existing tapped distribution transformers are clearly not BES Elements at this time. Under the proposed definition that clarity is lost. There are instances where “automatic interruption device” or “automatic interrupting device” is used. Each should be changed to include “fault” after “automatic.”</p>
<p><b>Response:</b> The Interpretation speaks to which Protection Systems are applicable to the PRC Standards, not which Elements are BES or non-BES. The SDT believes that the bright-line established by the draft BES definition is not necessarily the same bright-line that should be utilized to identify the Protection Systems that are applicable to the PRC Reliability Standards and should be addressed by a separate development project. No change made.</p>		
<p>Santee Cooper</p>		<p>What was the rationale for using aggregate capacity greater than 75 MVA on I2 and I5. I2 and I3 inclusions are not the same as defined by the SERC Regional Entity for MOD-024. The SERC guideline does not include an aggregate value for generating units.</p>
<p><b>Response:</b> After consulting with the NERC Board of Trustees and the NERC Standards Committee, the SDT has decided to forgo any attempt at changing generation thresholds at this time. There simply isn’t enough time or resources to do that topic justice with the mandated schedule. Therefore, the primary focus of the SDT efforts will be to address the directives in Orders 743 and 743a. However, this does not mean that the other issues will be dropped. Both the NERC Board of Trustees and the NERC Standards Committee have endorsed the idea that the Project 2010-17 SDT take a phased approach to this project with a new Standards Authorization Request (SAR) to address generation thresholds as well as several other issues that have arisen from SDT deliberations.</p>		
<p>NERC Staff Technical Review</p>		<p>The definition should include variable frequency transformers and back-to-back HVdc converters that connect portions of the system operated at 100 kV or higher, regardless of the dc voltage rating of the converter equipment, which often is less than 100 kV.</p> <p>Assuring reliable operation of nuclear plants requires that Elements subject to Nuclear Plant Interconnection Requirements are planned, designed, maintained, and operated in accordance with NERC Reliability Standards. An additional Inclusion I6 should be added to the definition to include “All transmission Elements subject to Nuclear Plant Interface Requirements (NPIRs) as agreed to by a Nuclear Plant Generator Operator and a Transmission Entity defined in NUC-001.”</p> <p>Assuring reliable operation of the interconnected transmission network also is dependent on reliable operation</p>

Organization	Yes or No	Question 13 Comment
		<p>of generating units that system operators rely on for capacity and Contingency Reserves. Additional Inclusions I7 and I8 should be added to include: * Real Power resources fully or partially relied on to fulfill a capacity obligation, and * Real Power resources (supply-side or Demand-Side Management) relied on to provide Contingency Reserves to its Balancing Authority.</p>
<p><b>Response:</b> The SDT believes that the language contained in the core definition (all Transmission Elements operated at 100 kV or higher) adequately captures specific components such as variable frequency transformers and back-to-back HVdc converters. No change made.</p> <p>The SDT does not believe that additional clarification beyond the designations currently established by the core definition and accompanying Inclusions and Exclusions are necessary to appropriately identify the vast majority of Elements that support the reliable operation of the interconnected transmission network. Additionally, the RoP Exception Process can be utilized to include facilities that are deemed necessary for the reliable operation of the interconnected transmission network but not captured by the BES definition. No change made.</p>		
NERC Transmission Issues Subcommittee (TIS)		<p>The definition should include variable frequency transformers and back-to-back HVdc converters that connect portions of the system operated at 100 kV or higher, regardless of the dc voltage rating of the converter equipment.</p>
<p><b>Response:</b> The SDT believes that the language contained in the core definition (all Transmission Elements operated at 100 kV or higher) adequately captures specific components such as, variable frequency transformers and back-to-back HVdc converters. No change made.</p>		
Dominion		<p>Does the SDT assert that there is no reliability gap because the impact of load on the BES is covered because the DP and LSE are registered and therefore must comply with applicable reliability standards? If so, why shouldn't the same apply to generation elements? GO and GOPs, just like DPs and LSEs are registered users of the bulk power system and must adhere to applicable reliability standards.</p> <p>Other comments Dominion also has the following comments which are based, to a large degree upon the webinar of May 19th. Dominion is concerned that while the BES definition is going through the standards development process, where stakeholders have the ability to ballot, the exception process is being treated as a change to the Rules of Procedure, with no associated stakeholder ballot. For this reason, Dominion prefers that the exception criteria itself be part of the BES definition standards development process. As Dominion reviews the Inclusions and Exclusions included by the SDT in the BES definition, we believe that the SDT could just have easily developed criteria to determine whether impact on the BES is material. We believe this would negate the need for the exception process proposed for the Rules of Procedure. However, if this course is not chosen, then Dominion requests the NERC BOT apply these changes in an 'all or none' fashion. That is, the BES definition and the exception process should both require NERC BOT approval or neither should be moved to FERC for its approval. We are confused as to how the definition, in particular the Inclusions and Exclusions, and the exception process are meant to be applied to, or by, the registered entity.</p>

Organization	Yes or No	Question 13 Comment
		<p>We thought we heard differing views from the panel; one stating that, if the Element or Facility met the Inclusion or Exclusion in the BES definition, then an exception request submittal is not required. On the other hand, we thought we heard that, unless an exception request submittal had been approved then 'status quo' applies.</p> <p>What is 'status quo' based on, the current BES definition or the BES definition being proposed? Would an entity need to track the effective date of the BES definition change in order to determine 'status quo'? How will submittal or non-submittal of an exception request by the registered entity be applied for compliance purposes? Dominion believes the correct answer is that and Element or Facility that meets the BES definition is included and if it doesn't meet the BES definition, isn't included. Only when an exception request has been submitted by an entity, approved and any appeal resolved, is inclusion or exclusion based on the impact to the bulk power system as determined by the criteria used in the exception process.</p>
<p><b>Response:</b> The SDT scope was determined by the language contained in Order Nos. 743 &amp; 743a in which the Commission provided guidance to the ERO to clarify the definition for continent-wide application. The Commission did not propose significant changes to the current application of the existing definition over the majority of the continent. Therefore the SDT has developed a draft core definition, together with BES designations (Inclusions and Exclusions) that provide the specificity necessary to identify the vast majority of BES Elements by utilizing the existing definition and criteria previously approved for this purpose. Although load is a component that can impact the reliability of the BES, the development of the definition is bound by the limitations documented in Section 215 of the Federal Power Act. Expanding the definition to include load would exceed the jurisdictional boundaries into the area of local distribution facilities. No change made.</p> <p>Upon initiation of the development project in response to Order Nos. 743 &amp; 743a, NERC staff and the NERC Standards Committee determined the appropriate mechanisms for the development of each aspect of the project. The revision of the BES definition and the development of the Technical Principles associated with the Exception Process are currently being developed through the Standards Development Process. The RoP Exception Process is being developed through the RoP process for the revision of the Rules of Procedure. The approvals will follow the applicable revision process. No change made.</p> <p>The BES definition (core definition and Inclusions &amp; Exclusions) will be applied to classify BES vs. non-BES Elements. The SDT believes that this will cover the vast majority of the facilities in question. The remaining facilities will be candidates for the Exception Process (RoP) where the Technical Principles will be utilized to determine if the facility is necessary for the reliable operation of the interconnected transmission network. The term 'status quo' was referring to the draft BES definition. Once approved (BES definition, Exception Process and the Technical Principles) the current BES definition will be retired. No change made.</p>		
MRO's NERC Standards Review Forum		<p>In order to provide a clear and concise definition, please add the Brightline Criteria that all facilities less than a 100kV are excluded unless those facilities meet the criteria of an Inclusion.</p>
<p><b>Response:</b> The SDT believes that the current draft BES definition provides sufficient clarity in establishing the bright-line of 100 kV and the identification of facilities operated at less than 100 kV for exclusion would be redundant and jeopardize the SDTs efforts of establishing clarity in the language of the definition. In an effort to provide additional guidance and in support of comments provided in response to Question 11, the SDT has modified the BES core definition with a</p>		

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 13 Comment
		<p>statement that specifically excludes 'local distribution facilities.</p> <p><b>Bulk Electric System (BES):</b> <u>Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</u></p>
SERC Planning Standards Subcommittee		<p>The comments expressed herein represent a consensus of the views of the above-named members of the SERC EC Planning Standards Subcommittee only and should not be construed as the position of SERC Reliability Corporation, its board, or its officers.</p>
<p><b>Response:</b> The SDT appreciates the clarification.</p>		
ACES Power Participating Members		<p>It is not clear if E1 covers networked sub-transmission. Consider the situation where a 138 kV line terminates into a 138/69 kV transformer, the 69 kV is networked and only serves load and possibly generation that does not meet any of the inclusion criteria. This is a situation that appears to meet the intent to exclude radial load under E1 and local distribution networks under E3 but does not appear to explicitly meet either criteria. E1 is not met because the 69 kV network is not radial and E3 is not met because it specifically limits the exclusion to 100 kV and above. This issue could be solved by making clear that E1 applies to even networked sub-transmission or by removing the voltage limit on E3 so that sub-transmission could be included within this exclusion criterion.</p>
<p><b>Response:</b> Exclusions E1 &amp; E3 identify facilities operated at a voltage of 100 kV or higher in an attempt to exclude those types of facilities that do not support the reliable operation of the interconnected transmission network. Facilities operated at a voltage level less than 100 kV are excluded by the 'bright-line' established by the BES core definition unless included through the RoP Exception Process. The SDT is unable to comment on specific system configurations without detailed information pertaining to the facility in question; however, the SDT believes that the application of the BES definition should start with the application of the 'bright-line' established at the 100 kV threshold.</p>		
BPA		<p>As presently written, this BES definition says that "Real Power resources ... and Reactive Power resources connected at 100kV or higher" are to be considered as part of the BES unless one of the specified exclusions applies. Though exclusion E2 specifically excludes "generating units that serve all or part of a retail Load ... on the customer's side of the meter", there is not a similar exclusion for Reactive Power resources that similarly provide such reactive support solely "on the customer's side of the meter". It seems that this results in such Reactive Power resources (i.e. capacitors, inductors, SVCs, etc.), customer side of the meter being defined as part of the BES. If this was not the SDT's intent, BPA requests a new exclusion to specifically exclude such Reactive Power resources "on the customer's side of the meter".</p>

Organization	Yes or No	Question 13 Comment
<p><b>Response:</b> The SDT agrees with the commenter’s concerns regarding retail customer-owned Reactive Power resources and has drafted an additional Exclusion E4 to address these concerns.</p> <p><b>E4 –</b> Reactive Power devices owned and operated by the retail customer solely for their own use.</p>		
<p>Hydro One Networks Inc</p>		<p>We believe that the concepts of inclusions and exclusions as part of the bright-line definition are excellent. However, these exclusions do not address adequately several complex issues along with directives in Order No. 743 and 743A, such as: differentiation between Transmission and Distribution, non-jurisdictional concerns, or distribution. BES definition itself is not a venue to address these complex issues and suggest that these should be addressed by the ERO’s exception procedure.</p> <p>We suggest that SDT consider: Removing I5 and adding E4 to exclude intermittent renewable generation (wind and solar). As stated earlier, such units are intermittent and the planning and operational standards and practices ensure that their unavailability or unexpected (sudden) loss of generation won’t jeopardize reliability of the network; therefore, they should not be BES. That the definition and/or exception process should provide acknowledgement and flexibility to avoid any regulatory conflicts. Introducing a concept of a new category of registration or BES Support (BESS) elements. These elements are NOT BES but support the reliable operation of the interconnected transmission network.</p> <p>A sub-set of relevant NERC Standards should still apply to BESS elements such as planning, design, and maintenance. However, they may not be contiguous or subject to mandatory compliance.</p> <p>We do plan to submit our comments on exception criteria and procedure as part of its process. However, we do suggest that the SDT: Carefully craft the exception criteria that is flexible and technically sound to adequately allow entities to present their case to the ERO for exception. Verify that the exception criteria should be at a high-level with key menu items of assessment that can be followed continent-wide by entities to put forward their exception for element(s) mentioned in exclusions or inclusions based on technical assessment, evidence and justification for its unique characteristics, configuration, and utilization. Acknowledge and provide provisions in both NERC exception criteria and exception process for federal, state and provincial jurisdictions.</p>
<p><b>Response:</b> The SDT agrees with the commenter that the Exception Process should be the primary mechanism for addressing the concerns surrounding issues such as: differentiation between Transmission and Distribution, non-jurisdictional concerns, or distribution. However, the SDT has made modifications to the BES core definition to address the issues associated with the jurisdictional concerns related to local distribution facilities.</p> <p><b>Bulk Electric System (BES):</b> <del>Unless modified by the lists shown below, All</del> Transmission Elements operated at 100 kV or higher, <del>and</del> Real Power <del>and</del> Reactive Power resources <del>as described below, and Reactive Power resources</del> connected at 100 kV or higher <del>unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</del></p>		

Organization	Yes or No	Question 13 Comment
		<p>Although dispersed power producing resources (wind, solar, etc.) can be intermittent suppliers of electrical generation to the interconnected transmission network, the SDT has been made aware of geographical areas that depend on these types of generation resources for the reliable operation of the interconnected transmission network which has prompted the development of Inclusion 14 (previously Inclusion 15). Inclusion 14 has been revised to address industry concerns identified in responses to Question 6.</p> <p><del>I 54</del> - Dispersed power producing resources with aggregate capacity greater than 75 MVA (gross aggregate nameplate rating) <u>utilizing a system designed primarily for aggregating capacity collector system, connected through</u> a common point <del>of interconnection to a system Element</del> at a voltage of 100 kV or above.</p> <p>The development of Reliability Standards is not limited in applicability to BES Elements. Reliability Standards are written against facilities that support the reliable operation of the interconnected transmission network. Therefore the SDT believes that the clarification of the BES definition does not require identification of these types of facilities and that the specific facilities in question are better addressed by the applicability of individual Reliability Standards and not through the BES definition or the Exception Process. No change made.</p> <p>Comments concerning the Technical Principles (Exception Criteria) associated with the RoP Exception Process will be addressed through the dedicated responses developed by the SDT and published in the specific Consideration of Comments document associated with that portion of the overall project.</p>
Edison Electric Institute		<p>Comments: EEI appreciates the efforts of the SDT and offers these comments to help guide its efforts. EEI believes that the statutory framework of the Federal Power Act and Section 215 specifically must govern the definition of BES. While FERC has declined to further define the term “Bulk-Power System” (“BPS”) and suggested in Order No. 743 that the BPS “reaches farther than those facilities that are included” in the BES, it is clear that the BES cannot extend further than the BPS, and therefore the statutory definition of BPS must be the guide for the SDT’s efforts, particularly with regard to the treatment of local distribution facilities. The BPS definition in Section 215 includes: (1) facilities and control systems necessary for operating an interconnected electric energy transmission network; and (2) electric energy from generation facilities needed to maintain transmission system reliability. But the term BPS does not include facilities used in the local distribution of electric energy. The definition of BES must comply with the statutory definition. EEI points to several issues to which it believes the SDT should pay particular attention. First, the facilities and control systems to be included within the BPS/BES must be necessary for operating an interconnected electric transmission network. Therefore, each of the proposed inclusions and exclusions must be measured against this requirement - are they necessary? It is insufficient to include a particular facility or element within the BES definition merely because it would be desirable to have such a facility covered under the BES or a particular standard.</p> <p>In addition, EEI believes that imposing a requirement that all contiguous elements be included is too broad and may sweep in facilities to the BES definition that are statutorily excluded because they are not necessary. For example, while blackstart resources may be “necessary,” including all facilities that are contiguous between a particular blackstart resource and the transmission system is likely to include elements that are not</p>

Organization	Yes or No	Question 13 Comment
		<p>“necessary” to the operation of the interstate transmission network and therefore not within the statutory definition. As a general rule, EEI believes it is appropriate to include contiguous elements or facilities above 100kV necessary for operating the interconnected transmission network, but not any below 100 kV unless the element is necessary to operate the interconnected transmission network. There is no reason to require a “contiguous” BES down to the local distribution facility level. Section 215 gives NERC and FERC jurisdiction over “users, owners and operators” of the BPS. Therefore, FERC has authority to require an entity that is not a BES facility to comply with applicable NERC requirements where necessary for BPS reliability. This approach would achieve the goals of BPS reliability without extending the full reach of BES applicability to facilities that may be local distribution facilities that are excluded from Section 215. Second, both the transmission and the generation facilities included within the BPS/BES must be tied to maintaining the reliable operation of the BPS. Section 215 defines the term “reliable operation” as “operating the elements of the bulk-power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cybersecurity incident, or unanticipated failure. The statute does not require that there be no loss of load. The statute is aimed at avoiding uncontrolled separation or cascading failures. Therefore, consistent with the statute, the definition of BES should only include elements that are necessary to prevent these occurrences. Third, the statute contains a specific exclusion for facilities used in the local distribution of electric energy (“local distribution facilities”). FERC has agreed in Orders No. 743 and 743-A that local distribution facilities are not subject to Section 215. FERC, as the agency implementing Section 215, has the authority to interpret what that means. In Order 743-A, FERC left it to NERC, and therefore to the SDT, to determine in the first instance which facilities are local distribution and therefore excluded and whether or not to use tests such as the Seven Factor Test from Order No. 888. Order No. 888 set out seven indicators, a combination of functional and technical tests, to assist companies and state commissions with separating local distribution facilities from FERC jurisdictional transmission facilities on a case by case basis. The seven factors are: (1) Local distribution facilities are normally in close proximity to retail customers; (2) Local distribution facilities are primarily radial in character; (3) Power flows into local distribution systems; it rarely, if ever, flows out; (4) When power enters into a local distribution system, it is not reconsigned or transported on to some other market; (5) Power entering a local distribution system is consumer in a comparatively restricted geographical area; (6) Meters are based at the transmission/local distribution interface to measure flows into the local distribution facilities; and (7) Local distribution systems will be of reduced voltage. EEI acknowledges that the Seven Factor test does not draw a bright line between facilities used in local distribution and transmission facilities and may not be a perfect fit for applying to specific pieces of equipment as the SDT has tried to do. However, many state commissions have made determination of what are local distribution facilities and FERC has concurred with these determinations. Therefore, EEI proposes that if NERC or FERC seek to include facilities (or class of facilities) in the BES that have been previously determined by a state commission to be local distribution through application of the Seven Factor Test, that there is a rebuttable presumption that these are facilities used in local distribution for purposes of</p>

Organization	Yes or No	Question 13 Comment
		<p>the BES definition. In order to overcome this presumption, NERC/FERC must make a showing demonstrating that these facilities “necessary” for the reliable operation of the BPS. EEI will address this and a procedure for seeking exclusion of facilities that previously have been determined to be local distribution in its comments to be submitted on the exceptions process. In applying the statutory exclusion for local distribution facilities, the SDT should ensure that the inclusions do not include local distribution facilities and that the exclusions are sufficient to exclude local distribution facilities. Similarly, it is not sufficient to include an element that would otherwise be a local distribution facility merely to support a facility clearly within the BES. For example, the SDT should consider the how the proposed criteria would classify types of equipment such as distribution voltage equipment - some, such as cap banks in a generation switchyard do support the transmission system versus a regulator on a distribution feeder - the former may be part of the BES and the latter unlikely or not at all.</p>
<p><b>Response:</b> The SDT has made modifications to the BES core definition to address the issues associated with the jurisdictional concerns related to local distribution facilities.</p> <p><b>Bulk Electric System (BES):</b> <u>Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</u></p> <p>The SDT agrees that the establishment of a contiguous BES could have the unintended consequences of being overly-inclusive and has made corresponding changes to the Inclusions to address this concern.</p> <p>The primary goal of the SDT in the revision of the definition of the BES is to improve clarity in the current language and to provide as much certainty as possible in the identification of BES and non-BES Elements. The Commission provided guidance within Order Nos. 743 &amp; 743a which identified the current application of the existing BES definition was essentially correct for the majority of the continent and directed clarification of the existing language to support consistent application across all regions. Additional guidance from the Commission spoke to significant changes in the scope of the definition with an expectation that the revision to the definition would not significantly expand or contract what is currently considered to be the BES. Limiting the draft definition to Elements where a loss could result in instability, uncontrolled separation, or cascading failures is a significant departure from the current definition and not in alignment with the expectations documented in the Orders (743 &amp; 743a). No change made.</p>		
<p>LG&amp;E and KU Energy LLC</p>		<p>Yes LG&amp;E and KU Energy have a concern that the approval and adoption of the BES definition project and BES exception procedure project are not linked. This would produce the possibility of the BES definition project completing and Registered Entities having to comply without having the appropriate and promised BES exception procedure in place to alleviate unreasonable compliance actions. More specifically, if the BES definition gets approved and BES exception procedure has not yet been approved (whether due to project delay or disapproval), then Registered Entities are required to ensure everything within the new definition is compliant, even if doing so is unreasonable or entirely unnecessary.</p>

**Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17**

Organization	Yes or No	Question 13 Comment
<p><b>Response:</b> It is the intention of the SDT and the RoP team to file all portions of the project (BES definition, RoP Exception Process, and the Technical Principles) as a single response to the directives contained in Order Nos. 743 &amp; 743a with the expectation that all portions would be approved at the same time.</p>		
<p>Alabama Public Service Commission</p>		<p>The Alabama Public Service Commission (APSC) appreciates the fact that a member of the Oregon PUC Staff is participating on this BES Definition drafting team. In reviewing the proposed definition, the APSC's focus is to ensure that appropriate definitional lines are drawn so that recognized jurisdictional boundaries are acknowledged and respected. The concern underlying this focus of the APSC is the fact that utilities must make significant investments to comply with mandatory reliability standards and, accordingly, compliance with such standards must be necessary and not duplicative. Furthermore, there should be a commensurate reliability benefit associated with the cost of the investments needed for compliance. The proposed definition and NERC's development of standards should focus on reliable operation of the interconnected electric transmission network (BES) in order to prevent local events from affecting other regions, not to ensure reliable operation at the local level.</p>
<p>Pennsylvania Public Utility Commission</p>		<p>The Pennsylvania Public Utility Commission offers the following comments in response to Standards Announcement Project 2010-17 BES Definition: As you know, Section 1211 of the Energy Policy Act of 2005, amending Section 215 of the Federal Power Act, provided for the promulgation of standards for the bulk power system by an Electric Reliability Organization subject to the approval of the U.S. Federal Energy Commission. Section 215 (a) states: 'SEC. 215. ELECTRIC RELIABILITY.' (a) DEFINITIONS.-For purposes of this section: (1) The term 'bulk-power system' means-(A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy. E.P.A. Act 2005, Section 1211, 16 U.S.C. Â§ 824 [emphasis supplied] While the PaPUC acknowledges the need for a more explicit definition of the Bulk Electric System (or, as it is stated in E.P.A. Act 2005, the "bulk power system"), we are concerned that the existing draft definition and stated exclusions is insufficiently clear and may be erroneously extended to distribution facilities that are currently subject to state jurisdiction expressly reserved by the language of E.P.A. Act 2005, Section 1211 (a). Exceptions E1-E4 are plainly drafted to address this issue, but there is a concern that the definition of "local distribution networks" contained in Exception E3 may not fully comport with the intent of Congress, particularly Exception E3 (d) which excepts facilities that are [n]ot used to transfer bulk power: The LDN is not used to transfer energy originating outside the LDN for delivery through the LDN. The proposed language appears to be contrary to Congressional intent as it implies that some local distribution facilities which "transfer bulk power" are indeed subject to the ERO standards process. Additionally, the draft BES, which distinguishes local distribution facilities between those that "transfer bulk power" and those that do not appears insufficiently precise, as bulk power is ultimately transferred through every portion of the local distribution network to end users. Our major concern is that this draft standard definition will collide with state</p>

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 13 Comment
		regulation of distribution facilities, particularly where state commissions are seeking to impose standards and protective arrangements more stringent than might be required by the Electric Reliability Organization or Regional Reliability Organization. Accordingly, it is recommended that the Draft BES be modified to specifically define distribution facilities and exclude them from the ambit of the Bulk Electric System definition, as well as making it clear that State reliability standards relating to the local distribution network are not overridden or modified by standards applicable to the Bulk Electric System.
National Association of Regulatory Utility Commissioners		Congress clearly recognized that State utility commissions are concerned about and committed to reliability at the distribution level; that's why Congress explicitly limited FERC's reach, and directed FERC not to attempt to regulate facilities used in local distribution. The NERC standard setting process for defining the Bulk Electric System must respect the statutory limitations under Federal Power Act Section 215 that explicitly excluded local distribution from the definition of the Bulk Power System (BPS). The Bulk Electric System, while not necessarily equivalent to the BPS (See FERC Order 743 A P 102), cannot exceed the limitations of the BPS and cannot include facilities used in the local distribution of electric energy. State Utility Commissions are concerned about and committed to reliability. These Commissions are in the best position to provide reliability oversight and standards for the local distribution system in their State.
<p><b>Response:</b> The SDT is developing a revised definition of the BES to identify the facilities that support the reliable operation of the interconnected transmission network. The SDT has revised the draft BES definition to address the potential jurisdictional boundaries that currently exist in regards to local distribution facilities.</p> <p><b>Bulk Electric System (BES):</b> <u>Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</u></p>		
Western Electricity Coordinating Council		The definition should also reference the exception process and technical justification allowed for further inclusion or exclusion from the BES.
Utility System Efficiencies, Inc.		The definition should also reference the exception process and technical justification allowed for further inclusion or exclusion from the BES.
<p><b>Response:</b> Such a statement was inadvertently left off of the first posted version of the definition.</p> <p>Note - Elements may be included or excluded on a case-by-case basis through the Rules of Procedure exception process.</p>		
Western Montana Electric Generating and Transmission		WVG&T has these additional concerns: The current definition provides that "Elements may be included or excluded on a case-by-case basis through the Rules of Procedure exception process." WVG&T is concerned that the SDT carefully delineate which entity has the burden of proof in the exclusion process. The WECC

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 13 Comment
Cooperative		<p>BESDTF approach, which we commend to the SDT, laid out these burdens in some detail. Under that approach, essentially, if a facility is excluded from the BES by virtue of the specific exclusions listed in the definition, the Regional Entity bears the burden of proving that the facility nonetheless has a material impact on the interconnected bulk transmission system and therefore should be included in the BES. On the other hand, if a facility is classified as BES by virtue of the list of inclusions set forth in the BES definition, it can still escape classification as BES, but bears the burden of demonstrating that its facility has no material impact on the interconnected transmission system. We urge the SDT to give careful consideration to these burden-of-proof questions and to follow the lead of the WECC BES Task Force.</p> <p>For the reasons we have explained in our answer to Question 11, we believe the Exception process is critical both to ensure that the BES definition is effective in producing measurable gains to bulk system reliability and to ensuring that the definition will comply with the limitations Congress placed in Section 215. Hence, we believe the entire BES definition, including the Exception process and related procedures, should be vetted through the NERC Standards Development Process, including the full comment periods and a ballot approvals provided for in that process. We are concerned that important elements of the BES definition have been assigned to the Rules of Procedure Team, and that changes in the Rules of Procedure are subject to approval in a process that provides considerably less due process and industry input than the Standards Development Process. Accordingly, we urge that all elements of the BES definition, including those elements that have been assigned to the Rules of Procedure Team, be vetted through the Standards Development Process.</p>
<p><b>Response:</b> The SDT believes that the burden of proof issue should be resolved through the development of the RoP Exception Process. Your comments will be forwarded to the RoP team for consideration.</p> <p>Upon initiation of the development project in response to Order Nos. 743 &amp; 743a, NERC staff and the NERC Standards Committee determined the appropriate mechanisms for the development of each aspect of the project. The revision of the BES definition and the development of the Technical Principles associated with the Exception Process are currently being developed through the Standards Development Process. The RoP Exception Process is being developed through the RoP process for the revision of the Rules of Procedure.</p>		
PacifiCorp		<p>Effective dates: While understanding that additional facilities will require up to two years to come into compliance, several facilities will also be excluded that are currently under the current bright line definition. Are utilities going to be responsible to maintain all NERC reliability standards during the two year period for facilities or elements that will be excluded by the new bright line definition? PacifiCorp proposes that the effective date for facilities being removed from the bright line become effective on the first day of the first calendar quarter after applicable regulatory approval. It is reasonable to retain the two year period for facilities that will be added to the BES.</p> <p>NERC Staff has submitted written comments to this project stating that the BES “must be contiguous.”</p>

Organization	Yes or No	Question 13 Comment
		<p>Instituting a contiguous BES with Inclusion I2, for example, would result in a substantially over-inclusive BES definition. The adoption of a “contiguous” BES is therefore likely to result in imposition of reliability standards on a substantial number of distribution elements that have nothing to do with improving or protecting the reliability of bulk transmission system. There is no compelling reason to adopt a “contiguous” BES that covers local distribution systems. Section 215 of the FPA provides FERC with jurisdictional authority over “users” as well as “owners” and “operators” of the bulk power system. Consequently, FERC has the jurisdictional authority to require generation and other entities to comply with applicable NERC requirements. Hence, even where an entity does not own or operate BES assets, it could still be required, for example, to provide necessary information to the applicable Reliability Coordinator or Planning Coordinator and to participate in programs to prevent instability, uncontrolled separation, or cascading outages to the bulk transmission system. This approach would fully achieve the goals of bulk transmission system reliability without imposing the full BES regulatory compliance burden on local distribution elements.</p> <p>Although not specifically the responsibility of the SDT, it should closely coordinate its efforts with the team developing the inclusion/exclusion process in the ROP. For instance, if the ROP team develops an overly onerous process to exclude elements which are not required to reliably operate the interconnected BES yet are not excluded through the bright-line definition then PacifiCorp would consider the bright-line definition to be over-inclusive.</p>

**Response:** The SDT agrees with the commenter and has made revisions to the Implementation Plan to address these concerns surrounding the implementation dates.

The SDT agrees that the establishment of a contiguous BES could have the unintended consequences of being overly-inclusive. Inclusion I2 has been revised and merged with Inclusion I3 (now Inclusion I2) and as a result the implication of the continuity of the BES has been removed. Additionally, the SDT recognizes the limitations associated with FERC’s jurisdiction as defined in the FPA Section 215 and has therefore provided additional clarification in the core BES definition to address these concerns.

**Bulk Electric System (BES):** ~~Unless modified by the lists shown below, All~~ Transmission Elements operated at 100 kV or higher, ~~and~~ Real Power ~~and~~ Reactive Power resources ~~as described below, and Reactive Power resources~~ connected at 100 kV or higher ~~unless such designation is modified by the list shown below.~~ This does not include facilities used in the local distribution of electric energy.

~~I 32 - Generating units resource(s) located at a single site with aggregate capacity greater than 75 MVA (with gross individual or gross aggregate nameplate rating) per the ERO Statement of Compliance Registry Criteria~~ including the generator terminals through the ~~high-side of the step-up GSU transformer(s),~~ connected ~~through a common bus operated~~ at a voltage of 100 kV or above.

It is the intention of the SDT and the RoP team to file all portions of the project (BES definition, RoP Exception Process, and the Technical Principles) as a single response to the directives contained in Order Nos. 743 & 743a with the expectation that all portions would be approved at the same time.

Organization	Yes or No	Question 13 Comment
Intellibind		Generation that is BES significant that is not connected at 100kV or above.
<p><b>Response:</b> This 'significant' generation should be identified with the appropriate technical justification, established and presented by the Regional Entity, in accordance with the Rules of Procedure Exception Process for 'inclusion' approval by the ERO. No change made.</p>		
City of Redding		<p>Additional concerns:</p> <p>The SDT has avoided directly addressing the predominate issues that plagues the industry. The two main issues are: a sound definition of the term “<i>necessary for operating the interconnected transmission network</i>” <b>and</b> “whether a particular facility is local distribution or transmission” as directed by FERC in both Orders 743 and 743A. As an example, in terms of pure operation of an interconnected transmission system there is only a small amount of the generation connected to the BES system where the energy is actually “necessary for operating the interconnected transmission network”. As the users of the system increase load and remote generation responds then the transmission system only needs the VAR support and reserves from a select set of generators, therefore the Definition goes too far, and creates a generalization that all generators over 20 MVA are “necessary”. This is especially not true if the generation is a load modifier embedded in a Distribution system and the generator only requires reserves from the BES. These services are a function of the BES and are paid for by the user.</p> <p>Redding is concerned that the SDT is intertwining the BES Definition and the Statement of Compliance Registry out of convenience. It is our view that the the NERC Registry Criteria serves a different function than the Definition in that it does not clarify what elements are BES elements but identifies the Owners, Operators, and Users of the BES and therefore the NERC Standards could be applied. The SDT does not have a technical justification to adopt the current thresholds in the Compliance Registry as part of the BES Definition. These thresholds have not been presented to the industry for validation or review. Additionally, the Statement of Compliance Registry was an initial attempt of NERC to begin a new regulation requirement and was not created through the NERC Standards Development Process.</p> <p>Redding suggests that the SDT, in the interest of reliability, recommend that the NERC Statement of Compliance Registry be modified to create a tiered level of responsibilities for entities. A 20 MVA generator has a different level of responsibility to the BES then an 800 MVA generation unit. A LDN that does not qualify for an exemption due to an impact on a path or flow gate should not be required to meet the full requirements of a Transmission Operator. This in fact reduces reliability by diverting the local training focus from the operation of a Local Control Center (LCC) and a sub-transmission system. Prior to the NERC Standards WECC had training classes for Sub-transmission Operators that were applicable to the reliable operation of a local Sub-transmission system. The implementation of the NERC Standards has decreased reliability in this area because the focus of coordinating with the LCC and sub-transmission level has been lost.</p>

Organization	Yes or No	Question 13 Comment
		<p><b>Response:</b> The SAR has clearly identified the responsibilities of the SDT in revising the definition of the BES. The scope does not include the additional definitions noted above. No change made.</p> <p>The Commission stated in Order Nos. 743 &amp; 743a that they believe the current application of the definition is correct and should be maintained. The current application of the definition is based on Commission language contained Order 693 which directs the use of the BES definition and NERC Statement of Compliance Registry to identify the functional entities required to be registered and which Reliability Standards will apply. The linkage between the BES definition and Registry Criteria was established by the Commission in Order No. 693 and uncontested by the industry at the time of filing. No change made.</p> <p>The ERO Statement of Compliance Registry is governed by the Rules of Procedure and under the responsibilities of the ERO Certification and Registration Department and does not fall under the current responsibility of the SDT as defined by the scope in the SAR for Project 2010-17. No change made.</p>
<p>Public Utility District No. 1 of Snohomish County, Washington</p>		<p>Snohomish County PUD has these additional concerns:</p> <p>We are concerned that the proposed 24-month delay in the effective date of the new definition will delay the potentially beneficial effects of the SDT’s efforts, especially for utilities that have been inappropriately registered for BES-related functions, which is a common situation in WECC. We therefore urge the new BES definition to become effective immediately upon approval by FERC or other applicable regulatory agencies. Entities that have been improperly registered for BES functions can then immediately file for deregistration and obtain the benefits of the new definition as soon as possible. For entities that have not previously been registered for BES-related functions but that would be required to register under the new definition, we do not object to the 24-month transition period proposed by the SDT to allow the newly-registered entity to attain compliance with newly-applicable reliability standards, many of which require new training for employees, new maintenance procedures, and complex new operational protocols. However, the transition period for newly-registered entities should be structured in a way that does not prevent entities seeking deregistration from benefitting from the new definition at the earliest possible date.</p> <p>The current definition provides that “Elements may be included or excluded on a case-by-case basis through the Rules of Procedure exception process.” Snohomish is concerned that the SDT carefully delineate which entity has the burden of proof in the exclusion process. The WECC BES Task Force approach, which we commend to the SDT, laid out these burdens in some detail. Under that approach, essentially, if a facility is excluded from the BES by virtue of the specific exclusions listed in the definition, the Regional Entity bears the burden of proving that the facility nonetheless has a material impact on the interconnected bulk transmission system and therefore should be included in the BES. On the other hand, if a facility is classified as BES by virtue of the list of inclusions set forth in the BES definition, it can still escape classification as BES, but bears the burden of demonstrating that its facility has no material impact on the interconnected transmission system. We urge the SDT to give careful consideration to these burden-of-proof questions and to follow the lead of the WECC BES Task Force.</p> <p>For the reasons we have explained in our answer to Question 11, we believe the Exception process is critical</p>

**Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17**

Organization	Yes or No	Question 13 Comment
		<p>both to ensure that the BES definition is effective in producing measurable gains to bulk system reliability and to ensuring that the definition will comply with the limitations Congress placed in Section 215. Hence, we believe the entire BES definition, including the Exception process and related procedures, should be vetted through the NERC Standards Development Process, including the full comment periods and a ballot approvals provided for in that process. We are concerned that important elements of the BES definition have been assigned to the Rules of Procedure Team, and that changes in the Rules of Procedure are subject to approval in a process that provides considerably less due process and industry input than the Standards Development Process. Compare NERC Rules of Procedure Â§ 1400 (providing for changes to Rules of Procedure upon approval of the NERC board and FERC) with NERC Standards Process Manual (Sept. 3, 2010) (providing for, e.g., posting of SDT proposals for comment, successive balloting, and super-majority approval requirements). Accordingly, we urge that all elements of the BES definition, including those elements that have been assigned to the Rules of Procedure Team, be vetted through the Standards Development Process. Further, we believe that the failure to vet all material elements of the BES definition through the Standards Development Process would constitute a violation of NERC’s bylaws and the requirements of the Standards Development Process.</p>
<p><b>Response:</b> The SDT agrees with the commenter and has made revisions to the Implementation Plan to address these concerns surrounding the implementation dates.</p> <p>The SDT believes that the burden of proof issue should be resolved through the RoP Exception Process. Your comments will be forwarded to the RoP team for consideration.</p> <p>Upon initiation of the development project in response to Order Nos. 743 &amp; 743a, NERC staff and the NERC Standards Committee determined the appropriate mechanisms for the development of each aspect of the project. The revision of the BES definition and the development of the Technical Principles associated with the Exception Process are currently being developed through the Standards Development Process. The RoP Exception Process is being developed through the RoP process for the revision of the Rules of Procedure.</p>		
Grand Haven Board of Light and Power		<p>I can not over emphasize how unreasonable it would be for our utility to have to register as a TO/TOP because of one asset (138kV circuit switcher) that serves a radial, load serving system. It is equally unreasonable for us to have to use a long and arduous exception process to qualify for deregistration. Please take this into consideration as you prepare the final definition.</p>
<p><b>Response:</b> The SDT is responsible for the revision of the BES definition. In fulfilling this responsibility the SDT is developing a definition that properly classifies facilities as BES or non-BES Elements. Defining registration requirements is not within the scope of Project 2010-17. No change made.</p>		
National Grid		<p>We are concerned that the proposed definition of BES and specified inclusions reaches farther into the electric system than the Bulk Power System (BPS) definition. The statutory framework of the Federal Power</p>

Organization	Yes or No	Question 13 Comment
		<p>and section 215 specifically must govern the definition of BES. It is clear in FERC’s Order No. 743 that BES should not extend further than BPS, therefore the statutory definition of BPS must be the guide for the SDT’s efforts, particularly with regard to the treatment of local distribution facilities. The BPS definition includes (1) facilities and control systems necessary for operating an interconnected electric energy transmission network; and (2) electric energy from generation facilities needed to maintain transmission system reliability. It does not include facilities used in the local distribution of electric energy. The definition of BES must comply with the statutory definition. First, the facilities and control systems to be included within the BPS/BES must be necessary for operating an interconnected electric transmission network. Therefore, one question to consider for each of the proposed inclusions and exclusions is “are they necessary?” A particular facility or element should not be included in the BES definition just because it would be desirable to have the facility considered BES or covered by a particular standard.</p> <p>Imposing a requirement that all contiguous elements be included is too broad and may sweep in facilities to the BES definition that are statutorily excluded because they are not necessary.</p> <p>Second, both the transmission and the generation facilities included within the BPS/BES must be tied to maintaining the reliable operation of the BPS. Section 215 defines the term “reliable operation” as “operating the elements of the bulk-power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of a sudden disturbance, including a cybersecurity incident, or unanticipated failure”. The statute does not require that there be no loss of load. The statute is aimed at avoiding uncontrolled separation or cascading failures. Therefore, the definition of BES should only include elements that are necessary to prevent these occurrences.</p>
<p><b>Response:</b> The SDT recognizes the limitations associated with FERC’s jurisdiction as defined in the FPA Section 215 and has therefore provided additional clarification in the core BES definition to address these concerns.</p> <p><b>Bulk Electric System (BES):</b> <u>Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. Wells Rural Electric Company		<p>Dear NERC Standards Drafting Team:Enclosed are Wells Rural Electric Company’s comments on NERC’s Proposed Continent-wide Definition of Bulk Electric System. We believe that NERC’s proposed Continent-wide Definition of Bulk Electric System is proceeding in the right direction on this important topic but that more work needs to be done. We would like to thank the Standards Drafting Team for their hard work. We support the detailed comments of the Snohomish County Public Utility District and Pacific Northwest Generating Cooperative with regard to the questions posed by the Comment Form for Project 2010-17 Definition of BES.We would like to emphasize these portions of Snohomish’s and PNGC’s comments:</p> <p>Question 1, both PNGC and Snohomish suggest that NERC start by adopting the statutory definition of the bulk power system as the core definition. We support that approach. That is, “(t) he term ‘Bulk Electric System’ means: (A) Facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and,(B) Electric energy from generation facilities needed to maintain transmission system reliability.The term does not include facilities used in the local distribution of</p>

Organization	Yes or No	Question 13 Comment
		<p>electric energy”. See 16 U.S.C. Â§ 824o(a)(1).”</p> <p>Question 7, we support the exclusion for radial lines as drafted.</p> <p>Question 9, we support the categorical exclusion of Local Distribution Networks from the BES as defined here, but with Snohomish’s clarifications.</p> <p>Question 10, we support exclusion E4, for small utilities, but we are unclear how small utilities are defined in the exclusion language presented here.</p> <p>Question 11, we support the approach to exclusion of local distribution facilities discussed in the draft but repeat that more work should be done on the definition so that facilities used in local distribution are not swept up into the BES. The primary value of clearly defining the BES is for registration determinations. We realize that clearly defining the BES also has value in determining which standards apply to registered entities. If a registered entity does not own any Elements of the BES that that registered entity should be able to efficiently and effectively demonstrate an exception. We encourage NERC to support the use of the BES definition for registration-issues and to develop the exception procedure for registered entities that do not own or operate any Elements of the BES.</p>
<p><b>Response:</b> The SDT appreciates the industry support for this project. Please see the SDT responses in Questions 1, 7, 9, 10, and 11 of this document.</p>		
ExxonMobil Research and Engineering		<p>There are certain transmission network configurations in the south east portion of the country where the majority of the interconnected transmission network is owned and maintained by a single utility company, but approximately one hundred substations that are located along the interconnected transmission network and utilized to transmit power between regions are owned by separate companies (i.e. many companies own a single transmission substation). The SDT should consider this configuration and the lack of uniform operation and maintenance practices that may exist due to the differences in how the companies implement NERC compliance.</p>
<p><b>Response:</b> The primary goal of the SDT in the revision of the definition of the BES is to improve clarity in the current language and to provide as much certainty as possible in the identification of BES and non-BES Elements. The Commission provided guidance within Order Nos. 743 &amp; 743a which identified the current application of the existing BES definition was essentially correct for the majority of the continent and directed clarification of the existing language to support consistent application across all regions. Additional guidance from the Commission spoke to significant changes in the scope of the definition with an expectation of the revision to the definition would not significantly expand or contract what is currently considered to be the BES. The SDT is unable to comment on specific system configurations without detailed information pertaining to the facility in question.</p>		
FortisBC		<p>We believe that the concepts of inclusions and exclusions as part of the bright-line definition are excellent. However, these exclusions do not address several directives in Order No. 743 and 743A, such as:</p>

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 13 Comment
		<p>differentiation between Transmission and Distribution, non-jurisdictional concerns, or distribution. We believe that the BES definition itself is not a venue to address these concerns but suggest that these issues should be explicitly addressed by the ERO’s exception criteria and exception process. Currently, the posted exception criterion is only a concept with many gaps and TBD, as posted details are later to follow. We suggest that the exception criteria should be a menu of technical items (load flows, stability analysis etc) and non technical items (type of loads such as distribution companies vs. major city center, national security etc). Entities should be required to assess and provide their own justification under each category with a conclusion that takes into account all of the relevant items for element(s) under exception, in a consistent template and table of contents. We suggest the SDT to avoid specification of any parameters as they would differ under different design concepts, system configurations, system characteristics and regulatory requirements.</p>
<p><b>Response:</b> The SDT agrees with the commenter that the Exception Process should be the primary mechanism for addressing the concerns surrounding issues such as: differentiation between Transmission and Distribution, non-jurisdictional concerns, or distribution. However the SDT has made modifications to the BES core definition to address the issues associated with the jurisdictional concerns related to local distribution facilities.</p> <p><b>Bulk Electric System (BES):</b> <u>Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</u></p> <p>Comments concerning the Technical Principles (Exception Criteria) associated with the RoP Exception Process will be addressed through the dedicated responses developed by the SDT and published in the specific Consideration of Comments document associated with that portion of the overall project.</p>		
MidAmerican Energy Company		<p>While there were no questions directed to the draft implementation plan in the comment form, if the intent was to also solicit comments on that plan, the schedule in that plan is likely too aggressive if the result of the revised BES definition is that new facilities are brought into the BES and are thereby obligated to now comply with standards they had not previously been required to meet. Perhaps a provision should be added to the implementation plan to address this situation and allow an extended schedule for new BES facilities to comply with applicable standards.</p>
<p><b>Response:</b> The SDT believes that the 24 month schedule for implementation is a reasonable compromise considering the Commission suggested timeframe of 18 months and the burden of newly registered functional entities in establishing compliance with the applicable Reliability Standards. The SDT did, however, extend the effective date by an additional quarter of a year based on stakeholder comments.</p>		
American Electric Power		<p>Usage of the NERC term “Element” clearly excludes associated auxiliary equipment such as protective relay systems and metering systems. If this is not the intent of the SDT, then there needs to be more comprehensive BES nomenclature established that distinguishes among the applicable primary-voltage equipment, the associated auxiliary equipment having an impact to the BES, and the associated ancillary</p>

Organization	Yes or No	Question 13 Comment
		equipment having no electrical impact to the BES. In addition, please see response to question 1 regarding the request for industry input on concurrent, closely related projects (approved definition of BES, the technical principles for demonstrating BES exception, and the exception process itself).
<p><b>Response:</b> The SDT has determined that the draft BES definition should identify BES Elements which are operated at a voltage of 100 kV or above. The SDT also has recognized the existence of facilities (i.e., auxiliary equipment and Protection Systems) that support the reliable operation of the interconnected transmission network but do not necessarily operate at voltages of 100 kV or above and should not necessarily be classified as BES Elements. Reliability of the interconnected transmission network is established by the application of Reliability Standards and the development of Reliability Standards is not limited in applicability to BES Elements. Reliability Standards are written against facilities that support the reliable operation of the interconnected transmission network. Therefore the SDT believes that the clarification of the BES definition does not require identification of these types of facilities and that the specific facilities in question are better addressed by the applicability of individual Reliability Standards and not through the BES definition or the Exception Process. No change made.</p>		
Farmington Electric Utility System		The Rules of Procedure for Exceptions should define the compliance expectation of the entity while an exception is being considered; similar to the CIP TFE process.
<p><b>Response:</b> The SDT believes that compliance expectation issues should be resolved through the RoP Exception Process. Your comments will be forwarded to the RoP team for consideration.</p>		
Colorado Springs Utilities		Colorado Springs Utilities supports the SDT's efforts to create an acceptable BES definition directly linked to an exemption process. Know that WECC has a task force, the Bulk Electric System Definition Task Force (BESDTF), which has done some notable work on this task. See WECC BESDTF Proposal 6, Appendix C ( <a href="http://www.wecc.biz/Standards/Development/BES/default.aspx">http://www.wecc.biz/Standards/Development/BES/default.aspx</a> ). The BES definition is very complex and the BESDTF has already addressed many of the tough issues that have yet to be addressed in this process, such as: <ul style="list-style-type: none"> <li>o Local Distribution Network definition for automatic exemption</li> <li>o Determination of radial facilities</li> <li>o Demarcation of BES and non-BES Elements</li> <li>o Alternate dispute resolution process</li> <li>o Assignment of the burden of proof for the exemption process</li> <li>o Technical approach for the inclusion/exclusion determination</li> </ul>
Sacramento Municipal Utility District (SMUD)		SMUD supports the SDT's efforts to create an acceptable BES definition directly linked to an exemption process. SMUD would also like to bring to the BES SDT's attention that the WECC the Bulk Electric System Definition Task Force has constructed the framework on this task that we encourage the SDT to review their work. SMUD would like to thank the BES SDT for consideration of these comments.
Tacoma Power		Tacoma Power supports the SDT's efforts to create an acceptable BES definition directly linked to an exemption process. Please be aware that the WECC has a task force, the Bulk Electric System Definition Task Force (BESDTF), which has done some notable work on this task. See WECC BESDTF Proposal 6, Appendix C ( <a href="http://www.wecc.biz/Standards/Development/BES/default.aspx">http://www.wecc.biz/Standards/Development/BES/default.aspx</a> ). The BES definition is very

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 13 Comment
		<p>complex and the BESDTF has already addressed many of the tough issues that have yet to be addressed in this process, such as:</p> <ul style="list-style-type: none"> <li>o Local Distribution Network definition for automatic exemption</li> <li>o Determination of radial facilities</li> <li>o Demarcation of BES and non-BES Elements</li> <li>o Alternate dispute resolution process</li> <li>o Assignment of the burden of proof for the exemption process</li> <li>o Technical approach for the inclusion/exclusion determination</li> </ul> <p>Thank you for consideration of our comments.</p>
<p><b>Response:</b> The SDT has taken into account the work product of several regional efforts in the development of the draft BES definition.</p>		
Consumers Energy Company		<p>Yes. We propose an alternative core BES definition to read as follows: “All network System Elements operated at 100 kV or higher, Real Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below.”</p> <p>We support extending the transition period to 24 months.</p>
<p><b>Response:</b> The SDT believes that the revised draft BES definition provides sufficient clarity in establishing the bright-line of 100 kV.</p> <p><b>Bulk Electric System (BES):</b> <u>Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</u></p> <p>Thank you for your support.</p>		
Occidental Energy Ventures Corp. (answers include all various Oxy affiliates)		<p>Occidental Energy Ventures Corp (“OEVC”) would like to emphasize that the proposed definition of the BES does not only impact OEVC and its affiliates. The proposed BES definition would include numerous facilities that are used for the local distribution of electric energy, not transmission, in direct contravention of Section 215 of the FPA. For example, there are likely hundreds, if not thousands, of retail customers that have self-provided “hard-tapped” facilities behind the retail delivery point. Those retail customers, many of who are likely unaware of the proposed BES definition, much less its impact, will have their facilities under the proposed BES definition suddenly become transmission facilities simply because their facilities are not separated from the BES by an automatic fault-interruption device.</p>
<p><b>Response:</b> The SDT believes that the changes made to the wording of the definition based on comments received will provide clarity and address the concerns provided by the commenter’s. In particular the SDT clarified the point of connection, removed the automatic interrupting device, moved the concept of the normally open switch to a note, and clarified the generation allowed within the system.</p> <p>In addition, the SDT wishes to point out that the definition also includes Exclusion E3 that can be used for multiple connections serving local networks. The SDT realizes that a bright-line definition may require entities to seek exceptions through the Rules of Procedure exception process.</p>		

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 13 Comment
Chevron Global Power, a division of Chevron U.S.A. Inc.		<p>Chevron U.S.A. Inc. has reviewed the proposed Bulk Electric System definition and is concerned that the proposed changes designed to enhance reliability and accountability of Transmission and Generation are inadvertently catching parties whose prime operations are distribution in nature. Chevron is proposing minor changes that will not affect the necessary regulation of the bulk power industry, but will exempt parties that are not crucial to reliability and provide mostly, if not entirely, distribution or self use service. In remote areas of west Texas, Chevron has hundreds of non contiguous producing properties and facilities located over hundreds of square miles. In some cases where the utility was close and had the capability to serve, Chevron took utility service. Where service was not available or the utility did not have the capability, Chevron built its own private power distribution system to service its own facilities. Chevron has no generation and takes all of its power from transmission providers. In at least one instance Chevron takes power at over 100 kV from a transmission provider. Chevron has an automated interruption device between its facilities and the transmission facilities. Currently this field takes power from an ERCOT transmission owner at above 100 kV and then distributes the power over a Chevron owned and operated power distribution system to Chevron facilities. This Chevron system includes a substation, transformers and other facilities necessary to take power at above 100 kV and distribute and step down the power as necessary. Chevron uses the power for offices, repair facilities, oil wells, separation facilities, gas plants, drilling new wells and other related oil and gas activities. Located within the area of the Chevron power distribution system are ranchers, pump stations, third party oil wells and other small users. These parties are not located near any utility or coop facilities. For decades Chevron has worked to accommodate these parties by working with the local utility, transmission owners and the Texas Public Utility Commission to allow electrical service to these remote users. Many of these ranchers and other users are not located near any utility lines. Costs could run to the hundreds of thousands of dollars (or more) to provide an interconnect from the utility. Instead of leaving these parties with no electrical service, a procedure was developed that allowed parties such as Chevron to accommodate the small end user. For example if a utility/coop was unable or unwilling to serve a rancher at a reasonable cost, the rancher could approach Chevron. The goal would be to execute a three party agreement between the rancher, Chevron and the service provider. Under the terms of the agreement, the Rancher would interconnect with the Chevron system. A utility quality meter capable of remote reading would be installed and the rancher would be responsible for all costs beginning at the meter. The rancher contracts with a power provider for his power. Every month the meter between the Transmission owner and Chevron would be read. This smart meter located at the interconnect with the transmission system and its soft ware would show all deduct metering (such as our rancher) so that any non Chevron parties on the Chevron distribution system's usage would clearly be listed. The transmission owner then provides the billing information to the rancher's power provider. Chevron receives no compensation from the rancher, power provider or transmission owner. Chevron provides the service strictly on an accommodation basis. The Texas Public Utility Commission recognizes the needs of parties in remote areas of Texas and has blessed this type of service. Chevron is not considered a utility for providing this type of service. Chevron is concerned that the above described private power distribution system may inadvertently be forced to register as a bulk electric</p>

Organization	Yes or No	Question 13 Comment
		<p>system provider. This private distribution system is clearly at the terminus of a radial line and provides service to Chevron owned and operated facilities. The system is large in area and has been built over a period longer than any current employee’s memory. Through what can be called “accidents of history” and a good neighbor policy, Chevron has accommodated parties that otherwise could not connect to utility quality power. This arrangement is blessed and encouraged by the State PUC. Chevron charges nothing for the service. The system is entirely distribution in nature and does not contribute to the reliability of the grid in any manner. The intent of the current rule making is not to encompass such a system. NERC needs to encourage parties such as Chevron to help bring power to remote areas and not discourage, or worse yet greatly increase the cost to provide such service. Chevron requests that the NERC include in its definition a statement making it clear that systems such as those described above should not be required to register. Chevron supports the technical changes suggested by ELCON in its filing. A party’s facility should not be considered an essential facility where the facility would otherwise be considered exempt except that it is providing distribution services as an accommodation to third parties. This is especially true when 1. The incumbent utility or coop is unable or unwilling to serve the third parties at a reasonable cost 2. The service to the third party is provided as an accommodation 3. The facility is not generating and/or selling power to the third party 4. The third party is purchasing power from a power provider</p>
<p><b>Response:</b> The primary goal of the SDT in the revision of the definition of the BES is to improve clarity in the current language and to provide as much certainty as possible in the identification of BES and non-BES Elements. The Commission provided guidance within Order Nos. 743 &amp; 743a which identified the current application of the existing BES definition was essentially correct for the majority of the continent and directed clarification of the existing language to support consistent application across all regions. Additional guidance from the Commission spoke to significant changes in the scope of the definition with an expectation of the revision to the definition would not significantly expand or contract what is currently considered to be the BES.</p> <p>The SDT believes that establishing a ‘bright-line’ approach to identify BES Elements will inherently incorrectly identify a small number of facilities. The Exception Process is designed to clear up these discrepancies and render the proper classification of those questionable facilities. The SDT believes that with the draft core definition and the BES designations (Inclusions and Exclusions) the vast majority of facilities will be correctly identified as BES or non-BES Elements and therefore will produce the consistent application and results as desired by the Commission’s language in Order Nos. 743 &amp; 743a.</p> <p>The SDT made several revisions to the definition that should address your concerns.</p>		
Muscatine Power and Water		<p>In order to provide a unambiguous and concise definition of the BES, we ask the SDT to please include in the bright-line criteria that “all facilities less than a 100kV are excluded unless those facilities meet the criteria of an Inclusion.”</p>
<p><b>Response:</b> The SDT believes that the current draft BES definition provides sufficient clarity in establishing the bright-line of 100 kV and the identification facilities operated at less than 100 kV for exclusion would be redundant and jeopardize the SDT’s efforts of establishing clarity in the language of the definition. If an effort to provide additional guidance and in support of comments provided in response to Question 11, the SDT has modified the BES core definition with a statement</p>		

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 13 Comment
<p>that specifically excludes 'local distribution facilities.</p> <p><b>Bulk Electric System (BES):</b> <u>Unless modified by the lists shown below, All Transmission Elements operated at 100 kV or higher, and Real Power and Reactive Power resources as described below, and Reactive Power resources connected at 100 kV or higher unless such designation is modified by the list shown below. This does not include facilities used in the local distribution of electric energy.</u></p>		
<p>BGE and on behalf of Constellation NewEnergy, Constellation Commodities Group and Constellation Control and Dispatch</p>		<p>BGE agrees with the SDT's position that support equipment such as UVLS and UFLS not be classified as BES. BGE strongly believes that including control centers and other BES support equipment in the BES definition is not necessary and will cause confusion. BGE commends the BES Definition Standards Drafting Team for the informative webinar on 5/19/2011. We were encouraged that the SDT's developed a transition plan for the implementation of the new BES definition. BGE urges the SDT to also address the issue of the addition of new BES elements (i.e., such as new designated blackstart resources which may include a cranking path that is reclassified as BES). A transition period would also be required for these situations. BGE appreciates the work of the drafting team and supports the goal to produce clear definition language so that upwards of 95% of the assets are clearly distinguished as either included or excluded from the BES. We are particularly sensitive to the potential for burdensome processes (e.g. TFEs) to be added to reliability compliance, so we appeal to the team for continued, vigilant consideration of the arduousness of the BES determination process. Also important to consider is that the subject of this comment form, the proposed BES definition, is only one part of the BES definition project. The accompanying technical principles for BES Exceptions and the Rule of Procedure Process must be evaluated together with the BES Definition to sufficiently understand the revisions. In the end, the Technical Principles and the BES Definition must coalesce and be clearly coordinated and understood. The BES Definition language must include reference to the role of the associated defining documents. One unambiguous document must not be made ambiguous by an associated document or process.</p>
<p><b>Response:</b> The SDT appreciates the supportive comments and has taken into consideration the concerns raised by the commenter in its deliberations.</p>		
<p>Exelon</p>		<p>The definition assumes some inclusions or exclusions based on levels of generation used in the NERC Compliance Registry Criteria. Exelon does not view Orders 743 and 743-A as requiring a view or justification of these thresholds. See Order No. 743-A at P 47 ("it was not our intent to disrupt the NERC Rules of Procedure or the Statement of Compliance Registry Criteria").</p>
<p><b>Response:</b> The SDT agrees with the commenter.</p>		
<p>Kootenai Electric Cooperative</p>		<p>Kootenai has these additional concerns: We are concerned that the proposed 24-month delay in the effective date of the new definition will delay the potentially beneficial effects of the SDT's efforts, especially for utilities that have been inappropriately registered for BES-related functions, which is a common situation in WECC.</p>

Organization	Yes or No	Question 13 Comment
		<p>We therefore urge the new BES definition to become effective immediately upon approval by FERC or other applicable regulatory agencies. Entities that have been improperly registered for BES functions can then immediately file for deregistration and obtain the benefits of the new definition as soon as possible. For entities that have not previously been registered for BES-related functions but that would be required to register under the new definition, we agree that 24 months is an appropriate transition period to allow the newly-registered entity to attain compliance with newly-applicable reliability standards, many of which require new training for employees, new maintenance procedures, and complex new operational protocols. However, the transition period for newly-registered entities should be structured in a way that does not prevent entities seeking deregistration from benefitting from the new definition at the earliest possible date. The current definition provides that “Elements may be included or excluded on a case-by-case basis through the Rules of Procedure exception process.” Kootenai is concerned that the SDT carefully delineate which entity has the burden of proof in the exclusion process. The WECC BESDTF approach, which we commend to the SDT, laid out these burdens in some detail. Under that approach, essentially, if a facility is excluded from the BES by virtue of the specific exclusions listed in the definition, the Regional Entity bears the burden of proving that the facility nonetheless has a material impact on the interconnected bulk transmission system and therefore should be included in the BES. On the other hand, if a facility is classified as BES by virtue of the list of inclusions set forth in the BES definition, it can still escape classification as BES, but bears the burden of demonstrating that its facility has no material impact on the interconnected transmission system. We urge the SDT to give careful consideration to these burden-of-proof questions and to follow the lead of the WECC BES Task Force.</p> <p>For the reasons we have explained in our answer to Question 11, we believe the Exception process is critical both to ensure that the BES definition is effective in producing measurable gains to bulk system reliability and to ensuring that the definition will comply with the limitations Congress placed in Section 215. Hence, we believe the entire BES definition, including the Exception process and related procedures, should be vetted through the NERC Standards Development Process, including the full comment periods and a ballot approvals provided for in that process. We are concerned that important elements of the BES definition have been assigned to the Rules of Procedure Team, and that changes in the Rules of Procedure are subject to approval in a process that provides considerably less due process and industry input than the Standards Development Process. Accordingly, we urge that all elements of the BES definition, including those elements that have been assigned to the Rules of Procedure Team, be vetted through the Standards Development Process.</p>
<p><b>Response:</b> The SDT agrees with the commenter and has made revisions to the Implementation Plan to address these concerns surrounding the implementation dates.</p> <p>The SDT believes that the burden of proof issue should be resolved through the development RoP Exception Process. Your comments will be forwarded to the</p>		

Organization	Yes or No	Question 13 Comment
		<p>RoP team for consideration.</p> <p>Upon initiation of the development project in response to Order Nos. 743 &amp; 743a, NERC staff and the NERC Standards Committee determined the appropriate mechanisms for the development of each aspect of the project. The revision of the BES definition and the development of the Technical Principles associated with the Exception Process are currently being developed through the Standards Development Process. The RoP Exception Process is being developed through the RoP process for the revision of the Rules of Procedure.</p>
Springfield Utility Board		<p>Springfield Utility Board requests that NERC create a distinction between the terms BPS and BES. Are the two to be used interchangeably, or will BPS no longer be used? SUB suggests NERC consider adopting the statutory definition of the Bulk Power System as the core definition of the Bulk Electric System.</p> <p>May 26, 2011 Dear NERC Standards Drafting Team: Thank you for the opportunity to comment on NERC's proposed Continent-wide Definition of Bulk Electric System. We believe that NERC's proposed Bulk Electric System definition is proceeding in the right direction, but that more work needs to be done. SUB's specific concerns are as follows:</p> <p>Bulk Power System (BPS) and Bulk Electric System (BES) - Springfield Utility Board requests that NERC create a distinction between the terms BPS and BES. Are the two to be used interchangeably, or will BPS no longer be used? SUB suggests NERC consider adopting the statutory definition of the Bulk Power System as the core definition of the Bulk Electric System.</p> <p>Clear definition of Radial - Because there still appears to be inconsistencies in both definition and application, SUB encourages NERC to develop a concise definition of a radial system. For example, if a system is normally operated as radial, but could be operated closed (by manually closing a breaker), would it be considered a radial or close-looped system? If the answer is "that a closed system", is this in all cases, or are there exceptions?</p> <p>Registration Status - SUB understands that one of the primary values of clearly defining the BES is for registration determinations, as well as determining which of the Standards apply to registered entities. SUB encourages NERC to support the use of the BES definition for entity registration, and to develop the exception procedure for registered entities that do not own or operate any BES Elements.</p> <p>Springfield Utility Board appreciates FERC and NERC's efforts to create a continent-wide definition of Bulk Electric System, and appreciates the opportunity to provide comment. Tracy Richardson Springfield Utility Board SUB requests NERC to consider the situation where an entity has multiple, but separate systems. The entity is required to become a Registered Entity because the sum of their individual systems meets the thresholds, but portions of their physically separated systems taken individually would otherwise not reach the threshold for registration. For example, an entity may be responsible for service over a third party's transmission for distribution service to a single end user with a load less than =&lt;25MW that has a hard tap into the third parties' transmission. Because the load has a hard tap, it is technically served from more than</p>

Organization	Yes or No	Question 13 Comment
		<p>one transmission source. If there are no other loads served along the tap or along the third party's transmission segment, SUB believes that this type of situation warrants exclusion from the BES as it would otherwise be excluded - except for the fact that the combination of that service and other separate systems that the entity is responsible for triggers registration.</p> <p>SUB is concerned that devices such as shunt capacitor banks may be overlooked. For example, is a radial system serving only load with a shunt capacitor bank included or excluded from BES? It does raise the issue "what does "serving only load mean, exactly?" If a capacitor bank is used for purposes of managing reliability within an local network and the local network would otherwise be classified as an LDN, is the local network still classified as an LDN?</p>
Springfield Utility Board		<p>These comments are supplemental to Springfield Utility Board's comments provided to NERC on May 26, 2011 filed by Tracy Richardson. Please see the May 26 comments. This supplemental comment deals with the concept of "serving only load" and the classification of what types of generation are incorporated into the definition of generation for purposes of BES inclusion or exclusion. SUB's comment is that generation normally operated as backup generation for retail load is not counted as generation for purposes of determining generation thresholds for inclusion or exclusion from the BES. For purposes of BES inclusion or exclusion, a system with load and generation normally operated as backup generation for retail load is considered "serving only load" when using generation normally operated as backup generation for retail load (See Inclusions I2, I3, I5, and Exclusions E1, E2, E3). The rationale is that backup generation for retail load is normally used during a localized outage and for testing for reliability during a localized outage event. Including backup generation for retail load in generation thresholds (e.g. 75MVA) would not reflect generation used for restoration or reliability of the BES. Including backup generation for retail load in generation threshold calculations would cause an inappropriate inclusion of elements and devices, accelerate the triggering of inclusion (and may make exclusion provisions meaningless), and push more activity of excluding smaller systems from the BES into the exception process.</p>

**Response:** The SAR for Project 2010-17 identifies the scope of the SDTs responsibilities. The scope does not include revision or any level of assessment of the term Bulk Power System. Therefore any recommended revision to the definition of the BPS or recommendation on the usage or application of the term is not within the responsibilities of the SDT. No change made.

The SDT has crafted language in Exclusion E1 that clearly identifies what constitutes a radial facility.

The SDT is revising the definition of the BES and use or application of this definition for registration purposes solely resides under the responsibilities of the Certification and Registration department at NERC.

The SDT is revising the definition of the BES to identify BES Elements without regard to the ownership of such facilities. Ownership is an issue better addressed by the registration process or the applicability of specific Reliability Standards. The SDT is not in a position to comment on specific situations without the opportunity

Organization	Yes or No	Question 13 Comment
		<p>to review all available information pertaining to the facility in question.</p> <p>The SDT agrees with the commenter and has crafted revised Inclusion I5 language that specifically addresses Reactive Power resources.</p> <p><u>I5 –Static or dynamic devices dedicated to supplying or absorbing Reactive Power that are connected at 100 kV or higher, or through a dedicated transformer with a high-side voltage of 100 kV or higher, or through a transformer that is designated in Inclusion I1.</u></p> <p>The vast array of functional qualities of generation does not lend itself to a ‘bright-line’ concept of identifying BES Elements. Therefore the SDT has opted for the size threshold designation of generating facilities and allows for use of the Exception Process for further analysis of the facility and potential exclusion from or inclusion to the BES. No change made.</p>
City of St. George		<p>What are proposed transition implementation plans for facilities that will now be included in the definition? The implementation plan indicates 24 months which may or may not be enough depending on the response time to exception process. How will a pending exception action affect compliance requirements and effective dates? It should be at least 24 months after it has been determined that a facility must be included.</p>
		<p><b>Response:</b> The SDT believes that the proposed 24 month period is sufficient time for entities to achieve the appropriate level of compliance with the Reliability Standards. Comments concerning the Exception Process will be directed to the Rules of Procedure team for review. The SDT did, however, extend the effective date by an additional quarter of a year based on stakeholder comments.</p>
CenterPoint Energy		<p>CenterPoint Energy appreciates the opportunity to provide comments. In reviewing the draft definition, CenterPoint Energy believes the SDT may have unintentionally expanded the definition of the BES beyond the statutory definition in Section 215. Facilities included in the BES should be those facilities that are necessary for the reliable operation of the BES. Many interconnected facilities operated at 100kV and above, particularly those that are operated between 100kV and 200kV, are interconnected primarily to enhance the service provided to customers, rather than to maintain reliable operation of the BES. In addition; CenterPoint Energy is concerned with the addition of another exception process to the Rules of Procedure (ROP). In orders 743 and 743-A, the Commission allowed the ERO latitude to develop a definition that varied from the Commission’s recommendation. CenterPoint Energy supports the inclusion/exclusion approach of the SDT and believes it should be possible to define what constitutes the BES without an exception process. Historically, exception processes within the ROP have been cumbersome, labor intensive, confusing, and require on-going maintenance and quarterly or annual updates. Indeed, in question 10 of this comment form the SDT recognizes the burden of administrating an exception process. While CenterPoint Energy understands the SDT may feel pressure to produce a product quickly, the Company does not believe the expedited nature justifies an inferior product. CenterPoint Energy recommends the SDT continue developing criteria that clearly defines BES facilities based on the Section 215 language. Once that is accomplished, an exception process will not be needed.</p>

Organization	Yes or No	Question 13 Comment
<p><b>Response:</b> The primary goal of the SDT in the revision of the definition of the BES is to improve clarity in the current language and to provide as much certainty as possible in the identification of BES and non-BES Elements. The Commission provided guidance within Order Nos. 743 &amp; 743a which identified the current application of the existing BES definition was essentially correct for the majority of the continent and directed clarification of the existing language to support consistent application across all regions. Additional guidance from the Commission spoke to significant changes in the scope of the definition with an expectation of the revision to the definition would not significantly expand or contract what is currently considered to be the BES. No change made.</p> <p>The SDT believes that establishing a ‘bright-line’ approach to identify BES Elements will inherently incorrectly identify a small number of facilities. The Exception Process is designed to clear up these discrepancies and render the proper classification of those questionable facilities. The SDT believes that with the draft core definition and the BES designations (Inclusions and Exclusions) the vast majority of facilities will be correctly identified as BES or non-BES Elements and therefore will produce the consistent application and results as desired by the Commission’s language in Order Nos. 743 &amp; 743a.</p> <p>The SDT made several changes to the definition, based on stakeholder comments that provide additional clarity to the definition. Please see the revised definition.</p>		
Southern California Edison Company		<p>As discussed during the May 19, 2011 NERC Webinar, SCE supports having one-line diagrams illustrating examples of the line and bus arrangements as they pertain to the BES Definition included as part of a set of support documents. A good start for these diagrams would be the ones developed by the WECC Bulk Electric System Definition Task Force (WECC BESDTF). These diagrams were developed by WECC to better illustrate the demarcation between BES and non-BES facilities and provide important information and insight into the WECC system.</p>
<p><b>Response:</b> The SDT has taken into account the work product of several regional efforts in the development of the draft BES definition. The SDT also recognizes the value of a supporting reference document and will consider future development based on the project timeline and available resources.</p>		
Midstate Electric Cooperative		<p>Yes MSEC has these additional concerns: The current definition provides that “Elements may be included or excluded on a case-by-case basis through the Rules of Procedure exception process.” MSEC is concerned that the SDT carefully delineate which entity has the burden of proof in the exclusion process. The WECC BESDTF approach, which we commend to the SDT, laid out these burdens in some detail. Under that approach, essentially, if a facility is excluded from the BES by virtue of the specific exclusions listed in the definition, the Regional Entity bears the burden of proving that the facility nonetheless has a material impact on the interconnected bulk transmission system and therefore should be included in the BES. On the other hand, if a facility is classified as BES by virtue of the list of inclusions set forth in the BES definition, it can still escape classification as BES, but bears the burden of demonstrating that its facility has no material impact on the interconnected transmission system. We urge the SDT to give careful consideration to these burden-of-proof questions and to follow the lead of the WECC BES Task Force.</p> <p>For the reasons we have explained in our answer to Question 11, we believe the Exception process is critical both to ensure that the BES definition is effective in producing measurable gains to bulk system reliability and</p>

Organization	Yes or No	Question 13 Comment
		<p>to ensuring that the definition will comply with the limitations Congress placed in Section 215. Hence, we believe the entire BES definition, including the Exception process and related procedures, should be vetted through the NERC Standards Development Process, including the full comment periods and a ballot approvals provided for in that process. We are concerned that important elements of the BES definition have been assigned to the Rules of Procedure Team, and that changes in the Rules of Procedure are subject to approval in a process that provides considerably less due process and industry input than the Standards Development Process. Accordingly, we urge that all elements of the BES definition, including those elements that have been assigned to the Rules of Procedure Team, be vetted through the Standards Development Process.</p> <p>Dear NERC Standards Drafting Team:Enclosed are MSEC’s comments on NERC’s Proposed Continent-wide Definition of Bulk Electric System. We believe that NERC’s proposed Continent-wide Definition of Bulk Electric System is proceeding in the right direction on this important topic but that more work needs to be done. We would like to thank the Standards Drafting Team for their hard work. We support the detailed comments of the Snohomish County Public Utility District and Pacific Northwest Generating Cooperative with regard to the questions posed by the Comment Form for Project 2010-17 Definition of BES.We would like to emphasize these portions of Snohomish’s and PNGC’s comments:</p> <p>Question 1, both PNGC and Snohomish suggest that NERC start by adopting the statutory definition of the bulk power system as the core definition. We support that approach. That is, “(t) he term ‘Bulk Electric System’ means: (A) Facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and,(B) Electric energy from generation facilities needed to maintain transmission system reliability.The term does not include facilities used in the local distribution of electric energy”. See 16 U.S.C. Â§ 824o(a)(1).”</p> <p>Question 7, we support the exclusion for radial lines as drafted.</p> <p>Question 9, we support the categorical exclusion of Local Distribution Networks from the BES as defined here, but with Snohomish’s clarifications.</p> <p>Question 10, we support exclusion E4, for small utilities, but we are unclear how small utilities are defined in the exclusion language presented here.</p> <p>Question 11, we support the approach to exclusion of local distribution facilities discussed in the draft but repeat that more work should be done on the definition so that facilities used in local distribution are not swept up into the BES.The primary value of clearly defining the BES is for registration determinations. We realize that clearly defining the BES also has value in determining which standards apply to registered entities. If a registered entity does not own any Elements of the BES that that registered entity should be able to efficiently and effectively demonstrate an exception. We encourage NERC to support the use of the BES definition for registration-issues and to develop the exception procedure for registered entities that do not own or operate</p>

**Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17**

Organization	Yes or No	Question 13 Comment
		any Elements of the BES.
<p><b>Response:</b> The SDT believes that the burden of proof issue should be resolved through the development RoP Exception Process. Your comments will be forwarded to the RoP DT for consideration.</p> <p>Upon initiation of the development project in response to Order Nos. 743 &amp; 743a, NERC staff and the NERC Standards Committee determined the appropriate mechanisms for the development of each aspect of the project. The revision of the BES definition and the development of the Technical Principles associated with the Exception Process are currently being developed through the Standards Development Process. The RoP Exception Process is being developed through the RoP process for the revision of the Rules of Procedure. No change made.</p> <p>The SDT appreciates the industry support for this project. Please see the SDT responses in Questions 1, 7, 9, 10, and 11 of this document.</p>		
Illinois Municipal Electric Agency		Being a Joint Action Agency and Joint Registration Organization representing small municipal utility interests, IMEA appreciates this initiative to better define electric systems that should and should not be considered part of the Bulk Electric System. In addition to those comments provided above, IMEA supports comments addressing other concerns as submitted by the Transmission Access Policy Study Group and the Small Entity Working Group.
<p><b>Response:</b> Please see the SDT responses to the Transmission Access Policy Study Group and the Small Entity Working Group comments.</p>		
Long Island Power Authority		The SDT should clarify that Local Distribution Networks, including any facilities that are within the LDN, are not subject to Reliability Standard Requirements pursuant to Section 215 of the Federal Power Act.
<p><b>Response:</b> The Local Distribution Network concept was developed to allow facilities operated at 100 kV or higher, that serve a distribution function, to be eligible for exclusion if specific criteria are met. The use of the term 'Local Distribution Network' has resulted in some confusion by the industry in relation to the exclusion of local distribution facilities identified in Section 215 of the Federal Power Act. The SDT has elected to revise the Exclusion to be termed 'Local Networks' to eliminate the confusion as to what type of facilities are being addressed by the Exclusion.</p>		
Clark Public Utilities		The process for identifying facilities as part of an LDN needs to be stated. Clark has heard that this will be through a self-certification process, however, there is no written description how a utility classifies its transmission facilities as an LDN.
<p><b>Response:</b> The SDT envisions that the current practice of self-identification continues with the revised definition of the BES. No change made.</p>		
Pepco Holdings Inc		1) It would be very helpful to include examples (with an explanation and diagram) of the various configurations that meet each of the inclusions and exclusions. Can the next draft include such examples to provide further clarity to the definitions? Consideration should be given to developing an attachment for this

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 13 Comment
		<p>material and a method to add appropriate examples in the future.</p> <p>2) The proposal is silent on whether associated auxiliary and protection and control system equipment that could automatically trip a BES facility independent of the protection and control equipment's voltage level are included as part of the BES. The RFC BES definition specially addresses this issue as an example. Does IRO-005 cover those elements so it is not necessary to address these in this proposal? Consideration should be given to referencing the issue in the BES document.</p>
<p><b>Response:</b> 1) The SDT has taken into account the work product of several regional efforts in the development of the draft BES definition. The SDT also recognizes the value of a supporting reference document and will consider future development based on the project timeline and available resources.</p> <p>2) The SDT has determined that the draft BES definition should identify BES Elements which are operated at a voltage of 100 kV or above. The SDT also has recognized the existence of facilities (i.e., auxiliary equipment and Protection Systems) that support the reliable operation of the interconnected transmission network but do not necessarily operate at voltages of 100 kV or above and should not necessarily be classified as BES Elements. Reliability of the interconnected transmission network is established by the application of Reliability Standards and the development of Reliability Standards is not limited in applicability to BES Elements. Reliability Standards are written against facilities that support the reliable operation of the interconnected transmission network. Therefore the SDT believes that the clarification of the BES definition does not require identification of these types of facilities and that the specific facilities in question are better addressed by the applicability of individual Reliability Standards and not through the BES definition or the Exception Process. No change made.</p>		
Vigilante Electric Cooperative		<p>Dear NERC Standards Drafting Team: Enclosed are Vigilante Electric Cooperative, Inc's (VIEC) comments on NERC's Proposed Continent-wide Definition of the Bulk Electric System (BES). We believe that NERC's proposed definition of the Bulk Electric System is moving in the right direction and we thank the Standards Drafting Team for their hard work. We support the comments of the Snohomish County Public Utility District and Pacific Northwest Generating Cooperative with regard to questions posed by the comment form for Project 2010-17. We would like to add the following additional comments:</p> <p>With regard to exclusion E3, part e) - we do not believe that just because an element is on a list that it cannot be excluded. If an element meets all of the criteria to be excluded, then it should be excluded and removed from the list. Otherwise, we strongly agree that LDNs have no material impact on the BES. We also strongly encourage the continued development of a reasonable method for determination of inclusion/exclusion. We believe that there should be a clearer path that would ultimately allow a utility to pursue being included/excluded from registration with WECC. Many small utilities have an element that may actually have no material impact on the BES yet is required to comply with all WECC standards.</p> <p>We also would like to comment on the WECC compliance bulletin of April 15, 2011. While we greatly appreciate the recognition that radial T-Taps with transformer or distribution protection schemes have no material impact to the BES, we would encourage you to take this the additional logical step to actually remove these instances from WECC responsibilities. This would help reduce the burden both on WECC and the</p>

Organization	Yes or No	Question 13 Comment
		<p>individual entities and save everyone involved a tremendous amount of time, effort and money. We again thank the Team for their efforts and appreciate the opportunity to be allowed to comment on these issues.</p>
		<p><b>Response:</b> The primary goal of the SDT in the revision of the definition of the BES is to improve clarity in the current language and to provide as much certainty as possible in the identification of BES and non-BES Elements. The Commission provided guidance within Order Nos. 743 &amp; 743a which identified the current application of the existing BES definition was essentially correct for the majority of the continent and directed clarification of the existing language to support consistent application across all regions. Additional guidance from the Commission spoke to significant changes in the scope of the definition with an expectation of the revision to the definition would not significantly expand or contract what is currently considered to be the BES. No change made.</p> <p>The SDT is drafting a definition with the expectation of consistent application across the continent. The introduction or removal of specific language to address specific circumstances that may reside in the WECC footprint would not support this concept. No change made.</p> <p>The SDT is not in a position to comment on a WECC Compliance Bulletin.</p>
Central Lincoln		<p>We believe the Exception process is critical both to ensure that the BES definition is effective in producing measurable gains to bulk system reliability and to ensuring that the definition will comply with the limitations Congress placed in Section 215. Hence, we believe the entire BES definition, including the Exception process and related procedures, should be vetted through the NERC Standards Development Process, including the full comment periods and a ballot approvals provided for in that process. We are concerned that important elements of the BES definition have been assigned to the Rules of Procedure Team, and that changes in the Rules of Procedure are subject to approval in a process that provides considerably less due process and industry input than the Standards Development Process. Accordingly, we urge that all elements of the BES definition, including those elements that have been assigned to the Rules of Procedure Team, be vetted through the Standards Development Process.</p> <p>We note also that the SAR still does not apply the definition to all registered entity types in violation of the FERC order to provide a continent-wide definition. Please include PSEs in the SAR also.</p> <p>We are concerned that the proposed 24-month delay in the effective date of the new definition will delay the potentially beneficial effects of the SDT's efforts, especially for utilities that have been inappropriately required to meet BES reliability standards, which is a common situation in WECC. We therefore urge the new BES definition to become effective immediately upon approval by FERC or other applicable regulatory agencies. Entities that have been improperly required to meet standards can then immediately redirect resources to where they are truly needed. For entities that have not previously been registered for BES-related functions but that would be required to register under the new definition, we agree that 24 months is an appropriate transition period to allow the newly-registered entity to attain compliance with newly-applicable reliability standards, many of which require new training for employees, new maintenance procedures, and complex new operational protocols. However, the transition period for newly-registered entities should be structured in</p>

Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17

Organization	Yes or No	Question 13 Comment
		a way that does not prevent other entities from benefitting from the new definition at the earliest possible date.
<p><b>Response:</b> Upon initiation of the development project in response to Order Nos. 743 &amp; 743a, NERC staff and the NERC Standards Committee determined the appropriate mechanisms for the development of each aspect of the project. The revision of the BES definition and the development of the Technical Principles associated with the Exception Process are currently being developed through the Standards Development Process. The RoP Exception Process is being developed through the RoP process for the revision of the Rules of Procedure. No change made.</p> <p>The draft BES definition identifies assets that meet specific criteria for classification as a BES Element. The NERC Functional Model defines the Purchase Selling Entity (PSE) as: The functional entity that purchases or sells, and takes title to, energy, capacity, and reliability related services. The ownership or responsibility of assets should trigger the registration of the functional entity in question in another area of registration. No change made.</p> <p>The SDT agrees with the commenter and has made revisions to the Implementation Plan to address these concerns surrounding the implementation dates.</p>		
New England States Committee on Electricity		<p>As a general matter, the definition should reference the Exception Process, which may cause assets and facilities to be further “included” or “excluded.”</p> <p>In particular, once a facility has qualified for Exclusion it is not clear how that status is maintained.</p>
<p><b>Response:</b> The phrase requested was inadvertently omitted from the first posting.</p> <p><u>Note -</u> Elements may be included or excluded on a case-by-case basis through the Rules of Procedure exception process.</p> <p>The SDT believes that maintaining an approved Exclusion should be resolved through the RoP Exception Process. Your comments will be forwarded to the RoP DT for consideration.</p>		
PPL Energy Plus and PPL Generation		<p>The BES definition strives to draw a line between transmission customers (load and generation) and the “network” that makes up the bulk electric system. All transmission customers served by the network are not necessarily part of the network just like an on-ramp is not part of the Interstate highway, even though on-ramps deliver cars to the Interstate highway. FERC Order 743 paragraph 115 clearly gives guidance to the NERC BES Definition Team (BESDT) on developing fair exclusion criteria for facilities not necessary for the operation of the grid. PPL Generation and PPL Energy Plus (PPL) are concerned that the FERC order is being read overly expansively to include much more generation in the BES than FERC intended. In the NERC BESDT's latest proposed version of a BES definition, the definition appears to apply to small radial generators (Inclusions I2 and I3) but not to large radial loads (Exclusions E1 and E3). The BESDT has chosen to exclude or include LDNs based solely on the direction of power flow (see for example Exclusion E3-c) when the magnitude of the power flow is more critical than the direction. An example of the stark contrast between treatment of looped and radial facilities is exemplified by the exclusion of looped load and generation facilities of almost any size (Exclusion E3) from the BES, versus the seeming omission of any effort to</p>

Organization	Yes or No	Question 13 Comment
		<p>exclude radially connected generation facilities over 20 MVA. Clearly, FERC Order 743-A paragraph 55 instructs the BESDT to consider “additional facility characteristics” other than voltage to come up with a fair inclusion/exclusion process. The exclusion of looped facilities serving load and generation and the inclusion of radial facilities serving only generation does not appear consistent. Moreover, it ignores the physical reality that radial generator lead lines cannot be overloaded by outages on parallel paths because there are no parallel paths. Further, the MW flow on a radial line is well known and limited to a known maximum (limited to the larger of the generation or load on the end of the line): clearly reasons for exclusion. The BESDT should look carefully at FERC Order 743 paragraph 73 which describes the characteristics of the electrical network that the BES is trying to define. In that order, FERC justified its bright-line, 100 kV threshold, explaining that “many facilities operated at 100 kV and above have a significant effect on the overall functioning of the grid” because they share the following characteristics: 1. “operate in parallel with other high voltage and extra high voltage facilities”.i. The “bright line” at 100 kV recognizes many 100 kV lines parallel other HV/EHV lines and can be significantly loaded by failure of the HV/EHV lines. This does not apply to radial lines, even at 100 kV and above.2. “interconnect significant amounts of generation sources”3. “operate as part of a defined flow gate”4. have a “parallel nature” and are capable of “caus[ing] or contribute[ing] to significant bulk system disturbances”.i. Radial lines cannot cause significant BES disturbances since the outage of a radial line is studied in all N-1 planning studies and if the TPL standards are followed, an N-1 should not cause such disturbances. To their credit, the BESDT recognizes part of paragraph 73 in Exclusion E3-d and E3-e (possibly exempting many hundreds of MVA load) but yet fails to exclude radial lines serving generators from the BES “network”. Generation should be excluded from the definition of the BES on the same basis as load. PPL requests the BESDT clearly exclude radial generators up to 200 MVA (1200 amps at 100 kV). This exclusion is clearly justified because it would recognize many (if not all) loads and generators served radially do NOT possess the Network Transmission Facilities characteristics described in FERC Order 743 paragraph 73. PPL hopes that the NERC BESDT will recognize (as FERC Order 743 in paragraph 120 recognizes) that radial facilities and distribution facilities can both be excluded.</p>
<p><b>Response:</b> The SDT scope was determined by the language contained in Order Nos. 743 &amp; 743a in which the Commission provided guidance to the ERO to clarify the definition for continent-wide application. The Commission did not propose significant changes to the current application of the existing definition over the majority of the continent. Therefore the SDT has developed a draft core definition, together with BES designations (Inclusions and Exclusions) that provide the specificity necessary to identify the vast majority of BES Elements by utilizing the existing definition and criteria previously approved for this purpose. Although load is a component that can impact the reliability of the BES, the development of the definition is bound by the limitations documented in Section 215 of the Federal Power Act. Expanding the definition to include load would exceed the jurisdictional boundaries into the area of local distribution facilities. No change made.</p> <p>The BES definition (core definition and Inclusions &amp; Exclusions) will be applied to classify BES vs. non-BES Elements. The SDT believes that this will cover the vast majority of the facilities in question. The remaining facilities will be candidates for the Exception Process (RoP) where the Technical Principles will be utilized to determine if the facility is necessary for the reliable operation of the interconnected transmission network. Please see the revisions made to the revised definition.</p>		

**Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17**

Organization	Yes or No	Question 13 Comment
Manitoba Hydro		<p>Manitoba Hydro supports a 100kV bright line definition of the BES (excluding radial systems) that is consistent across all regions.</p> <p>We do not agree with the proposed impact based exception procedure and believe that the BES definition should be stand-alone.</p> <p>In addition, the complexity of the proposed BES definition and associated exception process may not provide the goal of uniform application of the BES definition and moves the burden of assessment and approval to the ERO.</p>
<p><b>Response:</b> The SDT believes that establishing a 'bright-line' approach to identify BES Elements will inherently incorrectly identify a small number of facilities. The Exception Process, a Commission identified component of the project, is designed to clear up these discrepancies and render the proper classification of those questionable facilities. The SDT believes that with the draft core definition and the BES designations (Inclusions and Exclusions) the vast majority of facilities will be correctly identified as BES or non-BES Elements and therefore will produce the consistent application and results as desired by the Commission's language in Order Nos. 743 &amp; 743a.</p> <p>The primary goal of the SDT in the revision of the definition of the BES is to improve clarity in the language and to provide as much certainty in the identification of BES and non-BES Elements. Although the clarifications added to the core definition and the inclusions and exclusions have lengthened and increased the complexity of the definition as a whole, the SDT feels that the improvements in clarity have increased the ability to apply the definition to achieve consistent results.</p>		
Consolidated Edison Co. of NY, Inc.		<p>The 'core' definition is not clear as to whether an Element would be included if it meets any one (or must meet more than one) of the 5 Inclusion criteria for inclusion?</p>
<p><b>Response:</b> As inclusions speak to specific facilities and are not necessarily related other than for identification of BES Elements; if a facility meets the criteria of a single inclusion then the facility is classified as a BES Element. Therefore only one (1) inclusion must be met for a facility to be classified a BES Element.</p>		
Independent Electricity System Operator		<p>We have no other concerns with the definition but we believe a guide demonstrating the correct application of the definition under various transmission system configurations would be useful.</p>
<p><b>Response:</b> The SDT also recognizes the value of a supporting reference document and will consider future development based on the project timeline and available resources.</p>		
NB Power Transmission		<p>Currently, the posted exception criterion is only a concept with many gaps and TBD, as posted details are later to follow. The exception criteria should be a menu of technical items (load flows, stability analysis etc). Entities should be required to assess and provide their own justification under each category with a conclusion that takes into account all of the relevant items for element(s) under exception, in a consistent</p>

**Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17**

Organization	Yes or No	Question 13 Comment
		<p>template and table of contents. Suggest the SDT to avoid specification of any parameters as they would differ under different design concepts, system configurations, system characteristics and regulatory requirements. An “all encompassing” comment is that the definition is too lengthy with an overly prescriptive exception process. The importance of the BES definition is recognized throughout the industry for its importance, and as such it should be simple, clear, and straightforward.</p>
<p><b>Response:</b> Comments concerning the Technical Principles (Exception Criteria) associated with the RoP Exception Process will be addressed through the dedicated responses developed by the SDT and published in the specific Consideration of Comments document associated with that portion of the overall project.</p>		
<p>Orange and Rockland Utilities, Inc.</p>		<p>It was mentioned that Cranking Paths of Blackstart Resources are defined as BES. How about the path(s) of generation units that will be deemed as BES? Please clarify.</p>
<p><b>Response:</b> The SDT has revised the Inclusion that identified Blackstart Cranking Paths as BES Elements. A significant number of comments identified that the Cranking Path could utilize local distribution facilities and could cross jurisdictional boundaries which should not be classified as BES Elements. Additionally the Inclusions related to generation facilities have been revised to eliminate the language which suggested paths between generation and the transmission are required to be contiguous Elements of the BES.</p>		
<p>AltaLink</p>		<p>We believe that the concepts of inclusions and exclusions as part of the bright-line definition are excellent. However, these exclusions do not address several directives in Order No. 743 and 743A, such as: differentiation between Transmission and Distribution, non-jurisdictional concerns, or distribution. We believe that the BES definition itself is not a venue to address these concerns but suggest that these issues should be explicitly addressed by the ERO’s exception criteria and exception process. Currently, the posted exception criterion is only a concept with many gaps and TBD, as posted details are later to follow. We suggest that the exception criteria should be a menu of technical items (load flows, stability analysis etc) and non technical items (type of loads such as distribution companies vs. major city center, national security etc). Entities should be required to assess and provide their own justification under each category with a conclusion that takes into account all of the relevant items for element(s) under exception, in a consistent template and table of contents. We suggest the SDT to avoid specification of any parameters as they would differ under different design concepts, system configurations, system characteristics and regulatory requirements.</p>
<p><b>Response:</b> The SDT agrees with the commenter that the Exception Process should be the primary mechanism for addressing the concerns surrounding issues such as: differentiation between Transmission and Distribution, non-jurisdictional concerns, or distribution. However the SDT has made modifications to the BES core definition to address the issues associated with the jurisdictional concerns related to local distribution facilities.</p> <p><b>Bulk Electric System (BES):</b> <del>Unless modified by the lists shown below, All</del> Transmission Elements operated at 100 kV or higher, <del>and</del> Real Power <del>and</del> Reactive Power resources <del>as described below, and Reactive Power resources</del> connected at 100 kV or higher <del>unless such designation is modified by the list</del></p>		

**Consideration of Comments on Revisions Made to the Definition of Bulk Electric System — Project 2010-17**

Organization	Yes or No	Question 13 Comment
<p><del>shown below.</del> <u>This does not include facilities used in the local distribution of electric energy.</u></p> <p>Comments concerning the Technical Principles (Exception Criteria) associated with the RoP Exception Process will be addressed through the dedicated responses developed by the SDT and published in the specific Consideration of Comments document associated with that portion of the overall project.</p>		
<p>Modern Electric Water Company</p>		<p>1) The SDT states that “one of the basic tenets that the SDT is following is to avoid changes in registration due the revised definition”. We stress the implications of a missed opportunity and the importance of a usable BES definition, because if the revised definition does not allow the industry (both registered and non-registered entities) as well as the regional reliability organizations to focus on and conduct business in a fashion that promotes reliable and efficient system operation (not just ultra-conservative compliance monitoring), then NERC has failed to do its job in this particular instance.</p> <p>2) The proposed implementation plan indicates that the effective date of this definition is not for at least 24 months after regulatory approval. We strongly disagree with this suggested approach as it does not provide for any benefit from this much-needed improvement. We believe the SDT intended to imply that entities not currently registered would have at least 24 months to become compliant with applicable standards if the improved BES definition suddenly swept them into the BES as it did for many small utilities on June 18, 2007. The definition should become effective immediately upon regulatory approval, and transition plans for newly-registered entities could specify longer timeframes.</p> <p>3) As currently drafted, NERC’s Statement of Compliance Registry Criteria (Revision 5.0) contains the text of NERC’s approved BES definition. Upon approval of any other language, the SCRC will become inaccurate without review and modification.</p>
<p><b>Response:</b> 1) The goals and assumptions established by the SDT are based on the documented Commission expectations in Orders Nos. 743 &amp; 743a. Opportunity does exist to further revise the definition beyond the clarification identified by the Commission in the Orders, however, technical justification is required to deviate from the current application of the current BES definition. No change made.</p> <p>2) The SDT agrees with the commenter and has made revisions to the Implementation Plan to address these concerns surrounding the implementation dates.</p> <p>3) Review and potential revision of the NERC Statement of Compliance Registry is beyond the scope of the current SAR for this project. No change made.</p>		

Diagram below refers to BGE comment for Q7:

## Technical Principles for Demonstrating BES Exceptions

An entity must request an exception under this Exception Procedure before any Element(s) that is included in the BES by application of the BES definition and designations can be excluded from the BES. Likewise, an entity must request an exception under this Exception Procedure before any Element(s) that is excluded from the BES by application of the BES definition and designations can be included in the BES.

Due to the importance of Blackstart Resources and their designated blackstart Cranking Paths to restoration efforts, no exceptions will be allowed for those items.

Entities that have Element(s) already designated as excluded under the BES definition and designations do not have to seek exception under the Exception Procedure.

The reasonableness of any such demonstration will be subject to review and remand by the ERO itself, or by any agency having regulatory or statutory oversight of NERC as the ERO (e.g., FERC or appropriate Canadian authorities).

Specific content of the application is spelled out elsewhere in this appendix.

### **Exception Criteria – Exclusions**

Entities can submit an application to seek an exception from the BES definition, including designations, by demonstrating the Element(s) are not necessary to reliably operate the interconnected transmission network as demonstrated by one or both of the following:

1. The Element(s) meet all of the following characteristics:
  - a. System Element(s) are located in close electrical proximity to Load.
    - i. Electrical proximity is a measurement of system impedance between the interconnected transmission network and the Load centers connected to the Element(s) within the system seeking exception. Loads within the system seeking exception are in close electrical proximity if they are separated by an impedance of no greater than TBD.

- ii. Evidence to support this position could include impedance cut-sheets or power flow data.
- b. System Elements are treated as radial in character.
  - i. This can be demonstrated by the way the connections to the BES are operated, e.g., the Element(s) are not operated as part of the BES with disconnection procedures for when a Disturbance occurs.
  - ii. This can also be demonstrated by the way the Element(s) are treated in operations, for example, they are not included in a regional dispatch.
  - iii. Evidence to support this position could include a one-line diagram and pertinent Operating Procedures.
- c. Power flows into the system, but rarely flows out.
  - i. This can be demonstrated through transactional records where it is shown that flow out occurs only under a very limited set of conditions and for a limited quantity of energy.
  - ii. The limited set of conditions must clearly state the conditions where power flows out, for example, only under specified Contingency events.
  - iii. Transactional records provided must be for the same time specified in the Exception Rules of Procedure for performing periodic exception self-certifications (presently two years).
  - iv. The maximum amount of energy flowing out is TBD MWh per year.
  - v. Evidence to support this position could include hourly energy data (MWh) for the most recent 12 month period.
- d. Power entering the system is not intentionally transported through the system to some other system.
  - i. This can be demonstrated by operational procedures that restrict use of delivered power to that system.
  - ii. Evidence to support this position could include pertinent Operating Procedures.

OR,

- 2. The Element(s) in question can be demonstrated as not being necessary for reliable operation of the interconnected transmission network as follows:
  - a. Based on the model used in the most recent applicable planning assessment:
    - i. If required, update the model to reflect your local conditions.
    - ii. If the model was updated, then run TPL studies for the first two years of the Near-term Transmission Planning Horizon.
    - iii. Document all assumptions made in the analysis.
    - iv. Analyze the subject Element(s) against the following criteria:
      - 1. Having a distribution factor of TBD% for any other Element.

2. Allowable transient voltage dip – criteria TBD
  3. Allowable transient frequency excursion – criteria TBD
  4. Voltage deviation – criteria TBD
  5. Transient Stability – positively damped
  6. Steady-state Stability – positively damped
  7. No cascading outages
  8. Other
- v. If within the criteria in all cases, then the Element(s) can be excluded.
  - vi. If not within the criteria, then the Element(s) can't be excluded.
- b. The ERO can override this criterion but would need to provide additional justification to support their finding.

### **Exception Criteria – Inclusions**

Entities can submit an application to seek an exception for an inclusion in the BES based on the following condition:

1. The Element(s) in question can be demonstrated as being necessary for reliable operation of the interconnected transmission network as follows:
  - a. Run TPL studies based on the existing model used in the most recent applicable planning assessment.
  - b. Monitor the contribution of the disputed Element(s).
  - c. Analyze against criteria set by SDT through industry feedback.
    1. Having a distribution factor of TBD% for any other Element.
    2. Allowable transient voltage dip – criteria TBD
    3. Allowable transient frequency excursion – criteria TBD
    4. Voltage deviation – criteria TBD
    5. Transient Stability – not positively damped
    6. Steady-state Stability – not positively damped
    7. Cascading outages
    8. Other
  - d. If within the criteria, then the Element(s) can't be included.
  - e. If not within the criteria, then the Element(s) can be included.
  - f. The ERO can override this criterion but would need to provide additional justification to support their finding.

## **Comment Form for 1<sup>st</sup> Draft of Project 2010-17: Definition of BES (BES) Technical Principles for Demonstrating BES Exceptions**

---

Please **DO NOT** use this form. Please use the [electronic comment form](#) to submit comments on the first draft of the Project 2010-17: Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions. **Only** submit comments on the first draft Technical Principles for Demonstrating BES Exceptions. The comments must be submitted by **June 10, 2011**.

If you have questions please contact Ed Dobrowolski at [ed.dobrowolski@nerc.net](mailto:ed.dobrowolski@nerc.net) or by telephone at 609-947-3673.

### **Background Information Definition of the BES (Project 2010-17)**

In parallel with the definition project, another stakeholder team outside the standards development process has been set up to develop a change to the NERC Rules of Procedure (ROP) to allow for entities to apply for excluding Elements from the BES that might otherwise be included according to the proposed definition and designations. This same process would be used by Registered Entities to justify including Elements in the BES that might otherwise be excluded according to the proposed definition and designations. This process would also be utilized for those situations where the core definition and designations do not clearly identify whether an Element is BES or not. The ROP team will develop the process for seeking an exception from the definition and designations, but the Definition of the BES Standards Drafting Team (DBESSDT), through the standards development process, has developed the criteria necessary for applying for an exception.

The exclusion exception process has been set up as a choice between two alternative forms of evidence. The first choice is seen as less onerous in nature as it does not require extensive technical analysis. An entity must choose which path it wants to pursue.

The inclusion exception process requires more detailed analysis and only one choice is provided.

The first draft of the criteria that has been posted contains the evidence that must be presented by an entity seeking an exception as well as specific criteria for how that evidence will be evaluated. The SDT is seeking industry feedback not just on the approach being presented but also on the specific numeric thresholds that will be used. Comments received from this posting will help to determine the final criteria that the industry will be required to adhere to. Therefore, industry feedback is vital to the development process.

It should be noted that the actual application process is described in the Rules of Procedure document that has been posted concurrent with the criteria document.

## Standards Announcement

Technical Principles for Demonstrating BES Exceptions

Appendix 5C - BES Component Exception Process

Two Comment Periods Open May 11-June 10, 2011

Webinar Scheduled on Thursday, May 19, 2011

**Now available at:** [http://www.nerc.com/filez/standards/Project2010-17\\_BES.html](http://www.nerc.com/filez/standards/Project2010-17_BES.html) and  
[http://www.nerc.com/filez/standards/Rules\\_of\\_Procedure-BES.html](http://www.nerc.com/filez/standards/Rules_of_Procedure-BES.html)

On April 28, the BES Definition Drafting Team (DBES SDT) posted a revised draft BES definition for comment through May 27, 2011. This announcement identifies two additional documents related to the BES Definition that are also being posted for comment.

### **Two 30-day Comment Periods Open through 8 p.m. on June 10, 2011**

To allow for comment in concert with the proposed definition of the Bulk Electric System under NERC Standards Project 2010-17, NERC is requesting comments on a proposed revision to the NERC Rules of Procedure to add *Appendix 5C Bulk Electric System Component Exception Procedure*. The proposed Appendix 5C is being posted for a 30-day comment period through **8 p.m. Eastern on Friday, June 10, 2011**.

In addition, a proposed approach to developing evidence to support an application for a BES Exception, *Technical Principles for Demonstrating BES Exceptions*, has been posted for a 30-day comment period until **8 p.m. Eastern on Friday, June 10, 2011**.

A webinar has been scheduled for Thursday, May 19 from 11:00 a.m. to 1:00 p.m. Eastern to review all three documents associated with the BES Definition project. A separate announcement will be sent with registration instructions for this webinar.

### **Instructions for Submitting Comments on the Proposed Technical Principles for Demonstrating BES Exceptions**

Please use this [electronic form](#) to submit comments. If you experience any difficulties in using the electronic form, please contact Monica Benson at [monica.benson@nerc.net](mailto:monica.benson@nerc.net). An off-line, unofficial copy of the comment form is posted on the project page: [http://www.nerc.com/filez/standards/Project2010-17\\_BES.html](http://www.nerc.com/filez/standards/Project2010-17_BES.html)

### **Instructions for Submitting Comments on the Proposed Rules of Procedure Modifications to Incorporate a Process for Requesting BES Exceptions**

Please use this [electronic form](#) to submit comments. If you experience any difficulties in using the electronic form, please contact Elizabeth Heenan at [Elizabeth.heenan@nerc.net](mailto:Elizabeth.heenan@nerc.net). An off-line, unofficial copy of the comment form is posted on the project page: [http://www.nerc.com/filez/standards/Rules\\_of\\_Procedure-BES.html](http://www.nerc.com/filez/standards/Rules_of_Procedure-BES.html)

## Next Steps

The DBES SDT will consider all comments received on the Technical Principles for Demonstrating BES Exceptions and make revisions to the document to incorporate stakeholder input. The team will post its response to comments prior to the next posting.

The BES ROP team will consider comments on the proposed changes to NERC's Rules of Procedure and make revisions if appropriate. An additional 45 day comment period on Appendix 5C is contemplated in August as Project 2010-17 is prepared for balloting.

## Project Background

On November 18, 2010 FERC issued [Order 743](#) and directed NERC to revise the definition of Bulk Electric System so that the definition encompasses all Elements and Facilities necessary for the reliable operation and planning of the interconnected bulk power system. Additional specificity will reduce ambiguity and establish consistency across all Regions in distinguishing between BES and non-BES Elements and Facilities.

In addition, NERC was directed to develop a process for identifying any Elements or Facilities that should be excluded from the BES. NERC is working to address these directives with two drafting teams – the definition of Bulk Electric System (BES) is being revised through the standard development process and a BES Definition Exception Process is being developed as a proposed modification to the Rules of Procedure. The proposed approach to developing evidence to support an application for a BES Exception, *Technical Principles for Demonstrating BES Exceptions*, was drafted by the BES Definition SDT with assistance from the BES Rules of Procedure team.

The work of the BES Definition team is posted at: [http://www.nerc.com/filez/standards/Project2010-17\\_BES.html](http://www.nerc.com/filez/standards/Project2010-17_BES.html)

The work of the BES Rules of Procedure Definition Exception Process has been publicly posted at: [http://www.nerc.com/filez/standards/Rules\\_of\\_Procedure-BES.html](http://www.nerc.com/filez/standards/Rules_of_Procedure-BES.html).

## Standards Process

The [Standard Processes Manual](#) contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

Individual
Angela P Gaines
Portland General Electric Company
<p>The proposed Continent-wide Definition of Bulk Electric System has an Exclusion rule (E1) which describes how radial facilities connected from a single Transmission source will not be considered part of the BES when the radial system meets subcategory (a), (b), or (c). For the proposed Technical Principles for Demonstrating BES Exemptions, the Exemption Criteria - Exclusions permits the entity to submit an application seeking exclusion from the BES definition when the network meets all of the following characteristics: a. System Elements are located in close electrical proximity to Load b. System Elements are treated as radial in nature c. Power flows into the system, but rarely flows out d. Power entering the system is not intentionally transported through the system to some other system Portland General Electric Company (PGE) asserts that subcategory (b) should be stricken from the criteria, since radial elements are already addressed in the Continent-wide Definition of Bulk Electric System. This subcategory specifies that to meet the criteria, System Elements must be "treated" as radial in nature. To be "treated" as radial, a system will inherently demonstrate compliance with all of subcategories (a), (c), and (d); and therefore, the inclusion of subcategory (b) is redundant in nature. In addition, PGE believes that Exception Criteria Exclusion 1.a.i. is ambiguous because it does not provide a clear definition of where the "interconnected transmission network" ends and the "Load center" begins. Also, PGE notes that a per unit impedance value will vary contingent on base voltage, so PGE does not believe this measure should be used in measuring "close proximity to Load." Finally, PGE notes that the qualifiers "close," "treated," "rarely" and "intentionally"</p>

are used in the current version of the proposed document. In following FERC's most recent Docket No. RM11-18 regarding the revised TPL standards, there should be an effort to replace all qualifiers with more quantifiable terms.

Group

Electric Market Policy

Connie Lowe

Yes

Yes

The word rarely should be struck from this item. It is meaningless in the context for which it is used and offers little to characterize an element or connection since it does not contain a measure.

Yes

Yes

Yes

Generation Owners and Generation Operators are typically not given access to non-public transmission information, especially that where a NDA or CEII signature is required. It would be virtually impossible for a GO to refute proposed inclusion of an Element owned by the GO unless they procure the services of a consulting firm with access to the data. And, even then, the consultant couldn't provide specifics of the evaluation only their findings.

Yes

Dominion is concerned that the provision of the proposed technical principles prohibiting the seeking of an exclusion for a cranking path for blackstart resources will include local distribution facilities within the definition of the BES. This conflicts with the definition of "Bulk Power System" in Section 215 of the Federal Power Act, which excludes facilities used in local distribution.

Yes

Although Dominion didn't see a specific form to address comments on Appendix 5B to the NERC ROP, Dominion would like to point out a particular area of concern with that Appendix. Dominion requests that NERC include explicit language stating that exclusion or inclusion of an element (for compliance purposes) begins only after approval/disapproval and any associated appeal has been reviewed and a final decision reached. Dominion would also like to point out that it assisted in the preparation of the Edison Electric Institute's comments and therefore agrees with the comments raised by EEI.

Group

PacifiCorp

Sandra Shaffer

No

All of PacifiCorp's responses are based on the application of these items to a given interconnection and not on a continental basis. See comments on question 10. Setting a standard for close electrical proximity using an impedance measurement does not address a proper measurement in all interconnections. A better, more accurate measurement would be to utilize fault duty. Low fault duties provide a good measurement of impact on the BES. Fault Duty at adjacent BES substations should not exceed 5,000 MVA.

Yes

All of PacifiCorp's responses are based on the application of these items to a given interconnection and not on a continental basis. See comments on question 10. If this requirement is added to the four requirements to capture local distribution networks, which are often operated in a looped configuration, which may still be included in the BES by the proposed BES bright-line due to generator inclusions, then this requirement has merit. Otherwise, exclusion E1 in the proposed BES bright-line definition already covers this item and it becomes redundant.

Yes

All of PacifiCorp's responses are based on the application of these items to a given interconnection and not on a continental basis. See comments on question 10. This criterion is very similar to a part of exclusion 3 of the proposed bright-line, which requires that power flows into the system. If the intent of this requirement is to capture local distribution networks that may be included under the proposed bright-line definition, then this requirement has merit. PacifiCorp proposes that instead of using a measure of energy, that the SDT utilize a measure of time and recommends that flow out of the system be limited to 15% on an annual basis. PacifiCorp does not have a technical justification for 15%, nor does it believe that a technical justification can be provided for any reasonable percent of time used, or MWh used to be applied equally to all interconnections.

Yes

All of PacifiCorp's responses are based on the application of these items to a given interconnection and not on a continental basis. See comments on question 10. This criterion is very similar to parts of exclusion 3 of the proposed bright-line, which states "d) Not used to transfer bulk power: The LDN is not used to transfer energy originating outside the LDN for delivery through the LDN; and e) Not part of a Flowgate or transfer path: The LDN does not contain a monitored Facility of a permanent flowgate in the Eastern Interconnection, a major transfer path within the Western Interconnection as defined by the Regional Entity, or a comparable monitored Facility in the Quebec Interconnection, and is not a monitored Facility included in an Interconnection Reliability Operating Limit (IROL)." If the intent of this requirement is to capture local distribution networks that may be included under the proposed bright-line definition, then this requirement has merit.

No

5a. Comments on approach: All of PacifiCorp's responses are based on a given interconnection and not on a continental basis. See comments on question 10. Using any technical criteria will allow many elements to be excluded from the BES regardless of the element's criticality to the interconnected system. Whatever technical criteria is established should only be applied to elements under 200 kV and any radial elements above 200 kV

5b. Comments on distribution factor measurement: All of PacifiCorp's responses are based on a given interconnection and not on a continental basis. See comments on question 10. Distribution factor has little to no bearing on entities in the Western Interconnection.

Yes

All of PacifiCorp's responses are based on a given interconnection and not on a continental basis. Fault duty may be appropriate for certain interconnections only.

Yes

Please refer to additional comments in question 13 regarding a contiguous BES.

No

Yes

The SDT proposal combined with the ROP proposal may be in conflict with Section 215 of the Federal Power Act, which requires "facilities used in the local distribution of electric energy" be excluded. The processes proposed may be over inclusive and by default require several elements which are not required for the reliable operation of the BES to in fact be included in the definition of "BES."

Yes

The SDT has proposed several technical criteria to be used to determine if an element has an impact on the reliability of the BES. PacifiCorp believes that the majority of non-BES elements can be excluded using a modified proposed bright-line and/or using the non-technical approach. However, in the event an entity requires additional justification to remove non-BES elements from the BES, then PacifiCorp feels the technical criteria should be established on an interconnection basis, not on a continent-wide basis. Because of the number of operating and geographic differences among the interconnections, to try to establish technical criteria on a continental basis would introduce confusion. PacifiCorp believes it is impossible to establish technical criteria that will allow unique interconnections to be treated in a comparable manner.

Group

ReliabilityFirst

Jim Uhrin

No

it is far too complicated for the smaller entities

Yes

yes only true radial without any impact should be excluded otherwise include it

No

All power flow studies can be don eto show a small impact, this is how the system is planned. This will only cause more confusion and debate between the FERC, NERC the Regions and registered entities

No

no one knows when some event will occur, putting this limitation will only cause debate. Any impact is an impact and should be included

No

to complicated and will only raise debate between FERC, NERC, the Regions and the Registered Entities

any impact is an impact, even generation is re-dispatched at 0% in some cases.

any impact is an impact, planning criteria between 3 & 5 % is often used and not allowed, why inject this into what define the BES. the criteria is applied it should be included

any impact is an impact. planning criteria between 5 & 10 % is often used and restricted to guard

No
Individual
Michael Jones
National Grid
No
We feel that there is no relation between the proximity to load and system reliability. The impedance is technically irrelevant, and we suggest that this criteria be dropped. If the criteria is not dropped, there should be clarification on what is meant by "Load". For instance are you really referring to "major load centers"? In many areas of the country Load is connected all along a 100kV line and hence much of a line is in close proximity to Load – but it could be small industrial loads and not significant load centers. If significant Load Centers is what the drafting team was driving at then, we believe it should be explicit. We also believe that if the drafting team is defining some technical criteria, then it should not be in the exception process. It should be included as part of the core definition. The exception process should be strictly limited to the procedures for application and approval and should not include substantive elements.
Yes
We agree that elements that are treated as radial should be allowed to request an exception. We would like more clarification about what is meant by "regional dispatch". To the extent definitions of terms such as "regional dispatch" are necessary; they should be addressed in the core definition development process. The exception process should be strictly limited to the procedures for application and approval and should not include substantive elements. We would also like clarification on whether all three criteria under bullet b are required to show if the element is treated as radial, or if meeting one is enough.
Yes
We agree with this requirement, but feel that assigning a specific value to the energy flowing out of the system in MWh is unnecessary. The energy flowing out of a system depends on the size of the area, and thus could vary widely. Another concern is about non-wires alternatives (NWA). One type of non-wires alternative that is considered during planning studies is to reduce the amount of load on our system by paying customers to not operate during peak hours. One scenario to consider is a generator connected on a radial line that qualifies as BES, and will need upgrades if the generator runs frequently. If this generator produces power close to the MWh threshold in the specified time frame per NERC criteria, does it mean the utility company will have to consider paying the generator owner money to shut down in order to keep total MWh generation below the threshold and avoid BES criteria required radial line upgrades? This is another reason assigning a specific value to the energy flowing out of the system is unnecessary. We would like clarification on whether all criteria (i,ii,iii,iv,v) need to be met, or if just meeting one criteria is sufficient. We feel that meeting criteria 1.c.1, 1.c.ii OR 1.c.iii is sufficient in showing that power rarely flows out of the system. Criteria 1.c.iv and 1.c.v should be removed. The exception process should be strictly limited to the procedures for application and approval and should not include substantive elements.
No
We feel that this requirement is not specific enough. "System" is too general. It should be clear what is intended by "system". Also, we would like more clarification about what is meant by "intentionally transport". Is the intent to mean there is a contract between a generator and load? The exception process should be strictly limited to the procedures for application and approval and should not include substantive elements.
We do not agree with all the criteria listed in point 2.a.iv. For example we believe that the term in 2.a.vi.6 "Steady-state Stability – positively damped" does not relate to the concept of steady-state stability. We believe an acceptable measure of steady-state stability would be an angle difference

across the transmission line. That difference can vary depending on the line; however, a rule of thumb is typically 45 degrees which provides a 30% steady state stability margin. As mentioned previously, the exception process should be strictly limited to the procedures for application and approval and should not include substantive elements.

We don't think this measurement is necessarily relevant in determining whether an element is necessary to system reliability. This criterion can be removed from the list. The exception process should be strictly limited to the procedures for application and approval and should not include substantive elements.

Yes

The NERC process could potentially be very lengthy and could interfere with the timely completion of our studies. In the technical paths for exclusions, bullet v states "If within the criteria in all cases, then the Elements can be excluded." This could lead to a very high number of studies that need to be done to prove an element should be excluded. For this reason, National Grid endorses a more streamlined process. We propose a process where entities would only need to submit a short form that briefly describes what they would like to exempt and the reason why, along with a one-line diagram. The entity who is requesting the exception would have to maintain records that show why the elements can be exempted until NERC performs an audit. At the audit, the entity can show the proof of why the element should be granted an exception. This process also allows for the application to remain public and reduces documentation burdens, because the non-public, CEII, or NERC CIP protected supporting documentation is maintained by the applicant. In this process, the entity first submits the application to their RE, and if approved by the RE, the application is submitted to NERC. The entity should be able to appeal if either the RE or NERC denies the application; however, it should be clear that for the second appeal to NERC, the decision is made by a different group than whoever decided on the first appeal. The appeal process in this exception procedure could be similar to the appeal process set by CMEP (compliance, monitoring and enforcement program). For entities that don't wish to wait until the next audit, there can be an optional process by which the proposed exception can be reviewed to provide an immediate ruling. Also, there should be a grace period after the audit is performed if audit staff concludes that an exception or inclusion granted by the initial application is not supported by adequate evidence. NERC's approval of an exception during this initial application process should stand until an Entity is audited and a final audit report is issued. There should also be an implementation period included in the audit report for the entity to come into compliance if the audit report disagrees with the initial exception approval. Absent evidence of fraud or intentional misrepresentation by the entity, there should be no non-compliance assessed for the period from initial exception approval to the final audit report. This process would need to allow participation or comments by Regional Entities, Reliability Coordinators, and/or Balancing Authorities in the application process, but should not allow participation by other third parties.

There should be a non-technical process for inclusions similar to the exclusions process.

No

No

Insufficient time was provided to fully undertake this inquiry.

Yes

The exception process should be strictly limited to the procedures for application and approval and should not include substantive elements.

Group

Tennessee Valley Authority

Richard Dearman

Yes
We agree with the requirement of an element being radial in character as being a qualifier for exclusion thru the non-technical analysis. However, we recommend that the term "radial in character" needs to be better defined. In addition, the language is confusing and we recommend the following: i.: suggest replacing "disconnection procedures" with "automatic disconnection devices" ii.: The intent of this item is not clear, and the term "regional dispatch" is not defined. Recommend the item be clarified or deleted.
Yes
One possible starting point for selecting a MWh threshold: Generators of 20 MVA or less are typically exempt from detailed modeling requirements. Suggest that reverse flows of this level or less, for a period of 24 hours or less would be an acceptable threshold. Therefore, this would provide a basis for selecting a threshold MWh level for reverse flows into the system under part iv. of 20 MW x 24 hours = 480 MWh per year.
No
There is not sufficient evidence provided by the SDT to distinguish between this fourth item for exclusion and the third item for exclusion. They both seem to fall in line with what is excluded per the bright line exclusion E3 (or Local Distribution Networks), but as written, it would be difficult to measure what is meant by "is not intentionally transported through" in this fourth item just as it would be difficult to measure what's meant by "flows into the system, but rarely flows out" for the third item. Such an exclusion should be required to include some technical analysis, but not extensive technical analysis (at least the inclusion of power flow base case as a minimum).
No
As written, most of this approach makes no sense. The words imply that if you have planned the system properly, you can exclude it from the BES! In TPL studies you make sure that voltage dips, frequency excursions, voltage deviations are acceptable, oscillations are damped, and no cascading outages occur. So if you meet the performance requirements of TPL studies, you can exclude the element from the BES. What good is this?
This is the only part of this technical analysis that may make sense. If the loss of any element of the BES results in a distribution factor of less than X% on the element being considered for exclusion, then exclude it. We suggest a value of 3% for this, since 3% is the threshold typically used in transfer studies.
As stated above, it does not make sense to use this category.
As stated above, it does not make sense to use this category.
As stated above, it does not make sense to use this category.
Yes
Comments: Revise second paragraph to read "Due to the importance of designated Blackstart Resources and their Cranking Paths to restore efforts, no exceptions will be allowed for those items that are included in a system restoration plan." Technical rationale: Multiple Blackstart Resources and Cranking Paths are frequently available but are not included in a system restoration plan. System restoration plans describe the Blackstart resources and cranking paths that are deemed to be necessary for system restoration. Section "Exception Criteria – Exclusions": Add 1.e. "Generation that is inoperable and not planned to be placed back into service but not yet officially decommissioned." Technical rationale: These facilities are not relied on to insure the reliability of the BES.
No
Applications for inclusion of facilities into the BES should include justification for doing so. However, there should not necessarily be specific criteria that must be met, but the importance of the facility to the BES should be clearly demonstrated.

No
The relevance and rationale for this criterion is unknown. If this criterion is intended to exempt elements, like circuit switchers, that are part of the distribution transformer circuits operated above 100 kV, and located within a mile of the BES interconnection point, then NSRF would expect the wording to be "in close electric proximity to the BES" rather than in "close electric proximity to Load". Requesting the SDT explain the relevance and rationale for this criterion before agreeing on its inclusion.
No
Radial in Character –propose that this criterion be removed for the reason that it does not illustrate any materially different characteristics beyond Exclusion E1 of the bright-line BES definition.
No
Proposing that this criterion be eliminated because it does not describe any materially different characteristics beyond Exclusion E3 of the bright-line BES definition.
No
This criterion should be eliminated based on the fact that it does not describe any materially different characteristics beyond Exclusion E3 of the BES definition.
No
Would like to propose that this technical analysis criterion be changed to criteria that are more closely tied to the Adequate Level of Reliability (ALR) characteristics. Would like to offer the following alternate criteria as possible examples, "(1) the BES can be controlled to stay within acceptable limits following a fault on or loss of the Element; (2) the BES performs acceptably subsequent to credible contingences of the Element; (3) the Element does not limit the impact and scope of instability and cascading outages once they occur; (4) BES Facilities are protected from undesirable damage by operating the Element within its ratings; (5) the reliability of the BES can be restored promptly subsequent to a fault on or loss of the Element; and (6) the BES has the ability to supply the aggregate electric power and energy requirements of the electricity consumers at all times, taking into account scheduled or reasonably expected unscheduled outages of the Element. Currently not aware of any continent-wide appropriate BES performance metrics for voltage dip, frequency excursion, voltage deviation, stability, etc. and would speculate that different values are likely for the different regions and system characteristics across the continent. Thus, it is not advisable to try to adopt unproven values without reasonable industry investigation and development.
Suggest replacing this aspect with those cited above because a distribution factor measurement indicates how much system changes influence the element, not how much a loss of the element would compromise the ALR of the BES. Currently unable to establish a clear correlation between this factor and any of the six characteristics of Adequate Level of Reliability (ALR) of the BES.
Suggest replacing this factor with those cited above because there is presently no established, continent-wide, acceptable transient voltage dip performance level for evaluating whether a fault or loss of the element would not compromise the ALR of the BES. In addition, the appropriate performance level for this factor may be different in other areas and system characteristics across the continent.
Suggest replacing this factor with those cited above. There are recognized, continent-wide transient frequency performance levels in the PRC-006-1 standard; however, the elements that are applicable to this standard are not necessarily BES elements and the transient frequency response requirements are not intended to be a criterion for BES classification.
Requesting the STD replace this factor with those cited above. At this time there is no established, continent-wide, acceptable (steady state) voltage deviation performance level for evaluating whether

a fault or loss of the element would not compromise the ALR of the BES. Moreover, the appropriate performance level for this factor may vary for different areas and system characteristics across the continent.

Yes

Recommending that this process address the six characteristics of the Definition of Adequate Level of Reliability (ALR) as listed in the comments above in Question #5. Also recommend that municipalities and other small entities having transmission systems designed to serve local load only, operated below 200 kV and not having any IROL's or SOL's be excluded from the BES definition. Rationale: this could affect smaller registered entities within a BA. The standards, especially those for Transmission Operators, aren't written for the smaller utilities. A small, municipal utility could have 75 MW of generation and operate a 115 kV looped system around their service area that is used primarily to serve their own load. Subsequently, they get forced into significant compliance requirements that does not enhance the reliability of the BES whatsoever.

No

Would like to propose that the technical analysis criterion be replaced by criteria that are more closely tied to the Adequate Level of Reliability (ALR) characteristics. The following alternate criteria are offered as possible examples, "(1) the BES cannot be controlled to stay within acceptable limits following a fault on or loss of the Element; (2) the BES does not perform acceptably after credible contingences of the Element; (3) the Element limits the impact and scope of instability and cascading outages when they occur; (4) BES facilities are not protected from unacceptable damage by operating the Element within its ratings; (5) the integrity of the BES cannot be restored promptly following a fault on or loss of the Element; and (6) the BES does not have the ability to supply the aggregate electric power and energy requirements of the electricity consumers at all times, taking into account scheduled or reasonably expected unscheduled outages of the Element. Currently not aware of any continent-wide appropriate BES performance measures for voltage dip, frequency excursion, voltage deviation, stability, etc. and would speculate that different values are likely for different regions and system characteristics across the continent. Therefore, would like to state that it is not advisable to try to adopt unproven values without reasonable industry investigation and development.

Proposing to replace this factor with those cited above because a distribution factor measurement indicates how much system changes affect the element, not how a fault or loss of the element would compromise the ALR of the BES. There is no clear correlation between this factor and any of the six characteristics of Adequate Level of Reliability (ALR) of the BES.

Propose replacing this factor with those cited above because there is presently no established, continent-wide, acceptable transient voltage dip performance level for evaluating whether a fault or loss of the element would compromise the ALR of the BES. In addition, the appropriate performance level for this factor may vary for different areas and system characteristics across the continent.

Propose replacing this factor with those cited above because there are established, continent-wide transient frequency performance levels in the PRC-006-1 standard, but the elements that are applicable to the standard do not have to be BES elements and the transient frequency response requirements are not intended to be a criterion for BES classification.

Propose replacing this factor with those cited above because there is presently no established, continent-wide, acceptable (steady state) voltage deviation performance level for evaluating whether a fault or loss of the element would compromise the ALR of the BES. In addition, the appropriate performance level for this factor may vary for different areas and system characteristics across the continent.

No

No

Yes

1. Propose replacing the wording in the Exclusion preface, Exclusion 2 preface, and Inclusion 1 preface of "not necessary to reliably operate the interconnected transmission network" with "necessary to maintain an Adequate Level of Reliability (ALR) of the Bulk Electric System". 2. Currently having reservations concerning the following statement made in the introduction of this document: " Due to the importance of Blackstart Resources and their designated blackstart Cranking

Paths to restoration efforts, no exceptions will be allowed for those items." This does not allow for a provision to exclude any designated Blackstart Cranking Path (at any voltage) even though there may be technical justification for it. 3. The first page states that "Specific content of this application is spelled out elsewhere in this appendix." Request the SDT describe where this appendix will be published and indicate if this is a compliance document or just technical "guidance"? 4. By having the following statement included for both exclusions and inclusions will lead to disagreement: "The ERO can override this criterion but would need to provide additional justification to support their finding." Suggesting that any override should include adequate technical justification and not interfere with other statutory requirements. Also, it does not clarify or identify who would make the determination whether NERC has made adequate justification to override the criterion. 5. Do not believe that the "Inclusion" process should be completely removed from BES Definition. Would like to recommend using bright-line criteria indentifying everything 100 kV and above to be considered BES and then allow for the "Exception" process to take out Facilities that do not have an impact on the reliability of the BES. Selecting BES Facilities based on bright-line criteria is what FERC requested in its Order regarding BES Definition. This would streamline and simplify the process by removing a large quantity of exceedingly unnecessary paperwork.

Yes

First, thank you for the opportunity to comment on the Technical Principles for Demonstrating BES Exceptions. We appreciate the work that NERC has done on these principles and the other related efforts to revise the definition of the BES. In response to question #1, we note only that using impedance to benchmark system load proximity would likely not yield clear demarcations. High voltage relative or per-unit impedances are considered typically much lower than low voltage impedances. Hence, in the absence of phase shifting transformers, service compensation, or other mitigation factors, power typically flows over the highest voltage lines, which offer the lowest impedance.

Yes

We agree conceptually that facilities operating as radials rather than as integrated portions of the integrated bulk transmission system should be excluded from the BES definition. However, to be consistent with the draft BES definition, the term "radial in character" should be explicitly defined as facilities that may include one or more lines into a load area or referenced as a local distribution network. In addition, we agree that the manner in which a system is operated during BES disturbances may be an indication of whether that facility is radial in character. That being said, we are concerned that, to the extent the SDT considers regional disconnect procedures, it should be careful to note that UFLS and UVLS relays are often embedded within local distribution facilities and, while it is necessary for the UFLS and UVLS relays to be properly armed to protect the BES in the event of a severe system disturbance, the local distribution facilities interconnected with those relays should not, and cannot legally, be classified as BES.

Yes

We agree conceptually that one critical characteristic distinguishing facilities that must be excluded from the BES from facilities that should be included is the manner in which power flows on those facilities. Hence, the SDT has properly identified power flows as one important characteristic that identifies BES facilities. We also agree conceptually that the fact that power may flow out of facilities onto the grid during a few hours in a year or during extreme contingencies should not change the characterization of the facilities in question as excluded from the BES. Accordingly, we support inclusion of power flow analysis as one element of characteristics that can be used to exclude facilities from the BES even if the facilities do not pass each of the bright-line thresholds laid down in the BES definition. We also agree that transactional and hourly generation records are an appropriate basis for making the determination since these can be used to demonstrate that demand within a system exceeds generation within that system in most hours and that power therefore does not flow onto the grid, and also to determine the number of hours where this is not the case and the amount by which generation within the system exceeds demand. In order to identify facilities that are not necessary for the operation of the BES under this text, we propose that any facility where real power flows in 90 percent of the time or more under normal ("N-0" or All Lines in Service) operating conditions should

be held to meet this test. That facilities meet this test could be demonstrated using metering or supervisory control and data acquisition ("SCADA") data records over the course on two years. While we agree with the SDT's view that power should flow predominantly in the direction of load for excluded facilities, we are concerned that this characteristic may no longer be a defining characteristic as the electric industry evolves in the future. If distributed generation becomes the future norm for new power generation facilities, it may no longer make sense to look at power flow as a defining characteristic. That is, even if a sufficient number of small distributed generation facilities were constructed on certain facilities to cause power to flow out of those facilities more than ten percent of the time, the fundamental character of those facilities will not have changed. Finally, we believe that power flow analysis under this item should consider actual power flow, not scheduled power flow.

Yes

As a matter of operation, power is scheduled across transmission lines. Further, transmission lines in the Western Interconnection (either individually or as part of a transmission path) are rated for total transmission capacity and available transmission capacity, and transmission rights can be purchased on such lines, if available, on an OASIS. Facilities that do not share any of these operational characteristics should not be part of the BES. Accordingly, we agree that if power is not intentionally transported through particular facilities, those facilities should not be considered part of the BES. We also agree that examining the Operating Procedures applicable to particular facilities will provide a ready guide to whether power is intentionally scheduled across those facilities. We suggest, however, that the SDT look beyond those protocols that fall within the NERC Glossary's definition of Operating Procedure. For example, in the West, transmission paths are almost all listed in the WECC Path Rating Catalog. Similarly, it is not clear whether scheduling protocols, OASIS operations, and the other factors listed above qualify as Operating Procedures. Hence, we urge the SDT to list such specific operational characteristics as part of this test. Finally, as noted in our answer to Question 3, we are concerned that, if distributed generation advances significantly, power transport may cease to be a meaningful measure for determining whether a facility is part of the BES, and we believe that power flow analysis should consider actual power flow, not scheduled power flow.

Yes

We agree conceptually with the idea that two different paths to exclusion should be adopted, one relying upon readily identifiable characteristics that are ordinarily associated with non-BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES. Snohomish Public Utility District has prepared a White Paper proposing a performance-based approach to support the technical determination whether Elements should be excluded from the BES, which we commend to the SDT for study. We also commend the work of the WECC BES Task Force and the WECC Technical Studies Subcommittee, both of which have devoted substantial time and resources to developing a workable and technically defensible process for excluding Elements classified as BES based upon their electrical characteristics. See WECC BES Task Force Proposal 6, App. A at 3-9 & App. B at pp. B-4 to B-7 (posted Feb. 18, 2011) (available at: <http://www.wecc.biz/Standards/Development/BES/default.aspx>). We recommend that the SDT modify its approach to the technical exclusion process to match the approach advocated in Snohomish's White Paper, which is based upon the approach recommended by the WECC BES Task Force.

The use of distribution factors, such as Power Transfer Distribution Factors ("PTDF") and Outage Transfer Distribution Factor ("OTDF") provide insight into the relative impedance of neighboring systems. However in the Western Interconnection it has never been a definitive indicator of whether a system fault with delayed clearing would impact a neighboring electric system. While we understand that many entities from the Eastern Interconnection support the use of such factors, we believe the approach is unlikely to work in the Western Interconnection. Based on the significant differences between the four major interconnections in North America, we suggest that a detailed technical exemption process be allowed on an interconnections wide basis. The Western Interconnection is a "hub and spoke system" where loads are very remote from large generation plants, with margins that are based on stability limits. By contrast, the Eastern Interconnection is a tightly meshed system with loads and generation in close proximity, often creating margins that are based on thermal limitations. These differences manifest themselves in a variety of ways for various operations. For example, the

Western Interconnection uses a rated-paths methodology while the Eastern Interconnection uses transmission load relief mechanisms. Consistent with FERC order 743-A, we support exemption criteria for individual frequency independent regions, or interconnections.

Specific transient voltage dip thresholds are proposed on page 15 of Snohomish's White Paper. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should produce no more than a 20% voltage drop for no more than 20 cycles in a Category B contingency and no more than a 20% drop for 40 cycles in a Category C contingency. Technical justification for these thresholds is provided on pages 12-16 of Snohomish's White Paper.

Page 15 of Snohomish's White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided on pages 12-16 of the White Paper.

Please see our response to Question 5d.

No

Yes

As a general matter, we agree with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid justification showing that the Elements in question contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. We also agree that the SDT has, in general, identified the correct technical approach, although we recommend that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in Snohomish's White Paper, in the WECC BES Task Force Proposal 6, and in our answer to Question 5. While we support the SDT's overall approach, we believe subsection (f) of the proposed inclusion criteria, which would allow NERC to "override this criterion" if it provides "additional justification" for doing so is both unnecessary and creates confusion and uncertainty in what is otherwise a clear and concise process. Subsection (f) is unnecessary because if the technical process laid out in subsections (a) through (e) fails to provide any evidence that the contested Element(s) create a material impact on the reliability of the bulk interconnected transmission network, there is no reason to classify those Element(s) as BES, and that should be the end of the question. Subsection (f) creates needless uncertainty because it allows NERC to override the technical criteria laid out in subsections (a) through (e) if "additional justification" is provided, but there is no suggestion as to what this additional justification might be. Nor is there any explanation as to why additional justification might be necessary after the criteria in subsections (a) through (e) have been exhausted.

Please see our corresponding answers to Question 5 for 7b-7e.

No

As discussed on page 12 of Snohomish's White Paper, there may be a few isolated cases where additional data will need to be provided to run a valid technical analysis under the criteria set forth in the Exception Procedure. These cases should be exceedingly rare, however, because the starting point for the technical analysis we recommend is the current base case operated by the relevant RE, and in nearly every case, the base case can be expected to model any Element that conceivably has a material impact on the reliable operation of the bulk system. In those rare cases where it does not, we believe the owner or operator of the subject Element should be able to provide the needed data, although we propose that the relevant owner or operator be relieved of this burden if it can be demonstrated that the nearest electrically interconnected Element has no material impact on the bulk system.

No

Yes

In general, , as we discuss above, the Technical Principles for Demonstrating BES Exceptions present a reasonable approach to resolving questions of inclusion and exclusion in the BES that the BES

definition itself does not clearly resolve. However, we caution that these principles for demonstrating exceptions cannot, and must not, take the place of a consideration of, and criteria under whether, any specific piece of equipment is subject to FERC, the ERO, and Regional Entity jurisdiction in the first instance. Section 215 of the Federal power Act (FPA) sets out clear limits of jurisdiction of FERC, the ERO, and Regional Entities for purposes of developing and enforcing reliability standards. Specifically, Section 215(i) provides that the ERO "shall have authority to develop and enforce compliance with reliability standards for only the Bulk-Power System." 16 U.S.C. § 824o(a)(1) (emphasis added). Section 215(a)(1) of the statute defines the term "Bulk-Power System" or "BPS" as: (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy." Id. As we have explained in our comments on the BES definition, that definition should expressly account for these jurisdictional limitations up front. This would allow for the jurisdictional limitation consideration as the very first step in determining whether or not a particular piece of equipment is part of the BES. The Technical Principles for Demonstrating BES Exceptions, on the other hand, provides a completely separate set of criteria for exclusion from the BES and would come into play only after application of the full BES definition to a particular piece of equipment and determination that the BES definition does not provide a satisfactory answer as to whether that piece of equipment is or is not part of the BES. This is acceptable insofar as it goes, but, because (1) the criteria in the Technical Principles are distinct from the jurisdictional limits of Section 215 of the FPA, and (2) consideration of the Technical Principles would essentially be the last, or one of the last, steps in the process, the Technical Principles cannot substitute for, in any way, consideration of the jurisdictional limitations of the FPA. Again, we cannot overemphasize enough how important it is to have the jurisdictional consideration be the very first step in the process of determining whether a particular piece of equipment is or is not part of the BES. Again, thank you for the opportunity to comment. We look forward to continuing to work with NERC and stakeholders to develop a BES definition that is both workable and lawful.

RoLynda Shumpert

South Carolina Electric and Gas

No

SCE&G disagrees with the assumption that the proximity of a BES facility to Load is indicative of it's importance to BES reliability. Some lower voltage facilities can be quite short and thus have lower impedance but be important to BES reliability. Furthermore, the term "Load centers" is not defined leaving it subject to interpretation. Assuming a load center has many busses, where would the measurement be made - From the most distant load bus in the load center or the nearest? Similarly - does a single facility get measured from it's terminal to the load center or does the presence or lack of breakers need to be considered when selecting the measurement point?

Yes

SCE&G agrees with the requirement of an element being radial in character as being a qualifier for exclusion thru the non-technical analysis. However, we recommend that the term "radial in character" be better defined. In addition, the language is confusing and we would like to recommend the following: i.: suggest replacing "disconnection procedures" with "automatic disconnection devices" ii.: The intent of this item is not clear, and the term "regional dispatch" is not defined. Recommend the item be clarified or deleted.

Yes

One possible starting point for selecting a MWh threshold: Generators of 20 MVA or less are typically exempt from detailed modeling requirements. Suggest that reverse flows of this level or less, for a period of 24 hours or less would be an acceptable threshold. Therefore, this would provide a basis for selecting a threshold MWh level for reverse flows into the system under part iv. of 20 MW x 24 hours = 480 MWh per year

No

There is not sufficient evidence provided by the SDT to distinguish between this fourth item for exclusion and the third item for exclusion. They both seem to fall in line with what is excluded per the bright line exclusion E3 (or Local Distribution Networks), but as written, it would be difficult to measure what is meant by "is not intentionally transported through" in this fourth item just as it

would be difficult to measure what's meant by "flows into the system, but rarely flows out" for the third item. Such an exclusion should be required to include some technical analysis, but not extensive technical analysis (at least the inclusion of power flow base case as a minimum).

No

As written, most of this approach makes no sense. The words imply that if you have planned the system properly, you can exclude it from the BES! In TPL studies you make sure that voltage dips, frequency excursions, voltage deviations are acceptable, oscillations are damped, and no cascading outages occur. So if you meet the performance requirements of TPL studies, you can exclude the element from the BES. This does not seem to be what was intended.

This is the only part of this technical analysis that may make sense. If the loss of any element of the BES results in a distribution factor of less than X% on the element being considered for exclusion, then exclude it. We suggest a value of 3% for this, since 3% is the threshold typically used in transfer studies.

As stated above, it does not make sense to use this category.

As stated above, it does not make sense to use this category.

As stated above, it does not make sense to use this category.

Yes

Revise second paragraph to read "Due to the importance of designated Blackstart Resources and their Cranking Paths to restore efforts, no exceptions will be allowed for those items that are included in a system restoration plan." Technical rationale: Multiple Blackstart Resources and Cranking Paths are frequently available but are not included in a system restoration plan. System restoration plans describe the Blackstart resources and cranking paths that are deemed to be necessary for system restoration. Section "Exception Criteria – Exclusions": Add 1.e. "Generation that is inoperable and not planned to be placed back into service but not yet officially decommissioned." Technical rationale: These facilities are not relied on to insure the reliability of the BES.

No

SCE&G recommends that applications for inclusion of facilities into the BES should include justification for doing so. However, there should not necessarily be specific criteria that must be met, but the importance of the facility to the BES should be clearly demonstrated.

1.a.i. Electrical Proximity - If impedance is to be used as a measure of electrical proximity, which in turn is a replacement for geographical proximity, then how would the presence of parallel lines, capacitors, phase-angle regulators (PARs), tap-changing transformers, generation and reactors be treated in determining electrical proximity? How does this approach effectively differentiate between transmission and distribution lines of the same voltage and length? When using impedance, how is "greater than" determined? Sum of the Impedances - Would the filing entity simply add up the in-series impedances for each radial Element to demonstrate its electrical proximity? For example, would the sum of the impedances from this radial path example be equal to the sum of the two feeder and transformer impedances, i.e., measured from a 230 kV bus along a 230 kV feeder, through a 230/138 kV step-down transformer, and an in-series 138 kV feeder to a 138/13.8 kV step-down distribution

transformer? What impedance would the SDT apply to a PAR (or tap-changing transformer) and to the overall path if a PAR (or tap-changing transformer) were located in-series with the measured Elements? 1.a.ii. Power Flows – What is the meaning of “power flow data” as the term is used here and how is the meaning different from the term when used under 1.c. Power flows into the system, but rarely flows out? Should this sentence use the phrase “impedance data extracted from a load flow study” instead? Entities should be required to identify the significance of the element’s physical characteristics. Such identification can be done through a simple checklist along with any relevant comments. The SDT should revise the exception criteria to seek an alternative language and/or revise exclusion criteria (a), which will require entities to provide the previously stated information for their element.

No

The term “regional dispatch” is not defined. Provide a definition or reference to a definition to be used in making this determination. Recommend adoption of the alternate term “operational control.” 1.b.ii, Operational Control - The SDT should consider using the terms “under the operational control of a Balancing Authority.” It is instructive that the overarching requirement for a finding of transmission system integration in Mansfield was that the facilities be under operational control of the Independent System Operator (ISO). \* \* Southern Cal. Edison Co., 92 FERC ¶ 61,070 at 61,255 (2000), reh’g denied 108 FERC ¶ 61,085 (2004). Replace the example in 1.b.i. with a clearer example. Entities should be allowed to demonstrate the radial characteristics to determine if they are permitted for an exception, and demonstrate compliance with radial defining criteria.

No

If an entity provides hourly MWh power flow data on a radial for a 12-month period (under v.) showing no power flow reversals, would transaction data (under i. through iv.) still be required? Could the entity just say “no transactional records?” If there were power flow reversals, wouldn’t the power flow data (provided under v.) also show those, e.g., the amount and duration? Isn’t this request redundant? If reversing power flows on a feeder caused it to fail one of the criteria, could the radial still be excluded, or is it necessary for the Element to pass all requirements? Alternatively, could the entity choose to file for Exclusion of that Element under the technical analysis option? What happens and what are the implications when the two approaches produce different outcomes? Recommend that “iv. The maximum amount of energy flowing out” limit be set to no more than 24 hours of reverse power flows within any rolling 12-month period. Consider avoiding prescribing values and eliminate bullet (iv). The intended performance outcome should be described, but without setting values. This should not have any impact on the reliability of the transmission network if items 1, 2 and 3 are satisfied.

Yes

No

This method may allow an entity to exclude Elements which perform a transmission function, but that are not the most limiting Element. “Not being necessary for reliability operation” needs definition. The SDT should consider developing a Guidance Document to provide examples and insights to guide prospective filing entities. The TPL Reliability Standards already describe the full set of requirements for a reliable system. Why are added requirements necessary? Why would any such added criteria not conflict with the TPL Reliability Standards to the extent that they were either more or less restrictive? Entities should be given an option to conduct an analysis to demonstrate if an element is necessary for the operation of a transmission network. NERC should specify all the relevant criteria categories to be listed as under 2 (a). NERC should avoid prescribing numerical values, but instead establish a range of values (or reference industry standards) that would be consistent with industry/ regional standards or practices without compromising the reliability of the transmission network.

2.a. The term “Planning Assessment” is not a defined term in the NERC Glossary of Terms Used and should not be capitalized, or it should be defined. 2.a.iv.1. Distribution Factor - This is a judgment of what feeder power flow participation level is material and what is non-material. While TDF and OTDF analysis is an indication of contributions from the element, the SDT should avoid setting values and instead describe the intended performance outcome from a distribution factor measurement. Note that ultimately NERC as an ERO or relevant regulatory authority will approve the application and can assess the performance outcome in their decision making presented in an entity’s application.

Voltage dip is specified in terms of duration and retained voltage, usually expressed in percentage.

Suggest that either the SDT avoid using voltage dip as a criteria, or clearly specify that the transient voltage not exceed the X limit of Y cycles (time). References to relevant industry standards such as IEEE standard 1346-1998 should be made.

Suggest that for assigning a value for transient frequency response, entities conduct and submit to the SDT their quantitative and qualitative technical assessment based on the conditions of the element(s) under the application. Do not establish a fixed binary value within the exception criteria but rather focus on the performance outcome. See 5 (a) above.

Voltage deviation is generally expressed as a percentage, between the voltage at a given instant at a point in the system. Do not establish a fixed binary value within the exception criteria but rather focus on the performance outcome. Adequate voltage performance does not guarantee system voltage stability. Steady state stability is the ability of the grid to remain in synchronism during relatively slow or normal load or generation changes, and to damp out oscillations caused by such changes. The requirement should suggest that following checks are carried out to ensure system voltage stability for both the pre-contingency period and the steady state post-contingency period: • Properly converged pre- and post-contingency power flows are to be obtained with the critical parameter increased up to 10% with typical generation as applicable; • All of the properly converged cases obtained must represent stable operating points. This is to be determined for each case by carrying out P-V analysis at all critical buses to verify that for each bus the operating point demonstrates acceptable margin on the power transfer; and • The damping factor must be acceptable (the real part of the eigen values of the reduced Jacobian matrix are positive).

Yes

An impact-based method should be available for entities seeking Exclusions and Inclusions. The method should not allow excess regional discretion and unintended continent-wide variation. Recommend the power Transfer Distribution Factor (power TDF) approach mentioned in the reply to Question 5 above. If the Transmission Planner (TP) or Planning Authority (PA), were tasked with performing such analyses using standardized assumptions, then regional discretion could be minimized. Technical Analysis must fundamentally use NERC – TPL methodology and testing requirements.

No

Inclusions criteria should mirror the Exclusion criteria, and that consistent values should be employed for Inclusions here and for Exclusions above. That is, for example, if 0.95 to 1.05 (+/- 5%) p.u. is adopted as an acceptable voltage deviation range for Exclusions, then Elements resulting in post-transient system voltage deviations outside that range should be candidates for Inclusion. Further, all assumptions should also be fully documented for any proposed Inclusions. Also refer to comments on exclusions.

See reply to Questions 5b and 6 above.

Refer to the response to Question 5c

Refer to the response to Question 5d

See reply to Questions 5e and 6 above.

No

Yes

It is imperative to understand that the NERC's revised definition will have a direct impact on entities across North America and may conflict with regulatory requirements, Codes, and Licenses. FERC in its Orders 743 and 743A has directed NERC to address these concerns. For Ontario, the BES exception criteria shall meet the expectations of Ontario's regulator (Ontario Energy Board) which has the sole authority and responsibility for the reliability of customer connections and loads within Ontario. Therefore, it will be necessary to accommodate NERC's proposed definition of BES or the exception process with the Ontario situation. The SDT and RoP teams should: • Modify the exception criteria and procedure to provide regulatory flexibility with requirements to conduct basic technical analysis , to allow entities to consistently present their case to the ERO and/or the regulator for a step by step expedited evaluation. • Include provisions in both the NERC exception criteria and exception process for federal, state and provincial jurisdictions. These provisions should provide clear guidance so that, if and when there are deviations from the exception criteria, they are identified with technical and regulatory justifications ensuring there is no adverse impact on the interconnected transmission

network. • Understand that the path to generating facilities need not be always BES contiguous. Generating units can/should be required to be planned, designed, and operated in accordance with a subset of NERC Standards, but should not always require contiguous paths.

Yes

Exception criteria should be crafted at a high-level with key menu items of assessment that can be followed continent-wide by entities to put forward their exception(s) for element(s) that are not necessary for the interconnected transmission network based on technical assessment, evidence and justification for unique characteristics, configuration, and utilization. (Also see suggestions/ comments in Question 6)

Individual

Josh Dellinger

Glacier Electric Cooperative

No

I do not think that the proximity to load should be a factor in determining whether or not an element should be included in the BES. Rather, the purpose of the element should be the important factor. If an element only serves load, then that should be the most important factor and the proximity (electrical or physical) to that load should not matter.

No

I do agree that radial elements should definitely be excluded. However, I believe that non-radial elements should be able to be excluded by Path 1 as well. If a small local distribution system is operated non-radially for the purpose of improving reliability for its loads, then that system should be eligible for exclusion from the BES. I also believe that language needs to be included that makes the provision for radial elements that can be temporarily and briefly looped together during switching to prevent an outage (e.g. for transformer maintenance) to also be excluded from the BES.

No

Regarding using power flow into and out of a system as a criterion for BES exclusion, I do not think that establishing a hard MWh per year is the proper approach to take. Once again, I believe that the purpose of the system should be the most important factor. If the purpose of a system is to serve load or transport non-essential generation (i.e. wind power), then that system should be able to be excluded.

No

I believe that there should be a provision for systems that intentionally transport variable, non-essential generation (such as systems that transport wind power) to be excluded from the BES. By nature, these types of systems cannot be essential to the BES due to the variability of the generation, and, therefore, should be able to be excluded from the BES.

No

I strongly agree that there should be a way for elements to be excluded from the BES based on a technical analysis. However, the current approach only provides one technical avenue for exclusion and that is through a transmission planning study. Performing and analyzing such a study could be very, very difficult for a small entity to do. If this is the approach that NERC continues with, then I believe there needs to be some extra language outlining who is responsible for performing and analyzing these transmission planning studies. The question is should the RRO (WECC, etc.) be responsible for performing the study and determining through the technical criteria what elements are included and excluded in the BES, or should that responsibility fall on control area operators within an RRO, or should that responsibility fall on individual entities? I believe it should fall on either the RROs or the control area operators within the RROs. Perhaps an alternative approach could be to establish a few technical checks that could be evaluated first before a transmission planning study is required. For example, a max fault MVA value could be established and if the available fault MVA at an element is less than the established value, then that element could be excluded without having to go through a transmission planning study. If the available fault MVA at the element is above the established value, then the study would have to be done for determination.

Yes

Perhaps using an element's available fault MVA as a "quick screening" method to quickly determine if an element should be included or excluded. If an element's available fault MVA exceeds a properly established value, then a more detailed technical analysis can be done to determine whether or not the element truly should be included in the BES. But if the element's available fault MVA is less than the established value, then that element could quickly be excluded.

Yes  
I do strongly agree that there should be an avenue for elements to be included or excluded from the BES based on technical analysis. I do believe who's responsibility it will be to perform and analyze the transmission planning studies needs to be clarified.

Yes  
It could be very, very difficult and costly for small utilities to perform the necessary transmission planning studies described in the proposal. I think there needs to be language clarifying how smaller utilities should be able to obtain this data.

New York State Department of Public Service

The core BES definition based on a 100 kV brightline is an overreach of bulk system designation under the provisions of the Federal Power Act; a properly specified BES core definition would avoid the extensive analysis required under the exceptions procedure. That said, the proposed principles for use in the exceptions process are consistent with previous FERC efforts to distinguish between transmission and local distribution. The upfront exclusion of applying the proposed principles to blackstart cranking path facilities is a potential overreach into the local distribution system and can be counter productive reliability. Mandating compliance of NERC standards to cranking paths will result in the specification of only one cranking path by host utilities to minimize costs, where designating

multiple paths in restoration paths would provide the flexibility needed to minimize customer outage duration.

Individual

John Bee

Exelon

No

The term "close proximity" is ambiguous and open ended. Exelon believes that all facilities used in local distribution of electric energy that are presently under state jurisdiction should be excluded from the BES regardless of system impedance.

No

The term "rarely" is ambiguous and should be removed or quantified. Furthermore, the requirement for power flow analysis will be viewed by many entities as extensive technical analysis.

No

This item calls for the use of criteria in order to prove that a facility should be excluded the BES. First of all, the items 5b – 5e do indeed require extensive technical analysis which will be outside of the capabilities of many users of the BES. Furthermore, it is not clear who's criteria will be used? The user's? The Transmission Owner's? The Planning Authority's? This question of ownership needs to be resolved and in itself poses a problem for this process. If differing criteria levels are used across the continent, there remains the possibility that similarly-situated facilities in different Regions will not be treated consistently.

No

: Exelon points out that most of the Regions don't have Region-wide criteria for distribution factor measurement, voltage excursions, or transient frequency response for use in this proposed Inclusion Process. In addition, most of the Regions do not have region-wide criteria developed for these attributes. If differing criteria levels are used across the continent, there remains the possibility that similarly-situated facilities in different Regions will not be treated consistently.

Yes

As mentioned above, this process will require extensive technical analysis from users, owners, operators and the Regions. In many cases, the Principles anticipate the use of criteria that is not in existence today. Rather than reinforcing the bright line approach, these Principles have the potential to create processes that will result in high costs with little to no corresponding benefits to reliability.

Yes

To the extent facilities used in local distribution of electric energy may be included in the BES, the proposed principles are in conflict with the Federal Power Act.

No

GTC disagrees with the assumption that the proximity of a BES facility to Load is indicative of its importance to BES reliability. Some lower voltage facilities can be quite short and thus have lower impedance but be important to BES reliability. Furthermore, the term "Load centers" is not defined leaving it subject to interpretation. Assuming a load center has many busses, where would the measurement be made - From the most distant load bus in the load center or the nearest? Similarly - does a single facility get measured from its terminal to the load center or does the presence or lack of breakers need to be considered when selecting the measurement point?

Yes

GTC agrees with the requirement of an element being radial in character as being a qualifier for exclusion thru the non-technical analysis. However, GTC recommends that the term "radial in character" needs to be better defined. In addition, the language is confusing and the PSS would like to recommend the following: i.: suggest replacing "disconnection procedures" with "automatic disconnection devices" ii.: The intent of this item is not clear, and the term "regional dispatch" is not defined. Recommend the item be clarified or deleted.

Yes

One possible starting point for selecting a MWh threshold: Generators of 20 MVA or less are typically exempt from detailed modeling requirements. Suggest that reverse flows of this level or less, for a period of 24 hours or less would be an acceptable threshold. Therefore, this would provide a basis for selecting a threshold MWh level for reverse flows into the system under part iv. of 20 MW x 24 hours = 480 MWh per year.

No

As written, most of this approach makes no sense. The words imply that if you have planned the system properly, you can exclude it from the BES! In TPL studies you make sure that voltage dips, frequency excursions, voltage deviations are acceptable, oscillations are damped, and no cascading outages occur. So if you meet the performance requirements of TPL studies, you can exclude the element from the BES. What good is this?

This is the only part of this technical analysis that may make sense. If the loss of any element of the BES results in a distribution factor of less than X% on the element being considered for exclusion, then exclude it. We suggest a value of 3% for this, since 3% is the threshold typically used in transfer studies.

As stated above, it does not make sense to use this category.

As stated above, it does not make sense to use this category.

As stated above, it does not make sense to use this category.

Yes

Revise second paragraph to read "Due to the importance of designated Blackstart Resources and their Cranking Paths to restore efforts, no exceptions will be allowed for those items that are included in a system restoration plan." Technical rationale: Multiple Blackstart Resources and Cranking Paths are frequently available but are not included in a system restoration plan. System restoration plans describe the Blackstart resources and cranking paths that are deemed to be necessary for system restoration. Section "Exception Criteria – Exclusions": Add 1.e. "Generation that is inoperable and not planned to be placed back into service but not yet officially decommissioned." Technical rationale: These facilities are not relied on to insure the reliability of the BES.

No

GTC recommends that applications for inclusion of facilities into the BES should include justification for doing so. However, there should not necessarily be specific criteria that must be met, but the importance of the facility to the BES should be clearly demonstrated.

No
There is not sufficient evidence provided by the SDT to distinguish between this fourth item for exclusion and the third item for exclusion. They both seem to fall in line with what is excluded per the bright line exclusion E3 (or Local Distribution Networks), but as written, it would be difficult to measure what is meant by "is not intentionally transported through" in this fourth item just as it would be difficult to measure what's meant by "flows into the system, but rarely flows out" for the third item. Such an exclusion should be required to include some technical analysis, but not extensive technical analysis (at least the inclusion of power flow base case as a minimum).
No

No

We generally support this exclusion option concept, to the extent that it is fashioned after the FERC Seven Factor test. However, we have a number of questions as to how it might work in practice. 1.a.i. Electrical Proximity - If impedance is to be used as a measure of electrical proximity, which in turn is a replacement for geographical proximity, then how would the presence of parallel lines, capacitors, phase-angle regulators (PARs), tap-changing transformers, generation and reactors be treated in determining electrical proximity? How does this approach effectively differentiate between transmission and distribution lines of the same voltage and length? When using impedance, how is "greater than" determined? Sum of the Impedances - Would the filing entity simply add up the in-series impedances for each radial Element to demonstrate its electrical proximity? For example, would the sum of the impedances from this example radial path be equal to the sum of the two feeder and transformer impedances, i.e., measured from a 230 kV bus along a 230 kV feeder, through a 230/138 kV step-down transformer, and an in-series 138 kV feeder to a 138/13.8 kV step-down distribution transformer? What impedance would the SDT apply to a PAR (or tap-changing transformer) and to the overall path if a PAR (or tap-changing transformer) were located in-series with the measured Elements? 1.a.ii. Power Flows – What is the meaning of "power flow data" as the term is used here and how is the meaning different from the term when used under 1.c. Power flows into the system, but rarely flows out? Should this sentence use the phrase "impedance data extracted from a load flow study" instead?

No

We generally support this exclusion option concept, to the extent that it is fashioned after the FERC Seven Factor test. However, we have a number of questions as to how it might work in practice. For example, the term "regional dispatch" is not defined. Please provide a definition or reference to a definition to be used in making this determination. Below we recommend adoption of the alternate term "operational control." 1.b.ii, Operational Control - The SDT should consider using the terms "under the operational control of a Balancing Authority." It is instructive that the overarching requirement for a finding of transmission system integration in Mansfield was that the facilities be under operational control of the Independent System Operator (ISO).\* \* Southern Cal. Edison Co., 92 FERC ¶ 61,070 at 61,255 (2000), reh'g denied 108 FERC ¶ 61,085 (2004). Replace the example in 1.b.i. with a clearer example.

No

We generally support this exclusion option concept, to the extent that it is fashioned after the FERC Seven Factor test. However, we have a number of questions as to how it might work in practice. For example: • If an entity provides hourly MWh power flow data on a radial for a 12-month period (under v.) showing no power flow reversals, would transaction data (under i. through iv.) still be required? Couldn't the entity just say "no operating records?" • If there were power flow reversals, wouldn't the power flow data (provided under v.) also show those, e.g., the amount and duration? Isn't this request redundant? If not, why not? Please explain. • If reversing power flows on a feeder caused it to fail one of the criteria, could the radial still be excluded, or is it necessary for the Element to pass all requirements? Alternatively, could the entity choose to file for Exclusion of that Element under the technical analysis option? What happens and what are the implications when the two approaches produce different outcomes? We recommend that "iv. The maximum amount of energy flowing out" limit be set to no more than 24 hours of reverse power flows within any rolling 12-month period. Replace "transactional records" with "operating records."

Yes

No

The technical analysis approach may have merit. However, we have a number of questions about how it would be implemented in practice. We are concerned that this method may allow an entity to exclude Elements simply because they are not the most limiting Element in a particular TPL analysis. What does "not being necessary for reliability operation" mean? Please define. The SDT should consider developing a Guidance Document to provide examples and insights to guide prospective filing entities. The TPL Reliability Standards already describe the full set of requirements for a reliable system. Why are added requirements necessary? Why would any such added criteria not conflict with the TPL Reliability Standards to the extent that they were either more or less restrictive?

2.a. The term "Planning Assessment" is not a defined term in the NERC Glossary of Terms Used and should not be capitalized, or alternatively it should be defined. 2.a.iv.1. Distribution Factor - The issue comes down to a judgment call concerning what feeder power flow participation level is material and what is non-material. In New York, the NYISO has traditionally used a 1% power transfer distribution factor (power TDF) cut-off. Feeders showing less than a 1% power transfer in a study are not materially participating in transmission.

The NYISO uses a 0.95 to 1.05 p.u. as the acceptable range for post-transient system conditions.

Yes

An impact-based method should be available for entities seeking Exclusions and Inclusions. The method should not allow excess regional discretion and unintended continent-wide variation. We recommend the power Transfer Distribution Factor (power TDF) approach mentioned in the reply to Question 6 above. If the Transmission Planner (TP) or Planning Authority (PA), e.g., the NYISO, were tasked with performing such analyses, using standardized assumptions, then regional discretion could be minimized.

No

We believe that Inclusions criteria should mirror the Exclusion criteria, and that consistent values should be employed for Inclusions here and for Exclusions above. That is, for example, if 0.95 to 1.05 (+/- 5%) p.u. is adopted as an acceptable voltage deviation range for Exclusions, then Elements resulting in post-transient system voltage deviations outside that range should be candidates for Inclusion. Further, all assumptions should also be fully documented for any proposed Inclusions.

We do not agree that all four criteria under exclusion #1 need be applied in combination to an element to determine its material impact. Assets satisfying all four defining criteria would seem exceedingly small and likely already excluded by the BES definition. This exception criteria appears redundant to, and shadows the NERC BES definition draft's language excluding radial elements and local distribution networks, and as such add little value to the exclusions built into the BES definitions. Further, the language of the exception criteria addresses transmission elements and doesn't provide exclusion criteria for generation assets. We would hope that NERC could develop criteria to exempt certain generation, especially those small resources on local distribution networks wherein the generation is completely allocated to local load. Language in section 215 of the FPA excludes distribution "elements." We assert that generation on a distribution network serving only load on that network is an "element" of the network and deserves exclusionary defining criteria.
Using these criteria assumes that every asset must be radial in nature in order to receive consideration that it may not be material to the BES. This then implies that the BES is a contiguous connected system as only radial off-shoots could receive exemption consideration. We disagree. Our assertion is that the BES is comprised of assets that due to their size or location are vital to a sound BES but may or may not necessarily be connected to each other. This defining criteria in the exception could be a stand-alone criteria or stricken.
No
We agree in general, however believe there is little distinction between the defining criteria in this exception and the local distribution network exclusion already provided for in the BES definition. We would like to see added language that provides an exclusion for all elements on such a system, to include generation regardless of MVA rating, wherein the power flows are generally into the system. We would agree that a number of MWh of annual outflow needs to be established as a limitation to the size and amount of generation under consideration. This exclusion should be geared towards smaller municipal or like sized systems having no material impact upon a BA much less the region.
No
We generally agree with this requirement. If a system has redundant transmission to move power that is normally wheeled through, the question of materiality could be addressed by technical analysis.
We generally agree with having two paths towards exclusion.

SUB agrees with providing an exclusion exception for System Elements that are treated as “radial in character”, but feels this should be part of the core definition in NERC’s Proposed Continent-wide Definition of Bulk Electric System rather than requiring an exclusion/exemption application process. In SUB’s May 27, 2011 BES definition comments SUB expressed concern that there still appears to be inconsistencies in both definition and application of “radial.” SUB encourages NERC to develop a concise definition. For example, if a system is normally operated as radial, but could be operated closed (for example, by manually closing a breaker), would it be considered a radial or close-looped system?
No
NERC’s Proposed Continent-wide Definition of Bulk Electric System contains Exclusion E3 (LDNs) as part of the BES core definition. Why would this fourth item be necessary in demonstrating BES Exceptions if LDNs are already excluded as part of NERC’s core BES definition?
Yes
In general, SUB supports a technical analysis approach as a secondary/ alternative option for qualifying to apply for BES Element exclusions.
No
NERC’s Exception Criteria for Inclusions states that, “Entities can submit an application to see an exception for an inclusion in the BES...”, but SUB would ask NERC to clarify whether an entity can 1) seek an inclusion exception for them only, or 2) can an entity seek an inclusion exception for another entity? SUB would not support another entity having the ability to file for another entity.
Yes
<ul style="list-style-type: none"> <li>• The four characteristics defined in the “Exception Criteria – Exclusions” portion of Technical Principles for Demonstrating BES Exceptions appears to be in conflict with, rather than in parallel to, the exceptions which are part of the proposed “core definition” in the Proposed Continent-wide Definition of Bulk Electric System. SUB proposes that NERC postpone work related to Technical Principles for Demonstrating BES Exceptions until a continent-wide BES definition is approved.</li> <li>• FERC Order No. 743 states, “We believe that it would be worthwhile for NERC to consider formalizing the criteria for inclusion of critical facilities operated below 100 kV in developing the exemption process”. However, there is no mention of critical facilities operated below 100 kV in NERC’s Exception Criteria. SUB would encourage NERC to include critical facilities consideration in their exception criteria.</li> </ul>
Yes
SUB has the following concerns regarding NERC’s Technical Principles for Demonstrating BES Exceptions: <ul style="list-style-type: none"> <li>• Clear Definition of Radial - As previously addressed in our BES Definition comments,</li> </ul>

SUB would encourage a more clear definition of a "radial" versus "closed-loop" system. Because there still appears to be inconsistencies in both definition and application, SUB encourages NERC to develop a concise definition of a radial system. For example, if a system is normally operated as radial, but could be operated as closed (by manually closing a breaker), would it be considered a radial or close-looped system? If the answer is close-looped, then is this in all cases, or are there exceptions? • Approval of Exceptions – SUB would like for NERC to clarify the process for receiving, reviewing, and accepting or rejecting exception applications. The Technical Principles for Demonstrating BES Exceptions states that, "...will be subject to review and remand by the ERO itself, or by any agency having regulatory or statutory oversight of NERC as the ERO." During NERC's presentation at APPA's BES Definition webinar, it was explained that the exception process would look like the following: 1. Entity applies for exemption, 2. Region receives application, verifies received, and forward to NERC with recommendation(s), and 3. NERC makes final determination (decision is appealable by entity). For consistent application of the exemption procedure, SUB would encourage NERC to adopt the process as it was communicated during the APPA webinar, with regions making recommendations, but NERC making the final decision. • Duration of Approved Exclusions/Inclusions – The Technical Principles for Demonstrating BES Exceptions does not indicate the duration for approved exclusions or inclusions. How long are granted exclusions/inclusions? Permanent? Annual? Other? • Publication of Exceptions – For consistent application, as well as transparency and accountability, SUB would request that all exceptions be published ; those applied for, as well as whether they were rejected or accepted, as well as decision rationale.

No

We disagree with this exception and believe that Section 1.a. should be deleted in it's entirety and replaced with a definition that excludes remote areas of a generally lesser overall value to reliability and includes areas that are heavily networked serving large loads. The premise of the existing section 1.a. seems at odds with overall system reliability and possibly removes large metropolitan areas from the BES definition. How is close electrical proximity to load defined? A maximum number of Ohms? Heavily networked areas will have lower impedance and are more likely to serve larger amounts of demand and are therefore more likely to be impactful on the overall integrity of the BES.

No

This three part definition of radial presented in section 1.b. appears cumbersome and requires more definition. With regard to b.i - Where is the disturbance? Is sending a person to the field to perform manual disconnection a requirement of this exception? This item is so vague that we have difficulty providing replacement language as we do not understand its intent. With regard to b.ii – Elements (Excluding generators) are not dispatched in operations. If this approach were to be taken, what would be the criteria for the way the Element is treated in Operations? Again, this item is so vague that we have difficulty providing replacement language. The existing definition appears to require a good deal of technical scrutiny and be at odds with the goal of having a path for evidence that does not include extensive technical analysis. Overall it seems simpler to replace section b with a simpler definition of radial such as – all load served from a single substation at a single voltage level.

No

Section 1.c again appears to allow the exclusion of large portions of the system in metropolitan areas. How does this differ from the LDN exclusion already presented in the definition? Section c should simply be deleted.

No

This appears to be the same as section 1.c and again possibly allows for the exclusion of large portions of the system in metropolitan areas. Section 1.d. should simply be deleted.

No

The use of distribution factors is a significant concern. The term distribution factor is used a number of ways in the industry. Is this determined using the percentage pickup on the element in question following the loss of another element, or is this the percentage of a transfer that is picked up on the element in question, or a combination of both? Item 2.a.ii states that the TPL studies have to be run if the model is updated. The distribution factor is not required to be calculated as part of the TPLs and

therefore will require additional analysis in all circumstances, not just when the model is updated.

Comments were already included above.
No
No
Yes
Any generator that is studied individually will not be shown as material since the electric system is designed to allow the outage of any individual generator. Generators must be studied within the context of the electric system to assess materiality. The generator and its interconnecting transmission facilities would likely be able to be excluded based on this process although they meet the Registry Criteria thresholds requiring inclusion.

SPP Standards Review Group
Robert Rhodes
No
Physical characteristics as described in 1.a.i. do not capture the true picture of the functionality of an Element. Rather than use impedance perhaps the SDT should use 'radial' or 'having one source' as the descriptive term.
No
Could the SDT clarify what is meant by 'disconnection procedures' in 1.b.ii? It appears that the SDT is okay with excluding an element that can be switched out of service without removing another element. How are automatic breaker operations or manual switching factored into disconnection procedures? We need clarification on this. More and better examples, including the type of connectivity to the grid, would be helpful.
No
Rather than combining two conflicting criterion – 'rarely' and the number of MWh of backflow allowed annually – we would suggest the following. 1) That the maximum outflow doesn't create an issue on the BES. This would be determined by study of the system and conditions. Or 2) when the condition exists, be able to mitigate the condition within a prescribed time relevant to the prevailing system conditions.
No

It may be better to focus on the purpose, or need, of a facility, the functionality of the facility, rather than how electric flows impacted the facility during a given situation. Therefore, we would suggest moving away from the term 'intent'.

No

There are situations where setting a minimum TDF will not work due to the nature of the TDF. For example, a radial line connected to a bus with two networked lines. The radial line serves only load and would normally be excluded from the BES. However, if we use the TDF as a factor the radial line would be included in the BES since the TDFs would be high.

Yes

We would suggest that the SDT consider an exclusion for networked municipal systems operating below 200kV which have more than 75 MVA of generation and whose systems do not include flowgates or IROLs.

No

Please see our comment in 5b above.

No

Yes

In Question 5 regarding the Transient and Steady State Stability criteria, we would suggest establishing criteria for the damping such that the time required to return to normal is limited. Damping in 1-5% range may be sufficient to accomplish this. Also, delete 2.a.iv.8. in the Exclusion Criteria and 1.c.8. in the Inclusion Criteria.

No

What does rarely mean? How is maintenance conditions considered? This is simply worded but conceptually extremely complicated.

No

The wording is ambiguous. What is meant by system? Different voltage levels, Owners?

No

This is not very different from trying to demonstrate no adverse impact outside the local area.

Distribution factor requires a definition.

Measured where on the BES?

Measured where on BES?

No

Procees is complicated and fraught with interpretations.

Group
Western Electricity Coordinating Council
Michelle Mizumori
Yes
As long as this remains an "AND" statement, WECC supports this concept. It helps to support the concept that the element is used as distribution to serve Load, rather than to transfer bulk power. However, some correlation between the size of the Load and the size of an element may be needed. For example, a line that can carry 600 MW in close electrical proximity a 20-MW Load may not meet the intent of this characteristic. Furthermore, the criteria must define where the load is located for the measure of electrical proximity. In planning models, loads are often aggregated to a higher voltage substation bus, while in a distribution system model they are typically modeled along a distribution feeder. The SDT should clarify how it intends for the load to be modeled for this analysis of close proximity.
No
This characteristic is vague and subjective. It is unclear what "radial in character" means, and the methods for demonstration do not appropriately clarify the meaning. WECC recommends that the SDT determine what it is looking for to show "radial in character" and clearly identify that concept in the methods for demonstration. It is not clear how Operating Procedures can demonstrate that an element is "radial in character" nor is it clear how a re-evaluation might be processed if such Operating Procedures, ownership, or operations change. WECC believes that BES inclusion or exclusion should be based on physical, technical characteristics of the element, and requests a justification for use of procedural or contractual documentation as evidence of a technical principle.
Yes
WECC agrees in concept with this characteristic, but it needs to be clarified whether the items i-v are "AND" statements. WECC also suggests that i and ii be switched and re-worded. Suggested language for ii would be "A limited set of conditions where power flows out must be identified; for example, only under specified Contingency events." Then i can become a sub-bullet of ii. It must also be clarified that the specified conditions must have a technical justification to show that the element is not "necessary for reliable operation." Otherwise it is not clear that the "limited conditions" are truly a justification for exclusion. Any non-zero MWh limit must have a technical justification, otherwise zero should be used. In addition to the imports/exports from the system, the size of the system (in MW) should also be defined.
Yes
WECC agrees in concept with this characteristic, but believes that there needs to be more clarity of what constitutes the evidence. Since flow data is used for characteristic c, it seems that the same sort of data (but separated into hourly flow in and hourly flow out) could be used to demonstrate this. Otherwise, a simple procedure that claims "power entering this system is not intentionally transported through the system to some other system" would meet the letter of the law, but gives no description of how this is achieved. If Operating Procedures are allowed, more clarity must be provided on what those procedures must entail.
Yes
WECC agrees in concept that a technical analysis can be used and should be allowed to show that an element is not necessary for reliable operation. However, the technical analysis must be based on sound reasoning and a justification must be given as to why the analysis makes a showing that the element is not necessary for reliable operation. Furthermore, the technical principles must identify what category(ies) of TPL studies must be run. Finally, the values used for the threshold criteria and/or disturbances must be more stringent than the applicable TPL criteria/disturbances. Otherwise the argument becomes circular because all BES elements must meet the TPL criteria, so by meeting them all elements could be excluded.

Yes
WECC recommends that the SDT consider not only the single-phase faults used in the TPL standards, but also the effect of more severe events such as two- or three-phase faults, with delayed clearing and the necessity of the element in those cases.
Yes
Yes
The Owner should have all of the data to perform this analysis for an Exclusion; however, an Inclusion would likely be sought by an entity other than the Owner (i.e., Regional Entity, RC, BA, TOP) that may not have sufficient data. It should be clarified in the Rules of Procedure that such an entity has the right to request such data and that the Owner must provide such data.
Yes
It must be clear that under NERC Standard IRO-010, the Reliability Coordinators are required to obtain information relating to the operation of the bulk power system within their respective areas. In light of this requirement, Reliability Coordinators may request the submittal of information for network facilities that ultimately are not determined to be BES facilities. It would be reasonable to also include a requirement that Reliability Coordination staff will explain why they require the requested information from non-BES facilities when seeking such information.
Yes
The biggest concern is that the Technical Principles and the reasoning behind them need to be fully explained. The SDT has mentioned on calls the possibility of a white paper or resource document, and WECC fully supports the creation of such a document. This white paper should describe the rationale for the criteria as well as how that indicates that the element is necessary for reliable operation. Also, the justification for the ERO to override these criteria should be clarified. It should be clear that the ERO's ability to override these criteria is on a case-by-case basis.

Yes
Suggested additional method. The Element(s) meet all the following characteristics: 1) generally radial in nature, and 2) used to supply a retail customer from the point of delivery to the load regardless of voltage. Evidence to support this position could be an interconnection agreement indicating the point of delivery, a one-line diagram showing the point of delivery and load, etc. The

technical rationale is that protection of the BES for facilities serving a retail customer is the responsibility of the service provider (e.g., transmission owner/operator). These facilities are distribution facilities and are not now part of the BPS. Alternatively, this could be an Exclusion in the BES Definition as it is in the current definition.

Yes

The proposed technical principles seem to be in contradiction to the exemption in FPA Section 215 against the inclusion in the BES of facilities used in the local distribution of electric energy.

Yes

The Technical Principles and the new BES Definition seem to include a significant number of retail customers as proposed. Surely this is not the intent of these changes. There should be an exclusion along the lines of Comment 6.

No

agree in principle that one characteristic of local distribution systems is that they are usually confined to a relatively limited geographic area, as opposed to transmission systems, which (especially in the West) tend to cover very large distances. We also believe the proximity test may be a sensible way to identify local distribution facilities. However, we believe that the proximity test may be unnecessary, and if an Element or group of Elements meets other tests proposed by the SDT, it should be excluded from the BES, even if it does not meet the proximity test.

Yes

agree conceptually that systems operating as radials rather than as integrated portions of the integrated bulk transmission system should be excluded from the BES definition. That is because local distribution systems typically operate adjacent to, or at the end of transmission lines, and function operationally to move power from the Transmission Service Provider's point of delivery of bulk power that has moved across the integrated bulk transmission system to end-users located within the local distribution utility's service territory. To be consistent with the draft BES definition, the term "radial in character" should be explicitly defined as a system that may include one or more lines into a load area or referenced as a local distribution network. In addition, we agree that the manner in which a system is operated during BES disturbances may be an indication of whether that system is radial in character. That being said, we are concerned that, to the extent the SDT considers regional disconnect procedures, it should be careful to note that UFLS and UVLS relays are often embedded within local distribution systems and, while it is necessary for the UFLS and UVLS relays to be properly armed to protect the BES in the event of a severe system disturbance, the local distribution system interconnected with those relays should not, and cannot legally, be classified as BES.

Yes

agree conceptually that one critical characteristic distinguishing local distribution facilities that must be excluded from the BES from transmission facilities that should be included is the manner in which power flows on those facilities. Power on local distribution systems generally flows only from the interconnected transmission source and across the distribution system for delivery to end-use customers. By contrast, power on transmission systems generally flows in two (or multiple, in networked systems) directions and is delivered in bulk to distribution utilities rather than to end-users. Hence, the SDT has properly identified power flows as one important characteristic that distinguishes BES transmission systems from local distribution systems. We agree conceptually that the fact that power may flow out of a local distribution system onto the grid during a few hours in a year or during extreme contingencies should not change the characterization of the system as local distribution. Accordingly, we support inclusion of power flow analysis as one element of characteristics

that can be used to exclude local distribution facilities from the BES even if the facilities do not pass each of the bright-line thresholds laid down in the BES definition. We also agree that transactional and hourly generation records are an appropriate basis for making the determination since these can be used to demonstrate that demand within a local distribution system exceeds generation within that system in most hours and that power therefore does not flow onto the grid, and also to determine the number of hours where this is not the case and the amount by which generation within the system exceeds demand. In order to identify systems that are not necessary for the operation of the BES under this text, we propose that any system where real power flows into the local distribution system 90 percent of the time or more under normal ("N-0" or All Lines in Service) operating conditions should be held to meet this test. That a system meets this test could be demonstrated using metering or supervisory control and data acquisition ("SCADA") data records over the course of two years. In addition, the presence of generation within a local distribution system that only modifies the level of the load served by the bulk system, but does not result in power being injection into the bulk system, does not change the reliability effect of the local network and therefore should not require the local network to be classified as BES.

Yes

agrees that the SDT's fourth test, which asks whether power is intentionally transported through a system, identifies a key characteristic of local distribution facilities that distinguishes such facilities from interconnect bulk transmission facilities that are properly considered part of the BES. In fact, we believe this may be the most important and readily identifiable distinction. As a matter of operation, power is scheduled across transmission lines. Further, transmission lines in the Western Interconnection (either individually or as part of a transmission path) are rated for total transmission capacity and available transmission capacity, and transmission rights can be purchased on such lines, if available, on an OASIS. Local distribution systems do not share any of these operational characteristics. Accordingly, we agree that if power is not intentionally transported through a particular system, that system is not used for transmission and should not be considered part of the BES. We also agree that examining the Operating Procedures applicable to a particular system will provide a ready guide to whether power is intentionally scheduled across that system. We suggest, however, that the SDT look beyond those protocols that fall within the NERC Glossary's definition of Operating Procedure. For example, in the West, transmission paths are almost all listed in the WECC Path Rating Catalog. Similarly, it is not clear whether scheduling protocols, OASIS operations, and the other factors listed above qualify as Operating Procedures. Hence, we urge the SDT to list such specific operational characteristics as part of this test.

Yes

agree conceptually with the idea that two different paths to exclusion should be adopted, one relying upon readily identifiable characteristics that are ordinarily associated with local distribution and not BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES.

The use of distribution factors, such as Power Transfer Distribution Factors ("PTDF") and Outage Transfer Distribution Factor ("OTDF") provide insight into the relative impedance of neighboring systems. However in the Western Interconnection it has never been a definitive indicator of whether a system fault with delayed clearing would impact a neighboring electric system. While we understand that many entities from the Eastern Interconnection support the use of such factors, we believe the approach is unlikely to work in the Western Interconnection. Based on the significant differences between the four major interconnections in North America, we suggest that a detailed technical exemption process be allowed on an interconnections wide basis. The Western Interconnection is a "hub and spoke system" where loads are very remote from large generation plants, with margins that are based on stability limits. By contrast, the Eastern Interconnection is a tightly meshed system with loads and generation in close proximity, often creating margins that are based on thermal limitations. These differences manifest themselves in a variety of operations. For example, the Western Interconnection uses a rated paths methodology while the Eastern Interconnection uses transmission load relief mechanisms. Consistent with FERC order 743-A we support exemption criteria for individual frequency independent regions, or interconnections.

we propose that, if an Element is to be excluded from the BES, removal of that Element should

produce no more than a 20% voltage drop for no more than 20 cycles in a Category B contingency and no more than a 20% drop for 40 cycles in a Category C contingency.
we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more.
we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more.
No
supports the exemption of generation interconnected to local distribution networks if the generation is less than 300 MW capacity and where the power generated is consumed within the LDN and rarely flows out of the LDN consistent with the section III.c.4 [Exclusion] of the NERC Statement of Compliance Registry Criteria as well as the Load modifiers used in the Eastern Interconnection. "Load Modifiers" (small generators that only affect load at the distribution level)."
Yes
Elements otherwise excluded from the BES should be included only upon a technically valid showing that the Elements contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system.
Yes
Obtaining data creates a cost and should be minimized as possible.
No
the proposed BES Definition could conflict with Section 215 of the Federal Power Act if the Definition, the Exception Process, and the Technical Criteria do not effectively exclude facilities used in local distribution from the BES or if the BES definition does not focus on cascading outages, separation events, and instability on the interconnected bulk system. These statutory limits on the scope of the BES and reliability standards are a minimum that must be met.
Yes
supports the approach to the exclusion process proposed by the SDT, which provides two different paths to exclusion, one based on readily-identifiable operational characteristics of a system, and one based on technical reliability analysis. We believe it is important to provide for the first path, based on operational characteristics, so that systems that are marginally disqualified under the BES Definition (because, for example, generation within the system exceeds demand for a few hours a year) can obtain an exclusion without the large investment of resources that otherwise might be required for a full-scale technical analysis. we question whether the first subsection of the characteristic test, relating to system proximity, is necessary, and we are concerned that the requirement that a system meet all four requirements of the characteristics test may be overly restrictive. For example, it is easy to imagine a distribution system in a rural area that covers a widely dispersed area, so that load is many miles from the relevant generation/transmission source, and that the system therefore does not meet the electrical proximity element, but meets the other three elements of the characteristics test. Such a system should be excluded because it clearly serves a local distribution function, and not a transmission function, as demonstrated by the fact that the system meets subsections (c) (power flows into the system but rarely flows out ) and (d) (power is not intentionally transported over the system). Accordingly, we recommend that the SDT consider eliminating the first test. In the alternative, the SDT should consider allowing exempting a system from the BES if it, for example, meets three of the four criteria rather than all four.
Individual
Ed Davis
Entergy Services
No
Entergy does not agree with the assumption that the proximity of a BES facility to Load is indicative of it's importance to BES reliability. Some lower voltage facilities can be quite short and thus have lower impedance but be important to BES reliability. Likewise some facilites remote from load centers may

have virtually no impact on BES reliability. There is also insufficient information as to how the impedance would be measured (locations of measurements within and outside of the "Load pockets". This Exemption Criteria should be removed. The term "Load centers" is not defined leaving it subject to interpretation. "Loads" are not BES Elements and therefore can not be exempted from being considered BES Elements. Item 1.a.i - "Loads within the system seeking exception are in close electrical proximity if they are separated by an impedance of no greater than TBD." This sentence needs to be deleted.

Yes

Entergy agrees that radial facilities should be excluded directly. However, the "radial in character" language is nebulous. A simpler approach could be to allow exceptions for facilities which become radial as a consequence of a normal system response to a disturbance (breakers opening during normal clearing of a fault).

No

Power flows into or out of a portion of the BES may characterize BES facilities less important to BES reliability but without limits to the size of the area, it would be difficult to show compliance. An entire state could be excluded from the BES. Additionally, there is no process specified to review the characteristics as transmission topology and resources change over time.

No

There is not sufficient evidence provided by the SDT to distinguish between this fourth item for exclusion and the third item for exclusion. They both seem to fall in line with what is excluded per the bright line exclusion E3 (or Local Distribution Networks), but as written, it would be difficult to measure what is meant by "is not intentionally transported through" in this fourth item just as it would be difficult to measure what's meant by "flows into the system, but rarely flows out" for the third item. Such an exclusion should be required to include some technical analysis, but not extensive technical analysis (at least the inclusion of power flow base case as a minimum).

No

The entire approach seems overly complex and difficult to document.

Yes

Revise second paragraph to read "Due to the importance of designated Blackstart Resources and their Cranking Paths to restore efforts, no exceptions will be allowed for those items that are included in a system restoration plan." Technical rationale: Multiple Blackstart Resources and Cranking Paths are frequently available but are not included in a system restoration plan. System restoration plans describe the Blackstart resources and cranking paths that are deemed to be necessary for system restoration. Section "Exception Criteria – Exclusions": Add 1.e. "Generation that is inoperable and not planned to be placed back into service but not yet officially decommissioned." Technical rationale: These facilities are not relied on to insure the reliability of the BES.

No

It is unclear why an inclusion process should be necessary. Including facilities not otherwise included in the basic definition should be at the discretion of the TO.

No

Individual
Jack Stamper
Clark Public Utilities
Yes
Clark believes the proximity test should be considered be a valid factor in determining whether a facility is part of the BES or not. Just as this factor is used in the consideration on whether a facility is part of a Local Distribution Network. Clark is not convinced that “proximity” and “impedance” are interchangeable. While impedance will be lower for shorter distances it will also be affected by other factors that are not indicative of close proximity. Distance seems more appropriate to use since it would complement a literal interpretation of the term proximity.
Yes
Clark agrees conceptually that systems operating as radials rather than as integrated portions of the integrated bulk transmission system should be excluded from the BES definition. That is because local distribution systems typically operate adjacent to, or at the end of transmission lines, and function operationally to move power from the Transmission Service Provider’s point of delivery of bulk power that has moved across the integrated bulk transmission system to end-users located within the local distribution utility’s service territory. To be consistent with the draft BES definition, the term “radial in character” should be explicitly defined as a system that may include one or more lines into a load area or referenced as a local distribution network. In addition, Clark agrees that the manner in which a system is operated during BES disturbances may be an indication of whether that system is radial in character. That being said, we are concerned that, to the extent the SDT considers regional disconnect procedures, it should be careful to note that UFLS and UVLS relays are often embedded within local distribution systems and, while it is necessary for the UFLS and UVLS relays to be properly armed to protect the BES in the event of a severe system disturbance, the local distribution system interconnected with those relays should not.
Yes
Clark agrees conceptually that one critical characteristic distinguishing local distribution facilities that must be excluded from the BES from transmission facilities that should be included is the manner in which power flows on those facilities. Power on local distribution systems generally flows only from the interconnected transmission source and across the distribution system for delivery to end-use customers. By contrast, power on transmission systems generally flows in two (or multiple, in networked systems) directions and is delivered in bulk to distribution utilities rather than to end-users. Hence, the SDT has properly identified power flows as one important characteristic that distinguishes BES transmission systems from local distribution systems. In order to identify systems that are not necessary for the operation of the BES under this text, we propose that any system where real power flows into the local distribution system 90 percent of the time or more under normal operating conditions.
Yes
Clark agrees that the SDT’s fourth test, which asks whether power is intentionally transported through a system, identifies a key characteristic of local distribution facilities that distinguishes such facilities from interconnect bulk transmission facilities that are properly considered part of the BES. Clark believes this may be the most important and readily identifiable distinction. Accordingly, Clark agrees that if power is not intentionally transported through a particular system, that system is not used for transmission and should not be considered part of the BES.
Yes
Clark agrees conceptually with the idea that two different paths to exclusion should be adopted, one relying upon readily identifiable characteristics that are ordinarily associated with local distribution and not BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES. Clark supports the technical arguments and the White Paper presented by Snohomish County PUD in their comments. Clark recommends that the SDT modify its approach to the technical exclusion process to match the approach advocated in the White Paper, which is based upon the approach recommended by the WECC BES Task Force.

The use of distribution factors, such as Power Transfer Distribution Factors ("PTDF") and Outage Transfer Distribution Factor ("OTDF") provide insight into the relative impedance of neighboring systems. However in the Western Interconnection it has never been a definitive indicator of whether a system fault with delayed clearing would impact a neighboring electric system. While we understand that many entities from the Eastern Interconnection support the use of such factors, we believe the approach is unlikely to work in the Western Interconnection.

Specific transient voltage dip thresholds are proposed at page 15 of Snohomish's White Paper. For example, Clark proposes that, if an Element is to be excluded from the BES, removal of that Element should produce no more than a 20% voltage drop for no more than 20 cycles in a Category B contingency and no more than a 20% drop for 40 cycles in a Category C contingency. Technical justification for these thresholds is provided at pages 12-16 of the White Paper.

Page 15 of Snohomish's White Paper also sets forth recommended thresholds for transient frequency response. For example, Clark proposes that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided at pages 12-16 of the White Paper.

See Clark's comments on 5c and 5d.

No

Yes

As a general matter, Clark agrees with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid showing that the Elements contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. Clark also agrees that the SDT has, in general, identified the correct technical approach, although Clark recommends that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in the Snohomish PUD White Paper, in the WECC BES Task Force Proposal 6, and in Clark's answer to Question 5.

See comments in 5.

No

As discussed on page 12 of the Snohomish White Paper, there may be a few isolated cases where additional data will need to be provided to run a valid technical analysis under the criteria set forth in the Exception Procedure. These cases should be exceedingly rare, however, because the starting point for the technical analysis Clark recommends is the current base case operated by the relevant Regional Entity, and in nearly every case, the base case can be expected to model any Element that conceivably has a material impact on the reliable operation of the bulk system. In those rare cases where it does not, we believe the owner or operator of the subject Element should be able to provide the needed data.

No

Individual

Dave Markham

Central Electric Cooperative

Yes

First, thank you for the opportunity to comment on the Technical Principles for Demonstrating BES Exceptions. We appreciate the work that NERC has done on these principles and the other related efforts to revise the definition of the BES. In response to question #1, we note only that using impedance to benchmark system load proximity would likely not yield clear demarcations. High voltage relative or per-unit impedances are considered typically much lower than low voltage impedances. Hence, in the absence of phase shifting transformers, service compensation, or other

mitigation factors, power typically flows over the highest voltage lines, which offer the lowest impedance.

Yes

We agree conceptually that facilities operating as radials rather than as integrated portions of the integrated bulk transmission system should be excluded from the BES definition. However, to be consistent with the draft BES definition, the term "radial in character" should be explicitly defined as facilities that may include one or more lines into a load area or referenced as a local distribution network. In addition, we agree that the manner in which a system is operated during BES disturbances may be an indication of whether that facility is radial in character. That being said, we are concerned that, to the extent the SDT considers regional disconnect procedures, it should be careful to note that UFLS and UVLS relays are often embedded within local distribution facilities and, while it is necessary for the UFLS and UVLS relays to be properly armed to protect the BES in the event of a severe system disturbance, the local distribution facilities interconnected with those relays should not, and cannot legally, be classified as BES.

Yes

We agree conceptually that one critical characteristic distinguishing facilities that must be excluded from the BES from facilities that should be included is the manner in which power flows on those facilities. Hence, the SDT has properly identified power flows as one important characteristic that identifies BES facilities. We also agree conceptually that the fact that power may flow out of facilities onto the grid during a few hours in a year or during extreme contingencies should not change the characterization of the facilities in question as excluded from the BES. Accordingly, we support inclusion of power flow analysis as one element of characteristics that can be used to exclude facilities from the BES even if the facilities do not pass each of the bright-line thresholds laid down in the BES definition. We also agree that transactional and hourly generation records are an appropriate basis for making the determination since these can be used to demonstrate that demand within a system exceeds generation within that system in most hours and that power therefore does not flow onto the grid, and also to determine the number of hours where this is not the case and the amount by which generation within the system exceeds demand. In order to identify facilities that are not necessary for the operation of the BES under this text, we propose that any facility where real power flows in 90 percent of the time or more under normal ("N-0" or All Lines in Service) operating conditions should be held to meet this test. That facilities meet this test could be demonstrated using metering or supervisory control and data acquisition ("SCADA") data records over the course of two years. While we agree with the SDT's view that power should flow predominantly in the direction of load for excluded facilities, we are concerned that this characteristic may no longer be a defining characteristic as the electric industry evolves in the future. If distributed generation becomes the future norm for new power generation facilities, it may no longer make sense to look at power flow as a defining characteristic. That is, even if a sufficient number of small distributed generation facilities were constructed on certain facilities to cause power to flow out of those facilities more than ten percent of the time, the fundamental character of those facilities will not have changed. Finally, we believe that power flow analysis under this item should consider actual power flow, not scheduled power flow.

Yes

As a matter of operation, power is scheduled across transmission lines. Further, transmission lines in the Western Interconnection (either individually or as part of a transmission path) are rated for total transmission capacity and available transmission capacity, and transmission rights can be purchased on such lines, if available, on an OASIS. Facilities that do not share any of these operational characteristics should not be part of the BES. Accordingly, we agree that if power is not intentionally transported through particular facilities, those facilities should not be considered part of the BES. We also agree that examining the Operating Procedures applicable to particular facilities will provide a ready guide to whether power is intentionally scheduled across those facilities. We suggest, however, that the SDT look beyond those protocols that fall within the NERC Glossary's definition of Operating Procedure. For example, in the West, transmission paths are almost all listed in the WECC Path Rating Catalog. Similarly, it is not clear whether scheduling protocols, OASIS operations, and the other factors listed above qualify as Operating Procedures. Hence, we urge the SDT to list such specific operational characteristics as part of this test. Finally, as noted in our answer to Question 3, we are concerned that, if distributed generation advances significantly, power transport may cease to be a meaningful measure for determining whether a facility is part of the BES, and we believe that power flow analysis should consider actual power flow, not scheduled power flow.

Yes

We agree conceptually with the idea that two different paths to exclusion should be adopted, one relying upon readily identifiable characteristics that are ordinarily associated with non-BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES. Snohomish Public Utility District has prepared a White Paper proposing a performance-based approach to support the technical determination whether Elements should be excluded from the BES, which we commend to the SDT for study. We also commend the work of the WECC BES Task Force and the WECC Technical Studies Subcommittee, both of which have devoted substantial time and resources to developing a workable and technically defensible process for excluding Elements classified as BES based upon their electrical characteristics. See WECC BES Task Force Proposal 6, App. A at 3-9 & App. B at pp. B-4 to B-7 (posted Feb. 18, 2011) (available at: <http://www.wecc.biz/Standards/Development/BES/default.aspx>). We recommend that the SDT modify its approach to the technical exclusion process to match the approach advocated in Snohomish's White Paper, which is based upon the approach recommended by the WECC BES Task Force.

The use of distribution factors, such as Power Transfer Distribution Factors ("PTDF") and Outage Transfer Distribution Factor ("OTDF") provide insight into the relative impedance of neighboring systems. However in the Western Interconnection it has never been a definitive indicator of whether a system fault with delayed clearing would impact a neighboring electric system. While we understand that many entities from the Eastern Interconnection support the use of such factors, we believe the approach is unlikely to work in the Western Interconnection. Based on the significant differences between the four major interconnections in North America, we suggest that a detailed technical exemption process be allowed on an interconnections wide basis. The Western Interconnection is a "hub and spoke system" where loads are very remote from large generation plants, with margins that are based on stability limits. By contrast, the Eastern Interconnection is a tightly meshed system with loads and generation in close proximity, often creating margins that are based on thermal limitations. These differences manifest themselves in a variety of ways for various operations. For example, the Western Interconnection uses a rated-paths methodology while the Eastern Interconnection uses transmission load relief mechanisms. Consistent with FERC order 743-A, we support exemption criteria for individual frequency independent regions, or interconnections.

Specific transient voltage dip thresholds are proposed on page 15 of Snohomish's White Paper. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should produce no more than a 20% voltage drop for no more than 20 cycles in a Category B contingency and no more than a 20% drop for 40 cycles in a Category C contingency. Technical justification for these thresholds is provided on pages 12-16 of Snohomish's White Paper.

Page 15 of Snohomish's White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided on pages 12-16 of the White Paper.

Please see our response to Question 5d.

No

Yes

As a general matter, we agree with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid justification showing that the Elements in question contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. We also agree that the SDT has, in general, identified the correct technical approach, although we recommend that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in Snohomish's White Paper, in the WECC BES Task Force Proposal 6, and in our answer to Question 5. While we support the SDT's overall approach, we believe subsection (f) of the proposed inclusion criteria, which would allow NERC to "override this criterion" if it provides "additional justification" for doing so is both unnecessary and creates confusion and uncertainty in what is otherwise a clear and concise process. Subsection (f) is unnecessary

because if the technical process laid out in subsections (a) through (e) fails to provide any evidence that the contested Element(s) create a material impact on the reliability of the bulk interconnected transmission network, there is no reason to classify those Element(s) as BES, and that should be the end of the question. Subsection (f) creates needless uncertainty because it allows NERC to override the technical criteria laid out in subsections (a) through (e) if "additional justification" is provided, but there is no suggestion as to what this additional justification might be. Nor is there any explanation as to why additional justification might be necessary after the criteria in subsections (a) through (e) have been exhausted.

Please see our corresponding answers to Question 5 for 7b-7e.

No

As discussed on page 12 of Snohomish's White Paper, there may be a few isolated cases where additional data will need to be provided to run a valid technical analysis under the criteria set forth in the Exception Procedure. These cases should be exceedingly rare, however, because the starting point for the technical analysis we recommend is the current base case operated by the relevant RE, and in nearly every case, the base case can be expected to model any Element that conceivably has a material impact on the reliable operation of the bulk system. In those rare cases where it does not, we believe the owner or operator of the subject Element should be able to provide the needed data, although we propose that the relevant owner or operator be relieved of this burden if it can be demonstrated that the nearest electrically interconnected Element has no material impact on the bulk system.

No

Yes

In general, as we discuss above, the Technical Principles for Demonstrating BES Exceptions present a reasonable approach to resolving questions of inclusion and exclusion in the BES that the BES definition itself does not clearly resolve. However, we caution that these principles for demonstrating exceptions cannot, and must not, take the place of a consideration of, and criteria under whether, any specific piece of equipment is subject to FERC, the ERO, and Regional Entity jurisdiction in the first instance. Section 215 of the Federal Power Act (FPA) sets out clear limits of jurisdiction of FERC, the ERO, and Regional Entities for purposes of developing and enforcing reliability standards. Specifically, Section 215(i) provides that the ERO "shall have authority to develop and enforce compliance with reliability standards for only the Bulk-Power System." 16 U.S.C. § 824o(a)(1) (emphasis added). Section 215(a)(1) of the statute defines the term "Bulk-Power System" or "BPS" as: (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy." Id. As we have explained in our comments on the BES definition, that definition should expressly account for these jurisdictional limitations up front. This would allow for the jurisdictional limitation consideration as the very first step in determining whether or not a particular piece of equipment is part of the BES. The Technical Principles for Demonstrating BES Exceptions, on the other hand, provides a completely separate set of criteria for exclusion from the BES and would come into play only after application of the full BES definition to a particular piece of equipment and determination that the BES definition does not provide a satisfactory answer as to whether that piece of equipment is or is not part of the BES. This is acceptable insofar as it goes, but, because (1) the criteria in the Technical Principles are distinct from the jurisdictional limits of Section 215 of the FPA, and (2) consideration of the Technical Principles would essentially be the last, or one of the last, steps in the process, the Technical Principles cannot substitute for, in any way, consideration of the jurisdictional limitations of the FPA. Again, we cannot overemphasize enough how important it is to have the jurisdictional consideration be the very first step in the process of determining whether a particular piece of equipment is or is not part of the BES. Again, thank you for the opportunity to comment. We look forward to continuing to work with NERC and stakeholders to develop a BES definition that is both workable and lawful.

Clearwater Power Electric Cooperative
Yes
<p>First, thank you for the opportunity to comment on the Technical Principles for Demonstrating BES Exceptions. We appreciate the work that NERC has done on these principles and the other related efforts to revise the definition of the BES. In response to question #1, we note only that using impedance to benchmark system load proximity would likely not yield clear demarcations. High voltage relative or per-unit impedances are considered typically much lower than low voltage impedances. Hence, in the absence of phase shifting transformers, service compensation, or other mitigation factors, power typically flows over the highest voltage lines, which offer the lowest impedance.</p>
Yes
<p>We agree conceptually that facilities operating as radials rather than as integrated portions of the integrated bulk transmission system should be excluded from the BES definition. However, to be consistent with the draft BES definition, the term "radial in character" should be explicitly defined as facilities that may include one or more lines into a load area or referenced as a local distribution network. In addition, we agree that the manner in which a system is operated during BES disturbances may be an indication of whether that facility is radial in character. That being said, we are concerned that, to the extent the SDT considers regional disconnect procedures, it should be careful to note that UFLS and UVLS relays are often embedded within local distribution facilities and, while it is necessary for the UFLS and UVLS relays to be properly armed to protect the BES in the event of a severe system disturbance, the local distribution facilities interconnected with those relays should not, and cannot legally, be classified as BES.</p>
Yes
<p>We agree conceptually that one critical characteristic distinguishing facilities that must be excluded from the BES from facilities that should be included is the manner in which power flows on those facilities. Hence, the SDT has properly identified power flows as one important characteristic that identifies BES facilities. We also agree conceptually that the fact that power may flow out of facilities onto the grid during a few hours in a year or during extreme contingencies should not change the characterization of the facilities in question as excluded from the BES. Accordingly, we support inclusion of power flow analysis as one element of characteristics that can be used to exclude facilities from the BES even if the facilities do not pass each of the bright-line thresholds laid down in the BES definition. We also agree that transactional and hourly generation records are an appropriate basis for making the determination since these can be used to demonstrate that demand within a system exceeds generation within that system in most hours and that power therefore does not flow onto the grid, and also to determine the number of hours where this is not the case and the amount by which generation within the system exceeds demand. In order to identify facilities that are not necessary for the operation of the BES under this text, we propose that any facility where real power flows in 90 percent of the time or more under normal ("N-O" or All Lines in Service) operating conditions should be held to meet this test. That facilities meet this test could be demonstrated using metering or supervisory control and data acquisition ("SCADA") data records over the course on two years. While we agree with the SDT's view that power should flow predominantly in the direction of load for excluded facilities, we are concerned that this characteristic may no longer be a defining characteristic as the electric industry evolves in the future. If distributed generation becomes the future norm for new power generation facilities, it may no longer make sense to look at power flow as a defining characteristic. That is, even if a sufficient number of small distributed generation facilities were constructed on certain facilities to cause power to flow out of those facilities more than ten percent of the time, the fundamental character of those facilities will not have changed. Finally, we believe that power flow analysis under this item should consider actual power flow, not scheduled power flow.</p>
Yes
<p>As a matter of operation, power is scheduled across transmission lines. Further, transmission lines in the Western Interconnection (either individually or as part of a transmission path) are rated for total transmission capacity and available transmission capacity, and transmission rights can be purchased on such lines, if available, on an OASIS. Facilities that do not share any of these operational characteristics should not be part of the BES. Accordingly, we agree that if power is not intentionally transported through particular facilities, those facilities should not be considered part of the BES. We</p>

also agree that examining the Operating Procedures applicable to particular facilities will provide a ready guide to whether power is intentionally scheduled across those facilities. We suggest, however, that the SDT look beyond those protocols that fall within the NERC Glossary's definition of Operating Procedure. For example, in the West, transmission paths are almost all listed in the WECC Path Rating Catalog. Similarly, it is not clear whether scheduling protocols, OASIS operations, and the other factors listed above qualify as Operating Procedures. Hence, we urge the SDT to list such specific operational characteristics as part of this test. Finally, as noted in our answer to Question 3, we are concerned that, if distributed generation advances significantly, power transport may cease to be a meaningful measure for determining whether a facility is part of the BES, and we believe that power flow analysis should consider actual power flow, not scheduled power flow.

Yes

We agree conceptually with the idea that two different paths to exclusion should be adopted, one relying upon readily identifiable characteristics that are ordinarily associated with non-BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES. Snohomish Public Utility District has prepared a White Paper proposing a performance-based approach to support the technical determination whether Elements should be excluded from the BES, which we commend to the SDT for study. We also commend the work of the WECC BES Task Force and the WECC Technical Studies Subcommittee, both of which have devoted substantial time and resources to developing a workable and technically defensible process for excluding Elements classified as BES based upon their electrical characteristics. See WECC BES Task Force Proposal 6, App. A at 3-9 & App. B at pp. B-4 to B-7 (posted Feb. 18, 2011) (available at: <http://www.wecc.biz/Standards/Development/BES/default.aspx>). We recommend that the SDT modify its approach to the technical exclusion process to match the approach advocated in Snohomish's White Paper, which is based upon the approach recommended by the WECC BES Task Force.

The use of distribution factors, such as Power Transfer Distribution Factors ("PTDF") and Outage Transfer Distribution Factor ("OTDF") provide insight into the relative impedance of neighboring systems. However in the Western Interconnection it has never been a definitive indicator of whether a system fault with delayed clearing would impact a neighboring electric system. While we understand that many entities from the Eastern Interconnection support the use of such factors, we believe the approach is unlikely to work in the Western Interconnection. Based on the significant differences between the four major interconnections in North America, we suggest that a detailed technical exemption process be allowed on an interconnections wide basis. The Western Interconnection is a "hub and spoke system" where loads are very remote from large generation plants, with margins that are based on stability limits. By contrast, the Eastern Interconnection is a tightly meshed system with loads and generation in close proximity, often creating margins that are based on thermal limitations. These differences manifest themselves in a variety of ways for various operations. For example, the Western Interconnection uses a rated-paths methodology while the Eastern Interconnection uses transmission load relief mechanisms. Consistent with FERC order 743-A, we support exemption criteria for individual frequency independent regions, or interconnections.

Specific transient voltage dip thresholds are proposed on page 15 of Snohomish's White Paper. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should produce no more than a 20% voltage drop for no more than 20 cycles in a Category B contingency and no more than a 20% drop for 40 cycles in a Category C contingency. Technical justification for these thresholds is provided on pages 12-16 of Snohomish's White Paper.

Page 15 of Snohomish's White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided on pages 12-16 of the White Paper.

Please see our response to Question 5d.

No

Yes

As a general matter, we agree with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid justification showing that the Elements in question contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. We also agree that the SDT has, in general, identified the correct technical approach, although we recommend that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in Snohomish's White Paper, in the WECC BES Task Force Proposal 6, and in our answer to Question 5. While we support the SDT's overall approach, we believe subsection (f) of the proposed inclusion criteria, which would allow NERC to "override this criterion" if it provides "additional justification" for doing so is both unnecessary and creates confusion and uncertainty in what is otherwise a clear and concise process. Subsection (f) is unnecessary because if the technical process laid out in subsections (a) through (e) fails to provide any evidence that the contested Element(s) create a material impact on the reliability of the bulk interconnected transmission network, there is no reason to classify those Element(s) as BES, and that should be the end of the question. Subsection (f) creates needless uncertainty because it allows NERC to override the technical criteria laid out in subsections (a) through (e) if "additional justification" is provided, but there is no suggestion as to what this additional justification might be. Nor is there any explanation as to why additional justification might be necessary after the criteria in subsections (a) through (e) have been exhausted.

Please see our corresponding answers to Question 5 for 7b-7e.

No

As discussed on page 12 of Snohomish's White Paper, there may be a few isolated cases where additional data will need to be provided to run a valid technical analysis under the criteria set forth in the Exception Procedure. These cases should be exceedingly rare, however, because the starting point for the technical analysis we recommend is the current base case operated by the relevant RE, and in nearly every case, the base case can be expected to model any Element that conceivably has a material impact on the reliable operation of the bulk system. In those rare cases where it does not, we believe the owner or operator of the subject Element should be able to provide the needed data, although we propose that the relevant owner or operator be relieved of this burden if it can be demonstrated that the nearest electrically interconnected Element has no material impact on the bulk system.

Yes

First, thank you for the opportunity to comment on the Technical Principles for Demonstrating BES Exceptions. We appreciate the work that NERC has done on these principles and the other related efforts to revise the definition of the BES. In response to question #1, we note only that using impedance to benchmark system load proximity would likely not yield clear demarcations. High voltage relative or per-unit impedances are considered typically much lower than low voltage impedances. Hence, in the absence of phase shifting transformers, service compensation, or other mitigation factors, power typically flows over the highest voltage lines, which offer the lowest impedance.

Yes

We agree conceptually that facilities operating as radials rather than as integrated portions of the integrated bulk transmission system should be excluded from the BES definition. However, to be consistent with the draft BES definition, the term "radial in character" should be explicitly defined as facilities that may include one or more lines into a load area or referenced as a local distribution network. In addition, we agree that the manner in which a system is operated during BES disturbances may be an indication of whether that facility is radial in character. That being said, we are concerned that, to the extent the SDT considers regional disconnect procedures, it should be careful to note that UFLS and UVLS relays are often embedded within local distribution facilities and, while it is necessary for the UFLS and UVLS relays to be properly armed to protect the BES in the event of a severe system disturbance, the local distribution facilities interconnected with those relays should not, and cannot legally, be classified as BES.

Yes

We agree conceptually that one critical characteristic distinguishing facilities that must be excluded from the BES from facilities that should be included is the manner in which power flows on those facilities. Hence, the SDT has properly identified power flows as one important characteristic that identifies BES facilities. We also agree conceptually that the fact that power may flow out of facilities onto the grid during a few hours in a year or during extreme contingencies should not change the characterization of the facilities in question as excluded from the BES. Accordingly, we support inclusion of power flow analysis as one element of characteristics that can be used to exclude facilities from the BES even if the facilities do not pass each of the bright-line thresholds laid down in the BES definition. We also agree that transactional and hourly generation records are an appropriate basis for making the determination since these can be used to demonstrate that demand within a system exceeds generation within that system in most hours and that power therefore does not flow onto the grid, and also to determine the number of hours where this is not the case and the amount by which

generation within the system exceeds demand. In order to identify facilities that are not necessary for the operation of the BES under this text, we propose that any facility where real power flows in 90 percent of the time or more under normal ("N-0" or All Lines in Service) operating conditions should be held to meet this test. That facilities meet this test could be demonstrated using metering or supervisory control and data acquisition ("SCADA") data records over the course on two years. While we agree with the SDT's view that power should flow predominantly in the direction of load for excluded facilities, we are concerned that this characteristic may no longer be a defining characteristic as the electric industry evolves in the future. If distributed generation becomes the future norm for new power generation facilities, it may no longer make sense to look at power flow as a defining characteristic. That is, even if a sufficient number of small distributed generation facilities were constructed on certain facilities to cause power to flow out of those facilities more than ten percent of the time, the fundamental character of those facilities will not have changed. Finally, we believe that power flow analysis under this item should consider actual power flow, not scheduled power flow.

Yes

As a matter of operation, power is scheduled across transmission lines. Further, transmission lines in the Western Interconnection (either individually or as part of a transmission path) are rated for total transmission capacity and available transmission capacity, and transmission rights can be purchased on such lines, if available, on an OASIS. Facilities that do not share any of these operational characteristics should not be part of the BES. Accordingly, we agree that if power is not intentionally transported through particular facilities, those facilities should not be considered part of the BES. We also agree that examining the Operating Procedures applicable to particular facilities will provide a ready guide to whether power is intentionally scheduled across those facilities. We suggest, however, that the SDT look beyond those protocols that fall within the NERC Glossary's definition of Operating Procedure. For example, in the West, transmission paths are almost all listed in the WECC Path Rating Catalog. Similarly, it is not clear whether scheduling protocols, OASIS operations, and the other factors listed above qualify as Operating Procedures. Hence, we urge the SDT to list such specific operational characteristics as part of this test. Finally, as noted in our answer to Question 3, we are concerned that, if distributed generation advances significantly, power transport may cease to be a meaningful measure for determining whether a facility is part of the BES, and we believe that power flow analysis should consider actual power flow, not scheduled power flow.

Yes

We agree conceptually with the idea that two different paths to exclusion should be adopted, one relying upon readily identifiable characteristics that are ordinarily associated with non-BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES. Snohomish Public Utility District has prepared a White Paper proposing a performance-based approach to support the technical determination whether Elements should be excluded from the BES, which we commend to the SDT for study. We also commend the work of the WECC BES Task Force and the WECC Technical Studies Subcommittee, both of which have devoted substantial time and resources to developing a workable and technically defensible process for excluding Elements classified as BES based upon their electrical characteristics. See WECC BES Task Force Proposal 6, App. A at 3-9 & App. B at pp. B-4 to B-7 (posted Feb. 18, 2011) (available at: <http://www.wecc.biz/Standards/Development/BES/default.aspx>). We recommend that the SDT modify its approach to the technical exclusion process to match the approach advocated in Snohomish's White Paper, which is based upon the approach recommended by the WECC BES Task Force.

The use of distribution factors, such as Power Transfer Distribution Factors ("PTDF") and Outage Transfer Distribution Factor ("OTDF") provide insight into the relative impedance of neighboring systems. However in the Western Interconnection it has never been a definitive indicator of whether a system fault with delayed clearing would impact a neighboring electric system. While we understand that many entities from the Eastern Interconnection support the use of such factors, we believe the approach is unlikely to work in the Western Interconnection. Based on the significant differences between the four major interconnections in North America, we suggest that a detailed technical exemption process be allowed on an interconnections wide basis. The Western Interconnection is a "hub and spoke system" where loads are very remote from large generation plants, with margins that

are based on stability limits. By contrast, the Eastern Interconnection is a tightly meshed system with loads and generation in close proximity, often creating margins that are based on thermal limitations. These differences manifest themselves in a variety of ways for various operations. For example, the Western Interconnection uses a rated-paths methodology while the Eastern Interconnection uses transmission load relief mechanisms. Consistent with FERC order 743-A, we support exemption criteria for individual frequency independent regions, or interconnections.

Specific transient voltage dip thresholds are proposed on page 15 of Snohomish's White Paper. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should produce no more than a 20% voltage drop for no more than 20 cycles in a Category B contingency and no more than a 20% drop for 40 cycles in a Category C contingency. Technical justification for these thresholds is provided on pages 12-16 of Snohomish's White Paper.

Page 15 of Snohomish's White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided on pages 12-16 of the White Paper.

Please see our response to Question 5d.

No

Yes

As a general matter, we agree with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid justification showing that the Elements in question contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. We also agree that the SDT has, in general, identified the correct technical approach, although we recommend that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in Snohomish's White Paper, in the WECC BES Task Force Proposal 6, and in our answer to Question 5. While we support the SDT's overall approach, we believe subsection (f) of the proposed inclusion criteria, which would allow NERC to "override this criterion" if it provides "additional justification" for doing so is both unnecessary and creates confusion and uncertainty in what is otherwise a clear and concise process. Subsection (f) is unnecessary because if the technical process laid out in subsections (a) through (e) fails to provide any evidence that the contested Element(s) create a material impact on the reliability of the bulk interconnected transmission network, there is no reason to classify those Element(s) as BES, and that should be the end of the question. Subsection (f) creates needless uncertainty because it allows NERC to override the technical criteria laid out in subsections (a) through (e) if "additional justification" is provided, but there is no suggestion as to what this additional justification might be. Nor is there any explanation as to why additional justification might be necessary after the criteria in subsections (a) through (e) have been exhausted.

Please see our corresponding answers to Question 5 for 7b-7e.

No

As discussed on page 12 of Snohomish's White Paper, there may be a few isolated cases where additional data will need to be provided to run a valid technical analysis under the criteria set forth in the Exception Procedure. These cases should be exceedingly rare, however, because the starting point for the technical analysis we recommend is the current base case operated by the relevant RE, and in nearly every case, the base case can be expected to model any Element that conceivably has a material impact on the reliable operation of the bulk system. In those rare cases where it does not, we believe the owner or operator of the subject Element should be able to provide the needed data, although we propose that the relevant owner or operator be relieved of this burden if it can be demonstrated that the nearest electrically interconnected Element has no material impact on the bulk system.

No

Yes

In general, as we discuss above, the Technical Principles for Demonstrating BES Exceptions present a reasonable approach to resolving questions of inclusion and exclusion in the BES that the BES definition itself does not clearly resolve. However, we caution that these principles for demonstrating exceptions cannot, and must not, take the place of a consideration of, and criteria under whether, any specific piece of equipment is subject to FERC, the ERO, and Regional Entity jurisdiction in the first instance. Section 215 of the Federal power Act (FPA) sets out clear limits of jurisdiction of FERC, the ERO, and Regional Entities for purposes of developing and enforcing reliability standards. Specifically, Section 215(i) provides that the ERO "shall have authority to develop and enforce compliance with reliability standards for only the Bulk-Power System." 16 U.S.C. § 824o(a)(1) (emphasis added). Section 215(a)(1) of the statute defines the term "Bulk-Power System" or "BPS" as: (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy." Id. As we have explained in our comments on the BES definition, that definition should expressly account for these jurisdictional limitations up front. This would allow for the jurisdictional limitation consideration as the very first step in determining whether or not a particular piece of equipment is part of the BES. The Technical Principles for Demonstrating BES Exceptions, on the other hand, provides a completely separate set of criteria for exclusion from the BES and would come into play only after application of the full BES definition to a particular piece of equipment and determination that the BES definition does not provide a satisfactory answer as to whether that piece of equipment is or is not part of the BES. This is acceptable insofar as it goes, but, because (1) the criteria in the Technical Principles are distinct from the jurisdictional limits of Section 215 of the FPA, and (2) consideration of the Technical Principles would essentially be the last, or one of the last, steps in the process, the Technical Principles cannot substitute for, in any way, consideration of the jurisdictional limitations of the FPA. Again, we cannot overemphasize enough how important it is to have the jurisdictional consideration be the very first step in the process of determining whether a particular piece of equipment is or is not part of the BES. Again, thank you for the opportunity to comment. We look forward to continuing to work with NERC and stakeholders to develop a BES definition that is both workable and lawful.

Yes

First, thank you for the opportunity to comment on the Technical Principles for Demonstrating BES Exceptions. We appreciate the work that NERC has done on these principles and the other related efforts to revise the definition of the BES. In response to question #1, we note only that using impedance to benchmark system load proximity would likely not yield clear demarcations. High voltage relative or per-unit impedances are considered typically much lower than low voltage impedances. Hence, in the absence of phase shifting transformers, service compensation, or other mitigation factors, power typically flows over the highest voltage lines, which offer the lowest impedance.

Yes

We agree conceptually that facilities operating as radials rather than as integrated portions of the integrated bulk transmission system should be excluded from the BES definition. However, to be consistent with the draft BES definition, the term "radial in character" should be explicitly defined as facilities that may include one or more lines into a load area or referenced as a local distribution network. In addition, we agree that the manner in which a system is operated during BES disturbances may be an indication of whether that facility is radial in character. That being said, we are concerned that, to the extent the SDT considers regional disconnect procedures, it should be careful to note that UFLS and UVLS relays are often embedded within local distribution facilities and, while it is necessary for the UFLS and UVLS relays to be properly armed to protect the BES in the event of a severe system disturbance, the local distribution facilities interconnected with those relays should not, and cannot legally, be classified as BES.

Yes

We agree conceptually that one critical characteristic distinguishing facilities that must be excluded from the BES from facilities that should be included is the manner in which power flows on those

facilities. Hence, the SDT has properly identified power flows as one important characteristic that identifies BES facilities. We also agree conceptually that the fact that power may flow out of facilities onto the grid during a few hours in a year or during extreme contingencies should not change the characterization of the facilities in question as excluded from the BES. Accordingly, we support inclusion of power flow analysis as one element of characteristics that can be used to exclude facilities from the BES even if the facilities do not pass each of the bright-line thresholds laid down in the BES definition. We also agree that transactional and hourly generation records are an appropriate basis for making the determination since these can be used to demonstrate that demand within a system exceeds generation within that system in most hours and that power therefore does not flow onto the grid, and also to determine the number of hours where this is not the case and the amount by which generation within the system exceeds demand. In order to identify facilities that are not necessary for the operation of the BES under this text, we propose that any facility where real power flows in 90 percent of the time or more under normal ("N-O" or All Lines in Service) operating conditions should be held to meet this test. That facilities meet this test could be demonstrated using metering or supervisory control and data acquisition ("SCADA") data records over the course on two years. While we agree with the SDT's view that power should flow predominantly in the direction of load for excluded facilities, we are concerned that this characteristic may no longer be a defining characteristic as the electric industry evolves in the future. If distributed generation becomes the future norm for new power generation facilities, it may no longer make sense to look at power flow as a defining characteristic. That is, even if a sufficient number of small distributed generation facilities were constructed on certain facilities to cause power to flow out of those facilities more than ten percent of the time, the fundamental character of those facilities will not have changed. Finally, we believe that power flow analysis under this item should consider actual power flow, not scheduled power flow.

Yes

As a matter of operation, power is scheduled across transmission lines. Further, transmission lines in the Western Interconnection (either individually or as part of a transmission path) are rated for total transmission capacity and available transmission capacity, and transmission rights can be purchased on such lines, if available, on an OASIS. The Western Interconnection is a "hub and spoke system" where loads are very remote from large generation plants, with margins that are based on stability limits. By contrast, the Eastern Interconnection is a tightly meshed system with loads and generation in close proximity, often creating margins that are based on thermal limitations. These differences manifest themselves in a variety of ways for various operations. For example, the Western Interconnection uses a rated-paths methodology while the Eastern Interconnection uses transmission load relief mechanisms. Consistent with FERC order 743-A, we support exemption criteria for individual frequency independent regions, or interconnections.

Specific transient voltage dip thresholds are proposed on page 15 of Snohomish's White Paper. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should produce no more than a 20% voltage drop for no more than 20 cycles in a Category B contingency and no more than a 20% drop for 40 cycles in a Category C contingency. Technical justification for these thresholds is provided on pages 12-16 of Snohomish's White Paper.

Page 15 of Snohomish's White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided on pages 12-16 of the White Paper.

Please see our response to Question 5d.

No

Yes

As a general matter, we agree with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid justification showing that the Elements in question contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. We also agree that the SDT has, in general, identified the correct technical approach, although we recommend that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in Snohomish's White Paper, in the WECC BES Task Force Proposal 6, and in our answer to Question 5. While we support the SDT's overall approach, we believe subsection (f) of the proposed inclusion criteria, which would allow NERC to "override this criterion" if it provides "additional justification" for doing so is both unnecessary and creates confusion and uncertainty in what is otherwise a clear and concise process. Subsection (f) is unnecessary because if the technical process laid out in subsections (a) through (e) fails to provide any evidence that the contested Element(s) create a material impact on the reliability of the bulk interconnected transmission network, there is no reason to classify those Element(s) as BES, and that should be the end of the question. Subsection (f) creates needless uncertainty because it allows NERC to override the technical criteria laid out in subsections (a) through (e) if "additional justification" is provided, but there is no suggestion as to what this additional justification might be. Nor is there any explanation as to why additional justification might be necessary after the criteria in subsections (a) through (e)

have been exhausted.
Please see our corresponding answers to Question 5 for 7b-7e.
No
As discussed on page 12 of Snohomish's White Paper, there may be a few isolated cases where additional data will need to be provided to run a valid technical analysis under the criteria set forth in the Exception Procedure. These cases should be exceedingly rare, however, because the starting point for the technical analysis we recommend is the current base case operated by the relevant RE, and in nearly every case, the base case can be expected to model any Element that conceivably has a material impact on the reliable operation of the bulk system. In those rare cases where it does not, we believe the owner or operator of the subject Element should be able to provide the needed data, although we propose that the relevant owner or operator be relieved of this burden if it can be demonstrated that the nearest electrically interconnected Element has no material impact on the bulk system.
No
Yes
In general, as we discuss above, the Technical Principles for Demonstrating BES Exceptions present a reasonable approach to resolving questions of inclusion and exclusion in the BES that the BES definition itself does not clearly resolve. However, we caution that these principles for demonstrating exceptions cannot, and must not, take the place of a consideration of, and criteria under whether, any specific piece of equipment is subject to FERC, the ERO, and Regional Entity jurisdiction in the first instance. Section 215 of the Federal power Act (FPA) sets out clear limits of jurisdiction of FERC, the ERO, and Regional Entities for purposes of developing and enforcing reliability standards. Specifically, Section 215(i) provides that the ERO "shall have authority to develop and enforce compliance with reliability standards for only the Bulk-Power System." 16 U.S.C. § 824o(a)(1) (emphasis added). Section 215(a)(1) of the statute defines the term "Bulk-Power System" or "BPS" as: (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy." Id. As we have explained in our comments on the BES definition, that definition should expressly account for these jurisdictional limitations up front. This would allow for the jurisdictional limitation consideration as the very first step in determining whether or not a particular piece of equipment is part of the BES. The Technical Principles for Demonstrating BES Exceptions, on the other hand, provides a completely separate set of criteria for exclusion from the BES and would come into play only after application of the full BES definition to a particular piece of equipment and determination that the BES definition does not provide a satisfactory answer as to whether that piece of equipment is or is not part of the BES. This is acceptable insofar as it goes, but, because (1) the criteria in the Technical Principles are distinct from the jurisdictional limits of Section 215 of the FPA, and (2) consideration of the Technical Principles would essentially be the last, or one of the last, steps in the process, the Technical Principles cannot substitute for, in any way, consideration of the jurisdictional limitations of the FPA. Again, we cannot overemphasize enough how important it is to have the jurisdictional consideration be the very first step in the process of determining whether a particular piece of equipment is or is not part of the BES. Again, thank you for the opportunity to comment. We look forward to continuing to work with NERC and stakeholders to develop a BES definition that is both workable and lawful.

Yes
First, thank you for the opportunity to comment on the Technical Principles for Demonstrating BES Exceptions. We appreciate the work that NERC has done on these principles and the other related efforts to revise the definition of the BES. In response to question #1, we note only that using

impedance to benchmark system load proximity would likely not yield clear demarcations. High voltage relative or per-unit impedances are considered typically much lower than low voltage impedances. Hence, in the absence of phase shifting transformers, service compensation, or other mitigation factors, power typically flows over the highest voltage lines, which offer the lowest impedance.

Yes

We agree conceptually that facilities operating as radials rather than as integrated portions of the integrated bulk transmission system should be excluded from the BES definition. However, to be consistent with the draft BES definition, the term "radial in character" should be explicitly defined as facilities that may include one or more lines into a load area or referenced as a local distribution network. In addition, we agree that the manner in which a system is operated during BES disturbances may be an indication of whether that facility is radial in character. That being said, we are concerned that, to the extent the SDT considers regional disconnect procedures, it should be careful to note that UFLS and UVLS relays are often embedded within local distribution facilities and, while it is necessary for the UFLS and UVLS relays to be properly armed to protect the BES in the event of a severe system disturbance, the local distribution facilities interconnected with those relays should not, and cannot legally, be classified as BES.

Yes

We agree conceptually that one critical characteristic distinguishing facilities that must be excluded from the BES from facilities that should be included is the manner in which power flows on those facilities. Hence, the SDT has properly identified power flows as one important characteristic that identifies BES facilities. We also agree conceptually that the fact that power may flow out of facilities onto the grid during a few hours in a year or during extreme contingencies should not change the characterization of the facilities in question as excluded from the BES. Accordingly, we support inclusion of power flow analysis as one element of characteristics that can be used to exclude facilities from the BES even if the facilities do not pass each of the bright-line thresholds laid down in the BES definition. We also agree that transactional and hourly generation records are an appropriate basis for making the determination since these can be used to demonstrate that demand within a system exceeds generation within that system in most hours and that power therefore does not flow onto the grid, and also to determine the number of hours where this is not the case and the amount by which generation within the system exceeds demand. In order to identify facilities that are not necessary for the operation of the BES under this text, we propose that any facility where real power flows in 90 percent of the time or more under normal ("N-O" or All Lines in Service) operating conditions should be held to meet this test. That facilities meet this test could be demonstrated using metering or supervisory control and data acquisition ("SCADA") data records over the course on two years. While we agree with the SDT's view that power should flow predominantly in the direction of load for excluded facilities, we are concerned that this characteristic may no longer be a defining characteristic as the electric industry evolves in the future. If distributed generation becomes the future norm for new power generation facilities, it may no longer make sense to look at power flow as a defining characteristic. That is, even if a sufficient number of small distributed generation facilities were constructed on certain facilities to cause power to flow out of those facilities more than ten percent of the time, the fundamental character of those facilities will not have changed. Finally, we believe that power flow analysis under this item should consider actual power flow, not scheduled power flow.

Yes

As a matter of operation, power is scheduled across transmission lines. Further, transmission lines in the Western Interconnection (either individually or as part of a transmission path) are rated for total transmission capacity and available transmission capacity, and transmission rights can be purchased on such lines, if available, on an OASIS. Facilities that do not share any of these operational characteristics should not be part of the BES. Accordingly, we agree that if power is not intentionally transported through particular facilities, those facilities should not be considered part of the BES. We also agree that examining the Operating Procedures applicable to particular facilities will provide a ready guide to whether power is intentionally scheduled across those facilities. We suggest, however, that the SDT look beyond those protocols that fall within the NERC Glossary's definition of Operating Procedure. For example, in the West, transmission paths are almost all listed in the WECC Path Rating Catalog. Similarly, it is not clear whether scheduling protocols, OASIS operations, and the other factors listed above qualify as Operating Procedures. Hence, we urge the SDT to list such specific operational characteristics as part of this test. Finally, as noted in our answer to Question 3, we are

concerned that, if distributed generation advances significantly, power transport may cease to be a meaningful measure for determining whether a facility is part of the BES, and we believe that power flow analysis should consider actual power flow, not scheduled power flow.

Yes

We agree conceptually with the idea that two different paths to exclusion should be adopted, one relying upon readily identifiable characteristics that are ordinarily associated with non-BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES. Snohomish Public Utility District has prepared a White Paper proposing a performance-based approach to support the technical determination whether Elements should be excluded from the BES, which we commend to the SDT for study. We also commend the work of the WECC BES Task Force and the WECC Technical Studies Subcommittee, both of which have devoted substantial time and resources to developing a workable and technically defensible process for excluding Elements classified as BES based upon their electrical characteristics. See WECC BES Task Force Proposal 6, App. A at 3-9 & App. B at pp. B-4 to B-7 (posted Feb. 18, 2011) (available at: <http://www.wecc.biz/Standards/Development/BES/default.aspx>). We recommend that the SDT modify its approach to the technical exclusion process to match the approach advocated in Snohomish's White Paper, which is based upon the approach recommended by the WECC BES Task Force.

The use of distribution factors, such as Power Transfer Distribution Factors ("PTDF") and Outage Transfer Distribution Factor ("OTDF") provide insight into the relative impedance of neighboring systems. However in the Western Interconnection it has never been a definitive indicator of whether a system fault with delayed clearing would impact a neighboring electric system. While we understand that many entities from the Eastern Interconnection support the use of such factors, we believe the approach is unlikely to work in the Western Interconnection. Based on the significant differences between the four major interconnections in North America, we suggest that a detailed technical exemption process be allowed on an interconnections wide basis. The Western Interconnection is a "hub and spoke system" where loads are very remote from large generation plants, with margins that are based on stability limits. By contrast, the Eastern Interconnection is a tightly meshed system with loads and generation in close proximity, often creating margins that are based on thermal limitations. These differences manifest themselves in a variety of ways for various operations. For example, the Western Interconnection uses a rated-paths methodology while the Eastern Interconnection uses transmission load relief mechanisms. Consistent with FERC order 743-A, we support exemption criteria for individual frequency independent regions, or interconnections.

Specific transient voltage dip thresholds are proposed on page 15 of Snohomish's White Paper. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should produce no more than a 20% voltage drop for no more than 20 cycles in a Category B contingency and no more than a 20% drop for 40 cycles in a Category C contingency. Technical justification for these thresholds is provided on pages 12-16 of Snohomish's White Paper.

Page 15 of Snohomish's White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided on pages 12-16 of the White Paper.

Please see our response to Question 5d.

No

Yes

As a general matter, we agree with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid justification showing that the Elements in question contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. We also agree that the SDT has, in general, identified the correct technical approach, although we recommend that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in Snohomish's White Paper, in the WECC BES Task Force Proposal 6, and in our answer to Question 5. While we support the SDT's overall approach,

we believe subsection (f) of the proposed inclusion criteria, which would allow NERC to “override this criterion” if it provides “additional justification” for doing so is both unnecessary and creates confusion and uncertainty in what is otherwise a clear and concise process. Subsection (f) is unnecessary because if the technical process laid out in subsections (a) through (e) fails to provide any evidence that the contested Element(s) create a material impact on the reliability of the bulk interconnected transmission network, there is no reason to classify those Element(s) as BES, and that should be the end of the question. Subsection (f) creates needless uncertainty because it allows NERC to override the technical criteria laid out in subsections (a) through (e) if “additional justification” is provided, but there is no suggestion as to what this additional justification might be. Nor is there any explanation as to why additional justification might be necessary after the criteria in subsections (a) through (e) have been exhausted.

Please see our corresponding answers to Question 5 for 7b-7e.

Finally, as noted in our answer to Question 3, we are concerned that, if distributed generation advances significantly, power transport may cease to be a meaningful measure for determining whether a facility is part of the BES, and we believe that power flow analysis should consider actual power flow, not scheduled power flow.

Yes

We agree conceptually with the idea that two different paths to exclusion should be adopted, one relying upon readily identifiable characteristics that are ordinarily associated with non-BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES. Snohomish Public Utility District has prepared a White Paper proposing a performance-based approach to support the technical determination whether Elements should be excluded from the BES, which we commend to the SDT for study. We also commend the work of the WECC BES Task Force and the WECC Technical Studies Subcommittee, both of which have devoted substantial time and resources to developing a workable and technically defensible process for excluding Elements classified as BES based upon their electrical characteristics. See WECC BES Task Force Proposal 6, App. A at 3-9 & App. B at pp. B-4 to B-7 (posted Feb. 18, 2011) (available at: <http://www.wecc.biz/Standards/Development/BES/default.aspx>). We recommend that the SDT modify its approach to the technical exclusion process to match the approach advocated in Snohomish's White Paper, which is based upon the approach recommended by the WECC BES Task Force.

The use of distribution factors, such as Power Transfer Distribution Factors ("PTDF") and Outage Transfer Distribution Factor ("OTDF") provide insight into the relative impedance of neighboring systems. However in the Western Interconnection it has never been a definitive indicator of whether a system fault with delayed clearing would impact a neighboring electric system. While we understand that many entities from the Eastern Interconnection support the use of such factors, we believe the approach is unlikely to work in the Western Interconnection. Based on the significant differences between the four major interconnections in North America, we suggest that a detailed technical exemption process be allowed on an interconnections wide basis. The Western Interconnection is a "hub and spoke system" where loads are very remote from large generation plants, with margins that are based on stability limits. By contrast, the Eastern Interconnection is a tightly meshed system with loads and generation in close proximity, often creating margins that are based on thermal limitations. These differences manifest themselves in a variety of ways for various operations. For example, the Western Interconnection uses a rated-paths methodology while the Eastern Interconnection uses transmission load relief mechanisms. Consistent with FERC order 743-A, we support exemption criteria for individual frequency independent regions, or interconnections.

Specific transient voltage dip thresholds are proposed on page 15 of Snohomish's White Paper. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element

should produce no more than a 20% voltage drop for no more than 20 cycles in a Category B contingency and no more than a 20% drop for 40 cycles in a Category C contingency. Technical justification for these thresholds is provided on pages 12-16 of Snohomish's White Paper.

Page 15 of Snohomish's White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided on pages 12-16 of the White Paper.

Please see our response to Question 5d.

No

Yes

As a general matter, we agree with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid justification showing that the Elements in question contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. We also agree that the SDT has, in general, identified the correct technical approach, although we recommend that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in Snohomish's White Paper, in the WECC BES Task Force Proposal 6, and in our answer to Question 5. While we support the SDT's overall approach, we believe subsection (f) of the proposed inclusion criteria, which would allow NERC to "override this criterion" if it provides "additional justification" for doing so is both unnecessary and creates confusion and uncertainty in what is otherwise a clear and concise process. Subsection (f) is unnecessary because if the technical process laid out in subsections (a) through (e) fails to provide any evidence that the contested Element(s) create a material impact on the reliability of the bulk interconnected transmission network, there is no reason to classify those Element(s) as BES, and that should be the end of the question. Subsection (f) creates needless uncertainty because it allows NERC to override the technical criteria laid out in subsections (a) through (e) if "additional justification" is provided, but there is no suggestion as to what this additional justification might be. Nor is there any explanation as to why additional justification might be necessary after the criteria in subsections (a) through (e) have been exhausted.

Please see our corresponding answers to Question 5 for 7b-7e.

No

As discussed on page 12 of Snohomish's White Paper, there may be a few isolated cases where additional data will need to be provided to run a valid technical analysis under the criteria set forth in the Exception Procedure. These cases should be exceedingly rare, however, because the starting point for the technical analysis we recommend is the current base case operated by the relevant RE, and in nearly every case, the base case can be expected to model any Element that conceivably has a material impact on the reliable operation of the bulk system. In those rare cases where it does not, we believe the owner or operator of the subject Element should be able to provide the needed data, although we propose that the relevant owner or operator be relieved of this burden if it can be demonstrated that the nearest electrically interconnected Element has no material impact on the bulk system.

No

Yes

In general, as we discuss above, the Technical Principles for Demonstrating BES Exceptions present a reasonable approach to resolving questions of inclusion and exclusion in the BES that the BES definition itself does not clearly resolve. However, we caution that these principles for demonstrating exceptions cannot, and must not, take the place of a consideration of, and criteria under whether, any specific piece of equipment is subject to FERC, the ERO, and Regional Entity jurisdiction in the first instance. Section 215 of the Federal power Act (FPA) sets out clear limits of jurisdiction of FERC, the ERO, and Regional Entities for purposes of developing and enforcing reliability standards. Specifically, Section 215(i) provides that the ERO "shall have authority to develop and enforce compliance with

reliability standards for only the Bulk-Power System." 16 U.S.C. § 824o(a)(1) (emphasis added). Section 215(a)(1) of the statute defines the term "Bulk-Power System" or "BPS" as: (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy." Id. As we have explained in our comments on the BES definition, that definition should expressly account for these jurisdictional limitations up front. This would allow for the jurisdictional limitation consideration as the very first step in determining whether or not a particular piece of equipment is part of the BES. The Technical Principles for Demonstrating BES Exceptions, on the other hand, provides a completely separate set of criteria for exclusion from the BES and would come into play only after application of the full BES definition to a particular piece of equipment and determination that the BES definition does not provide a satisfactory answer as to whether that piece of equipment is or is not part of the BES. This is acceptable insofar as it goes, but, because (1) the criteria in the Technical Principles are distinct from the jurisdictional limits of Section 215 of the FPA, and (2) consideration of the Technical Principles would essentially be the last, or one of the last, steps in the process, the Technical Principles cannot substitute for, in any way, consideration of the jurisdictional limitations of the FPA. Again, we cannot overemphasize enough how important it is to have the jurisdictional consideration be the very first step in the process of determining whether a particular piece of equipment is or is not part of the BES. Again, thank you for the opportunity to comment. We look forward to continuing to work with NERC and stakeholders to develop a BES definition that is both workable and lawful.

Yes

First, thank you for the opportunity to comment on the Technical Principles for Demonstrating BES Exceptions. We appreciate the work that NERC has done on these principles and the other related efforts to revise the definition of the BES. In response to question #1, we note only that using impedance to benchmark system load proximity would likely not yield clear demarcations. High voltage relative or per-unit impedances are considered typically much lower than low voltage impedances. Hence, in the absence of phase shifting transformers, service compensation, or other mitigation factors, power typically flows over the highest voltage lines, which offer the lowest impedance.

Yes

We agree conceptually that facilities operating as radials rather than as integrated portions of the integrated bulk transmission system should be excluded from the BES definition. However, to be consistent with the draft BES definition, the term "radial in character" should be explicitly defined as facilities that may include one or more lines into a load area or referenced as a local distribution network. In addition, we agree that the manner in which a system is operated during BES disturbances may be an indication of whether that facility is radial in character. That being said, we are concerned that, to the extent the SDT considers regional disconnect procedures, it should be careful to note that UFLS and UVLS relays are often embedded within local distribution facilities and, while it is necessary for the UFLS and UVLS relays to be properly armed to protect the BES in the event of a severe system disturbance, the local distribution facilities interconnected with those relays should not, and cannot legally, be classified as BES.

Yes

We agree conceptually that one critical characteristic distinguishing facilities that must be excluded from the BES from facilities that should be included is the manner in which power flows on those facilities. Hence, the SDT has properly identified power flows as one important characteristic that identifies BES facilities. We also agrees conceptually that the fact that power may flow out of facilities onto the grid during a few hours in a year or during extreme contingencies should not change the characterization of the facilities in question as excluded from the BES. Accordingly, we support inclusion of power flow analysis as one element of characteristics that can be used to exclude facilities from the BES even if the facilities do not pass each of the bright-line thresholds laid down in the BES definition. We also agree that transactional and hourly generation records are an appropriate basis for making the determination since these can be used to demonstrate that demand within a system

exceeds generation within that system in most hours and that power therefore does not flow onto the grid, and also to determine the number of hours where this is not the case and the amount by which generation within the system exceeds demand. In order to identify facilities that are not necessary for the operation of the BES under this text, we propose that any facility where real power flows in 90 percent of the time or more under normal ("N-O" or All Lines in Service) operating conditions should be held to meet this test. That facilities meet this test could be demonstrated using metering or supervisory control and data acquisition ("SCADA") data records over the course on two years. While we agree with the SDT's view that power should flow predominantly in the direction of load for excluded facilities, we are concerned that this characteristic may no longer be a defining characteristic as the electric industry evolves in the future. If distributed generation becomes the future norm for new power generation facilities, it may no longer make sense to look at power flow as a defining characteristic. That is, even if a sufficient number of small distributed generation facilities were constructed on certain facilities to cause power to flow out of those facilities more than ten percent of the time, the fundamental character of those facilities will not have changed. Finally, we believe that power flow analysis under this item should consider actual power flow, not scheduled power flow.

Yes

As a matter of operation, power is scheduled across transmission lines. Further, transmission lines in the Western Interconnection (either individually or as part of a transmission path) are rated for total transmission capacity and available transmission capacity, and transmission rights can be purchased on such lines, if available, on an OASIS. Facilities that do not share any of these operational characteristics should not be part of the BES. Accordingly, we agree that if power is not intentionally transported through particular facilities, those facilities should not be considered part of the BES. We also agree that examining the Operating Procedures applicable to particular facilities will provide a ready guide to whether power is intentionally scheduled across those facilities. We suggest, however, that the SDT look beyond those protocols that fall within the NERC Glossary's definition of Operating Procedure. For example, in the West, transmission paths are almost all listed in the WECC Path Rating Catalog. Similarly, it is not clear whether scheduling protocols, OASIS operations, and the other factors listed above qualify as Operating Procedures. Hence, we urge the SDT to list such specific operational characteristics as part of this test. Finally, as noted in our answer to Question 3, we are concerned that, if distributed generation advances significantly, power transport may cease to be a meaningful measure for determining whether a facility is part of the BES, and we believe that power flow analysis should consider actual power flow, not scheduled power flow.

Yes

We agree conceptually with the idea that two different paths to exclusion should be adopted, one relying upon readily identifiable characteristics that are ordinarily associated with non-BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES. Snohomish Public Utility District has prepared a White Paper proposing a performance-based approach to support the technical determination whether Elements should be excluded from the BES, which we commend to the SDT for study. We also commend the work of the WECC BES Task Force and the WECC Technical Studies Subcommittee, both of which have devoted substantial time and resources to developing a workable and technically defensible process for excluding Elements classified as BES based upon their electrical characteristics. See WECC BES Task Force Proposal 6, App. A at 3-9 & App. B at pp. B-4 to B-7 (posted Feb. 18, 2011) (available at: <http://www.wecc.biz/Standards/Development/BES/default.aspx>). We recommend that the SDT modify its approach to the technical exclusion process to match the approach advocated in Snohomish's White Paper, which is based upon the approach recommended by the WECC BES Task Force.

The use of distribution factors, such as Power Transfer Distribution Factors ("PTDF") and Outage Transfer Distribution Factor ("OTDF") provide insight into the relative impedance of neighboring systems. However in the Western Interconnection it has never been a definitive indicator of whether a system fault with delayed clearing would impact a neighboring electric system. While we understand that many entities from the Eastern Interconnection support the use of such factors, we believe the approach is unlikely to work in the Western Interconnection. Based on the significant differences between the four major interconnections in North America, we suggest that a detailed technical

exemption process be allowed on an interconnections wide basis. The Western Interconnection is a “hub and spoke system” where loads are very remote from large generation plants, with margins that are based on stability limits. By contrast, the Eastern Interconnection is a tightly meshed system with loads and generation in close proximity, often creating margins that are based on thermal limitations. These differences manifest themselves in a variety of ways for various operations. For example, the Western Interconnection uses a rated-paths methodology while the Eastern Interconnection uses transmission load relief mechanisms. Consistent with FERC order 743-A, we support exemption criteria for individual frequency independent regions, or interconnections.

Specific transient voltage dip thresholds are proposed on page 15 of Snohomish’s White Paper. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should produce no more than a 20% voltage drop for no more than 20 cycles in a Category B contingency and no more than a 20% drop for 40 cycles in a Category C contingency. Technical justification for these thresholds is provided on pages 12-16 of Snohomish’s White Paper.

Page 15 of Snohomish’s White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided on pages 12-16 of the White Paper. Page 15 of Snohomish’s White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided on pages 12-16 of the White Paper.

Please see our response to Question 5d.

No

Yes

As a general matter, we agree with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid justification showing that the Elements in question contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. We also agree that the SDT has, in general, identified the correct technical approach, although we recommend that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in Snohomish’s White Paper, in the WECC BES Task Force Proposal 6, and in our answer to Question 5. While we support the SDT’s overall approach, we believe subsection (f) of the proposed inclusion criteria, which would allow NERC to “override this criterion” if it provides “additional justification” for doing so is both unnecessary and creates confusion and uncertainty in what is otherwise a clear and concise process. Subsection (f) is unnecessary because if the technical process laid out in subsections (a) through (e) fails to provide any evidence that the contested Element(s) create a material impact on the reliability of the bulk interconnected transmission network, there is no reason to classify those Element(s) as BES, and that should be the end of the question. Subsection (f) creates needless uncertainty because it allows NERC to override the technical criteria laid out in subsections (a) through (e) if “additional justification” is provided, but there is no suggestion as to what this additional justification might be. Nor is there any explanation as to why additional justification might be necessary after the criteria in subsections (a) through (e) have been exhausted.

Please see our corresponding answers to Question 5 for 7b-7e.

The Technical Principles for Demonstrating BES Exceptions, on the other hand, provides a completely separate set of criteria for exclusion from the BES and would come into play only after application of the full BES definition to a particular piece of equipment and determination that the BES definition does not provide a satisfactory answer as to whether that piece of equipment is or is not part of the BES. This is acceptable insofar as it goes, but, because (1) the criteria in the Technical Principles are distinct from the jurisdictional limits of Section 215 of the FPA, and (2) consideration of the Technical Principles would essentially be the last, or one of the last, steps in the process, the Technical Principles cannot substitute for, in any way, consideration of the jurisdictional limitations of the FPA. Again, we cannot overemphasize enough how important it is to have the jurisdictional consideration be the very first step in the process of determining whether a particular piece of equipment is or is not part of the BES. Again, thank you for the opportunity to comment. We look forward to continuing to work with NERC and stakeholders to develop a BES definition that is both workable and lawful.

Yes
First, thank you for the opportunity to comment on the Technical Principles for Demonstrating BES Exceptions. We appreciate the work that NERC has done on these principles and the other related efforts to revise the definition of the BES. In response to question #1, we note only that using impedance to benchmark system load proximity would likely not yield clear demarcations. High voltage relative or per-unit impedances are considered typically much lower than low voltage impedances. Hence, in the absence of phase shifting transformers, service compensation, or other mitigation factors, power typically flows over the highest voltage lines, which offer the lowest impedance.

Yes

We agree conceptually that facilities operating as radials rather than as integrated portions of the integrated bulk transmission system should be excluded from the BES definition. However, to be consistent with the draft BES definition, the term "radial in character" should be explicitly defined as facilities that may include one or more lines into a load area or referenced as a local distribution network. In addition, we agree that the manner in which a system is operated during BES disturbances may be an indication of whether that facility is radial in character. That being said, we are concerned that, to the extent the SDT considers regional disconnect procedures, it should be careful to note that UFLS and UVLS relays are often embedded within local distribution facilities and, while it is necessary for the UFLS and UVLS relays to be properly armed to protect the BES in the event of a severe system disturbance, the local distribution facilities interconnected with those relays should not, and cannot legally, be classified as BES.

Yes

We agree conceptually that one critical characteristic distinguishing facilities that must be excluded from the BES from facilities that should be included is the manner in which power flows on those facilities. Hence, the SDT has properly identified power flows as one important characteristic that identifies BES facilities. We also agree conceptually that the fact that power may flow out of facilities onto the grid during a few hours in a year or during extreme contingencies should not change the characterization of the facilities in question as excluded from the BES. Accordingly, we support inclusion of power flow analysis as one element of characteristics that can be used to exclude facilities from the BES even if the facilities do not pass each of the bright-line thresholds laid down in the BES definition. We also agree that transactional and hourly generation records are an appropriate basis for making the determination since these can be used to demonstrate that demand within a system exceeds generation within that system in most hours and that power therefore does not flow onto the grid, and also to determine the number of hours where this is not the case and the amount by which generation within the system exceeds demand. In order to identify facilities that are not necessary for the operation of the BES under this text, we propose that any facility where real power flows in 90 percent of the time or more under normal ("N-0" or All Lines in Service) operating conditions should be held to meet this test. That facilities meet this test could be demonstrated using metering or supervisory control and data acquisition ("SCADA") data records over the course on two years. While we agree with the SDT's view that power should flow predominantly in the direction of load for excluded facilities, we are concerned that this characteristic may no longer be a defining characteristic as the electric industry evolves in the future. If distributed generation becomes the future norm for new power generation facilities, it may no longer make sense to look at power flow as a defining characteristic. That is, even if a sufficient number of small distributed generation facilities were constructed on certain facilities to cause power to flow out of those facilities more than ten percent of the time, the fundamental character of those facilities will not have changed. Finally, we believe that power flow analysis under this item should consider actual power flow, not scheduled power flow.

Yes

As a matter of operation, power is scheduled across transmission lines. Further, transmission lines in the Western Interconnection (either individually or as part of a transmission path) are rated for total transmission capacity and available transmission capacity, and transmission rights can be purchased on such lines, if available, on an OASIS. Facilities that do not share any of these operational characteristics should not be part of the BES. Accordingly, we agree that if power is not intentionally transported through particular facilities, those facilities should not be considered part of the BES. We also agree that examining the Operating Procedures applicable to particular facilities will provide a ready guide to whether power is intentionally scheduled across those facilities. We suggest, however, that the SDT look beyond those protocols that fall within the NERC Glossary's definition of Operating Procedure. For example, in the West, transmission paths are almost all listed in the WECC Path Rating Catalog. Similarly, it is not clear whether scheduling protocols, OASIS operations, and the other factors listed above qualify as Operating Procedures. Hence, we urge the SDT to list such specific operational characteristics as part of this test. Finally, as noted in our answer to Question 3, we are concerned that, if distributed generation advances significantly, power transport may cease to be a meaningful measure for determining whether a facility is part of the BES, and we believe that power flow analysis should consider actual power flow, not scheduled power flow.

Yes

We agree conceptually with the idea that two different paths to exclusion should be adopted. one

relying upon readily identifiable characteristics that are ordinarily associated with non-BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES. Snohomish Public Utility District has prepared a White Paper proposing a performance-based approach to support the technical determination whether Elements should be excluded from the BES, which we commend to the SDT for study. We also commend the work of the WECC BES Task Force and the WECC Technical Studies Subcommittee, both of which have devoted substantial time and resources to developing a workable and technically defensible process for excluding Elements classified as BES based upon their electrical characteristics. See WECC BES Task Force Proposal 6, App. A at 3-9 & App. B at pp. B-4 to B-7 (posted Feb. 18, 2011) (available at: <http://www.wecc.biz/Standards/Development/BES/default.aspx>). We recommend that the SDT modify its approach to the technical exclusion process to match the approach advocated in Snohomish's White Paper, which is based upon the approach recommended by the WECC BES Task Force.

The use of distribution factors, such as Power Transfer Distribution Factors ("PTDF") and Outage Transfer Distribution Factor ("OTDF") provide insight into the relative impedance of neighboring systems. However in the Western Interconnection it has never been a definitive indicator of whether a system fault with delayed clearing would impact a neighboring electric system. While we understand that many entities from the Eastern Interconnection support the use of such factors, we believe the approach is unlikely to work in the Western Interconnection. Based on the significant differences between the four major interconnections in North America, we suggest that a detailed technical exemption process be allowed on an interconnections wide basis. The Western Interconnection is a "hub and spoke system" where loads are very remote from large generation plants, with margins that are based on stability limits. By contrast, the Eastern Interconnection is a tightly meshed system with loads and generation in close proximity, often creating margins that are based on thermal limitations. These differences manifest themselves in a variety of ways for various operations. For example, the Western Interconnection uses a rated-paths methodology while the Eastern Interconnection uses transmission load relief mechanisms. Consistent with FERC order 743-A, we support exemption criteria for individual frequency independent regions, or interconnections.

Specific transient voltage dip thresholds are proposed on page 15 of Snohomish's White Paper. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should produce no more than a 20% voltage drop for no more than 20 cycles in a Category B contingency and no more than a 20% drop for 40 cycles in a Category C contingency. Technical justification for these thresholds is provided on pages 12-16 of Snohomish's White Paper.

Page 15 of Snohomish's White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided on pages 12-16 of the White Paper.

Please see our response to Question 5d.

No

Yes

As a general matter, we agree with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid justification showing that the Elements in question contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. We also agree that the SDT has, in general, identified the correct technical approach, although we recommend that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in Snohomish's White Paper, in the WECC BES Task Force Proposal 6, and in our answer to Question 5. While we support the SDT's overall approach, we believe subsection (f) of the proposed inclusion criteria, which would allow NERC to "override this criterion" if it provides "additional justification" for doing so is both unnecessary and creates confusion and uncertainty in what is otherwise a clear and concise process. Subsection (f) is unnecessary because if the technical process laid out in subsections (a) through (e) fails to provide any evidence that the contested Element(s) create a material impact on the reliability of the bulk interconnected

transmission network, there is no reason to classify those Element(s) as BES, and that should be the end of the question. Subsection (f) creates needless uncertainty because it allows NERC to override the technical criteria laid out in subsections (a) through (e) if "additional justification" is provided, but there is no suggestion as to what this additional justification might be. Nor is there any explanation as to why additional justification might be necessary after the criteria in subsections (a) through (e) have been exhausted.

Please see our corresponding answers to Question 5 for 7b-7e.

No

As discussed on page 12 of Snohomish's White Paper, there may be a few isolated cases where additional data will need to be provided to run a valid technical analysis under the criteria set forth in the Exception Procedure. These cases should be exceedingly rare, however, because the starting point for the technical analysis we recommend is the current base case operated by the relevant RE, and in nearly every case, the base case can be expected to model any Element that conceivably has a material impact on the reliable operation of the bulk system. In those rare cases where it does not, we believe the owner or operator of the subject Element should be able to provide the needed data, although we propose that the relevant owner or operator be relieved of this burden if it can be demonstrated that the nearest electrically interconnected Element has no material impact on the bulk system.

No

Yes

In general, as we discuss above, the Technical Principles for Demonstrating BES Exceptions present a reasonable approach to resolving questions of inclusion and exclusion in the BES that the BES definition itself does not clearly resolve. However, we caution that these principles for demonstrating exceptions cannot, and must not, take the place of a consideration of, and criteria under whether, any specific piece of equipment is subject to FERC, the ERO, and Regional Entity jurisdiction in the first instance. Section 215 of the Federal power Act (FPA) sets out clear limits of jurisdiction of FERC, the ERO, and Regional Entities for purposes of developing and enforcing reliability standards. Specifically, Section 215(i) provides that the ERO "shall have authority to develop and enforce compliance with reliability standards for only the Bulk-Power System." 16 U.S.C. § 824o(a)(1) (emphasis added). Section 215(a)(1) of the statute defines the term "Bulk-Power System" or "BPS" as: (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy." Id. As we have explained in our comments on the BES definition, that definition should expressly account for these jurisdictional limitations up front. This would allow for the jurisdictional limitation consideration as the very first step in determining whether or not a particular piece of equipment is part of the BES. The Technical Principles for Demonstrating BES Exceptions, on the other hand, provides a completely separate set of criteria for exclusion from the BES and would come into play only after application of the full BES definition to a particular piece of equipment and determination that the BES definition does not provide a satisfactory answer as to whether that piece of equipment is or is not part of the BES. This is acceptable insofar as it goes, but, because (1) the criteria in the Technical Principles are distinct from the jurisdictional limits of Section 215 of the FPA, and (2) consideration of the Technical Principles would essentially be the last, or one of the last, steps in the process, the Technical Principles cannot substitute for, in any way, consideration of the jurisdictional limitations of the FPA. Again, we cannot overemphasize enough how important it is to have the jurisdictional consideration be the very first step in the process of determining whether a particular piece of equipment is or is not part of the BES. Again, thank you for the opportunity to comment. We look forward to continuing to work with NERC and stakeholders to develop a BES definition that is both workable and lawful.

For example, the Western Interconnection uses a rated-paths methodology while the Eastern Interconnection uses transmission load relief mechanisms. Consistent with FERC order 743-A, we support exemption criteria for individual frequency independent regions, or interconnections.

Specific transient voltage dip thresholds are proposed on page 15 of Snohomish's White Paper. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should produce no more than a 20% voltage drop for no more than 20 cycles in a Category B contingency and no more than a 20% drop for 40 cycles in a Category C contingency. Technical justification for these thresholds is provided on pages 12-16 of Snohomish's White Paper.

Page 15 of Snohomish's White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided on pages 12-16 of the White Paper.

Please see our response to Question 5d.

No

Yes

As a general matter, we agree with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid justification showing that the Elements in question contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. We also agree that the SDT has, in general, identified the correct technical approach, although we recommend that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in Snohomish's White Paper, in the WECC BES Task Force Proposal 6, and in our answer to Question 5. While we support the SDT's overall approach, we believe subsection (f) of the proposed inclusion criteria, which would allow NERC to "override this criterion" if it provides "additional justification" for doing so is both unnecessary and creates confusion and uncertainty in what is otherwise a clear and concise process. Subsection (f) is unnecessary because if the technical process laid out in subsections (a) through (e) fails to provide any evidence that the contested Element(s) create a material impact on the reliability of the bulk interconnected transmission network, there is no reason to classify those Element(s) as BES, and that should be the end of the question. Subsection (f) creates needless uncertainty because it allows NERC to override the technical criteria laid out in subsections (a) through (e) if "additional justification" is provided, but there is no suggestion as to what this additional justification might be. Nor is there any explanation as to why additional justification might be necessary after the criteria in subsections (a) through (e) have been exhausted.

Please see our corresponding answers to Question 5 for 7b-7e.

Yes

As discussed on page 12 of Snohomish's White Paper, there may be a few isolated cases where additional data will need to be provided to run a valid technical analysis under the criteria set forth in the Exception Procedure. These cases should be exceedingly rare, however, because the starting point for the technical analysis we recommend is the current base case operated by the relevant RE, and in nearly every case, the base case can be expected to model any Element that conceivably has a material impact on the reliable operation of the bulk system. In those rare cases where it does not, we believe the owner or operator of the subject Element should be able to provide the needed data, although we propose that the relevant owner or operator be relieved of this burden if it can be demonstrated that the nearest electrically interconnected Element has no material impact on the bulk system.

No

Yes

In general, as we discuss above, the Technical Principles for Demonstrating BES Exceptions present a reasonable approach to resolving questions of inclusion and exclusion in the BES that the BES definition itself does not clearly resolve. However, we caution that these principles for demonstrating exceptions cannot, and must not, take the place of a consideration of, and criteria under whether, any specific piece of equipment is subject to FERC, the ERO, and Regional Entity jurisdiction in the first instance. Section 215 of the Federal Power Act (FPA) sets out clear limits of jurisdiction of FERC, the ERO, and Regional Entities for purposes of developing and enforcing reliability standards. Specifically, Section 215(i) provides that the ERO "shall have authority to develop and enforce compliance with reliability standards for only the Bulk-Power System." 16 U.S.C. § 824o(a)(1) (emphasis added). Section 215(a)(1) of the statute defines the term "Bulk-Power System" or "BPS" as: (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or

any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy." Id. As we have explained in our comments on the BES definition, that definition should expressly account for these jurisdictional limitations up front. This would allow for the jurisdictional limitation consideration as the very first step in determining whether or not a particular piece of equipment is part of the BES. The Technical Principles for Demonstrating BES Exceptions, on the other hand, provides a completely separate set of criteria for exclusion from the BES and would come into play only after application of the full BES definition to a particular piece of equipment and determination that the BES definition does not provide a satisfactory answer as to whether that piece of equipment is or is not part of the BES. This is acceptable insofar as it goes, but, because (1) the criteria in the Technical Principles are distinct from the jurisdictional limits of Section 215 of the FPA, and (2) consideration of the Technical Principles would essentially be the last, or one of the last, steps in the process, the Technical Principles cannot substitute for, in any way, consideration of the jurisdictional limitations of the FPA. Again, we cannot overemphasize enough how important it is to have the jurisdictional consideration be the very first step in the process of determining whether a particular piece of equipment is or is not part of the BES. Again, thank you for the opportunity to comment. We look forward to continuing to work with NERC and stakeholders to develop a BES definition that is both workable and lawful.

Yes

First, thank you for the opportunity to comment on the Technical Principles for Demonstrating BES Exceptions. We appreciate the work that NERC has done on these principles and the other related efforts to revise the definition of the BES. In response to question #1, we note only that using impedance to benchmark system load proximity would likely not yield clear demarcations. High voltage relative or per-unit impedances are considered typically much lower than low voltage impedances. Hence, in the absence of phase shifting transformers, service compensation, or other mitigation factors, power typically flows over the highest voltage lines, which offer the lowest impedance.

Yes

We agree conceptually that facilities operating as radials rather than as integrated portions of the integrated bulk transmission system should be excluded from the BES definition. However, to be consistent with the draft BES definition, the term "radial in character" should be explicitly defined as facilities that may include one or more lines into a load area or referenced as a local distribution network. In addition, we agree that the manner in which a system is operated during BES disturbances may be an indication of whether that facility is radial in character. That being said, we are concerned that, to the extent the SDT considers regional disconnect procedures, it should be careful to note that UFLS and UVLS relays are often embedded within local distribution facilities and, while it is necessary for the UFLS and UVLS relays to be properly armed to protect the BES in the event of a severe system disturbance, the local distribution facilities interconnected with those relays should not, and cannot legally, be classified as BES.

Yes

We agree conceptually that one critical characteristic distinguishing facilities that must be excluded from the BES from facilities that should be included is the manner in which power flows on those facilities. Hence, the SDT has properly identified power flows as one important characteristic that identifies BES facilities. We also agree conceptually that the fact that power may flow out of facilities onto the grid during a few hours in a year or during extreme contingencies should not change the characterization of the facilities in question as excluded from the BES. Accordingly, we support inclusion of power flow analysis as one element of characteristics that can be used to exclude facilities from the BES even if the facilities do not pass each of the bright-line thresholds laid down in the BES definition. We also agree that transactional and hourly generation records are an appropriate basis for making the determination since these can be used to demonstrate that demand within a system exceeds generation within that system in most hours and that power therefore does not flow onto the grid, and also to determine the number of hours where this is not the case and the amount by which generation within the system exceeds demand. In order to identify facilities that are not necessary for

the operation of the BES under this text, we propose that any facility where real power flows in 90 percent of the time or more under normal ("N-O" or All Lines in Service) operating conditions should be held to meet this test. That facilities meet this test could be demonstrated using metering or supervisory control and data acquisition ("SCADA") data records over the course on two years. While we agree with the SDT's view that power should flow predominantly in the direction of load for excluded facilities, we are concerned that this characteristic may no longer be a defining characteristic as the electric industry evolves in the future. If distributed generation becomes the future norm for new power generation facilities, it may no longer make sense to look at power flow as a defining characteristic. That is, even if a sufficient number of small distributed generation facilities were constructed on certain facilities to cause power to flow out of those facilities more than ten percent of the time, the fundamental character of those facilities will not have changed. Finally, we believe that power flow analysis under this item should consider actual power flow, not scheduled power flow.

Yes

As a matter of operation, power is scheduled across transmission lines. Further, transmission lines in the Western Interconnection (either individually or as part of a transmission path) are rated for total transmission capacity and available transmission capacity, and transmission rights can be purchased on such lines, if available, on an OASIS. Facilities that do not share any of these operational characteristics should not be part of the BES. Accordingly, we agree that if power is not intentionally transported through particular facilities, those facilities should not be considered part of the BES. We also agree that examining the Operating Procedures applicable to particular facilities will provide a ready guide to whether power is intentionally scheduled across those facilities. We suggest, however, that the SDT look beyond those protocols that fall within the NERC Glossary's definition of Operating Procedure. For example, in the West, transmission paths are almost all listed in the WECC Path Rating Catalog. Similarly, it is not clear whether scheduling protocols, OASIS operations, and the other factors listed above qualify as Operating Procedures. Hence, we urge the SDT to list such specific operational characteristics as part of this test. Finally, as noted in our answer to Question 3, we are concerned that, if distributed generation advances significantly, power transport may cease to be a meaningful measure for determining whether a facility is part of the BES, and we believe that power flow analysis should consider actual power flow, not scheduled power flow.

Yes

We agree conceptually with the idea that two different paths to exclusion should be adopted, one relying upon readily identifiable characteristics that are ordinarily associated with non-BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES. Snohomish Public Utility District has prepared a White Paper proposing a performance-based approach to support the technical determination whether Elements should be excluded from the BES, which we commend to the SDT for study. We also commend the work of the WECC BES Task Force and the WECC Technical Studies Subcommittee, both of which have devoted substantial time and resources to developing a workable and technically defensible process for excluding Elements classified as BES based upon their electrical characteristics. See WECC BES Task Force Proposal 6, App. A at 3-9 & App. B at pp. B-4 to B-7 (posted Feb. 18, 2011) (available at: <http://www.wecc.biz/Standards/Development/BES/default.aspx>). We recommend that the SDT modify its approach to the technical exclusion process to match the approach advocated in Snohomish's White Paper, which is based upon the approach recommended by the WECC BES Task Force.

The use of distribution factors, such as Power Transfer Distribution Factors ("PTDF") and Outage Transfer Distribution Factor ("OTDF") provide insight into the relative impedance of neighboring systems. However in the Western Interconnection it has never been a definitive indicator of whether a system fault with delayed clearing would impact a neighboring electric system. While we understand that many entities from the Eastern Interconnection support the use of such factors, we believe the approach is unlikely to work in the Western Interconnection. Based on the significant differences between the four major interconnections in North America, we suggest that a detailed technical exemption process be allowed on an interconnections wide basis. The Western Interconnection is a "hub and spoke system" where loads are very remote from large generation plants, with margins that are based on stability limits. By contrast, the Eastern Interconnection is a tightly meshed system with

loads and generation in close proximity, often creating margins that are based on thermal limitations. These differences manifest themselves in a variety of ways for various operations. For example, the Western Interconnection uses a rated-paths methodology while the Eastern Interconnection uses transmission load relief mechanisms. Consistent with FERC order 743-A, we support exemption criteria for individual frequency independent regions, or interconnections.

Specific transient voltage dip thresholds are proposed on page 15 of Snohomish's White Paper. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should produce no more than a 20% voltage drop for no more than 20 cycles in a Category B contingency and no more than a 20% drop for 40 cycles in a Category C contingency. Technical justification for these thresholds is provided on pages 12-16 of Snohomish's White Paper.

Page 15 of Snohomish's White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided on pages 12-16 of the White Paper.

Please see our response to Question 5d.

No

Yes

As a general matter, we agree with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid justification showing that the Elements in question contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. We also agree that the SDT has, in general, identified the correct technical approach, although we recommend that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in Snohomish's White Paper, in the WECC BES Task Force Proposal 6, and in our answer to Question 5. While we support the SDT's overall approach, we believe subsection (f) of the proposed inclusion criteria, which would allow NERC to "override this criterion" if it provides "additional justification" for doing so is both unnecessary and creates confusion and uncertainty in what is otherwise a clear and concise process. Subsection (f) is unnecessary because if the technical process laid out in subsections (a) through (e) fails to provide any evidence that the contested Element(s) create a material impact on the reliability of the bulk interconnected transmission network, there is no reason to classify those Element(s) as BES, and that should be the end of the question. Subsection (f) creates needless uncertainty because it allows NERC to override the technical criteria laid out in subsections (a) through (e) if "additional justification" is provided, but there is no suggestion as to what this additional justification might be. Nor is there any explanation as to why additional justification might be necessary after the criteria in subsections (a) through (e) have been exhausted.

Please see our corresponding answers to Question 5 for 7b-7e.

Accordingly, we support inclusion of power flow analysis as one element of characteristics that can be used to exclude facilities from the BES even if the facilities do not pass each of the bright-line thresholds laid down in the BES definition. We also agree that transactional and hourly generation records are an appropriate basis for making the determination since these can be used to demonstrate that demand within a system exceeds generation within that system in most hours and that power therefore does not flow onto the grid, and also to determine the number of hours where this is not the case and the amount by which generation within the system exceeds demand. In order to identify facilities that are not necessary for the operation of the BES under this text, we propose that any facility where real power flows in 90 percent of the time or more under normal ("N-O" or All Lines in Service) operating conditions should be held to meet this test. That facilities meet this test could be demonstrated using metering or supervisory control and data acquisition ("SCADA") data records over the course on two years. While we agree with the SDT's view that power should flow predominantly in the direction of load for excluded facilities, we are concerned that this characteristic may no longer be a defining characteristic as the electric industry evolves in the future. If distributed generation becomes the future norm for new power generation facilities, it may no longer make sense to look at power flow as a defining characteristic. That is, even if a sufficient number of small distributed generation facilities were constructed on certain facilities to cause power to flow out of those facilities more than ten percent of the time, the fundamental character of those facilities will not have changed. Finally, we believe that power flow analysis under this item should consider actual power flow, not scheduled power flow.

Yes

As a matter of operation, power is scheduled across transmission lines. Further, transmission lines in the Western Interconnection (either individually or as part of a transmission path) are rated for total transmission capacity and available transmission capacity, and transmission rights can be purchased on such lines, if available, on an OASIS. Facilities that do not share any of these operational characteristics should not be part of the BES. Accordingly, we agree that if power is not intentionally transported through particular facilities, those facilities should not be considered part of the BES. We also agree that examining the Operating Procedures applicable to particular facilities will provide a ready guide to whether power is intentionally scheduled across those facilities. We suggest, however, that the SDT look beyond those protocols that fall within the NERC Glossary's definition of Operating Procedure. For example, in the West, transmission paths are almost all listed in the WECC Path Rating Catalog. Similarly, it is not clear whether scheduling protocols, OASIS operations, and the other factors listed above qualify as Operating Procedures. Hence, we urge the SDT to list such specific operational characteristics as part of this test. Finally, as noted in our answer to Question 3, we are concerned that, if distributed generation advances significantly, power transport may cease to be a meaningful measure for determining whether a facility is part of the BES, and we believe that power flow analysis should consider actual power flow, not scheduled power flow.

Yes

We agree conceptually with the idea that two different paths to exclusion should be adopted, one relying upon readily identifiable characteristics that are ordinarily associated with non-BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES.

Snohomish Public Utility District has prepared a White Paper proposing a performance-based approach to support the technical determination whether Elements should be excluded from the BES, which we commend to the SDT for study. We also commend the work of the WECC BES Task Force and the WECC Technical Studies Subcommittee, both of which have devoted substantial time and resources to developing a workable and technically defensible process for excluding Elements classified as BES based upon their electrical characteristics. See WECC BES Task Force Proposal 6, App. A at 3-9 & App. B at pp. B-4 to B-7 (posted Feb. 18, 2011) (available at: <http://www.wecc.biz/Standards/Development/BES/default.aspx>). We recommend that the SDT modify its approach to the technical exclusion process to match the approach advocated in Snohomish's White Paper, which is based upon the approach recommended by the WECC BES Task Force.

The use of distribution factors, such as Power Transfer Distribution Factors ("PTDF") and Outage Transfer Distribution Factor ("OTDF") provide insight into the relative impedance of neighboring systems. However in the Western Interconnection it has never been a definitive indicator of whether a system fault with delayed clearing would impact a neighboring electric system. While we understand that many entities from the Eastern Interconnection support the use of such factors, we believe the approach is unlikely to work in the Western Interconnection. Based on the significant differences between the four major interconnections in North America, we suggest that a detailed technical exemption process be allowed on an interconnections wide basis. The Western Interconnection is a "hub and spoke system" where loads are very remote from large generation plants, with margins that are based on stability limits. By contrast, the Eastern Interconnection is a tightly meshed system with loads and generation in close proximity, often creating margins that are based on thermal limitations. These differences manifest themselves in a variety of ways for various operations. For example, the Western Interconnection uses a rated-paths methodology while the Eastern Interconnection uses transmission load relief mechanisms. Consistent with FERC order 743-A, we support exemption criteria for individual frequency independent regions, or interconnections.

Specific transient voltage dip thresholds are proposed on page 15 of Snohomish's White Paper. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should produce no more than a 20% voltage drop for no more than 20 cycles in a Category B contingency and no more than a 20% drop for 40 cycles in a Category C contingency. Technical justification for these thresholds is provided on pages 12-16 of Snohomish's White Paper.

Page 15 of Snohomish's White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided on pages 12-16 of the White Paper.

Please see our response to Question 5d.

No

Yes

As a general matter, we agree with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid justification showing that the Elements in question contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. We also agree that the SDT has, in general, identified the correct technical approach, although we recommend that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in Snohomish's White Paper, in the WECC BES Task Force Proposal 6, and in our answer to Question 5. While we support the SDT's overall approach, we believe subsection (f) of the proposed inclusion criteria, which would allow NERC to "override this criterion" if it provides "additional justification" for doing so is both unnecessary and creates confusion and uncertainty in what is otherwise a clear and concise process. Subsection (f) is unnecessary because if the technical process laid out in subsections (a) through (e) fails to provide any evidence that the contested Element(s) create a material impact on the reliability of the bulk interconnected transmission network, there is no reason to classify those Element(s) as BES, and that should be the end of the question. Subsection (f) creates needless uncertainty because it allows NERC to override the technical criteria laid out in subsections (a) through (e) if "additional justification" is provided, but there is no suggestion as to what this additional justification might be. Nor is there any explanation as to why additional justification might be necessary after the criteria in subsections (a) through (e)

have been exhausted.
Please see our corresponding answers to Question 5 for 7b-7e.
No
As discussed on page 12 of Snohomish's White Paper, there may be a few isolated cases where additional data will need to be provided to run a valid technical analysis under the criteria set forth in the Exception Procedure. These cases should be exceedingly rare, however, because the starting point for the technical analysis we recommend is the current base case operated by the relevant RE, and in nearly every case, the base case can be expected to model any Element that conceivably has a material impact on the reliable operation of the bulk system. In those rare cases where it does not, we believe the owner or operator of the subject Element should be able to provide the needed data, although we propose that the relevant owner or operator be relieved of this burden if it can be demonstrated that the nearest electrically interconnected Element has no material impact on the bulk system.
No
Yes
In general, as we discuss above, the Technical Principles for Demonstrating BES Exceptions present a reasonable approach to resolving questions of inclusion and exclusion in the BES that the BES definition itself does not clearly resolve. However, we caution that these principles for demonstrating exceptions cannot, and must not, take the place of a consideration of, and criteria under whether, any specific piece of equipment is subject to FERC, the ERO, and Regional Entity jurisdiction in the first instance. Section 215 of the Federal power Act (FPA) sets out clear limits of jurisdiction of FERC, the ERO, and Regional Entities for purposes of developing and enforcing reliability standards. Specifically, Section 215(i) provides that the ERO "shall have authority to develop and enforce compliance with reliability standards for only the Bulk-Power System." 16 U.S.C. § 824o(a)(1) (emphasis added). Section 215(a)(1) of the statute defines the term "Bulk-Power System" or "BPS" as: (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy." Id. As we have explained in our comments on the BES definition, that definition should expressly account for these jurisdictional limitations up front. This would allow for the jurisdictional limitation consideration as the very first step in determining whether or not a particular piece of equipment is part of the BES. The Technical Principles for Demonstrating BES Exceptions, on the other hand, provides a completely separate set of criteria for exclusion from the BES and would come into play only after application of the full BES definition to a particular piece of equipment and determination that the BES definition does not provide a satisfactory answer as to whether that piece of equipment is or is not part of the BES. This is acceptable insofar as it goes, but, because (1) the criteria in the Technical Principles are distinct from the jurisdictional limits of Section 215 of the FPA, and (2) consideration of the Technical Principles would essentially be the last, or one of the last, steps in the process, the Technical Principles cannot substitute for, in any way, consideration of the jurisdictional limitations of the FPA. Again, we cannot overemphasize enough how important it is to have the jurisdictional consideration be the very first step in the process of determining whether a particular piece of equipment is or is not part of the BES. Again, thank you for the opportunity to comment. We look forward to continuing to work with NERC and stakeholders to develop a BES definition that is both workable and lawful.

Yes
First, thank you for the opportunity to comment on the Technical Principles for Demonstrating BES Exceptions. We appreciate the work that NERC has done on these principles and the other related efforts to revise the definition of the BES. In response to question #1. we note only that using

impedance to benchmark system load proximity would likely not yield clear demarcations. High voltage relative or per-unit impedances are considered typically much lower than low voltage impedances. Hence, in the absence of phase shifting transformers, service compensation, or other mitigation factors, power typically flows over the highest voltage lines, which offer the lowest impedance.

Yes

We agree conceptually that facilities operating as radials rather than as integrated portions of the integrated bulk transmission system should be excluded from the BES definition. However, to be consistent with the draft BES definition, the term "radial in character" should be explicitly defined as facilities that may include one or more lines into a load area or referenced as a local distribution network. In addition, we agree that the manner in which a system is operated during BES disturbances may be an indication of whether that facility is radial in character. That being said, we are concerned that, to the extent the SDT considers regional disconnect procedures, it should be careful to note that UFLS and UVLS relays are often embedded within local distribution facilities and, while it is necessary for the UFLS and UVLS relays to be properly armed to protect the BES in the event of a severe system disturbance, the local distribution facilities interconnected with those relays should not, and cannot legally, be classified as BES.

Yes

We agree conceptually that one critical characteristic distinguishing facilities that must be excluded from the BES from facilities that should be included is the manner in which power flows on those facilities. Hence, the SDT has properly identified power flows as one important characteristic that identifies BES facilities. We also agree conceptually that the fact that power may flow out of facilities onto the grid during a few hours in a year or during extreme contingencies should not change the characterization of the facilities in question as excluded from the BES. Accordingly, we support inclusion of power flow analysis as one element of characteristics that can be used to exclude facilities from the BES even if the facilities do not pass each of the bright-line thresholds laid down in the BES definition. We also agree that transactional and hourly generation records are an appropriate basis for making the determination since these can be used to demonstrate that demand within a system exceeds generation within that system in most hours and that power therefore does not flow onto the grid, and also to determine the number of hours where this is not the case and the amount by which generation within the system exceeds demand. In order to identify facilities that are not necessary for the operation of the BES under this text, we propose that any facility where real power flows in 90 percent of the time or more under normal ("N-0" or All Lines in Service) operating conditions should be held to meet this test. That facilities meet this test could be demonstrated using metering or supervisory control and data acquisition ("SCADA") data records over the course on two years. While we agree with the SDT's view that power should flow predominantly in the direction of load for excluded facilities, we are concerned that this characteristic may no longer be a defining characteristic as the electric industry evolves in the future. If distributed generation becomes the future norm for new power generation facilities, it may no longer make sense to look at power flow as a defining characteristic. That is, even if a sufficient number of small distributed generation facilities were constructed on certain facilities to cause power to flow out of those facilities more than ten percent of the time, the fundamental character of those facilities will not have changed. Finally, we believe that power flow analysis under this item should consider actual power flow, not scheduled power flow.

Yes

As a matter of operation, power is scheduled across transmission lines. Further, transmission lines in the Western Interconnection (either individually or as part of a transmission path) are rated for total transmission capacity and available transmission capacity, and transmission rights can be purchased on such lines, if available, on an OASIS. Facilities that do not share any of these operational characteristics should not be part of the BES. Accordingly, we agree that if power is not intentionally transported through particular facilities, those facilities should not be considered part of the BES. We also agree that examining the Operating Procedures applicable to particular facilities will provide a ready guide to whether power is intentionally scheduled across those facilities. We suggest, however, that the SDT look beyond those protocols that fall within the NERC Glossary's definition of Operating Procedure. For example, in the West, transmission paths are almost all listed in the WECC Path Rating Catalog. Similarly, it is not clear whether scheduling protocols, OASIS operations, and the other factors listed above qualify as Operating Procedures. Hence, we urge the SDT to list such specific operational characteristics as part of this test. Finally, as noted in our answer to Question 3, we are

concerned that, if distributed generation advances significantly, power transport may cease to be a meaningful measure for determining whether a facility is part of the BES, and we believe that power flow analysis should consider actual power flow, not scheduled power flow.

Yes

We agree conceptually with the idea that two different paths to exclusion should be adopted, one relying upon readily identifiable characteristics that are ordinarily associated with non-BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES. Snohomish Public Utility District has prepared a White Paper proposing a performance-based approach to support the technical determination whether Elements should be excluded from the BES, which we commend to the SDT for study. We also commend the work of the WECC BES Task Force and the WECC Technical Studies Subcommittee, both of which have devoted substantial time and resources to developing a workable and technically defensible process for excluding Elements classified as BES based upon their electrical characteristics. See WECC BES Task Force Proposal 6, App. A at 3-9 & App. B at pp. B-4 to B-7 (posted Feb. 18, 2011) (available at: <http://www.wecc.biz/Standards/Development/BES/default.aspx>). We recommend that the SDT modify its approach to the technical exclusion process to match the approach advocated in Snohomish's White Paper, which is based upon the approach recommended by the WECC BES Task Force.

The use of distribution factors, such as Power Transfer Distribution Factors ("PTDF") and Outage Transfer Distribution Factor ("OTDF") provide insight into the relative impedance of neighboring systems. However in the Western Interconnection it has never been a definitive indicator of whether a system fault with delayed clearing would impact a neighboring electric system. While we understand that many entities from the Eastern Interconnection support the use of such factors, we believe the approach is unlikely to work in the Western Interconnection. Based on the significant differences between the four major interconnections in North America, we suggest that a detailed technical exemption process be allowed on an interconnections wide basis. The Western Interconnection is a "hub and spoke system" where loads are very remote from large generation plants, with margins that are based on stability limits. By contrast, the Eastern Interconnection is a tightly meshed system with loads and generation in close proximity, often creating margins that are based on thermal limitations. These differences manifest themselves in a variety of ways for various operations. For example, the Western Interconnection uses a rated-paths methodology while the Eastern Interconnection uses transmission load relief mechanisms. Consistent with FERC order 743-A, we support exemption criteria for individual frequency independent regions, or interconnections.

Specific transient voltage dip thresholds are proposed on page 15 of Snohomish's White Paper. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should produce no more than a 20% voltage drop for no more than 20 cycles in a Category B contingency and no more than a 20% drop for 40 cycles in a Category C contingency. Technical justification for these thresholds is provided on pages 12-16 of Snohomish's White Paper.

Page 15 of Snohomish's White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided on pages 12-16 of the White Paper.

Please see our response to Question 5d.

No

Yes

As a general matter, we agree with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid justification showing that the Elements in question contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. We also agree that the SDT has, in general, identified the correct technical approach, although we recommend that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in Snohomish's White Paper, in the WECC BES Task Force Proposal 6, and in our answer to Question 5. While we support the SDT's overall approach,

we believe subsection (f) of the proposed inclusion criteria, which would allow NERC to “override this criterion” if it provides “additional justification” for doing so is both unnecessary and creates confusion and uncertainty in what is otherwise a clear and concise process. Subsection (f) is unnecessary because if the technical process laid out in subsections (a) through (e) fails to provide any evidence that the contested Element(s) create a material impact on the reliability of the bulk interconnected transmission network, there is no reason to classify those Element(s) as BES, and that should be the end of the question. Subsection (f) creates needless uncertainty because it allows NERC to override the technical criteria laid out in subsections (a) through (e) if “additional justification” is provided, but there is no suggestion as to what this additional justification might be. Nor is there any explanation as to why additional justification might be necessary after the criteria in subsections (a) through (e) have been exhausted.

Please see our corresponding answers to Question 5 for 7b-7e.

No

As discussed on page 12 of Snohomish’s White Paper, there may be a few isolated cases where additional data will need to be provided to run a valid technical analysis under the criteria set forth in the Exception Procedure. These cases should be exceedingly rare, however, because the starting point for the technical analysis we recommend is the current base case operated by the relevant RE, and in nearly every case, the base case can be expected to model any Element that conceivably has a material impact on the reliable operation of the bulk system. In those rare cases where it does not, we believe the owner or operator of the subject Element should be able to provide the needed data, although we propose that the relevant owner or operator be relieved of this burden if it can be demonstrated that the nearest electrically interconnected Element has no material impact on the bulk system.

BGE
No
BGE is not clear as to why "close electrical proximity to load" is appropriate to use as a factor in determining exclusion.
Yes
No comment.
No
BGE is generally opposed to this requirement because the MWh factor is too variable and/or may be utilized in a way contrary to reliable system operation.
Yes
BGE generally agrees with this requirement, but believes that the term "system" should be clarified.
Yes
BGE believes that there is value in allowing for exclusions through a technical analysis path. Because multiple entities may perform "planning assessments" using different models, the phrase, "**the* most recent *applicable* planning assessment" should be clarified to avoid ambiguity as to which model(s) are acceptable. It may be useful to designate the models used in the Planning Authority analyses as acceptable.
BGE requests that it be made clear that the 2(a) iv.1 criteria refers to the of the distribution factor for the loss of any other facility on the subject Element, whereas criteria 2 through 7 refer to the performance following the loss of the subject Element.
For PJM members, this figure is set at 5%. BGE suggests a lower figure such as 2-3%.
No comment.
BGE believe the loss of the facility in question should cause only a small voltage deviation to the BES (on the order of 1%).
No
No comment.
Yes
BGE believes that there is a value in allowing for inclusions through a technical analysis path; however, it is critical that such a path does not allow for unreasonable inclusion of facilities that do not warrant BES status.

It is important to consider that the Technical Principles for Demonstrating BES Exceptions is only one part of the BES definition project. The Technical Principles and the Rule of Procedure Process must be evaluated together with the BES Definition to sufficiently understand the revisions. In the end, the Technical Principles and the BES Definition must coalesce and be clearly coordinated and understood. The BES Definition language must include reference to the role of the associated defining documents. One unambiguous document must not be made ambiguous by an associated document or process. We appreciate the work of the drafting team and support the goal to produce clear definition language so that upwards of 95% of the assets are clearly distinguished as either included or excluded from the BES. We are particularly sensitive to the potential for burdensome processes (e.g. TFEs) to be added

to reliability compliance. We appeal to the team for continued, vigilant consideration of the arduousness of the BES determination process.

Group

NERC Staff

David Taylor

No

Electrical proximity to load is not an informative measure of whether Element(s) are necessary for reliable operation or the potential reliability impact of excluding Element(s) from the BES. Establishing a maximum impedance threshold as proposed would assure only that the excluded Element(s) do not span a large electrical distance. While minimizing impedance may be beneficial for some aspects of reliability, other aspects of BES reliability are improved with higher impedance. For example, higher impedance minimizes through-flow of power and minimizes impacts to BES reliability associated with faults and switching errors.

No

We believe that restating this measure as "System performance impacts are similar to radial systems" would be more in-line with the SDT intent and a better measure of whether Element(s) are necessary for reliable operation. We also believe that the best measure of whether Element(s) affect system performance in a manner similar to radial systems is through distribution factor analysis. Such analysis, when limited to this purpose, does not require extensive technical analysis. Analysis for a limited number of stressed transfer conditions, and contingencies involving the Element(s) under consideration and in the area of the Element(s) under consideration, is sufficient to demonstrate whether the system performance impacts are similar to radial systems.

No

Requiring that power flows into, and rarely out of, the Element(s) considered for exclusion is an appropriate measure, as is requiring an entity to define the conditions under which power will flow out. In addition to information such as specified contingencies in item (ii), details on the conditions should include other relevant information such as the system load level, generation dispatch, system transfer levels, etc., and the number of hours per year these conditions are expected. An exception request also should include the maximum flow expected. E.g., the following information would be useful in evaluating a request for exception: "Power will flow out only when line A is out of service, system load is at or below X percent of peak load, and generator B is on-line; based on the load duration curve for this area and the number of hours generator B is dispatched at these load levels, the exposure to power flow out for this contingency is limited to N hours per year and the maximum flow if the contingency occurred during these hours would be Y MW." This type of information will be far more informative than a pass/fail test as to whether a MWh threshold is expected to be exceeded. While a MWh threshold may be useful for evaluating requests, it is unlikely that a one-size-fits-all threshold could be established for evaluating exception requests.

No

Limitations on through-flow of power is an appropriate consideration; however, whether the power flow is intentional should not be a primary consideration. Intent is not measurable and most major disturbances are the result of unintentionally placing the system in an unreliable operating condition. The main clause in item (d) should be modified to reflect that transporting power to another system through the Element(s) to be excluded is prevented (such as by system configuration and/or impedance) or restricted (such as by Operating Procedures). Sub-items (i) and (ii) already are consistent with this revision to the main clause.

No

NERC staff is not opposed to development of evidence based on technical analysis; however, the type of analysis included in this exception criterion requires extensive resources and lacks sufficient detail to allow for consistent and repeatable application. Concerns with this approach include (1) the ability to provide sufficient guidance on the system conditions and contingencies necessary to support an exception request, (2) difficulty with identifying thresholds for items iv-1 through iv-4, and (3) the ability to address interdependencies among exception requests. These concerns can be addressed by deleting this second path for evidence and including technical analysis on a limited basis to assess performance as described in our response to Question 2. If the SDT elects to retain this second path for evidence, then our three concerns must be addressed. In particular with regard to our third

concern, the ERO must be able to deny requests for exception based on the cumulative impact of all previously approved exceptions.

No

No

NERC staff is not opposed to development of evidence based on technical analysis; however, we have the same concerns with the exception criterion for including Element(s) as with exception criterion 1 for excluding Element(s). The type of analysis included in this exception criterion requires extensive resources and lacks sufficient detail to allow for consistent and repeatable application. Additional concerns with this approach include (1) the ability to provide sufficient guidance on the system conditions and contingencies necessary to support an exception request, (2) difficulty with identifying thresholds for items iv-1 through iv-4, and (3) the ability to address interdependencies among exception requests.

No

No

Yes

A criterion should be added for supporting a request for inclusion of an Element. If an Element has been identified as causal or contributory to a Category 2 or higher event as defined in the ERO Event Analysis Process, that should be sufficient evidence that it is necessary for the Element to be planned, designed, maintained, and operated in accordance with NERC Reliability Standards. An assessment of the Element should include consideration of any corrective actions that have been implemented to prevent a reoccurrence. The Exception criteria also should include a list of characteristics of Elements that will not be considered for exclusion, on the basis that this list of characteristics already identifies the importance of such Elements to reliable operation of the interconnected transmission network. Characteristics should include: (1) Elements that are relied on in the determination of an Interconnection Reliability Operating Limit (IROL); (2) Blackstart resources and the designated blackstart Cranking Paths identified in the Transmission Operator's restoration plan regardless of voltage, (3) Elements subject to Nuclear Plant Interface Requirements (NPIRs) as agreed to by a Nuclear Plant Generator Operator and a Transmission Entity defined in NUC-001, and (4) Elements identified as required to comply with a NERC Reliability Standard by application of criteria defined within the standard (e.g., the test defined in PRC-023 to identify sub-200 kV Elements to which the standard is applicable.)

Individual

Rick

Spyker

No

We agree with this concept to allow entities to submit an exception application that does not include extensive technical analysis. Such an option will make the process efficient for all stakeholders, such as entities, Regions, NERC and relevant regulatory authority. However, our opinion is that there is no real relation between reliability and the proximity of load. Consistent with references in the FERC Order, we feel that it is much more important to identify and ensure if the element(s) are serving load pockets associated with large metropolitan load centers (e.g. New York City, Washington DC, Toronto), loads of significance to national security and/or as identified by relevant Federal, State or

Provincial Regulatory Authority. We believe that entities should be required to identify the significance of the elements' physical characteristics, such as the proximity of element or, being served or impacted by the element to a load of significant interest. Such identification can be done through a simple checklist along with any relevant comments. Therefore, we suggest the SDT to revise the exception criteria to seek an alternative language and/or re-craft exclusion criteria (a), which will require entities to provide the previously stated information for their element.

Yes

We agree with this concept. Entities should be allowed to demonstrate the radial characteristics to determine if they are permitted for an exception.

Yes

We agree with the criteria set out in 1(c), but suggest the SDT to avoid prescribing values and eliminate bullet (iv). The SDT should describe the intended performance outcome but avoid setting values. This should have little, if any impact on reliability of the transmission network if the items 1, 2 and 3 are satisfied.

Yes

Yes

We agree that entities should be given an option to conduct an analysis to demonstrate if an element is necessary or not for the operation of transmission network. We also support that NERC should specify all the relevant criteria category to be listed as under 2 (a). However, we suggest that NERC should avoid prescribing numerical values but establish a range of value (or reference industry standard) that would be consistent with industry/ regional standards or practices without compromising the reliability of transmission network.

The SDT should avoid setting values and instead describe the intended performance outcomes from the measurement

We suggest SDT to make references to relevant industry standard such as IEEE standards

The SDT should avoid setting values and instead describe the intended performance outcomes from the measurement

The SDT should avoid setting values and instead describe the intended performance outcomes from the measurement

Yes

Technical Analysis must fundamentally use NERC – TPL methodology and testing requirements.

Yes

We agree that entities should be allowed to conduct an analysis to demonstrate if an element is necessary or not for the operation of transmission network. We also support that NERC should specify all the relevant criteria category to be listed as under 2 (a). However, we suggest that NERC should avoid prescribing numerical values but establish a range of value (or reference industry standard) that would be consistent with industry/ regional standards or practices without compromising the reliability of transmission network.

No

Yes

NERC's revised definition will have a direct impact on entities across North America and may conflict with regulatory requirements, Codes, and Licenses. FERC in its Order 743 and 743A has directed NERC to address these concerns. We suggest the SDT and RoP teams should: • modify the exception criteria and procedure to provide regulatory flexibility with requirements to conduct basic technical analysis , to allow entities to consistently present their case to the ERO and/or the regulator for a step by step expedited evaluation. • Include provisions in both the NERC exception criteria and exception process for federal, state and provincial jurisdictions. These provisions should provide clear guidance

so that, if and when there are deviations from the exception criteria, they are identified with technical and regulatory justifications ensuring there is no adverse impact on the interconnected transmission network. • Understand that the path to generating facilities need not be always BES contiguous. Generating units can/should be required to be planned, designed, and operated in accordance with a subset of NERC Standards, but should not always require contiguous paths.

Yes

Exception criteria should be crafted at a high-level with key menu items of assessment that can be followed continent-wide by entities to put forward their exception for element(s) that are not necessary for the interconnected transmission network and based on technical assessment, evidence and justification for its unique characteristics, configuration, and utilization.

Individual

Clint Gerkenmeyer

Benton Rural Electric Association

No

We believe that the proximity test may be unnecessary, and if an Element or group of Elements meets the other three tests proposed by the SDT, it should be excluded from the BES, even if it does not meet the proximity test. Secondly, using impedance to benchmark system load proximity would likely not yield clear demarcations. High voltage relative or per-unit impedances are considered typically much lower than low voltage impedances. Hence, in the absence of phase shifting transformers, service compensation, or other mitigation factors, power typically flows over the highest voltage lines, which offer the lowest impedance.

Yes

Benton REA agrees conceptually that systems operating as radials rather than as integrated portions of the integrated bulk transmission system should be excluded from the BES definition. That is because local distribution systems typically operate adjacent to, or at the end of transmission lines, and function operationally to move power from the Transmission Service Provider's point of delivery of bulk power that has moved across the integrated bulk transmission system to end-users located within the local distribution utility's service territory. To be consistent with the draft BES definition, the term "radial in character" should be explicitly defined as a system that may include one or more lines into a load area or referenced as a local distribution network. In addition, we agree that the manner in which a system is operated during BES disturbances may be an indication of whether that system is radial in character. That being said, we are concerned that, to the extent the SDT considers regional disconnect procedures, it should be careful to note that UFLS and UVLS relays are often embedded within local distribution systems and, while it is necessary for the UFLS and UVLS relays to be properly armed to protect the BES in the event of a severe system disturbance, the local distribution system interconnected with those relays should not.

Yes

Benton REA agrees conceptually that one critical characteristic distinguishing local distribution facilities that must be excluded from the BES from transmission facilities that should be included is the manner in which power flows on those facilities. Power on local distribution systems generally flows only from the interconnected transmission source and across the distribution system for delivery to end-use customers. By contrast, power on transmission systems generally flows in two (or multiple, in networked systems) directions and is delivered in bulk to distribution utilities rather than to end-users. Hence, the SDT has properly identified power flows as one important characteristic that distinguishes BES transmission systems from local distribution systems. In order to identify systems that are not necessary for the operation of the BES under this text, we propose that any system where real power flows into the local distribution system 90 percent of the time or more under normal operating conditions.

Yes

Benton REA agrees that the SDT's fourth test, which asks whether power is intentionally transported through a system, identifies a key characteristic of local distribution facilities that distinguishes such facilities from interconnect bulk transmission facilities that are properly considered part of the BES. In fact, we believe this may be the most important and readily identifiable distinction. Accordingly, Benton REA agrees that if power is not intentionally transported through a particular system, that system is not used for transmission and should not be considered part of the BES. One exception may

be for a small embedded generation unit owned by a different party that may be "scheduled" out of an area, but in reality, does not produce any physical flow. These circumstances should not trigger inclusion.

Yes

We agree conceptually with the idea that two different paths to exclusion should be adopted, one relying upon readily identifiable characteristics that are ordinarily associated with local distribution and not BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES. Benton REA supports the technical arguments and the White Paper presented by Snohomish County PUD in their comments. We recommend that the SDT modify its approach to the technical exclusion process to match the approach advocated in the White Paper, which is based upon the approach recommended by the WECC BES Task Force.

The use of distribution factors, such as Power Transfer Distribution Factors ("PTDF") and Outage Transfer Distribution Factor ("OTDF") provide insight into the relative impedance of neighboring systems. However in the Western Interconnection it has never been a definitive indicator of whether a system fault with delayed clearing would impact a neighboring electric system. While we understand that many entities from the Eastern Interconnection support the use of such factors, we believe the approach is unlikely to work in the Western Interconnection.

Specific transient voltage dip thresholds are proposed at page 15 of Snohomish's White Paper. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should produce no more than a 20% voltage drop for no more than 20 cycles in a Category B contingency and no more than a 20% drop for 40 cycles in a Category C contingency. Technical justification for these thresholds is provided at pages 12-16 of the White Paper.

Page 15 of Snohomish's White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided at pages 12-16 of the White Paper.

Please see our response to Question 5d.

No

Yes

As a general matter, we agree with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid showing that the Elements contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. We also agree that the SDT has, in general, identified the correct technical approach, although we recommend that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in the Snohomish PUD White Paper, in the WECC BES Task Force Proposal 6, and in our answer to Question 5.

See exclusion comments Question 5

See exclusion comments Question 5

See exclusion comments Question 5

See exclusion comments Question 5

No

As discussed on page 12 of the Snohomish White Paper, there may be a few isolated cases where additional data will need to be provided to run a valid technical analysis under the criteria set forth in the Exception Procedure. These cases should be exceedingly rare, however, because the starting point for the technical analysis we recommend is the current base case operated by the relevant Regional Entity, and in nearly every case, the base case can be expected to model any Element that conceivably has a material impact on the reliable operation of the bulk system. In those rare cases where it does not, we believe the owner or operator of the subject Element should be able to provide the needed data.

No

As properly constructed Definition and Exceptions process should meet the legal requirements of Section 215.

Yes

Benton REA generally supports the approach to the exclusion process proposed by the SDT, which provides two different paths to exclusion, one based on readily-identifiable operational characteristics of a system, and one based on technical reliability analysis. We believe it is important to provide for the first path, based on operational characteristics, so that systems that are marginally disqualified under the BES Definition (because, for example, generation within the system exceeds demand for a few hours a year) can obtain an exclusion without the large investment of resources that otherwise might be required for a full-scale technical analysis. That being said, we question whether the first subsection of the characteristic test, relating to system proximity, is necessary, and we are concerned that the requirement that a system meet all four requirements of the characteristics test may be overly restrictive. For example, it is easy to imagine a distribution system in a rural area that covers a widely dispersed area, so that load is many miles from the relevant generation/transmission source, and that the system therefore does not meet the electrical proximity element, but meets the other three elements of the characteristics test. Such a system should be excluded because it clearly serves a local distribution function, and not a transmission function, as demonstrated by the fact that the system meets subsections (c) (power flows into the system but rarely flows out ) and (d) (power is not intentionally transported over the system). Accordingly, we recommend that the SDT consider eliminating the first test. In the alternative, the SDT should consider allowing exempting a system from the BES if it, for example, meets three of the four criteria rather than all four.

Yes
Using "proximity to load" is a reasonable metric, but would require further consideration given the impedance value eventually chosen to replace "TBD".
Yes
Considering whether or not the element is treated as radial is a reasonable approach.
Yes
Requiring that "power flows into the system, but rarely flows out" is a reasonable approach, but would require further consideration given the MWh value eventually chosen to replace "TBD".
Yes
Requiring that "power entering the system is not intentionally transported through the system to some other system" is a reasonable approach.
Yes
No
No
Yes
Each criterion specified would not be able to be provided, or even applicable, for each exclusion requested. If the criteria provided may be selected from as necessary for each request, then we have no concerns on our ability to provide the data. Our only concern would be if the intent is that each and every criterion specified must be provided for each request made.
No
AEP is not aware of any conflicts between the proposed approach and any regulatory function, rule order, tariff, rate schedule, legislative requirement or agreement, or jurisdictional issue.
Yes
AEP appreciates the work that the drafting teams have done within the various deliverables related to the BES definition, technical principles for demonstrating BES exceptions, and the BES definition exception process. AEP acknowledges the benefits of agreeing to a BES definition and exception process, and appreciates the drafting teams' requests for industry involvement. Due to the interrelated nature of the deliverables currently out for review regarding the BES definition and exception processes, it is difficult if not impossible, to comment "in isolation" on any individual facet of the project. For example, there needs to be a defined relationship between an approved definition of BES, the technical principles for demonstrating BES exception, and the exception process itself. When closely related projects such as these are done simultaneously, no individual deliverable can rely on the completed work of another. As a result, we risk having conflicting decision making across

these projects. As a result, AEP is not in the position to make further comments at this time beyond those recently and concurrently made regarding the BES definition and technical principles for demonstrating BES exceptions. We suggest that further work on these efforts, when appropriate, become more consolidated and that care be taken to not undertake concurrent efforts before sufficient progress has been made on important aspects of the project. AEP appreciates the drafting teams' requests for industry input, and looks forward to its future involvement after additional progress has been made on these issues.

No

A specific impedance value would not be appropriate for all regions and all configurations.

No

Radial system is already an explicit Exclusion by definition (E1). Does this imply that ALL radial systems require a request to be submitted for the RE and NERC approval that the elements are in fact radial? There may not be internal written procedures describing the radial system operation. The

evidence that an entity can provide should include a description or justification of the radial operation and non impact to the BES.

No

The characteristic statement should be reworded to say: "Power flow is generally load serving." The criteria as written have very burdensome MWh record requirements. Yearly totals for flows in and out and an overall description or justification for this exception should be allowable.

No

This criterion is very similar to the third item. Written operating procedures may not exist. The entity should be allowed to submit a description and justification.

No

Generally agree that a specific technical analysis approach (power flow studies) showing no impact on BES is appropriate, but don't know how to define specific criteria on which to base decision.

No

No

Same comments as question #5

Yes

The entity may not have the tools, model or resources to do a full transmission planning study

Yes

Facilities defined as local distribution facilities should not be forced into BES classification due to this new bright line definition.

Yes

Concern that as this proposal is written such that each exclusion in the BES definition (E1, E2 and E3) will require a submittal to approve that is an exclusion.

Consumers Energy Company (CECo) proposes that this criterion be eliminated, as it is not a definitive BES criterion. There is no correlation between the proximity of Elements that are 100kV and above to load.
Yes
Yes
Yes
No
Generally, this approach seems sound.
This criterion raises concerns. If based on transfer distribution factor it may have some merit, depending on the TBD value. However, the criteria should not be based on outage transfer distribution factor, as Draft 1 implies, since loss of certain local distribution facilities can result in local distribution load being transferred to other local distribution facilities. Distribution facilities should not be prevented from exclusion from BES.
The criterion related to Transient Voltage Deviations should be removed. This criterion, regardless of

value TBD, would be impossible to achieve, and would render this process meaningless. A fault on non-BES elements will cause significant transient voltage dips on nearby BES elements until the fault is cleared. If the non-BES element is at the same voltage level, the dip will result in near-zero voltages; if at different voltage levels, the dip magnitude will be determined by the ratio of the system Thévenin impedance at the BES to the intervening transformer impedance - if the system Thévenin impedance is 2% and the transformer impedance is 18%, the voltage on the BES will dip to 10%.

The criterion relative to frequency response should be removed. Frequency deviations can result from large changes in distribution load. Distribution facilities should not be prevented from being excluded from BES.

This criterion may be reasonable, depending on the TBD value. The TBD value may need to vary for different voltage levels or system configurations. The criteria needs to recognize that loss of multiple capacitors at the distribution level could result in significant voltage deviation at the BES and this must not prevent distribution facilities from being excluded from BES.

No

We believe all of the Inclusion criteria should be replaced by a single criterion, which would include any element that could cause cascading outages of greater than 1,000 MW.

If our suggestion in 7a is not adopted, we propose the following: If based on transfer distribution factor this criterion may have some merit, depending on the TBD value. However, the criterion should not be based on outage transfer distribution factor, as Draft 1 implies since loss of certain distribution facilities can result in distribution load being transferred to other interconnection points. Distribution facilities should not be classified as BES.

If our suggestion in 7a is not adopted, we propose the following: The criterion related to Transient Voltage Deviations should be removed from the Inclusion Process. This criterion, regardless of value TBD, would cause any element, perhaps even including radial Primary Distribution Facilities (8.2 kV, etc.) to be sequentially included as BES. A fault on non-BES elements will cause significant transient voltage dips on nearby BES elements until the fault is cleared. If the non-BES element is at the same voltage level, the dip will result in near-zero voltages; if at different voltage levels, the dip magnitude will be determined by the ratio of the system Thévenin impedance at the BES to the intervening transformer impedance - if the system Thévenin impedance is 2% and the transformer impedance is 18%, the voltage on the BES will dip to 10%.

If our suggestion in 7a is not adopted, we propose the following: The criterion relative to frequency response should be removed. Frequency deviations can result from large changes in distribution load. Distribution facilities should not be classified as BES.

If our suggestion in 7a is not adopted, we propose the following: This criterion may be reasonable, depending on the TBD value. The TBD value may need to vary for different voltage levels or system configurations. Loss of multiple capacitors at the distribution level could result in significant voltage deviation at the BES and the criterion should be developed so as not to result in Distribution facilities being classified as BES.

Yes

CECo is not able to formulate detailed comments at this time, as the criteria have not been finalized. There are a number of items that are somewhat open ended, i.e. TBD and Other. Once those gray areas are filled in, we will have a better idea of our ability to obtain the necessary data.

Yes

The Technical Principles for Demonstrating BES Exceptions should not conflict with the seven-factor test provisions of FERC Order 888. In particular, provisions should not be established by the Standard Drafting Team that contradict prior Commission rulings associated with seven-factor test provisions.

Yes

In addition to the owner, only those with jurisdictional authority, such as the ERO and RRO, should be permitted to register Exception Requests. A third party may have a business reason for wishing to encumber another entity with regulatory compliance risk and responsibility. In addition, this could create an additional strain on the Exception Request process due to an excessive number of requests from third parties. We do want to ensure that the term "Other", used in Exclusion Section 2.a.iv.8., and Inclusion Section 1.c.8., not remain in the final Technical Principles document.

Based on FERC Order 743 paragraph 120, radial and local distribution facilities should be excluded from the definition of the Bulk Electric System (BES). The exclusion of non-networked facilities such as radial lines is further re-enforced with Order 743 paragraph 73 which describes the characteristics of a network and does not include most generator interconnection facilities. In that order, FERC justified its bright-line, 100 kV threshold, explaining that "many facilities operated at 100 kV and above have a significant effect on the overall functioning of the grid" because they share the following characteristics: 1. "operate in parallel with other high voltage and extra high voltage facilities" i. The "bright line" at 100 kV recognizes many 100 kV lines parallel other HV/EHV lines and can be significantly loaded by failure of the HV/EHV lines. This does not apply to radial lines, even at 100 kV and above. 2. "interconnect significant amounts of generation sources" (emphasis added) 3. "operate as part of a defined flow gate" 4. have a "parallel nature" and are capable of "caus[ing] or contribute[ing] to significant bulk system disturbances". i. Radial lines cannot cause significant BES disturbances since the outage of a radial line is studied in all N-1 planning studies and if the TPL standards are followed, an N-1 should not cause such disturbances. Excluding generator lead lines is very practical because the physical reality of a radial generator lead line is that it cannot be overloaded by outages on parallel paths because there are no parallel paths. Further, the MW flow on a radial line is well known and limited to a known maximum (limited to the larger of the generation or load on the end of the line); clearly these are reasons for excluding radial lines. When and if a generator lead line is tapped by another generator or load, it is possible that the line between the tap point and the original point of interconnection might need to be rolled into the electrical network. However, at that time, it might also be possible for the transmission owner to purchase the line and make the tap point the new point of interconnection.
Yes
General PPL Supply concerns with draft Technical Principles for exclusion/inclusion: 1. It may be

premature to work on an exclusion/exemption/inclusion process since the BES definition is not established yet. A lot of work could be done on the Exclusion/Inclusion that is meaningless because there is some chance the exclusion/inclusion process will not complement or might duplicate the BES definition. 2. The proposal will result in inclusion of generation facilities that are not significant to BES reliability. 3. The exclusion/inclusion drafting team does not appear to have considered the FERC assessment in Order 743-A (17-Mar-11) that "material impact assessments" cannot be unduly subjective and must be technically based as stated in paragraph 47. a. For the material impact tests in the Exclusion/Inclusion Technical Principles to be technically based, it is important that the tests actually measure what FERC states are the characteristics of the BES (see Order 743 paragraph 73), namely 1) operate in parallel, 2) carry significant amounts of generation, 3) operate as part of a defined flowgate, 4) are parallel in nature and 5) are capable of causing or contributing to significant disturbances. The proposed tests do not make these measurements. b. Further, since all facilities already meet the technically based NERC planning and operating standards, any additional measure beyond these standards such as those created by the BES Exclusion/Inclusion drafting team will be unduly subjective, as these new measures go beyond the technical basis of the NERC standards. 4. It is unclear how the exclusion/inclusion drafting team considered FERC's concerns with the use of "material impact assessments," as described in Order 743, paragraph 85 ("no grounds on which to reasonably assume that the results of the material impact assessment are accurate, consistent, and comprehensive"). Specific comments on Technical Principles paper from NERC DT 20110510 A. Please add wording to make complete sentences as needed in order to clarify whether facilities meeting these criteria are included or excluded. For example, the clarifying words are added to the following Exclusion 1 to help the reader better understand the meaning. 1. "The elements that meet all of the following characteristics are not necessary for the reliable operation of the grid and are thus excluded:" a. System elements that are located in close electrical proximity to Load are exempt from inclusion in the BES. B. Notwithstanding the need for complete sentences to assure proper interpretation, the following comments should be considered by the drafting team: o Exclusion 1 a) uses an unduly subjective, non-technically based material impact test. o Exclusion 1 b) i and ii attempts to introduce disconnect procedures in the classification as "radial" which may hurt reliability by disconnecting radial equipment that could provide voltage support. The exclusion also introduces commercial (dispatch) considerations which may not be appropriate in a reliability-based document. o Exclusion 1 c) assuming "system" is short for "system elements", this requirement for exclusion is overly discriminatory to generators which flow power out. o Exclusion 1 d) is too vague to be useful because "system" seems to have more than one meaning in this requirement. o Exclusion 2 and Inclusion 1 in their entirety are unduly subjective, non-technically based material impact tests. We are concerned that the proposed inclusion and exclusion procedures could result in not only significant generation interconnection facilities being included in the BES – but also less significant generation interconnection facilities. Such a result would be inconsistent with FERC Order 743. Accordingly, PPL Supply respectfully requests NERC to: o Exclude radial facilities less than 100 kV and not black start (these facilities are excluded in the latest definition of the BES). o Exclude radial facilities greater than 100 kV but less than 200 MVA (proposed BES now includes generators over 20 MVA) o Exclude local distribution networks (LDNs) with flow into network up to 200 MVA o Currently, LDNs are excluded if they only absorb (not produce) net power (Technical Principles Exclusion 1-c). It is also appropriate to exclude LDNs with less than net 200 MVA flow into the BES electrical network. o Inclusion efforts should not consider such issues as proximity to markets, proximity to load or nuclear facilities, or length of generator lead line.

No

We believe that the proximity test may be unnecessary, and if an Element or group of Elements meets the other three tests proposed by the SDT, it should be excluded from the BES, even if it does not meet the proximity test. Secondly, using impedance to benchmark system load proximity would likely not yield clear demarcations. High voltage relative or per-unit impedances are considered typically much lower than low voltage impedances. Hence, in the absence of phase shifting transformers, service compensation, or other mitigation factors, power typically flows over the highest voltage lines, which offer the lowest impedance.

Yes

United Electric Co-op Inc agrees conceptually that systems operating as radials rather than as integrated portions of the integrated bulk transmission system should be excluded from the BES definition. That is because local distribution systems typically operate adjacent to, or at the end of transmission lines, and function operationally to move power from the Transmission Service Provider's point of delivery of bulk power that has moved across the integrated bulk transmission system to end-users located within the local distribution utility's service territory. To be consistent with the draft BES definition, the term "radial in character" should be explicitly defined as a system that may include one or more lines into a load area or referenced as a local distribution network. In addition, we agree that the manner in which a system is operated during BES disturbances may be an indication of whether that system is radial in character. That being said, we are concerned that, to the extent the SDT considers regional disconnect procedures, it should be careful to note that UFLS and UVLS relays are often embedded within local distribution systems and, while it is necessary for the UFLS and UVLS relays to be properly armed to protect the BES in the event of a severe system disturbance, the local distribution system interconnected with those relays should not.

Yes

United Electric Co-op Inc agrees conceptually that one critical characteristic distinguishing local distribution facilities that must be excluded from the BES from transmission facilities that should be included is the manner in which power flows on those facilities. Power on local distribution systems generally flows only from the interconnected transmission source and across the distribution system for delivery to end-use customers. By contrast, power on transmission systems generally flows in two (or multiple, in networked systems) directions and is delivered in bulk to distribution utilities rather than to end-users. Hence, the SDT has properly identified power flows as one important characteristic that distinguishes BES transmission systems from local distribution systems. In order to identify systems that are not necessary for the operation of the BES under this text, we propose that any system where real power flows into the local distribution system 90 percent of the time or more under normal operating conditions.

Yes

United Electric Co-op Inc agrees that the SDT's fourth test, which asks whether power is intentionally transported through a system, identifies a key characteristic of local distribution facilities that distinguishes such facilities from interconnect bulk transmission facilities that are properly considered part of the BES. In fact, we believe this may be the most important and readily identifiable distinction. Accordingly, United Electric Co-op Inc agrees that if power is not intentionally transported through a particular system, that system is not used for transmission and should not be considered part of the BES. One exception may be for a small embedded generation unit owned by a different party that may be "scheduled" out of an area, but in reality, does not produce any physical flow. These circumstances should not trigger inclusion.

Yes

We agree conceptually with the idea that two different paths to exclusion should be adopted, one relying upon readily identifiable characteristics that are ordinarily associated with local distribution and not BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES. United Electric Co-op Inc supports the technical arguments and the White Paper presented by Snohomish County PUD in their comments. We recommend that the SDT modify its approach to the technical exclusion process to match the approach advocated in the White Paper, which is based upon the approach recommended by the WECC BES Task Force.

The use of distribution factors, such as Power Transfer Distribution Factors ("PTDF") and Outage Transfer Distribution Factor ("OTDF") provide insight into the relative impedance of neighboring systems. However in the Western Interconnection it has never been a definitive indicator of whether a system fault with delayed clearing would impact a neighboring electric system. While we understand that many entities from the Eastern Interconnection support the use of such factors, we believe the approach is unlikely to work in the Western Interconnection.

Specific transient voltage dip thresholds are proposed at page 15 of Snohomish's White Paper. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should produce no more than a 20% voltage drop for no more than 20 cycles in a Category B

contingency and no more than a 20% drop for 40 cycles in a Category C contingency. Technical justification for these thresholds is provided at pages 12-16 of the White Paper.
Page 15 of Snohomish's White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided at pages 12-16 of the White Paper.
Please see our response to Question 5d.
No
Yes
As a general matter, we agree with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid showing that the Elements contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. We also agree that the SDT has, in general, identified the correct technical approach, although we recommend that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in the Snohomish PUD White Paper, in the WECC BES Task Force Proposal 6, and in our answer to Question 5.

No
As discussed on page 12 of the Snohomish White Paper, there may be a few isolated cases where additional data will need to be provided to run a valid technical analysis under the criteria set forth in the Exception Procedure. These cases should be exceedingly rare, however, because the starting point for the technical analysis we recommend is the current base case operated by the relevant Regional Entity, and in nearly every case, the base case can be expected to model any Element that conceivably has a material impact on the reliable operation of the bulk system. In those rare cases where it does not, we believe the owner or operator of the subject Element should be able to provide the needed data.
No
As properly constructed Definition and Exceptions process should meet the legal requirements of Section 215.
Yes
United Electric Co-op Inc generally supports the approach to the exclusion process proposed by the SDT, which provides two different paths to exclusion, one based on readily-identifiable operational characteristics of a system, and one based on technical reliability analysis. We believe it is important to provide for the first path, based on operational characteristics, so that systems that are marginally disqualified under the BES Definition (because, for example, generation within the system exceeds demand for a few hours a year) can obtain an exclusion without the large investment of resources that otherwise might be required for a full-scale technical analysis. That being said, we question whether the first subsection of the characteristic test, relating to system proximity, is necessary, and we are concerned that the requirement that a system meet all four requirements of the characteristics test may be overly restrictive. For example, it is easy to imagine a distribution system in a rural area that covers a widely dispersed area, so that load is many miles from the relevant generation/transmission source, and that the system therefore does not meet the electrical proximity element, but meets the other three elements of the characteristics test. Such a system should be excluded because it clearly serves a local distribution function, and not a transmission function, as demonstrated by the fact that the system meets subsections (c) (power flows into the system but rarely flows out ) and (d) (power is not intentionally transported over the system). Accordingly, we recommend that the SDT consider eliminating the first test. In the alternative, the SDT should consider allowing exempting a system from the BES if it, for example, meets three of the four criteria rather than all four.

Individual

Steve Alexanderson

Central Lincoln

No

Central Lincoln agrees in principle that one characteristic of local distribution systems is that they are usually confined to a relatively limited geographic area, as opposed to transmission systems, which (especially in the West) tend to cover very large distances. We also believe the proximity test may be a sensible way to identify local distribution facilities. However, as explained in more detail in our response to Question 10, we believe that the proximity test may be unnecessary, and if an Element or group of Elements meets the other three tests proposed by the SDT, it should be excluded from the BES, even if it does not meet the proximity test. Secondly, using impedance to benchmark system load proximity would likely not yield consistent demarcations. High voltage relative or per-unit impedances are typically much lower than low voltage impedances. Hence, in the absence of phase shifting transformers, service compensation, or other mitigation factors, power typically flows over the highest voltage lines, which offer the lowest impedance. Central Lincoln proposes that "proximity" be determined in the dictionary manner with units of distance.

No

Central Lincoln agrees that systems operating as radials rather than as integrated portions of the integrated bulk transmission system should be excluded from the BES definition. That is because local distribution systems typically operate adjacent to, or at the end of transmission lines, and function operationally to move power from the Transmission Service Provider's point of delivery of bulk power that has moved across the integrated bulk transmission system to end-users located within the local distribution utility's service territory. To be consistent with the draft BES definition, the term "radial in character" should be explicitly defined as a system that may include one or more lines into a load area or referenced as a local distribution network. In addition, we agree that the manner in which a system is operated during BES disturbances may be an indication of whether that system is radial in character. That being said, we are concerned that, to the extent the SDT considers regional disconnect procedures, it should be careful to note that UFLS and UVLS relays are often embedded within local distribution systems and, while it is necessary for the UFLS and UVLS relays to be properly armed to protect the BES in the event of a severe system disturbance, the local distribution system interconnected with those relays should not, and cannot legally, be classified as BES.

Yes

Central Lincoln agrees that one critical characteristic distinguishing local distribution facilities that must be excluded from the BES from transmission facilities that should be included is the manner in which power flows on those facilities. Power on local distribution systems generally flows only from the interconnected transmission source and across the distribution system for delivery to end-use customers. By contrast, power on transmission systems generally flows in two (or multiple, in networked systems) directions and is delivered in bulk to distribution utilities rather than to end-users. Hence, the SDT has properly identified power flows as one important characteristic that distinguishes BES transmission systems from local distribution systems. Central Lincoln also agrees that the fact that power may flow out of a local distribution system onto the grid during a few hours in a year or during extreme contingencies should not change the characterization of the system as local distribution. Accordingly, we support inclusion of power flow analysis as one element of characteristics that can be used to exclude local distribution facilities from the BES even if the facilities do not pass each of the bright-line thresholds laid down in the BES definition. We also agree that transactional and hourly generation records are an appropriate basis for making the determination since these can

be used to demonstrate that demand within a local distribution system exceeds generation within that system in most hours and that power therefore does not flow onto the grid, and also to determine the number of hours where this is not the case and the amount by which generation within the system exceeds demand. In order to identify systems that are not necessary for the operation of the BES under this test, we propose that any system where real power flows into the local distribution system 90 percent of the time or more under normal ("N-0" or All Lines in Service) operating conditions should be held to meet this test. That a system meets this test could be demonstrated using metering or supervisory control and data acquisition ("SCADA") data records over the course of two years. In addition, the presence of generation within a local distribution system that only modifies the level of the load served by the bulk system, but does not result in power being injection into the bulk system, does not change the reliability effect of the local network and therefore should not require the local network to be classified as BES.

No

Central Lincoln agrees that the SDT's fourth test, which asks whether power is intentionally transported through a system, identifies a key characteristic of local distribution facilities that distinguishes such facilities from interconnect bulk transmission facilities that are properly considered part of the BES. In fact, we believe this may be the most important and readily identifiable distinction. As a matter of operation, power is scheduled across transmission lines. Further, transmission lines in the Western Interconnection (either individually or as part of a transmission path) are rated for total transmission capacity and available transmission capacity, and transmission rights can be purchased on such lines, if available, on an OASIS. Local distribution systems do not share any of these operational characteristics. Accordingly, Central Lincoln agrees that if power is not intentionally transported through a particular system, that system is not used for transmission and should not be considered part of the BES. We also agree that examining the Operating Procedures applicable to a particular system will provide a ready guide to whether power is intentionally scheduled across that system. We suggest, however, that the SDT look beyond those protocols that fall within the NERC Glossary's definition of Operating Procedure. For example, in the West, transmission paths are almost all listed in the WECC Path Rating Catalog. Similarly, it is not clear whether scheduling protocols, OASIS operations, and the other factors listed above qualify as Operating Procedures. Hence, we urge the SDT to list such specific operational characteristics as part of this test.

Yes

We agree that two different paths to exclusion should be adopted, one relying upon readily identifiable characteristics that are ordinarily associated with local distribution and not BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES. Snohomish PUD has prepared a White Paper proposing a performance-based approach to support the technical determination whether Elements should be excluded from the BES, which are attached to their comments and we recommend to the SDT for study. We also commend the work of the WECC BES Task Force and the WECC Technical Studies Subcommittee, both of which have devoted substantial time and resources to developing a workable and technically defensible process for excluding Elements classified as BES based upon their electrical characteristics. See WECC BES Task Force Proposal 6, App. A at 3-9 & App. B at pp. B-4 to B-7 (posted Feb. 18, 2011) (available at: <http://www.wecc.biz/Standards/Development/BES/default.aspx>). We recommend that the SDT modify its approach to the technical exclusion process to match the approach advocated in Snohomish's White Paper, which is based upon the approach recommended by the WECC BES Task Force.

The use of distribution factors, such as Power Transfer Distribution Factors ("PTDF") and Outage Transfer Distribution Factor ("OTDF") provide insight into the relative impedance of neighboring systems. However in the Western Interconnection it has never been a definitive indicator of whether a system fault with delayed clearing would impact a neighboring electric system. While we understand that many entities from the Eastern Interconnection support the use of such factors, we believe the approach is unlikely to work in the Western Interconnection. Based on the significant differences between the four major interconnections in North America, Central Lincoln suggests that a detailed technical exemption process be allowed on an interconnections wide basis. The Western Interconnection is a "hub and spoke system" where loads are very remote from large generation

plants, with margins that are based on stability limits. By contrast, the Eastern Interconnection is a tightly meshed system with loads and generation in close proximity, often creating margins that are based on thermal limitations. These differences manifest themselves in a variety of operations. For example, the Western Interconnection uses a rated paths methodology while the Eastern Interconnection uses transmission load relief mechanisms. Consistent with FERC order 743-A Central Lincoln supports exemption criteria for individual frequency independent regions, or interconnections.

Fault induced transient voltage measurements will always be low if taken at a point electrically close to the fault during the fault. The question should be about voltage recovery following the clearing of the fault as in the TPL standards. The Technical Principles do not make this distinction, and the resulting effect would be the exclusion of elements that should be included and the inclusion of elements that should be excluded.

Page 15 of Snohomish's White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided at pages 12-16 of the White Paper.

Please see our response to Question 5d.

No

Yes

As a general matter, we agree with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid showing that the Elements contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. We also agree that the SDT has, in general, identified the correct technical approach, although we recommend that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in the Snohomish PUD White Paper, in the WECC BES Task Force Proposal 6, and in our answer to Question 5. While we support the SDT's overall approach, we believe subsection (f) of the proposed inclusion criteria, which would allow NERC to "override this criterion" if it provides "additional justification" for doing so is both unnecessary and creates confusion and uncertainty in what is otherwise a clear and concise process. Subsection (f) is unnecessary because if the technical process laid out in subsections (a) through (e) fails to provide any evidence that the contested Element(s) create a material impact on the reliability of the bulk interconnected transmission network, there is no reason to classify those Element(s) as BES, and that should be the end of the question. Subsection (f) creates needless uncertainty because it allows NERC to override the technical criteria laid out in subsections (a) through (e) if "additional justification" is provided, but there is no suggestion as to what this additional justification might be. Nor is there any explanation as to why additional justification might be necessary after the criteria in subsections (a) through (e) have been exhausted.

Please see 5b.

Please see 5c.

Please see 5d.

Please see 5e.

No

As discussed on page 12 of the Snohomish PUD White Paper, there may be a few isolated cases where additional data will need to be provided to run a valid technical analysis under the criteria set forth in the Exception Procedure. These cases should be exceedingly rare, however, because the starting point for the technical analysis we recommend is the current base case operated by the relevant RE, and in nearly every case, the base case can be expected to model any Element that conceivably has a material impact on the reliable operation of the bulk system. In those rare cases where it does not, we believe the owner or operator of the subject Element should be able to provide the needed data, although we propose that the relevant owner or operator be relieved of this burden if it can be demonstrated that the nearest electrically interconnected Element has no material impact on the bulk system.

No

As we explained in our response to Question 1 of the Comment Form on the 1st Draft of Definition of BES, filed on May 27, Central Lincoln believes that the proposed BES Definition could conflict with

Section 215 of the Federal Power Act if the Definition, the Exception Process, and the Technical Criteria do not effectively exclude facilities used in local distribution from the BES or if the BES definition does not focus on cascading outages, separation events, and instability on the interconnected bulk system. These statutory limits on the scope of the BES and reliability standards are a minimum that must be met.

Yes

Central Lincoln generally supports the approach to the exclusion process proposed by the SDT, which provides two different paths to exclusion, one based on readily-identifiable operational characteristics of a system, and one based on technical reliability analysis. We believe it is important to provide for the first path, based on operational characteristics, so that systems that are marginally disqualified under the BES Definition (because, for example, generation within the system exceeds demand for a few hours a year) can obtain an exclusion without the large investment of resources that otherwise might be required for a full-scale technical analysis. That being said, we question whether the first subsection of the characteristic test, relating to system proximity, is necessary, and we are concerned that the requirement that a system meet all four requirements of the characteristics test may be overly restrictive. For example, it is easy to imagine a distribution system in a rural area that covers a widely dispersed area, so that load is many miles from the relevant generation/transmission source, and that the system therefore does not meet the electrical proximity element, but meets the other three elements of the characteristics test. Such a system should be excluded because it clearly serves a local distribution function, and not a transmission function, as demonstrated by the fact that the system meets subsections (c) (power flows into the system but rarely flows out ) and (d) (power is not intentionally transported over the system). Accordingly, we recommend that the SDT consider eliminating the first test. In the alternative, the SDT should consider allowing exempting a system from the BES if it, for example, meets three of the four criteria rather than all four.

Group

New York State Reliability Council

Roger Clayton

No

NERC's Glossary definition of Load is "An end-use device or customer that receives power from the electric system." which is not specific enough to permit the definition of an appropriate impedance value. It is not clear from the proposed wording whether the exception applies to the Loads or the electrically close System Elements or both. In any case, the concept of a single impedance value as a metric is flawed because it could be a low impedance breaker or a relatively high impedance transformer connecting the BES to a "radial" Load center. This exclusion is superfluous given the radial test in item 2. Suggest dropping this exclusion test. N.B. The proposed criteria in items 1 – 4 must all be met in order for an element to qualify for an exclusion.

Yes

It should be clarified that radial Element(s) include all system elements in load pockets.

Yes

It should be clarified that this exclusion should not apply to inter-regional transfers, which clearly are candidates for inclusion as BES.

Yes

Yes

A single threshold value for performance based testing does not recognize differences in regional system characteristics. Therefore, regional approaches for at least generation exclusions should be used, like NPCC's A-10 criterion.

We recommend that this item be added to the BES definition.
Yes
We recommend that that the item be added to the BES definition.
Yes
The thresholds for power flows out of the system should be made consistent with Exclusion E2 in the definition. We recommend that this item be added to the BES definition.
Yes
This requirement should be further relaxed to allow for intentional flows that are provided as a courtesy to the local distribution company. In such cases, private, customer-owned facilities may be used to deliver power from a DP to a small number of the DP's retail customers who are unaffiliated with the owner/operator of the private network. These flows are generally de minimis. We also recommend that this item (with our qualification) be added to the BES definition.
Yes
Yes
We recommend an additional method (or alternatively this be added to the BES Definition Exception E1): System Elements are part of facilities, generally radial in nature, supplying a retail customers from the point of delivery to the load regardless of voltage. Evidence to support this position could be an interconnection agreement indicating the point of delivery, a one-line diagram showing the point of delivery and load etc. The technical rationale is that protection of the BES for facilities serving load is the responsibility of the service provider (e.g., TO/TOP). These facilities are distribution facilities and are not now part of the BPS.
Yes
NERC (and the BES SDT) should not assume that data pursuant to Large Generator Interconnection Agreements (LGIA) or the Large Generator Interconnection Procedures (LGIP) will be forthcoming on a timely basis for the purpose of demonstrating BES exceptions. While such information is generally available from ISOs and RTOs, it is not so forthcoming from vertically-integrated utilities in regions of the country not served by ISOs or RTOs because such utilities are generally hostile to third-party

generation in their service territory. They are capable of delaying or otherwise obstructing requests for data and information. We recommend that NERC or the SDT identify mechanisms for requesting and getting the necessary data and information. This process should be included in the NERC Rules of Procedure.

Yes

The proposed technical principles violate the exemption in FPA section 215 against the inclusion in the BES of facilities used in the local distribution of electric energy, given that the BES is a subset of the BPS.

Yes

The bright-line tests used in the revised BES definition and technical principles may capture the facilities of hundreds of entities that may not know that NERC exists or the enforceability of NERC Reliability Standards. The technical principles should be supplemented with a technical guide or appendix that provides examples of the steps that may be necessary to demonstrate BES exceptions.

Use of the 100 kV brightline and the core BES definition as proposed is an overreach into local distribution systems and an overreach of FERC's authority as set out in the FPA 215. A full engineering technical analysis - required every 2 years - is too onerous and not necessary for identifying most local distribution elements miss-identified as BES Elements. A simple screening methodology consistent with the 7-Factor Test (from FERC Order 888) is needed as the first stage of the exception process.

No
We believe that the proximity test may be unnecessary, and if an Element or group of Elements meets the other three tests proposed by the SDT, it should be excluded from the BES, even if it does not meet the proximity test. Secondly, using impedance to benchmark system load proximity would likely not yield clear demarcations. High voltage relative or per-unit impedances are considered

typically much lower than low voltage impedances. Hence, in the absence of phase shifting transformers, service compensation, or other mitigation factors, power typically flows over the highest voltage lines, which offer the lowest impedance.

Yes

Salem Electric agrees conceptually that systems operating as radials rather than as integrated portions of the integrated bulk transmission system should be excluded from the BES definition. That is because local distribution systems typically operate adjacent to, or at the end of transmission lines, and function operationally to move power from the Transmission Service Provider's point of delivery of bulk power that has moved across the integrated bulk transmission system to end-users located within the local distribution utility's service territory. To be consistent with the draft BES definition, the term "radial in character" should be explicitly defined as a system that may include one or more lines into a load area or referenced as a local distribution network. In addition, we agree that the manner in which a system is operated during BES disturbances may be an indication of whether that system is radial in character. That being said, we are concerned that, to the extent the SDT considers regional disconnect procedures, it should be careful to note that UFLS and UVLS relays are often embedded within local distribution systems and, while it is necessary for the UFLS and UVLS relays to be properly armed to protect the BES in the event of a severe system disturbance, the local distribution system interconnected with those relays should not.

Yes

Salem Electric agrees conceptually that one critical characteristic distinguishing local distribution facilities that must be excluded from the BES from transmission facilities that should be included is the manner in which power flows on those facilities. Power on local distribution systems generally flows only from the interconnected transmission source and across the distribution system for delivery to end-use customers. By contrast, power on transmission systems generally flows in two (or multiple, in networked systems) directions and is delivered in bulk to distribution utilities rather than to end-users. Hence, the SDT has properly identified power flows as one important characteristic that distinguishes BES transmission systems from local distribution systems. In order to identify systems that are not necessary for the operation of the BES under this text, we propose that any system where real power flows into the local distribution system 90 percent of the time or more under normal operating conditions.

Yes

Salem Electric agrees that the SDT's fourth test, which asks whether power is intentionally transported through a system, identifies a key characteristic of local distribution facilities that distinguishes such facilities from interconnect bulk transmission facilities that are properly considered part of the BES. In fact, we believe this may be the most important and readily identifiable distinction. Accordingly, Salem Electric agrees that if power is not intentionally transported through a particular system, that system is not used for transmission and should not be considered part of the BES. One exception may be for a small embedded generation unit owned by a different party that may be "scheduled" out of an area, but in reality, does not produce any physical flow. These circumstances should not trigger inclusion.

Yes

We agree conceptually with the idea that two different paths to exclusion should be adopted, one relying upon readily identifiable characteristics that are ordinarily associated with local distribution and not BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES. Salem Electric supports the technical arguments and the White Paper presented by Snohomish County PUD in their comments. We recommend that the SDT modify its approach to the technical exclusion process to match the approach advocated in the White Paper, which is based upon the approach recommended by the WECC BES Task Force.

The use of distribution factors, such as Power Transfer Distribution Factors ("PTDF") and Outage Transfer Distribution Factor ("OTDF") provide insight into the relative impedance of neighboring systems. However in the Western Interconnection it has never been a definitive indicator of whether a system fault with delayed clearing would impact a neighboring electric system. While we understand that many entities from the Eastern Interconnection support the use of such factors, we believe the

approach is unlikely to work in the Western Interconnection.
Specific transient voltage dip thresholds are proposed at page 15 of Snohomish's White Paper. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should produce no more than a 20% voltage drop for no more than 20 cycles in a Category B contingency and no more than a 20% drop for 40 cycles in a Category C contingency. Technical justification for these thresholds is provided at pages 12-16 of the White Paper.
Page 15 of Snohomish's White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided at pages 12-16 of the White Paper.
Please see our response to Question 5d.
No
Yes
As a general matter, we agree with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid showing that the Elements contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. We also agree that the SDT has, in general, identified the correct technical approach, although we recommend that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in the Snohomish PUD White Paper, in the WECC BES Task Force Proposal 6, and in our answer to Question 5.

No
As discussed on page 12 of the Snohomish White Paper, there may be a few isolated cases where additional data will need to be provided to run a valid technical analysis under the criteria set forth in the Exception Procedure. These cases should be exceedingly rare, however, because the starting point for the technical analysis we recommend is the current base case operated by the relevant Regional Entity, and in nearly every case, the base case can be expected to model any Element that conceivably has a material impact on the reliable operation of the bulk system. In those rare cases where it does not, we believe the owner or operator of the subject Element should be able to provide the needed data.
No
As properly constructed Definition and Exceptions process should meet the legal requirements of Section 215.
Yes
Salem Electric generally supports the approach to the exclusion process proposed by the SDT, which provides two different paths to exclusion, one based on readily-identifiable operational characteristics of a system, and one based on technical reliability analysis. We believe it is important to provide for the first path, based on operational characteristics, so that systems that are marginally disqualified under the BES Definition (because, for example, generation within the system exceeds demand for a few hours a year) can obtain an exclusion without the large investment of resources that otherwise might be required for a full-scale technical analysis. That being said, we question whether the first subsection of the characteristic test, relating to system proximity, is necessary, and we are concerned that the requirement that a system meet all four requirements of the characteristics test may be overly restrictive. For example, it is easy to imagine a distribution system in a rural area that covers a widely dispersed area, so that load is many miles from the relevant generation/transmission source, and that the system therefore does not meet the electrical proximity element, but meets the other three elements of the characteristics test. Such a system should be excluded because it clearly serves a local distribution function, and not a transmission function, as demonstrated by the fact that the system meets subsections (c) (power flows into the system but rarely flows out ) and (d) (power is not intentionally transported over the system). Accordingly, we recommend that the SDT consider

eliminating the first test. In the alternative, the SDT should consider allowing exempting a system from the BES if it, for example, meets three of the four criteria rather than all four.

No

We do not believe that a meaningful “not to exceed” impedance value can be proffered which would be appropriately useful across all regions. EEI recommends that Exclusion benchmarks should directly correlate to the BES definition exclusions as written. Although the “4 Item” approach was obviously intended to provide a simple approach, the outcome suggested in the draft was less than satisfactory and we submit it does not hold true to the exclusions provided by the Drafting Committee in their proposed BES Definition. (see additional comments provided at the end of the Comment form)

Yes

The verbiage used in the BES Principles document does not closely match the verbiage used in the NERC Bright-line Exclusion. For that reason, we submit the following alternative language. System Elements and Facilities treated in total as a radial system shall have the following characteristics: 1. Shall be separated from the BES with an Automatic Interrupting Device, AND 2. Only load serving and must be isolated from other radial systems through a normally open switching device, OR 3. Only include generation resources but cannot include any of the Inclusions (i.e., I2, I3, I4 and I5) identified in the BES Definition, OR 4. Is a combination of Load and Generation but cannot include any of the Inclusions (i.e., I2, I3, I4 and I5) identified in the BES Definition Evidences to be supplied shall include: • One-line Diagram clearly showing all demarcations between BES Facilities and the Radial System (including the Automatic Interrupting Device, AND • Operating procedures or interconnection agreements that indicate Generating Units contained within the Radial System are not dispatchable (if applicable), AND/OR • Operating procedures that show that the Radial System is not operated as part of the BES

Yes

Although EEI agrees in principle to the exclusion, we feel the current language has some problems which need to be addresses. Note the following: The word “rarely should be struck. It is meaningless in the context for which it is used and offers little to characterize an element or connection since it does not contain a measure. A more appropriate statement to broadly characterize a Non-BES element or connection would be the following: “Power flows are broadly characterized as Load Serving.” Items i. and iii. are excessive requirements which do not aide in defining what is “necessary for operating an interconnected electric transmission network”. What might be more a more useful measure is a comparison of total MW hours of load consumed vs. MW hours fed back into the BES as measured on an annual basis. Item v. – Hourly energy data (MWh) for the most recent 12 month period for every excluded BES element is an excessive requirement. Annual records indicating that MW hours consumed annually verses MW hours that flow through the non-BES element would be a better indicator in line with the definition.

Yes

A radial system by definition transports power from the BES System to a Distribution System, similarly an LDN operates in a like manner. A strict reading of the above criteria would exclude both from consideration yet the definition allows both. We believe that in an attempt to develop a set of criteria useful for all situations, the outcome has weakened the original intent as set in the Definition. Although much of the criteria used is largely appropriate, a stricter adherence to the BES definition criteria would substantially help to avoid confusion between what was developed as principles and what was developed as the BES Definition.

Yes

In general, we agree that an alternative path allowing a technical analysis to demonstrate that a Facility (or Element) should not be considered part of the BES is appropriate. However, we disagree with the measures offered and suggest an alignment with efforts already being developed within NERC’s Event Analysis Working Group. EEI proposes that the technical analysis criterion which has been proposed is too complicated, inconsistent with what is currently being done across the regions and submits that a better approach would be to align reliability impacts with the Event Analysis Criteria being developed by NERC’s EAWG. These criteria would be a better benchmark as to whether

a Facility or Element should be excluded from the BES. The proposed alternate criteria are as follows: (1) The loss of the Facility (or Element) would not interfere or negatively impact the BES from staying within acceptable limits (i.e., frequency, voltage and System Operating limits) following a fault on or loss of that Facility (or Element); (2) The loss of the Facility (or Element) would not interfere or negatively impact the BES from performing acceptably after credible contingences; (3) Facility (or Element) faults, failures, or trips do not push the system to a point of Instability or otherwise initiate cascading outages; (4) BES facilities are protected from unacceptable damage by operating the Facility (or Element) within its ratings; and (5) The unexpected loss of the Facility (or Element) does not negatively impact the BES from achieving its mission of to supply the aggregate electric power and energy requirements of its customers.

In general, we do not agree this is a relevant factor for consideration and should be excluded.

Presently no regional standards exist for allowable transient voltage dip beyond WECC. It is also doubtful a useful standard could be developed for all regions or interconnections.

Presently no regional standards exist for allowable transient frequency response beyond WECC. It is also doubtful a useful standard could be developed for all regions or interconnections.

Presently no regional standards exist for allowable voltage deviation beyond WECC. It is also doubtful a useful standard could be developed for all regions or interconnections.

Yes

Method 2 is largely based on System Planning Criteria developed by WECC. At the present time, we do not believe that any of the other regions have similar planning criteria for which they could use or could easily integrate similar criteria into useable Planning Standards which could be applied in useful manner across all regions. For this reason, it is recommended that a separate Design Committee be created which would include representatives from all regions. It is expected that this effort may be substantial but is necessary before Method 2 or the Inclusion Process as written could be used. We would further caution the use or imposition of such a process since some transmission owners may not have the necessary skills or tools required to conduct studies of this type (in-house) and imposing this level of evidence will likely cause many who cannot meet this requirement to include unnecessary elements diluting the BES as defined and negating the value of the exclusion process.

Yes

EEl is concerned that under the technical principles, some facilities that are local distribution facilities may be included the BES. This is in conflict with the definition of the Bulk Power System in Section 215 which excludes facilities used in local distribution. In particular, EEl is concerned that the provision of the technical principles prohibiting the seeking an Exclusion for a cranking path will include local distribution within the definition of BES.

Yes

We are concerned that the method used to characterize exclusions in Method 1 did not follow the proposed BES Definition and believe the process developed for Method 2 (and reused for Sub-100kV Inclusions) is overly complicated, lacks necessary regional standards to support the process and may prove too difficult for some companies to fully comply with thereby discouraging a consistent and uniform application of the definition across all regions and affected BES element owners. In the proposed (BES) definition and accompanying Inclusions and Exclusions, the Drafting Committee went to some effort to clearly and methodically define what was included and what was permissible to exclude. Unfortunately the NERC proposed "Technical Principles for Demonstrating BES Exceptions" did not follow that same clear and concise manner adding some confusion which could lead to inconsistent application of the Exclusion (and Inclusion) Criteria. For example, at no point did the "Principles" ever identify Inclusions I2 through I5 which were liberally used in the exclusion criteria

within the BES definition. Additionally within the body of the Proposed BES definition, there are three (3) approved Exclusions (E1 – Radial System; E2 – Small Customer Generator/Generation System and E3 – Local Distribution Networks). Each of the Exclusions have its own set of criteria used to define and characterize the methodology necessary to meet each exclusion, however, the “Principles” contained in this document only loosely follow the criteria provided and in some cases miss that criteria all together. We refer the SDT to the EEI comments previously submitted on the BES Definition regarding the relationship of the BES definition to the statutory exclusion of local distribution facilities.

Florida Municipal Power Agency

Frank Gaffney

No

Impedance is a function of a line’s length; it does not measure whether a line serves a BES function. A very long line can exist only to serve load, and a short line in an urban area (where the load is physically close to the grid) could be needed for transmission but would have low impedance. This proposed metric is thus both over- and under-inclusive, and should be discarded. Transfer distribution factor is a more appropriate metric, as described in FMPA’ response to Question 4. FMPA supports having two paths for exclusions, one that includes extensive technical analysis and another that does not. The path with less technical analysis is appropriate for Elements that a relatively high-level examination shows to be not relevant to the reliability of the grid. This opportunity should be available in the context of exclusions to reduce the burden on small entities. Reliability will not be impaired by this option; all exception requests will be reviewed by NERC, and in any case where NERC is less than certain that an exception is appropriate, NERC can perform any or all of the analyses that would be required for a more technical exclusion or inclusion, and a positive result on any one of the analyses would be sufficient justification to deny the exclusion request.

We believe that this criterion is intended, like those in 1(a) and (d), to determine whether an Element is planned and operated to function as part of the interconnected grid. It is, however, too vague to be useful and should be discarded.

The third item is “power flows into the system, but rarely flows out.” This criterion is vague. FMPA suggests instead the following language, which is consistent with FMPA’ comments on Exclusion E3 of the BES definition: “Neither the Element, nor any Elements that it connects to the grid (in aggregate), includes more than 75 MVA of generation used to meet the resource-adequacy requirements of electric utilities.”

Yes

FMPA supports the criterion in concept, but “intention[]” is a vague term and not relevant to an Element’s impact on the grid. We suggest instead that to obtain an exclusion for such a quasi-radial Element, the owner be required to demonstrate that the Element has no more than a 5% transfer distribution factor on any BES Element for transfers that could be curtailed through the NAESB TLR procedure (e.g., interchange transactions, or generator to load distribution factors (GLDF) for BES generators). Transfer distribution factor (or GLDF) is a good measure of an Element’s impact on the grid and is not subject to varying interpretations. In addition, NAESB standards are also approved by FERC and mandatory to jurisdictional entities. Hence, the 5% TDF “Curtailed Threshold” has already been approved by FERC as indicating an insufficient impact on the BES to be considered for TLR. And, it shows consistency between NERC and NEASB standards.

Yes

FMPA supports including specific technical criteria that Elements must meet to obtain an exclusion through the exception process. This approach will facilitate uniform application of the exception process. FMPA responds to the first five proposed criteria in response to 5b-5e below. In the sixth proposed criterion, “steady state stability” is ambiguous, does the SDT mean voltage stability, power angle curve stability, or small signal stability? The seventh proposed criterion, “No cascading outages,” is insufficiently granular and should be discarded. The criteria are intended to measure whether, among other things, a particular Element can cause a cascading outage. They need to set out how decision-makers will determine whether an Element can cause a cascading outage, not simply state that an Element that can cause a cascading outage cannot be excluded from the BES.

The first proposed criterion, “Having a distribution factor of 5% for any other Element,” should instead be “Having a distribution factor of 5% for Interchange Transactions or BES generator to load

curtailable in Transmission Loading Relief stages one through five.”
The second criterion, “Allowable transient voltage dip – criteria TBD,” should specify where the transient voltage dip is, i.e. “Allowable transient voltage dip on another BES Element for events on the Element that is a candidate of the Exception Request—criteria TBD.”
The third proposed criterion, “Allowable transient frequency excursion – criteria TBD,” should be rephrased like the second: “Allowable transient frequency excursion on another BES Element for events on the Element that is a candidate of the Exception Request – criteria TBD.”
The fourth proposed criterion should be revised in the same way as the second and third: “Voltage deviation on another BES Element for events on the Element that is a candidate of the Exception Request – criteria TBD.” The fifth proposed criterion should be similarly revised: “Transient Stability on another BES Element for events on the Element that is a candidate of the Exception Request – positively damped.”
Yes
TAPS proposes a simpler set of exclusion exception criteria: 1. Having a distribution factor of 5% for curtailable Interchange Transactions or BES generator – load identified in Transmission Loading Relief stages one through five, and 2. Category B and C contingencies on the Element that is the subject of the Exception Request meet the TPL-002 criteria for other BES Elements. (With the new TPL-001-3 standard recently approved by ballot, Category P0 through P7 contingencies on the Element that is subject of the Exception Request meets the criteria of P0 through P3 for other BES Elements) 3. The Element that is the subject of the Exception Request is not: (1) part of an IROL, (ii) part of a blackstart or cranking path used in a TOP’s restoration plan, and (iii) is not used in NUC-001 to provide service to a nuclear plant. TAPS believes these three criteria meet the intent of all of the criteria presented by the SDT.
FMPA supports using a uniform set of technical criteria to decide inclusion exceptions. Such an approach will facilitate uniform application of the criteria. In addition to having clear and uniform criteria, the technical analysis for inclusions and exclusions should use the same criteria (though one should of course be the inverse of the other). We note that the steps laid out for Inclusions do not quite track those in Exclusions 2(a). For example, Inclusions 1(b) states, confusingly, “Monitor the contribution of the disputed Element(s),” but there is no corresponding step in Exclusions 2(a). FMPA suggests that Inclusions 1 be revised to mirror Exclusions 2.
See FMPA comments in response to Question 5.
See FMPA comments in response to Question 5.
See FMPA comments in response to Question 5.
See FMPA comments in response to Question 5.
Yes
The third paragraph of the introduction to the Technical Principles is awkwardly worded and might be misconstrued. FMPA suggests the following rewording: “Entities are not required to seek exceptions under the Exception Procedure to exclude from the BES Element(s) that are already excluded under the BES definition and designations.” For the sake of consistency, Exclusions (1) should contain a provision analogous to Exclusions (2)(b) and Inclusions (1)(f) addressing the circumstances under which the ERO can override a demonstration based on these criteria. As noted above, one of those circumstances would be a demonstration by NERC that the Element in question meets the criteria for inclusion in the BES.

Duke Energy
No
Duke Energy does not agree that this characteristic materially demonstrates that an Element is not necessary for operating an interconnected electric transmission network. There is no correlation between the electrical proximity of an element to load and its necessity for operating an interconnected transmission network. In general, the path that does not include extensive technical analysis is not adequate to distinguish between the Elements that are and that are not necessary for

said operation.
No
This second characteristic does not add clarity to the E1 Exclusion in the proposed BES definition. And in general, the path that does not include extensive technical analysis is not adequate to distinguish between the Elements that are and that are not necessary for operating an interconnected electric transmission network.
No
This third characteristic does not add clarity to the E3 Exclusion in the proposed BES definition. And in general, the path that does not include extensive technical analysis is not adequate to distinguish between the Elements that are and that are not necessary for operating an interconnected electric transmission network.
No
This fourth characteristic does not add clarity to the E3 Exclusion in the proposed BES definition. And in general, the path that does not include extensive technical analysis is not adequate to distinguish between the Elements that are and that are not necessary for operating an interconnected electric transmission network.
Yes
Duke Energy agrees with the approach of using a technical analysis based on transmission system modeling but the specific criteria do not need to be specified here – they should be consistent with the latest revision of the TPL-001. R5 of TPL-001-2, Transmission System Planning Performance Requirements states that each Transmission Planner and Planning Coordinator shall have criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and the transient voltage response for its System. The technical analysis required for exclusion of an Element from the BES should evaluate the loss of the Element against a more conservative set of criteria than that specified by the Transmission Planner and Planning Coordinator responsible for that Element. There are currently no continent-wide performance levels defined for these evaluations, and there is no technical basis for developing performance levels that would be applicable continent wide.
This should be removed – there is no correlation between distribution factor and whether or not an element is necessary for reliable operation of the interconnected transmission network.
See general comment on approach.

We believe that the proximity test may be unnecessary, and if an Element or group of Elements meets the other three tests proposed by the SDT, it should be excluded from the BES, even if it does

not meet the proximity test. Secondly, using impedance to benchmark system load proximity would likely not yield clear demarcations. High voltage relative or per-unit impedances are considered typically much lower than low voltage impedances. Hence, in the absence of phase shifting transformers, service compensation, or other mitigation factors, power typically flows over the highest voltage lines, which offer the lowest impedance.

Yes

Grant agrees conceptually that systems operating as radials rather than as integrated portions of the integrated bulk transmission system should be excluded from the BES definition. That is because local distribution systems typically operate adjacent to, or at the end of transmission lines, and function operationally to move power from the Transmission Service Provider's point of delivery of bulk power that has moved across the integrated bulk transmission system to end-users located within the local distribution utility's service territory. To be consistent with the draft BES definition, the term "radial in character" should be explicitly defined as a system that may include one or more lines into a load area or referenced as a local distribution network. In addition, we agree that the manner in which a system is operated during BES disturbances may be an indication of whether that system is radial in character. That being said, we are concerned that, to the extent the SDT considers regional disconnect procedures, it should be careful to note that UFLS and UVLS relays are often embedded within local distribution systems and, while it is necessary for the UFLS and UVLS relays to be properly armed to protect the BES in the event of a severe system disturbance, the local distribution system interconnected with those relays should not.

Yes

Grant agrees conceptually that one critical characteristic distinguishing local distribution facilities that must be excluded from the BES from transmission facilities that should be included is the manner in which power flows on those facilities. Power on local distribution systems generally flows only from the interconnected transmission source and across the distribution system for delivery to end-use customers. By contrast, power on transmission systems generally flows in two (or multiple, in networked systems) directions and is delivered in bulk to distribution utilities rather than to end-users. Hence, the SDT has properly identified power flows as one important characteristic that distinguishes BES transmission systems from local distribution systems. In order to identify systems that are not necessary for the operation of the BES under this text, we propose that any system where real power flows into the local distribution system 90 percent of the time or more under normal operating conditions.

Yes

Grant agrees that the SDT's fourth test, which asks whether power is intentionally transported through a system, identifies a key characteristic of local distribution facilities that distinguishes such facilities from interconnect bulk transmission facilities that are properly considered part of the BES. In fact, we believe this may be the most important and readily identifiable distinction. Accordingly, Grant agrees that if power is not intentionally transported through a particular system, that system is not used for transmission and should not be considered part of the BES. One exception may be for a small embedded generation unit owned by a different party that may be "scheduled" out of an area, but in reality, does not produce any physical flow. These circumstances should not trigger inclusion.

Yes

We agree conceptually with the idea that two different paths to exclusion should be adopted, one relying upon readily identifiable characteristics that are ordinarily associated with local distribution and not BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES. Grant supports the technical arguments and the White Paper presented by Snohomish County PUD in their comments. We recommend that the SDT modify its approach to the technical exclusion process to match the approach advocated in the White Paper, which is based upon the approach recommended by the WECC BES Task Force.

The use of distribution factors, such as Power Transfer Distribution Factors ("PTDF") and Outage Transfer Distribution Factor ("OTDF") provide insight into the relative impedance of neighboring systems. However in the Western Interconnection it has never been a definitive indicator of whether a system fault with delayed clearing would impact a neighboring electric system. While we understand

that many entities from the Eastern Interconnection support the use of such factors, we believe the approach is unlikely to work in the Western Interconnection

Specific transient voltage dip thresholds are proposed at page 15 of Snohomish's White Paper. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should produce no more than a 20% voltage drop for no more than 20 cycles in a Category B contingency and no more than a 20% drop for 40 cycles in a Category C contingency. Technical justification for these thresholds is provided at pages 12-16 of the White Paper.

Page 15 of Snohomish's White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided at pages 12-16 of the White Paper.

Yes

As a general matter, we agree with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid showing that the Elements contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. We also agree that the SDT has, in general, identified the correct technical approach, although we recommend that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in the Snohomish PUD White Paper, in the WECC BES Task Force Proposal 6, and in our answer to Question 5.

No

As discussed on page 12 of the Snohomish White Paper, there may be a few isolated cases where additional data will need to be provided to run a valid technical analysis under the criteria set forth in the Exception Procedure. These cases should be exceedingly rare, however, because the starting point for the technical analysis we recommend is the current base case operated by the relevant Regional Entity, and in nearly every case, the base case can be expected to model any Element that conceivably has a material impact on the reliable operation of the bulk system. In those rare cases where it does not, we believe the owner or operator of the subject Element should be able to provide the needed data.

No

As properly constructed Definition and Exceptions process should meet the legal requirements of Section 215.

Yes

Grant generally supports the approach to the exclusion process proposed by the SDT, which provides two different paths to exclusion, one based on readily-identifiable operational characteristics of a system, and one based on technical reliability analysis. We believe it is important to provide for the first path, based on operational characteristics, so that systems that are marginally disqualified under the BES Definition (because, for example, generation within the system exceeds demand for a few hours a year) can obtain an exclusion without the large investment of resources that otherwise might be required for a full-scale technical analysis. That being said, we question whether the first subsection of the characteristic test, relating to system proximity, is necessary, and we are concerned that the requirement that a system meet all four requirements of the characteristics test may be overly restrictive. For example, it is easy to imagine a distribution system in a rural area that covers a widely dispersed area, so that load is many miles from the relevant generation/transmission source, and that the system therefore does not meet the electrical proximity element, but meets the other three elements of the characteristics test. Such a system should be excluded because it clearly serves a local distribution function, and not a transmission function, as demonstrated by the fact that the system meets subsections (c) (power flows into the system but rarely flows out ) and (d) (power is

not intentionally transported over the system). Accordingly, we recommend that the SDT consider eliminating the first test. In the alternative, the SDT should consider allowing exempting a system from the BES if it, for example, meets three of the four criteria rather than all four.

Hydro-Quebec TransEnergie

No

Close electrical proximity to load does not appear to be an appropriate criteria. There is no reason that this criteria would prevent exclusion of a radial system with long lines feeding far away loads. Instead of considering proximity to load, it would be better to consider the way the Element is connected to the BES and the function of the excluded part of the system, mainly to deserve loads or integrate some generation, but not to transfer power to another Balancing Authority. Those are covered by criteria b., c. and d., so we believe that criteria a. should not be maintained.

Yes

However, the point B.i. is hard to understand and would need clarification. Here is a proposal: "For an Element to be excluded from BES, its should be demonstrated that there are a proper disconnection procedure when facing a disturbance that would prevent this Element to impact the BES" ?. The point should be to make sure a fault on the Element will be isolated effectively without adverse impact on the BES, even when we have a second transmission source for the syb system seeking exclusion. Also, for point B. ii., it should be explained what is meant by the expression "regional dispatch". Is it an alternate way of transfer of power outside the Balancing Authority ?

Yes

However, this is only part of an exclusion. The point c. iv and v, MWh is not relevant for real-time operation. It would be more simple to put a time reference, such as a total number of days or a % of the time. In number iii, do you mean the first self certification ? In fact, the evidence for exclusion will be done once, but ROP suppose that the self certification will be done many times (every two years).

Yes

Yes

Comments on distribution factor measurement: The choice of the maximum distribution factor could be difficult to establish. For this point, the comparison of the distribution factor prior and after the events could be considered.

Comments on allowable transient voltage dip measurement: The TPL-001 to 004 do not specify any reference measurement for stability (such as Allowable transient voltage, frequency excursion, voltage deviation, etc.). Instead, it request that the system shall remain stable, without cascading or uncontrolled islanding. Also, it is requested that the Planning Entities shall define and document the criteria or methodology used in the analysis to identify System instability for conditions such as Cascading, voltage instability, or uncontrolled islanding. This is exactly what should be requested in the analysis and demonstration of Element seeking exclusion from BES. The analysis and burden of proof should be left to the Entity as is done in the TPL, considering that there are no common values with the different interconnection.

Yes

Technical demonstration should not be limited to technical principles stated in the "Technical Principles for Demonstrating BES Exceptions". Entities should be allowed to do their own demonstration with their own technical arguments. As an example, an Entity could consider a few level of application for the standards. As an example, the level #1 being the most important level, all standards would apply to this level, including more stringent criteria than the TPL standards. This would bring BES level #1 very robust and reliable, ensuring the reliability of the main system. A second BES level #2 could be define for local transmission to which would be applied most standards but excluding some of the C section of TPL. Attention would be given to proper reliable operation of the BES level #2. but with smaller level of investment on the design aspect. those regional

transmission part of the system being able to face higher risk for loss of continuity of service. Finally, for generation or Load Facility that would be excluded from both level of BES, minimum standards would still apply such as in protection or for generation. Through its own technical principles, the Entity could demonstrate that the highest level of BES is more reliable than what is expected by NERC's standard, but that in regional transmission part of the system, the C TPL standard would not apply with the only risk of lower continuity of service.

Yes

No

Yes

However, there is a conflict between the proposed approach and the regulatory framework applicable in the Quebec's Interconnexion or at least there are some important differences between both. Paragraph 95 of FERC Order 743 acknowledged the situation of non-FERC jurisdiction. As for the Quebec's Interconnexion, the BES definition and exclusion approach shall meet the expectations of Quebec's regulator, the Régie de l'Énergie du Québec, (Quebec Energy Board) which has the responsibility to ensure that electric power transmission in Quebec is carried out according to the reliability standards it adopts. In a recent order (D-2011-068), the Régie de l'Énergie du Québec has recognized several level of application for the Reliability Standards in Québec. It stated specifically that most reliability standards in Québec shall be applied to the Main Transmission System (MTS). One other level of application recognised by this decision is the NPCC Bulk Power System (BPS) to which the standards related to the protection system (PRC-004-1 and PRC-005-1) and those related to the design of the transmission system (TPL 001-0 to TPL-004-0) will be applicable (including the rest of the standards). The Main Transmission System definition is somewhat different than the Bulk Electric System definition. The Main Transmission System includes elements that impact the reliability of the grid, supply-demand balance and interchanges. It can be described as follows : The transmission system comprised of equipments and lines generally carrying large quantities of energy and of generating facilities of 50 MVA or more controlling reliability parameters: • Generation/load balancing • Frequency control • Level of operating reserves • Voltage control of the system and tie lines • Power flows within operating limits • Coordination and monitoring of interchange transactions • Monitoring of special protection systems • System restoration Therefore, it will be necessary to accommodate NERC's proposed definition of BES or the exception process with the Quebec situation where Entities are under a different jurisdiction. These differences include more than one level of application for the reliability standards, the Main Transmission System definition being the main one to which most reliability standards apply.

Eric Lee Christensen

for Snohomish County PUD

No

Snohomish agrees in principle that one characteristic of local distribution systems is that they are usually confined to a relatively limited geographic area, as opposed to transmission systems, which (especially in the West) tend to cover very large distances. We also believe the proximity test may be a sensible way to identify local distribution facilities. However, as explained in more detail in our response to Question 10, we believe that the proximity test may be unnecessary, and if an Element or group of Elements meets the other three tests proposed by the SDT, it should be excluded from the BES, even if it does not meet the proximity test. Further, using impedance to benchmark system load proximity would likely not yield clear demarcations. High voltage relative or per-unit impedances are considered typically much lower than low voltage impedances. Hence, in the absence of phase shifting

transformers, service compensation, or other mitigation factors, power typically flows over the highest voltage lines, which offer the lowest impedance.

Yes

Snohomish agrees conceptually that systems operating as radials rather than as integrated portions of the integrated bulk transmission system should be excluded from the BES definition. That is because local distribution systems typically operate adjacent to, or at the end of transmission lines, and function operationally to move power from the Transmission Service Provider's point of delivery of bulk power that has moved across the integrated bulk transmission system to end-users located within the local distribution utility's service territory. To be consistent with the draft BES definition, the term "radial in character" should be explicitly defined as a system that may include one or more lines into a load area or referenced as a local distribution network. In addition, we agree that the manner in which a system is operated during BES disturbances may be an indication of whether that system is radial in character. That being said, we are concerned that, to the extent the SDT considers regional disconnect procedures, it should be careful to note that UFLS and UVLS relays are often embedded within local distribution systems and, while it is necessary for the UFLS and UVLS relays to be properly armed to protect the BES in the event of a severe system disturbance, the local distribution system interconnected with those relays should not, and cannot legally, be classified as BES.

Yes

Snohomish agrees conceptually that one critical characteristic distinguishing local distribution facilities that must be excluded from the BES from transmission facilities that should be included is the manner in which power flows on those facilities. Power on local distribution systems generally flows only from the interconnected transmission source and across the distribution system for delivery to end-use customers. By contrast, power on transmission systems generally flows in two (or multiple, in networked systems) directions and is delivered in bulk to distribution utilities rather than to end-users. Hence, the SDT has properly identified power flows as one important characteristic that distinguishes BES transmission systems from local distribution systems. Snohomish also agrees conceptually that the fact that power may flow out of a local distribution system onto the grid during a few hours in a year or during extreme contingencies should not change the characterization of the system as local distribution. Accordingly, we support inclusion of power flow analysis as one element of characteristics that can be used to exclude local distribution facilities from the BES even if the facilities do not pass each of the bright-line thresholds laid down in the BES definition. We also agree that transactional and hourly generation records are an appropriate basis for making the determination since these can be used to demonstrate that demand within a local distribution system exceeds generation within that system in most hours and that power therefore does not flow onto the grid, and also to determine the number of hours where this is not the case and the amount by which generation within the system exceeds demand. In order to identify systems that are not necessary for the operation of the BES under this test, we propose that any system where real power flows into the local distribution system 90 percent of the time or more under normal ("N-0" or All Lines in Service) operating conditions should be held to meet this test. That a system meets this test could be demonstrated using metering or supervisory control and data acquisition ("SCADA") data records over the course on two years. In addition, the presence of generation within a local distribution system that only modifies the level of the load served by the bulk system, but does not result in power being injection into the bulk system, does not change the reliability effect of the local network and therefore should not require the local network to be classified as BES.

Yes

Snohomish agrees that the SDT's fourth test, which asks whether power is intentionally transported through a system, identifies a key characteristic of local distribution facilities that distinguishes such facilities from interconnect bulk transmission facilities that are properly considered part of the BES. In fact, we believe this may be the most important and readily identifiable distinction. As a matter of operation, power is scheduled across transmission lines. Further, transmission lines in the Western Interconnection (either individually or as part of a transmission path) are rated for total transmission capacity and available transmission capacity, and transmission rights can be purchased on such lines, if available, on an OASIS. Local distribution systems do not share any of these operational characteristics. Accordingly, Snohomish agrees that if power is not intentionally transported through a particular system, that system is not used for transmission and should not be considered part of the BES. We also agree that examining the Operating Procedures applicable to a particular system will

provide a ready guide to whether power is intentionally scheduled across that system. We suggest, however, that the SDT look beyond those protocols that fall within the NERC Glossary's definition of Operating Procedure. For example, in the West, transmission paths are almost all listed in the WECC Path Rating Catalog. Similarly, it is not clear whether scheduling protocols, OASIS operations, and the other factors listed above qualify as Operating Procedures. Hence, we urge the SDT to list such specific operational characteristics as part of this test.

Yes

We agree conceptually with the idea that two different paths to exclusion should be adopted, one relying upon readily identifiable characteristics that are ordinarily associated with local distribution and not BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES. Snohomish has prepared a White Paper proposing a performance-based approach to support the technical determination whether Elements should be excluded from the BES, which we attach to these comments and commend to the SDT for study. We also commend the work of the WECC BES Task Force and the WECC Technical Studies Subcommittee, both of which have devoted substantial time and resources to developing a workable and technically defensible process for excluding Elements classified as BES based upon their electrical characteristics. See WECC BES Task Force Proposal 6, App. A at 3-9 & App. B at pp. B-4 to B-7 (posted Feb. 18, 2011) (available at: <http://www.wecc.biz/Standards/Development/BES/default.aspx>). We recommend that the SDT modify its approach to the technical exclusion process to match the approach advocated in our White Paper, which is based upon the approach recommended by the WECC BES Task Force.

The use of distribution factors, such as Power Transfer Distribution Factors ("PTDF") and Outage Transfer Distribution Factor ("OTDF") provide insight into the relative impedance of neighboring systems. However in the Western Interconnection, such factors have never been a definitive indicator of whether a system fault with delayed clearing would impact a neighboring electric system. While we understand that many entities from the Eastern Interconnection support the use of such factors, we believe the approach is unlikely to work in the Western Interconnection. Based on the significant differences between the four major interconnections in North America, Snohomish suggests that a detailed technical exemption process be allowed on an interconnection-wide basis. The Western Interconnection is a "hub and spoke system" where loads are very remote from large generation plants, with margins that are based on stability limits. By contrast, the Eastern Interconnection is a tightly meshed system with loads and generation in close proximity, often creating margins that are based on thermal limitations. These differences manifest themselves in a variety of operations. For example, the Western Interconnection uses a rated paths methodology while the Eastern Interconnection uses transmission load relief mechanisms. Consistent with FERC Order 743-A, Snohomish supports exemption criteria for individual frequency independent regions, or interconnections.

Specific transient voltage dip thresholds are proposed at page 15 of Snohomish's White Paper. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should produce no more than a 20% voltage drop for no more than 20 cycles in a Category B contingency and no more than a 20% drop for 40 cycles in a Category C contingency. Technical justification for these thresholds is provided at pages 12-16 of the White Paper.

Page 15 of Snohomish's White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided at pages 12-16 of the White Paper.

Please see our response to Question 5d.

No

SNPD supports the exemption of generation interconnected to local distribution networks if the generation is less than 300 MW capacity and where the power generated is consumed within the LDN and rarely flows out of the LDN, using the proposed criteria described in our response to question 3. This proposal is consistent with the section III.c.4 [Exclusion] of the NERC Statement of Compliance Registry Criteria as well as the Load modifiers used in the Eastern Interconnection. "Load Modifiers" (small generators that only affect load at the distribution level)."

Yes
<p>As a general matter, we agree with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid showing that the Elements contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. We also agree that the SDT has, in general, identified the correct technical approach, although we recommend that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in our White Paper, in the WECC BES Task Force Proposal 6, and in our answer to Question 5. While we support the SDT's overall approach, we believe subsection (f) of the proposed inclusion criteria, which would allow NERC to "override this criterion" if it provides "additional justification" for doing so is both unnecessary and creates confusion and uncertainty in what is otherwise a clear and concise process. Subsection (f) is unnecessary because if the technical process laid out in subsections (a) through (e) fails to provide any evidence that the contested Element(s) create a material impact on the reliability of the bulk interconnected transmission network, there is no reason to classify those Element(s) as BES, and that should be the end of the question. Subsection (f) creates needless uncertainty because it allows NERC to override the technical criteria laid out in subsections (a) through (e) if "additional justification" is provided, but there is no suggestion as to what this additional justification might be. Nor is there any explanation as to why additional justification might be necessary after the criteria in subsections (a) through (e) have been exhausted.</p>
Please see our response to Question 5b.
Please see our response to Question 5c.
Please see our response to Question 5d.
Please see our response to Question 5d.
No
<p>As discussed on page 12 of our White Paper, there may be a few isolated cases where additional data will need to be provided to run a valid technical analysis under the criteria set forth in the Exception Procedure. These cases should be exceedingly rare, however, because the starting point for the technical analysis we recommend is the current base case operated by the relevant RE, and in nearly every case, the base case can be expected to model any Element that conceivably has a material impact on the reliable operation of the bulk system. In those rare cases where it does not, we believe the owner or operator of the subject Element should be able to provide the needed data, although we propose that the relevant owner or operator be relieved of this burden if it can be demonstrated that the nearest electrically interconnected Element has no material impact on the bulk system.</p>
Yes
<p>As we explained in considerable detail in our response to Question 1 of the Comment Form on the 1st Draft of Definition of BES, filed on May 27, Snohomish believes that the proposed BES Definition could conflict with Section 215 of the Federal Power Act if the Definition, the Exception Process, and the Technical Criteria do not effectively exclude facilities used in local distribution from the BES or if the BES definition does not focus on cascading outages, separation events, and instability on the interconnected bulk system. These statutory limits on the scope of the BES and reliability standards are a minimum that must be met.</p>
Yes
<p>Snohomish County PUD generally supports the approach to the exclusion process proposed by the SDT, which provides two different paths to exclusion, one based on readily-identifiable operational characteristics of a system, and one based on technical reliability analysis. We believe it is important to provide for the first path, based on operational characteristics, so that systems that are marginally disqualified under the BES Definition (because, for example, generation within the system exceeds demand for a few hours a year) can obtain an exclusion without the large investment of resources that otherwise might be required for a full-scale technical analysis. That being said, we question whether the first subsection of the characteristic test, relating to system proximity, is necessary, and we are concerned that the requirement that a system meet all four requirements of the characteristics test may be overly restrictive. For example, it is easy to imagine a distribution system in a rural area that covers a widely dispersed area, so that load is many miles from the relevant generation/transmission source, and that the system therefore does not meet the electrical proximity element, but meets the other three elements of the characteristics test. Such a system should be excluded because it clearly serves a local distribution function, and not a transmission function, as</p>

demonstrated by the fact that the system meets subsections (c) (power flows into the system but rarely flows out ) and (d) (power is not intentionally transported over the system). Accordingly, we recommend that the SDT consider eliminating the first test. In the alternative, the SDT should consider allowing exempting a system from the BES if it, for example, meets three of the four criteria rather than all four. We have pasted in the text of our White Paper below. Please contact us for a more readable version of the White Paper. White Paper A Performance-Based Exemption Process to Exclude Local Distribution Facilities from the Bulk Electric System April 2011 This White Paper proposes a transmission planning ("TPL") "performance-based" process to determine the local distribution facilities the North American Electric Reliability Corporation ("NERC") must exclude from the Bulk Electric System ("BES") pursuant to Section 215(a)(1) of the Federal Power Act ("FPA"). This process would apply to those local distribution facilities that are not automatically excluded under a bright-line BES definition. Consistent with Federal Energy Regulatory Commission ("FERC") Order Nos. 743 and 743-A, a performance-based exemption process would be objective, consistent, and transparent, and would adequately differentiate between local distribution and transmission, i.e., BES, facilities.

I. What Is Reliability? FPA Section 215 authorizes NERC to promulgate "reliability standards," subject to FERC approval. Section 215 defines "reliability standard" to mean a properly-approved requirement "to provide for the reliable operation of the bulk-power system." The statute, in turn, defines "reliable operation" to mean "operating the elements of the bulk-power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will not occur as a result of sudden disturbances, including . . . unanticipated failure of system elements."

II. What Is "Customer Service" or "Level of Service" ("LOS")? Local customer service or LOS relates to service failures on local utility systems that are wholly internalized rather than spilling onto the interconnected regional grid. These types of service failures relate to local customer service and LOS standards. The customers of those utilities will bear the full cost of complying with internal LOS standards and will obtain the full benefit of compliance to the extent that service levels on those systems improve. Accordingly, state public utility commissions (for regulated utilities) and independent boards (for non-regulated utilities) can fully and accurately weigh whether the benefits of compliance with such standards are justified by the costs they will pay. Intervention by NERC and a Regional Entity is not needed because a utility's actions related to level of service on its own system will neither unduly burden the customers of other systems, threaten the reliable delivery of power to those customers, nor create incidental benefits to those remote customers. In the absence of the need to protect customers of systems remote from the consequences of decisions made by an individual utility, there is no warrant for NERC or a Regional Entity to interfere with a utility's internal decision-making about the appropriate LOS to its own customers, and the costs that will be borne by those customers to achieve any particular level of service. In fact, in the "Savings Provisions" of Section 215, Congress specifically included language prohibiting NERC and Regional Entities from enforcing "compliance with standards for adequacy" of electric service. By law, these remain the exclusive province of local decision-makers.

III. The Need for a Material Impact Test In Order No. 743-A, FERC clarified that a material impact test is appropriate in the reliability context if the test can be shown to identify facilities needed for reliable operation. The following example of an outage demonstrates the need for an impact test to distinguish between LOS and Reliability, i.e., local distribution facilities and BES facilities.

A. Pre-Event Facts Local Utility Administration ("LUA") owns a 115 kV system that moves power from two points of delivery ("POD") and serves 1000 MW of load. A DC battery rack had an unexpected failure a few days after it was routinely inspected and LUA has not implemented Supervisory Control and Data Acquisition ("SCADA") so the DC battery voltage is not continuously monitored. The LUA system interconnects with BES Company's system which consists of 230 kV and 500 kV lines.

B. Event Facts A fault occurs and the breakers in substation 2 fail to operate due to a battery failure (Figure 1). This results in an outage for customers served by substations 1, 2, and 3 on the LUA system. Figure 1 C.

C. Post-Event Facts Immediately after the outage, LUA customer service receives numerous customer calls followed by a call from its Public Utility Commission/Local Utility Board ("PUC/LUB"). LUA dispatches crews immediately after being informed of the outage to identify and resolve the problem. Within 45 minutes, the fault is sectionalized and the all load is restored. The PUC/LUB receives complaints from LUA customers who identify economic and other adverse impacts of the outage. The PUC/LUB demands a report from the LUA that describes the event and restoration, as well as potential solutions. LUA submits a report which finds that the main solution to this problem involves the implementation of a SCADA system. The SCADA system scope of work includes battery voltage telemetry and would have identified the DC system issue and prevented the protection system failure,

resulting in only the loss of substation 3. The SCADA plan cost estimate is \$30 million and was presented three years earlier. The PUC/LUB evaluated the costs and benefits of the new SCADA system, but did not approve the project in order to reduce the budget and/or provide rate stability for the struggling local economy. LUA, the PUC/LUB, and customers will re-evaluate the merits of adding SCADA as well as other solutions such as increasing substation inspection runs, updating the battery fleet, and further investigating battery manufacture reliability records. Based on the LUA report, the battery bank failure rate immediately after routine inspections is expected to occur once every 3,500 years. Seventy battery banks are used on the LUA system, so a bank failure should be expected every 50 years. BES Company's neighboring 230kV and 500kV system does not experience an adverse system impact. Subsequently, BES Company identifies that one of its breakers operated at the LUA South POD. BES Company and LUA coordinate a review of the system protection scheme and BES Company determines that it operated correctly. BES Company verifies that the LUA outage did not create any thermal, voltage, or transient stability limit violations on the BES Company system. The Regional Entity, NERC, and FERC treat the outage as a Reliability Standards issue. The LUA System (highlighted in yellow) is considered part of the BES because it meets the "bright line" 20 MVA and 100 kV thresholds under the current BES definition and the NERC Statement of Compliance Registry Criteria ("SCRC"). The event would most likely be considered a TPL-003 category C event specifically C8 SLG Fault, with delayed clearing that may include a stuck breaker or protection system failure. The LUA Substation Department reviews its inspection records and has adequate documentation for the battery banks involved in the outage. As a result, LUA avoids substantial fines. However, during the inspection review, LUA notices that the battery bank in a similar distribution substation inspection schedule was completed three days late. Upon following further internal procedures, LUA finds that the battery bank was inspected three days late due to restoration efforts after a major wind storm. Although there were no LOS impacts, and the inspection schedule was unrelated to the outage, the Reliability Standards triggered a LUA self report to its Regional Entity which ultimately resulted in a \$50,000 penalty.

D. Summary This example identifies that in addition to a "bright line" BES exclusion process a more refined process such as a "performance based" reliability assessment is needed to distinguish BES facilities from distribution facilities if the NERC Statement of Compliance Registry Criteria ("SCRC") continues to be the benchmark for assessing BES facilities. It is clear from this example that the current 100 kV and 20 MVA thresholds cannot accurately classify what is and is not considered part of the BES. Defining BES facilities is important from the "Reliability Standard" and "LOS" perspectives as well as from a local and regional jurisdictional standpoint. There are multiple agencies identifying and approving what facilities should and should not be built, what programs should and should not be implemented, and if a fine should be paid by customers experiencing an outage without determining if it could have had an adverse impact on neighboring electric systems. Without a performance-based process, many small and medium electric utilities would be unnecessarily burdened.

IV. Neighboring System Rule It is important but not always easy to distinguish the difference between "reliability" and "LOS" impacts. One way to resolve this is to use the "neighboring system rule." Simplistically, if events on the host system's facilities can create an "adverse" or "material" impact on a neighboring electric (TO, TOP, BA) system, those facilities should be considered part of the BES as they are creating a reliability impact. If not, these facilities should not be considered part of the BES.

V. "Adverse" or "Material" Impact A key question in applying the "neighboring system rule" is what is an "adverse" or "material" impact, and what "performance based" assessment should be used to benchmark adverse or material. Because the electric system within an interconnection is frequency interdependent, theoretically every system change impacts the interconnected system to some degree. Turning on a light-switch that is connected to an operational 20 watt CFL (light bulb) theoretically impacts frequency, although to an undetectable degree. Therefore the term "material" or "adverse" impacts must be defined to distinguish observable impacts that affect reliability from minutia. A number of performance based exclusion examples have been proposed that use, Power Transfer Distribution Factors ("PTDF"), Line Outage Distribution Factors ("LODF"), fault duty or short circuit levels, reactive margin studies (P-V and Q-V), abbreviated or focused powerflow and transient stability analysis, as well as complete TPL assessment using multiple seasonal base cases, loading conditions, transfer levels. These methods demonstrate various metrics, they rank system strength (both real and reactive), the ability of power to flow through system under normal and outage conditions, and they determine steady state, voltage stability and transient (angular) stability performance. Although there may be advantages to a multi-step "performance based" approach that includes the exclusion examples above, this paper proposes a TPL-based assessment that is consistent with BES performance benchmarks used in assessing transmission

system performance in North America. The Western Electricity Coordinating Council ("WECC") BES Exclusion/Inclusion Assessment – 2-16-11 version provides a sound metrics in assessing the performance of a system as well as determining if a system can materially impact a neighboring system (Figure 2). It would be envisioned that each interconnection would develop a "Disturbance Performance Table of Allocable Effects on Other System". This table is necessary because the NERC TPL Performance Table does not provide actual performance details on acceptable transient and post transient voltage perturbations or minimum transient voltage frequencies. Figure 2 show the approved TPL-001 through TPL-004 performance tables. Figure 3 - Table 1 from the NERC TPL Reliability Standards VI. Performance Based Assessment Process The "performance based" methodology below is based on the "neighboring system rule" and the WECC BES Exclusion/Inclusion Assessment – 2-16-11 that was developed by the WECC Bulk Electric System Definition Task Force ("BESDTF"). The process focuses on exclusions rather than inclusion and specific response times, schedules, and process details have been removed as this will likely need to be determined by each, Regional Entity Representing the Interconnection ("RERI")

A. Purpose The purpose of this document is to set forth a "performance based" technical process for assessing whether elements with a nominal operating voltage greater than 100 kV and outside the NERC SCRC based excursion process should be excluded from the Bulk Electric System. An element is necessary to reliably operate an interconnected transmission system if it significantly affects neighboring Transmission Owners, Operators, and Balancing Authorities as described in Table 1 below. This paper proposes a method for assessing whether an element is necessary to support the reliability of an interconnected transmission system or if the element is limited to supporting local customer service levels.

B. Terms

Exclusion Assessment (EA) An assessment of whether a Subject Element or System has a material impact on neighboring Transmission Owners, Operators, and Balancing Authorities as described in Table 1 below and conducted in accordance with the process set forth in this document.

EA Base Case The interconnection approved, Base Case as modified to include the Subject Element, used to perform the assessment described in this document.

Regional Entity Representing the Interconnection The regional entity representing the interconnection

Registered Entity The entity registered to comply with mandatory reliability standards for a Registered Function.

Responsible Entity The entity responsible for performing the EA and verifying the results of the EA to the interconnection.

Subject System or Element of a System The System or Element of a System that is being examined by the EA.

C. Applicability

a. An EA may be performed:

- By a registered entity, or by a third party on behalf of a registered entity, to assess whether a Subject Element or system has a material impact on neighboring Transmission Owners, Operators, and Balancing Authorities as described in Table 1 may be excluded from the BES as set forth by the RERI.
- The RERI, or by a third party on behalf of the RERI, to assess whether a Subject Element or system has a material impact on neighboring Transmission Owners, Operators, and Balancing Authorities as described in Table 1 should be included as part of the BES as set by the RERI.

b. Frequency of analysis. The confirmed findings of an EA are valid until reversed by a subsequent EA. A new EA is required if:

- Significant changes are made to the network topology in the vicinity of the Subject Element; or
- RERI staff requests a new EA. Such request shall be provided in writing and shall include reasonable justification for the request.

D. Notifying the RERI of the Responsible Entity's intent to submit an EA finding or to perform an EA. The Responsible Entity shall notify the RERI in writing of its intent to submit such a finding. Such notice shall include:

- A general description of the Subject Element(s);
- One-line diagrams representing the Subject Element and applicable neighboring Elements; and
- A description of the base case that will be used in performing the EA and how that case will be stressed for the analysis.

E. Performing the Analysis

Base Case The base case(s) used for the studies shall be developed from current interconnection Operating Cases and shall simulate stressed conditions in the area of the element to be analyzed which (1) are reasonably expected to be achieved, consistent with the study period selected (e.g., hydro generation shall reflect seasonal water availability patterns) and (2) are expected to provide "worst-case" results (i.e., the greatest impact on voltage, flow, or transfer capability) during the upcoming operating year. The base case(s) shall be "stressed" by committing or de-committing generating units and adjusting generating unit output to increase the flow on the candidate element and the electrically nearest rated interconnection transfer path to the greatest extent possible, but not beyond their continuous ratings, for the initial set of conditions. To help minimize the possibility of dispute as to whether the base case(s) are suitably stressed, entities are encouraged to solicit input from subregional planning groups or other planning entities as the suitability of the base case(s) before undertaking the analyses described below.

- Non-represented Elements. If the Subject Element is not represented in the EA Base case:

- The Responsible Entity

shall provide to the RERI a written request to add the Responsible Entities data to the cases: o all data reasonably necessary to accurately and completely model the Subject Element in the EA Base case; and o A one-line diagram showing this element and other nearby Elements. If the nearest connected Element is not found to be necessary for the operation of an interconnected transmission system, the RERI shall notify the Responsible Entity to take no further action. F. Performance Based Methodology The impact an System or Element has on neighboring Transmission Owners, Operators, and Balancing Authorities as described in Table 1 shall be determined by assessing the performance of key measures of BES reliability through power flow, post-transient, and transient stability analysis with (1) the system, and the Subject Element, operating at reasonably stressed conditions that replicate expected system conditions under which the loss of the Subject Element would have the greatest impact on the key measures of reliability, and (2) the Subject Element removed from service, but without allowing for system readjustment. For the purposes of this analysis, "Elements" may be: (1) lines; (2) transformers; (3) buses or bus sections; (4) generating units; (5) shunt devices . i. Simulation 1: Requirement: Meet applicable NERC Reliability Standard (TPL-002 and TPL-003) and the RERI Disturbance Performance Table of Allocable Effects on Other System" Criteria performance for NERC TPL-002 and TPL-003 disturbances. Step 1: Run appropriate TPL-002 (N-1 contingency) studies of elements in the electrical vicinity of and including the Candidate Element (i.e., simulate primary protection operates as intended) Step 2: Run appropriate TPL-003 (N-2 contingency) studies of elements in the electrical vicinity of and including the Candidate Element. This would include both N-2 contingencies in which the Candidate Element would simultaneously be lost as part of a common mode failure, as well as contingencies in which the Candidate Element's primary protection fails. Automatic Remedial Action Schemes ("RAS") or Special Protection Schemes ("SPS") that are fully redundant (i.e., their failure is not credible) may be triggered during this simulation. If the failure of the RAS/SPS is a credible event, it should be considered as part of the N-2 analysis. ii. Simulation 2: Requirement: Remove the Candidate Element. Do not allow for system adjustment, and re-solve the base case. Then conduct applicable NERC Reliability Standard (TPL-002 and TPL-003) contingencies. Step 1: Remove Candidate Element (i.e., simulate unplanned opening of facility). Step 2: Assume no system adjustment. At this point, elements may be loaded above their continuous ratings but may not be loaded above their emergency ratings. Step 3: Perform NERC TPL-002 and TPL-003 (N-1 and N-2 contingency) studies. Step 4: If the analysis demonstrates performance that meets or exceeds that called for in the NERC Reliability Standards and RERI System Performance Criteria, the Candidate Element would be determined to not be necessary for the operation of an interconnected transmission system. Note: Consequential load tripping is allowed, and consequential and out-of-step generation tripping is allowed. Criteria Table 1: RERI Disturbance-Performance Table of Allowable Effects on Other Systems NERC and WECC Categories Outage Frequency Associated with the Performance Category (outage/year) Transient Voltage Dip Standard Minimum Transient Frequency Standard Post Transient Voltage Deviation Standard A System normal Not Applicable Nothing in addition to NERC B One element out-of-service  $\geq 0.33$  Not to exceed 25% at load busses or 30% at non-load busses. Not to exceed 20% for more than 20 cycles at load busses. Not below 59.6Hz for 6 cycles or more at a load bus. Not to exceed 5% at any bus. C Two or more elements out-of-service 0.033 – 0.33 Not to exceed 30% at any bus. Not to exceed 20% for more than 40 cycles at load busses. Not below 59.0Hz for 6 cycles or more at a load bus. Not to exceed 10% at any bus. D Extreme multiple-element outages < 0.033 Nothing in addition to NERC Figure 1. Voltage Performance Parameters RERI TPL criteria related to reactive power resources: 1. For transfer paths, voltage stability is required with the pre-contingency path flow modeled at a minimum of 105% of the path rating for system normal conditions (Category A) and for single contingencies (Category B). For multiple contingencies (Category C), post-transient voltage stability is required with the pre-contingency transfer path flow modeled at a minimum of 102.5% of the path rating. 2. For load areas, voltage stability is required for the area modeled at a minimum of 105% of the reference load level for system normal conditions (Category A) and for single contingencies (Category B). For multiple contingencies (Category C), post-transient voltage stability is required with the area modeled at a minimum of 102.5% of the reference load level. For this criterion, the reference load level is the maximum established planned load limit for the area under study. 3. Specific requirements that exceed the minimums specified in 1 and 2 may be established, to be adhered to by others, provided that technical justification has been approved by the RERI. 4. Item 3 applies to internal interconnection Systems. Submitting a Proposed Finding of Exclusion to the Regional Entity Information required. Once the analysis has been performed and the Subject Element/System has been determined to not have a material impact on neighboring Transmission Owners, Operators, and

Balancing Authorities as described in Table 1, and is unnecessary for the operation of an interconnected transmission system, the Responsible Entity shall submit the findings to the RERI. RERI Review of Proposed Findings The RERI operational/planning staff with technical expertise in powerflow studies shall review Proposed Findings of Exclusion submittals and shall determine if the assessment is deficient or agrees with the finding of exclusion. The RERI shall exempt the system elements from the BES, if the elements are approved for exclusion. If the exclusion of the BES elements change the Responsible Entities NERC functional registrations the Region shall support the Responsible Entity through the NERC deregistration process. Dispute Resolution A Responsible Entity or Registered Entity or Owner may appeal a Disputed Finding of Exclusion with the RERI to NERC. Ongoing Responsibilities a. Logging. The RERI shall create and maintain a comprehensive list, available for public review, of: i. All Elements with nominal operating voltages at or above 100 kV that have Confirmed Findings of Exclusion, or, through other aspects of the BES definition, have been excluded from the BES including an explanation of how the element was excluded through the definition; ii. All Elements with nominal operating voltages below 100 kV that have Findings of Inclusion; and iii. The status of all EAs in dispute. iv. The Responsible Entity would continue to provide system data to the neighboring Balancing Authorities and Transmission Owners and Operators and if applicable continue to coordinate underfrequency load shed and under voltage load shed scheme information. VII. Conclusion NERC should adopt the TPL-based assessment as proposed herein. A bright-line BES test will not exclude all load distribution facilities as required by the FPA. Further, a performance-based exemption process would be objective, consistent, and transparent, and would adequately differentiate between local distribution and transmission, i.e., BES, facilities.

Individual

Bill Dearing

Northwest Public Power Association (NWPPA)

No

We believe that the proximity test may be unnecessary, and if an Element or group of Elements meets the other three tests proposed by the SDT, it should be excluded from the BES, even if it does not meet the proximity test. Secondly, using impedance to benchmark system load proximity would likely not yield clear demarcations. High voltage relative or per-unit impedances are considered typically much lower than low voltage impedances. Hence, in the absence of phase shifting transformers, service compensation, or other mitigation factors, power typically flows over the highest voltage lines, which offer the lowest impedance.

Yes

NWPPA agrees conceptually that systems operating as radials rather than as integrated portions of the integrated bulk transmission system should be excluded from the BES definition. That is because local distribution systems typically operate adjacent to, or at the end of transmission lines, and function operationally to move power from the Transmission Service Provider's point of delivery of bulk power that has moved across the integrated bulk transmission system to end-users located within the local distribution utility's service territory. To be consistent with the draft BES definition, the term "radial in character" should be explicitly defined as a system that may include one or more lines into a load area or referenced as a local distribution network. In addition, we agree that the manner in which a system is operated during BES disturbances may be an indication of whether that system is radial in character. That being said, we are concerned that, to the extent the SDT considers regional disconnect procedures, it should be careful to note that UFLS and UVLS relays are often embedded within local distribution systems and, while it is necessary for the UFLS and UVLS relays to be properly armed to protect the BES in the event of a severe system disturbance, the local distribution system interconnected with those relays should not.

Yes

NWPPA agrees conceptually that one critical characteristic distinguishing local distribution facilities that must be excluded from the BES from transmission facilities that should be included is the manner in which power flows on those facilities. Power on local distribution systems generally flows only from the interconnected transmission source and across the distribution system for delivery to end-use customers. By contrast, power on transmission systems generally flows in two (or multiple, in networked systems) directions and is delivered in bulk to distribution utilities rather than to end-users. Hence, the SDT has properly identified power flows as one important characteristic that distinguishes BES transmission systems from local distribution systems. In order to identify systems

that are not necessary for the operation of the BES under this text, we propose that any system where real power flows into the local distribution system 90 percent of the time or more under normal operating conditions.

Yes

NWPPA agrees that the SDT's fourth test, which asks whether power is intentionally transported through a system, identifies a key characteristic of local distribution facilities that distinguishes such facilities from interconnect bulk transmission facilities that are properly considered part of the BES. In fact, we believe this may be the most important and readily identifiable distinction. Accordingly, NWPPA agrees that if power is not intentionally transported through a particular system, that system is not used for transmission and should not be considered part of the BES. One exception may be for a small embedded generation unit owned by a different party that may be "scheduled" out of an area, but in reality, does not produce any physical flow. These circumstances should not trigger inclusion.

Yes

We agree conceptually with the idea that two different paths to exclusion should be adopted, one relying upon readily identifiable characteristics that are ordinarily associated with local distribution and not BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES. NWPPA supports the technical arguments and the White Paper presented by Snohomish County PUD in their comments. We recommend that the SDT modify its approach to the technical exclusion process to match the approach advocated in the White Paper, which is based upon the approach recommended by the WECC BES Task Force.

The use of distribution factors, such as Power Transfer Distribution Factors ("PTDF") and Outage Transfer Distribution Factor ("OTDF") provide insight into the relative impedance of neighboring systems. However in the Western Interconnection it has never been a definitive indicator of whether a system fault with delayed clearing would impact a neighboring electric system. While we understand that many entities from the Eastern Interconnection support the use of such factors, we believe the approach is unlikely to work in the Western Interconnection.

Specific transient voltage dip thresholds are proposed at page 15 of Snohomish's White Paper. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should produce no more than a 20% voltage drop for no more than 20 cycles in a Category B contingency and no more than a 20% drop for 40 cycles in a Category C contingency. Technical justification for these thresholds is provided at pages 12-16 of the White Paper.

Page 15 of Snohomish's White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided at pages 12-16 of the White Paper.

See response to 5d

No

None

Yes

As a general matter, we agree with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid showing that the Elements contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. We also agree that the SDT has, in general, identified the correct technical approach, although we recommend that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in the Snohomish PUD White Paper, in the WECC BES Task Force Proposal 6, and in our answer to Question 5.

No

As discussed on page 12 of the Snohomish White Paper, there may be a few isolated cases where additional data will need to be provided to run a valid technical analysis under the criteria set forth in the Exception Procedure. These cases should be exceedingly rare, however, because the starting point for the technical analysis we recommend is the current base case operated by the relevant Regional Entity, and in nearly every case, the base case can be expected to model any Element that conceivably has a material impact on the reliable operation of the bulk system. In those rare cases where it does not, we believe the owner or operator of the subject Element should be able to provide the needed data.

No

As properly constructed Definition and Exceptions process should meet the legal requirements of Section 215.

Yes

NWPPA generally supports the approach to the exclusion process proposed by the SDT, which provides two different paths to exclusion, one based on readily-identifiable operational characteristics of a system, and one based on technical reliability analysis. We believe it is important to provide for the first path, based on operational characteristics, so that systems that are marginally disqualified under the BES Definition (because, for example, generation within the system exceeds demand for a few hours a year) can obtain an exclusion without the large investment of resources that otherwise might be required for a full-scale technical analysis. That being said, we question whether the first subsection of the characteristic test, relating to system proximity, is necessary, and we are concerned that the requirement that a system meet all four requirements of the characteristics test may be overly restrictive. For example, it is easy to imagine a distribution system in a rural area that covers a widely dispersed area, so that load is many miles from the relevant generation/transmission source, and that the system therefore does not meet the electrical proximity element, but meets the other three elements of the characteristics test. Such a system should be excluded because it clearly serves a local distribution function, and not a transmission function, as demonstrated by the fact that the system meets subsections (c) (power flows into the system but rarely flows out ) and (d) (power is not intentionally transported over the system). Accordingly, we recommend that the SDT consider eliminating the first test. In the alternative, the SDT should consider allowing exempting a system from the BES if it, for example, meets three of the four criteria rather than all four.

Group

Transmission Access Policy Study Group

Cynthia S. Bogorad

No

Impedance is a function of a line's length; it does not measure whether a line serves a BES function. A very long line can exist only to serve load, and a short line in an urban area (where the load is physically close to the grid) could be needed for transmission but would have low impedance. This proposed metric is thus both over- and under-inclusive, and should be discarded. Transfer distribution factor is a more appropriate metric, as described in TAPS' response to Question 4. TAPS supports having two paths for exclusions, one that includes extensive technical analysis and another that does not. The path with less technical analysis is appropriate for Elements that a relatively high-level examination shows to be not relevant to the reliability of the grid. This opportunity should be available in the context of exclusions to reduce the burden on small entities. Reliability will not be impaired by this option; all exception requests will be reviewed by NERC, and in any case where NERC is less than certain that an exception is appropriate, NERC can perform any or all of the analyses that would be required for a more technical exclusion or inclusion, and a positive result would be sufficient justification to deny the exclusion request.

No
We believe that this criterion is intended, like those in 1(a) and (d), to determine whether an Element is planned and operated to function as part of the interconnected grid. It is, however, too vague to be useful and should be discarded.
The third item is "power flows into the system, but rarely flows out." This criterion is vague. TAPS suggests instead the following language, which is consistent with TAPS' comments on Exclusion E3 of the BES definition: "Neither the Element, nor any Elements that it connects to the grid (in aggregate), includes more than 75 MVA of generation used to meet the resource-adequacy requirements of electric utilities."
Yes
TAPS supports the criterion in concept, but "intention[]" is a vague term and not relevant to an Element's impact on the grid. We suggest instead that to obtain an exclusion for such a quasi-radial Element, the owner be required to demonstrate that energy transfers subject to NAESB TLR procedures (Interchange Transactions or BES generator to load) have no more than a 5% transfer distribution factor (TDF) on the Element that is a candidate for exception. Transfer distribution factor is a good measure of an Element's impact on the grid and is not subject to varying interpretations.
Yes
TAPS supports including specific technical criteria that Elements must meet to obtain an exclusion through the exception process. This approach will facilitate uniform application of the exception process. TAPS responds to the first five proposed criteria in response to 5b-5e below. The seventh proposed criterion, "No cascading outages," is insufficiently granular and should be discarded. The criteria are intended to measure whether, among other things, a particular Element can cause a cascading outage. They need to set out how decision-makers will determine whether an Element can cause a cascading outage, not simply state that an Element that can cause a cascading outage cannot be excluded from the BES.
The first proposed criterion, "Having a distribution factor of 5% for any other Element," should instead be "Having a distribution factor of 5% for curtailable Interchange Transactions or BES generator to load identified in Transmission Loading Relief stages one through five." An Element with a higher distribution factor only on a non-BES Element should not be considered part of the BES on that account.
The second criterion, "Allowable transient voltage dip – criteria TBD," should specify where the transient voltage dip is, i.e. "Allowable transient voltage dip on another BES Element for events on the Element that is the subject of the Exception Request—criteria TBD."
The third proposed criterion, "Allowable transient frequency excursion – criteria TBD," should be rephrased like the second: "Allowable transient frequency excursion on another BES Element for events on the Element that is the subject of the Exception Request – criteria TBD."
The fourth proposed criterion should be revised in the same way as the second and third: "Voltage deviation on another BES Element for events on the Element that is the subject of the Exception Request – criteria TBD." The fifth proposed criterion should be similarly revised: "Transient Stability on another BES Element for events on the Element that is the subject of the Exception Request – positively damped."
Yes
TAPS proposes a simpler set of exclusion exception criteria: 1. Having a distribution factor of 5% for curtailable Interchange Transactions or BES generator to load identified in Transmission Loading Relief stages one through five; 2. Category B and C contingencies on the Element that is the subject of the Exception Request meet the TPL-002 criteria for other BES Elements. (With the new TPL-001-3 standard recently approved by ballot, Category P0 through P7 contingencies on the Element that is subject of the Exception Request meets the criteria of P0 through P3 for other BES Elements); and 3. The Element that is the subject of the Exception Request is not: (1) part of an IROL, (ii) part of a blackstart or cranking path used in a TOP's restoration plan, or (iii) used in NUC-001 to provide service to a nuclear plant. TAPS believes these three criteria meet the intent of all of the criteria presented by the SDT.
TAPS supports using a uniform set of technical criteria to decide inclusion exceptions. Such an approach will facilitate uniform application of the criteria. It is appropriate for there to be only one path, using technical analysis, for inclusions, because the analysis for inclusions should be performed

by Regional Entities and NERC (see TAPS comments on the BES Exception Process, also submitted today), which have more resources available than do the small entities that TAPS believes are likely to request exclusions based on the path for exclusions that does not include extensive technical analysis. In addition to having clear and uniform criteria, the technical analysis for inclusions and exclusions should use the same criteria (though one should of course be the inverse of the other). We note that the steps laid out for Inclusions do not quite track those in Exclusions 2(a). For example, Inclusions 1(b) states, confusingly, "Monitor the contribution of the disputed Element(s)," but there is no corresponding step in Exclusions 2(a). TAPS suggests that Inclusions 1 be revised to mirror Exclusions 2.

See TAPS comments in response to Question 5.

See TAPS comments in response to Question 5.

See TAPS comments in response to Question 5.

See TAPS comments in response to Question 5.

Yes

The third paragraph of the introduction to the Technical Principles is awkwardly worded and might be misconstrued. TAPS suggests the following rewording: "Entities are not required to seek exceptions under the Exception Procedure to exclude from the BES Element(s) that are already excluded under the BES definition and designations." For the sake of consistency, Exclusions (1) should contain a provision analogous to Exclusions (2)(b) and Inclusions (1)(f) addressing the circumstances under which the ERO can override a demonstration based on these criteria. As noted above, one of those circumstances would be a demonstration by NERC that the Element in question meets the criteria for inclusion in the BES.

Andrew Z Pusztai

American Transmission Company, LLC

No

ATC believes the relevance and rationale for this criterion is unknown. If this criterion is intended to exempt elements, like circuit switchers, that are part of the distribution transformer circuits operated above 100 kV, and located within a mile of the BES interconnection point, then ATC would expect the wording to be "in close electric proximity to the BES" rather than in "close electric proximity to Load". Otherwise, ATC requests the SDT explain the relevance and rationale for this criterion before agreeing on its inclusion.

No

Radial in Character – ATC proposes that this criterion be eliminated because it does not describe any materially different characteristics beyond Exclusion E1 of the bright-line BES definition.

No

ATC proposes that this criterion be eliminated because it does not describe any materially different characteristics beyond Exclusion E3 of the bright-line BES definition.

No

ATC proposes that this criterion be eliminated because it does not describe any materially different characteristics beyond Exclusion E3 of the BES definition.

No

ATC proposes that this technical analysis criterion be replaced by criteria that are more closely tied to the Adequate Level of Reliability (ALR) characteristics. The following alternate criteria are offered as possible examples, "(1) the BES can be controlled to stay within acceptable limits following a fault on or loss of the Element; (2) the BES performs acceptably after credible contingences of the Element; (3) the Element does not limit the impact and scope of instability and cascading outages when they occur; (4) BES facilities are protected from unacceptable damage by operating the Element within its ratings; and (5) the BES has the ability to supply the aggregate electric power and energy requirements of the electricity consumers at all times, taking into account scheduled or reasonably expected unscheduled outages of the Element. In addition, ATC is not aware of any continent-wide appropriate BES performance measures for voltage dip, frequency excursion, voltage deviation,

<p>stability, etc. and ATC speculates that different values are likely for different regions and system characteristics across the continent. As a result, ATC believes it is not advisable to try to adopt unproven values without reasonable industry investigation and development.</p>
<p>ATC proposes replacing this factor with those cited above in 5a because a distribution factor measurement indicates how much system changes affect the element, not how much a fault or loss of the element would compromise the ALR of the BES. There is no clear correlation between this factor and any of the six characteristics of Adequate Level of Reliability (ALR) of the BES.</p>
<p>ATC proposes replacing this factor with those cited above in 5a because there is presently no established, continent-wide, acceptable transient voltage dip performance level for evaluating whether a fault or loss of the element would not compromise the ALR of the BES. In addition, the appropriate performance level for this factor may vary for different areas and system characteristics across the continent.</p>
<p>ATC proposes replacing this factor with those cited above in 5a because there are established, continent-wide transient frequency performance levels in the PRC-006-1 standard, but the elements that are applicable to the standard do not have to be BES elements and the transient frequency response requirements are not intended to be a criterion for BES classification.</p>
<p>ATC proposes replacing this factor with those cited above in 5a because there is presently no established, continent-wide, acceptable (steady state) voltage deviation performance level for evaluating whether a fault or loss of the element would not compromise the ALR of the BES. In addition, the appropriate performance level for this factor may vary for different areas and system characteristics across the continent.</p>
<p>Yes</p>
<p>ATC recommends this process address the five characteristics of the Definition of Adequate Level of Reliability (ALR) as listed in the comments above in Question #5a.</p>
<p>No</p>

No
No
Yes
<p>1. ATC proposes replacing the wording in the Exclusion preface, Exclusion 2 preface, and Inclusion 1 preface of “not necessary to reliably operate the interconnected transmission network” with “necessary to maintain an Adequate Level of Reliability (ALR) of the Bulk Electric System”. 2. ATC has reservations on the following statement made in the introduction of this document: “ Due to the importance of Blackstart Resources and their designated blackstart Cranking Paths to restoration efforts, no exceptions will be allowed for those items.” This does not allow for a provision to exclude any designated Blackstart Cranking Path (at any voltage) even though there may be technical justification for it. 3. The first page states that “Specific content of this application is spelled out elsewhere in this appendix.” ATC requests the SDT describe where this appendix will be published. Furthermore, is it a compliance document or just technical “guidance”? 4. Having the following statement included for both exclusions and inclusions will create disagreement: “The ERO can override this criterion but would need to provide additional justification to support their finding.” ATC believes any override should have adequate technical justification and not interfere with other statutory requirements. Also, it does not clarify or identify who would make the determination whether NERC has made adequate justification to override the criterion.</p>

No
The purpose of this exception is unclear. It would be possible that a large transmission station with many network connections, which is close to a load (irrespective of size), would be excluded from the BES definition. Similarly, a reduction of system impedance, by transmission line re-conductoring for example, could remove assets out of the scope of the BES definition. The listed proposed criteria suggest values yet to be determined. It is unclear how this exception would support BES reliability.
No
The proposed criteria to substantiate a request for an exception should be removed as it does not introduce anything different than what is already proposed under the exclusions in the bright line BES definition. Specifically, radial systems are already excluded in the bright line definition E1.
No
Vague language such as “rarely” or “not intentionally” does not support a “bright line” approach, and is not measureable or auditable. Also, the sample evidence should not be included as part of the criteria. In addition, the proposed criteria to substantiate a request for an exception should be removed as it does not introduce anything different than what is already proposed under the exclusions in the bright line BES definition. Specifically, this item is already excluded in the bright line definition E3.
No

Specifically, this item is already excluded in the bright line definition E3.
No
Manitoba Hydro does not agree with an impact based approach to establishing BES elements as we believe it will result in regional differences in the application of the BES definition. In addition, the resources required to verify the assumptions made in the models used to substantiate a BES exception would be substantial with no benefit to reliability. As well, this section appears to be an incomplete process. As currently worded, if the model was not updated in step ii, then there is no requirement to run the TPL studies indicated in the remainder of step ii.

No
No
Manitoba Hydro does not agree with an impact based approach to establishing BES elements as we believe it will result in regional differences in the application of the BES definition. In addition, the resources required to verify the assumptions made in the models used to substantiate a BES exception would be substantial with no benefit to reliability.
No
We are concerned however that assumptions could be made to complete the technical analysis to support an exclusion that may not be appropriate.
Yes
Canadian Entities are not under FERC jurisdiction, so the revised BES Definition may not apply. A number of Canadian Entities have the BES defined within their provincial legislation. This may introduce differences and even contradictions between elements that are included in the BES according to provincial legislation and the NERC definition.
Yes
The exception procedure is a complicated and resource intensive process. To be most effective, the BES definition should be a stand-alone 100kV bright line with any exception criteria being specified within the definition. Additionally: -FERC Order 743 directed the revision of the Bulk Electric System (BES) definition to improve clarity, to reduce ambiguity, and to establish consistency across all Regions. The proposed impact based exception procedure undermines all three of these targets. -The Technical Exceptions eliminate the 100kV 'bright-line' definition and introduce regional differences, both of which are contradictory to the goals of the BES revision project. -The commitment for NERC to review and continuously monitor BES exceptions made through this process would be extremely onerous and resource intensive with little benefit to reliability. -To obtain industry consensus on the precise limits to determine if an element has sufficient impact on the BES to be included in the BES is not a reasonable or attainable endeavor.

No
The SRC fails to see how electrical proximity to load qualifies an element for exclusion from the BES. Such elements may indeed be involved in serving electricity to those loads. If those loads are critical loads, then why should the element be excluded from the BES?
No
The SRC generally agrees that radial elements likely may be excluded from the BES. However, there is insufficient information given as to what it means to be "not operated as part of the BES with disconnection procedures for when a Disturbance occurs". Further, is it possible that such radial elements are serving a remote "critical" load? One would think that, normally, critical loads would have arrangements for multiple sources, but could those multiple sources be individually considered to be radial?
No
The SRC believes that, if power EVER flows out, then the area is either not radial or it includes generation resources. There is insufficient information to determine whether this "limited quantity of energy" is indeed small. There could be very large amounts of load and generation resources within

that area. Such large quantities could represent a significant potential for sudden increases in load or unexpected energy injections.

No

Hasn't the reliability concern associated with "loop flows" been related to the unintentional flow of power through parts of the system?

Yes

Predictive analysis of an accurate model is useful in determining the importance of various elements of the system.

Distribution factors by themselves are not sufficient evidence that elements are not important to the system. Multiple elements may have significant distribution factors related to various portions of the system, but that doesn't necessarily mean that loss of those elements will result in a reliability risk to the system.

These "transient" and "voltage deviation" analyses are highly dependent upon sound and accurate dynamic system models. Much has been said in recent days about the suspicions that many such models are not truly accurate enough to predict system response that is close to what actually occurs.

See 5c

See 5c

Very small elements may be candidates for exclusion because such a small loss cannot cause reliability risk. An exception to this statement may be that, though small, the element is important to the service of a critical load.

Yes

The SRC generally agrees with the technical analysis approach to determining whether an element should be included in the BES. However, consideration should also be given to valid and supported evidence given by RCs and PCs, and, possibly TOPs and BAs to actual historical events that indicate significant importance of elements which, when lost, have resulted in reliability risk to the system.

New York Power Authority

Randy D. Crissman

No

NYPA does not see a need for this requirement. A radial element that specifically serves a load center will perform that task regardless of the electrical distance from the source to the load. Similarly, any loss of load in the load center will result in a corresponding need to reduce generation in the source system, regardless of the proximity of the load.

Yes

The definition of radial systems needs to be modified to include radials that are connected to a single transmission source by more than one automatic interruption devices, such as occurs with a "breaker and a half" arrangement.

Yes

NYPA generally agrees with this item. However, the term "system" needs to be better defined. It is not clear how power could flow out of a load only system. If reversing power flows on a feeder caused it to fail one of the criteria, could the radial still be excluded, or is it necessary for the Element to pass all requirements? Alternatively, could the entity choose to file for Exclusion of that Element under the technical analysis option? What happens and what are the implications when the two approaches produce different outcomes? An example of revised wording for "iv. The maximum amount of energy flowing out" would be no more than 24 hours of reverse power flows within any rolling 12-month

period. Consider avoiding prescribing values and eliminate bullet (iv). The intended performance outcome should be described, but without setting values. This should not have any impact on the reliability of the transmission network if items 1, 2 and 3 are satisfied.
Yes
NYPA agrees that power flow wheeled through a system indicates that the system potentially has more than one source. Therefore, the element in question is not radial.
Yes
In general, NYPA agrees with this approach except as noted below.
NYPA does not agree with this measurement. Distribution factors are dependent on the number of radial transmission lines that connect a single source to a load. For example, if two lines connect a single source to a load, and one line trips, the distribution factor provides a 100% increase in flow on the remaining line. If three lines connect the source to the load, and one line trips, the distribution factor for the remaining lines would be 50%. The SDT should avoid setting values and instead describe the intended performance outcome from a distribution factor measurement. Note that ultimately NERC as an ERO or relevant regulatory authority will approve the application and can assess the performance outcome in their decision making presented in an entity's application.
Suggest that either the SDT avoid using voltage dip as a criteria, or clearly specify that the transient voltage not exceed the X limit of Y cycles (time). References to relevant industry standards such as IEEE standard 1346-1998 should be made.
Suggest that for assigning a value for transient frequency response, entities conduct and submit to the SDT their quantitative and qualitative technical assessment based on the conditions of the element(s) under the application. Do not establish a fixed binary value within the exception criteria but rather focus on the performance outcome.
Voltage deviation is generally expressed as a percentage, between the voltage at a given instant at a point in the system. Do not establish a fixed binary value within the exception criteria but rather focus on the performance outcome.
No
Yes
In general, NYPA agrees with this approach except as noted below. Inclusions criteria should mirror the Exclusion criteria, and that consistent values should be employed for Inclusions here and for Exclusions above.

No
We do not agree with this requirement. These exclusion exception criteria should be deleted in their entirety and replaced with criteria that are objective, specific, and repeatable, or preferably not

replaced at all. Specific problems with the criteria as stated are: 1. A facility is not BES if all of "a" through "d" below apply: a. "System elements" are in "close electrical proximity to load" – this is vague, and a lower impedance between systems is higher likelihood of interaction between systems. Proximity measured in ohms should be related to the load level itself. A pair of values (ohms, load) is necessary for this purpose. Transient stability is affected by this value-pair. For a load pocket, an equivalent impedance (e.g., a sort of Thevenin impedance) between the network source and the load location could be defined. The impedances within the network source can also affect the assessment. Re-evaluation over time would be necessary if this path were adopted. This path of evidence (i.e., the path of engineering judgment) which does not include extensive technical analysis is an attempt to provide a definitive criteria for exception without going through the other path of evidence (i.e., the analytical path) which includes extensive technical analysis. Unless the analytical path has been clearly defined and sufficient data obtained from/on it, the path of engineering judgment could become difficult to establish. System parameters such as proximity to load, radial (or non-radial) configuration, power flow direction over time (either unintended or intended) will directly influence results of technical analysis evaluated for distribution factors, transient voltage dip and frequency excursions, voltage deviations, transient and steady-state stability, and sequence of events following a disturbance (i.e., either a cascading outage or a controlled outage). The two paths of evidence cannot be in conflict with each other.

No

We do not agree with this requirement. These exclusion exception criteria should be deleted in their entirety and replaced with criteria that are objective, specific, and repeatable, or preferably not replaced at all. Specific problems with the criteria as stated are: 1. A facility is not BES if all of "a" through "d" below apply: b. "System elements" are "treated as" radial "in character" – this is also vague, and based on operating procedures... what does "treated" involve? What is "character" in the context of system elements?

No

We do not agree with this requirement. These exclusion exception criteria should be deleted in their entirety and replaced with criteria that are objective, specific, and repeatable, or preferably not replaced at all. Specific problems with the criteria as stated are: 1. A facility is not BES if all of "a" through "d" below apply: c. Power flows into "the system" most of the time – this is vague and covers much of the 115 kV system.

No

We do not agree with this requirement. These exclusion exception criteria should be deleted in their entirety and replaced with criteria that are objective, specific, and repeatable, or preferably not replaced at all. Specific problems with the criteria as stated are: 1. A facility is not BES if all of "a" through "d" below apply: d. Power "entering" "the system" does not "intentionally" flow into another "system" – what does intentionally versus unintentionally mean?

No

A facility is not BES if it is not necessary for reliable system operation, based on a TPL-type analysis similar to NPCC Document A-10 "Classification of Bulk Power System Elements" – this type of analysis was rejected by FERC. Besides, at 115kV, calculated distribution factors for interfaces between areas (where higher voltage lines, e.g., at 230kV and 345kV, are included as part of the interface definition) tend to be small and inaccurate. The method used to calculate distribution factors is an approximate method which must be re-evaluated for small values of distribution factors.

No
A long radial line with a small transformer could have a relatively high impedance. Proximity to load has no real bearing on this procedure. Requirement 1.(a) should be deleted.
No
While we generally agree, 1.(b) should be changed to "normally radial." "Radial" should not be defined differently in the Rule of Procedure than in the BES Definition.
Yes
It may be more appropriate to use a threshold based on maximum power rather than on an annual energy threshold.
Yes
While we generally agree, "system" needs to be clarified, and should be changed to "transmission system." It may also need to be qualified by indicating a change in ownership of transmission systems. We also wonder if the concept of scheduling should be addressed rather than using the word "intentionally?"
No
This appears very similar to the "material impact" proposal that FERC has previously disallowed, so we recommend removing 2. If retained, remove 2.(b) because allowing the ERO to override the technical justification and analysis devalues such analysis to the point of it being meaningless.
If this approach is used, then there needs to be a clear technical rationale for defining the metric and for determining the threshold value.
If this approach is used, then there needs to be a clear technical rationale for defining the metric and for determining the threshold value.

If this approach is used, then there needs to be a clear technical rationale for defining the metric and for determining the threshold value.

Yes

No

Yes

The proposed principles seem preliminary and immature. In addition as noted in earlier comments they are not fully consistent with the proposed BES definition, particularly with respect to radial elements and local distribution networks. Such consistency should be incorporated before the next posting. We further feel that it is very unlikely that the technical evidence path can be placed on a sound technical foundation and matured by the end of this year as directed by the FERC. Key definitions are lacking and should be added to the document. For instance "distribution factor" is not carefully defined even though such factors can be calculated in a variety of ways.

Group

Hydro One

David Curtis

No

We agree with this concept to allow entities to submit an exception application that does not include extensive technical analysis. Such an option will make the process efficient for all stakeholders, such as entities, Regions, NERC and relevant regulatory authority. However, our opinion is that there is no real relationship between reliability and the proximity of load. If impedance is to be used as a measure of electrical proximity, which in turn is a replacement for geographical proximity, then how would the presence of parallel lines, capacitors, phase-angle regulators (PARs), tap-changing transformers, generation and reactors be treated in determining electrical proximity? Consistent with references in the FERC Order, we feel that it is much more important to identify and ensure if the BES element(s) are serving load pockets associated with large metropolitan load centers, loads of significance to national security and/or as identified by relevant Federal, State or Provincial Regulatory Authority. We urge the SDT to clarify the exception criteria for exclusions, based on the following questions: •How does the proximity impedance approach effectively differentiate between transmission and distribution lines of the same voltage and length? •When using impedance, how is "greater than" determined? •What impedance would the SDT apply to a PAR (or tap-changing transformer) and to the overall path if a PAR (or tap-changing transformer) were located in-series with the measured Elements? •What is the meaning of "power flow data" used here and how is the meaning different from the term when used under "1c) Power flows into the system, but rarely flows out"? Should this sentence use the phrase "impedance data extracted from a load flow study" instead? Finally we suggest that entities should be required to identify the significance of the element's physical characteristics. Such identification can be done through a simple checklist along with any relevant comments.

No

Entities should be allowed to demonstrate the radial characteristics to determine if they are permitted for an exception, and demonstrate compliance with radial defining criteria. The term "regional dispatch" is not defined. Therefore we suggest the SDT to provide a definition or reference to clarify regional dispatch in 1 b) II. We recommend adoption of the alternate term "operational control" and suggest that the SDT consider using the terms "under the operational control of a Balancing Authority" (It is instructive that the overarching requirement for a finding of transmission system integration in Mansfield was that the facilities be under operational control of the Independent System Operator. \*) \* Southern Cal. Edison Co., 92 FERC ¶ 61,070 at 61,255 (2000), reh'g denied 108 FERC ¶ 61,085 (2004).

No

We agree with the criteria set out in 1(c), but suggest the SDT to avoid prescribing values and eliminate bullet (IV). The SDT should also consider allowing: a) Power flow-out up to 20% of the minimum forecasted load for the element(s) over a 12 month period; or b) Maximum amount of

energy flowing out be set to no more than 24 hours of reverse power flows within any rolling 12-month period. The intended performance outcome should be described, but without setting values. This should not have any impact on the reliability of the transmission network if items 1, 2 and 3 are satisfied.

Yes

No

We agree that entities should be given an option to conduct an analysis to demonstrate whether or not an element is necessary for the operation of the transmission network. We also support that NERC should specify the entire relevant criteria category to be listed under exclusion criteria 2 (a). However, we suggest that NERC should avoid prescribing numerical values but establish a range of value (or reference industry standard) that would be consistent with industry/ regional standards or practices without compromising the reliability of the transmission network.

Distribution Factor is an estimate of what feeder power flow participation level material is and what non-material is. While TDF and OTDF analysis is an indication of contributions from the element, hence the SDT should avoid setting values and instead describe the intended performance outcome from a distribution factor measurement. Note that ultimately NERC as an ERO or relevant regulatory authority will approve the application and can assess the performance outcome in their decision making presented in an entity's application.

Voltage dip is specified in terms of duration and retained voltage, usually expressed in percentage. We advise against prescribing limits by the SDT, and instead suggest that either the SDT avoid relating voltage dip altogether or clearly specify that the transient voltage not exceed the X limit of Y cycles (time). We suggest SDT to make references to relevant industry standard such as IEEE standard 1346-1998. For example, a document effective in 2007 titled Ontario Resource and Transmission Assessment Criteria Issue 5.0 mentions that: "The minimum post-fault positive sequence voltage sag must remain above 70% of nominal voltage and must not remain below 80% of nominal voltage for more than 250 milliseconds within 10 seconds following a fault. Specific locations or grandfathered agreements may stipulate minimum post-fault positive sequence voltage sag criteria higher than 80%. IEEE standard 1346-1998 supports these limits."

We suggest that, in terms of assigning a value for transient frequency response, entities conduct and submit to the SDT their quantitative and qualitative technical assessment based on the conditions of the element(s) under the application. We suggest not to establish a fixed binary value within the exception criteria but rather focus on the performance outcome. See 5 (a)

Voltage deviation is generally expressed as a percentage, between the voltage at a given instant at a point in the system. We suggest not to establish a fixed binary value within the exception criteria but rather focus on the performance outcome. Adequate voltage performance does not guarantee system voltage stability. Steady state stability is the ability of the grid to remain in synchronism during relatively slow or normal load or generation changes and to damp out oscillations caused by such changes. We suggest that the requirement should suggest that following checks are carried out to ensure system voltage stability for both the pre-contingency period and the steady state post-contingency period: •Properly converged pre- and post-contingency power flows are to be obtained with the critical parameter increased up to 10% with typical generation as applicable; •All of the properly converged cases obtained must represent stable operating points. This is to be determined for each case by carrying out P-V analysis at all critical buses to verify that for each bus the operating point demonstrates acceptable margin on the power transfer as shown in the following section; and •The damping factor must be acceptable (the real part of the eigen values of the reduced Jacobian matrix are positive).

Yes

Technical Analysis must fundamentally use NERC – TPL methodology and testing requirements. We believe that an element may "not be necessary for the operation of the interconnected transmission system" if the remaining system can be operated without the element(s) for over 30 days and during peak load conditions. This assumption considers that loss of element(s) may result in outage to the connected load or generation during this period but will not have any adverse impact on the operation of the interconnected transmission network. Following are technical assessment categories that entities could be required when filing for exception: 1.Power flow •Primarily unidirectional (less than 20% of min load) 2.TPL Assessment •Load Flows Analysis •Thermal and Voltage Stability •Transient

Stability 3.TDF and OTDF assessment For entities filing an exception: [Step 1] Entities should undertake relevant and detailed technical assessment/analysis and describe their findings under each of the technical categories. Finally, the findings and conclusions should be listed in the form of maximum 6 bullets. [Step 2] Findings and conclusions from each of the technical categories should be presented in a spreadsheet including the categories that may not be relevant to the element(s). If a category is not relevant, it should be explained why. [Step 3] The final conclusion should be presented by taking the overall assessment in Step 2 by assessing contributions of each item and demonstrating that the element(s) is or is not necessary for the operation of interconnected transmission network. We suggest the above method and request entities to complete the table below, as this will allow entities to present their assessment of the element(s) that are under the consideration of exception. Measured Value ===== Load || Critical Load Affected? [yes][No] ----- •Radial •Local supply, e.g. distribution in nature •Large load center, critical load, national security Generation Characteristics || Critical Load Affected? [yes][No] ----- •Local load modifier, peak shaver •Behind meter or industrial load displacement •Must Run •Flow contribution outside of the elements under exception Cascading Outage || Critical Load Affected? [yes][No] ----- Measured Value ===== Max Dip [Voltage] Applicable Industry Practice (IEEE/CSA,Market Rules,etc.) Acceptable Level [in cycles] Assessment Results [in cycles] Does the assessment confirm successful recovery? [Yes] [No] Transient Voltage Dip [voltage] Transient Frequency Excursion [Hertz] Voltage deviation [Voltage] Transient Stability Steady State Stability

Yes

It is imperative to understand that the NERC's revised definition will have a direct impact on entities across North America and may conflict with regulatory requirements, Codes, and Licenses. FERC in its Order 743 and 743A has directed NERC to address these concerns. As for Ontario System, the BES exception criteria shall meet the expectations of Ontario's regulator (Ontario Energy Board) which has the sole authority and responsibility for the reliability of customer connections and loads within Ontario. Therefore, it will be necessary to accommodate NERC's proposed definition of BES or the exception process with the Ontario situation. We suggest the SDT and RoP teams should: •Modify the exception criteria and procedure to provide regulatory flexibility with requirements to conduct basic technical analysis, to allow entities to consistently present their case to the ERO and/or the regulator for a step by step expedited evaluation. •Include provisions in both the NERC exception criteria and exception process for federal, state and provincial jurisdictions. These provisions should provide clear guidance so that, if and when there are deviations from the exception criteria, they are identified with technical and regulatory justifications ensuring there is no adverse impact on the interconnected transmission network. •Understand that the path to generating facilities need not be always BES contiguous. Generating units can/should be required to be planned, designed, and operated in accordance with a subset of NERC Standards, but should not always require contiguous paths.

Yes

Exception criteria should be crafted at a high-level with key menu items of assessment that can be followed continent-wide by entities to put forward their exception for element(s) that are not necessary for the interconnected transmission network and based on technical assessment, evidence and justification for its unique characteristics, configuration, and utilization. (Also see suggestions/ comments on Question 6)

Yes
The second paragraph of the proposed Technical Principles states that "[d]ue to the importance of Blackstart Resources and their designated blackstart Cranking Paths to restoration efforts, no exceptions will be allowed for those items." This sentence should be deleted from the technical principles. An unintended consequence of subjecting all blackstart cranking pathways to inclusion in the BES by default would be to cause a Registered Entity, in order to minimize costs, to not declare every possible cranking path but instead limit to the minimum required cranking paths in order to comply with the standards, as opposed to designating multiple pathways. This consequence could be avoided by allowing blackstart cranking pathways to be evaluated for exceptions just like any other element.

NESCOE
No
The New England States Committee on Electricity ("NESCOE") appreciates the work of NERC's standard drafting team as well as the opportunity to provide comments on this matter. NESCOE is New England's Regional State Committee and the comments provided herein reflect the collective views of the six New England states. NESCOE's comments below reflect its general perspective that any new costs imposed as a result of the BES and its implementation, which costs ultimately fall on consumers, should provide meaningful reliability benefits. NESCOE questions the concept as presented and seeks further clarification. As a general matter, NESCOE believes the requirement that a proposed exception must meet all four criteria is overly restrictive and will result in only a narrow category of elements qualifying for exclusion from the BES. NESCOE suggests that a better approach would allow exclusions to be based on one or more criteria, depending on the nature of the element that is the subject of the application. With respect to the proposal, NESCOE does not believe it is possible to obtain agreement on the "proximity to load" criterion for additional exclusions from the BES when the underlying impedance value has not been determined and may be the subject of significant debate. While it is possible that NESCOE could support a single impedance value that would govern exclusion determinations, it notes that a uniform value may not adequately address varying system configurations throughout ISO-New England and neighboring control areas. NESCOE suggests that the standards setting process allow for further deliberation on possible proposed values. Other terms, such as "load center," also need definition.
No
As noted in Response 1, NESCOE believes exclusion determinations should not require a finding that all four proposed criteria are met. In addition, NESCOE believes that the criterion proposed here is

overly complex and that developing the evidence may be overly burdensome to the applicant. Radial paths should have a simple definition related to how the path is connected from a topological perspective. NESCOE suggests that a radial path be defined simply as a path having only one connection point to the BES, thereby presenting no opportunity for power flows parallel to the BES network. Under fault situations, these excluded paths can be isolated from the BES with suitable NERC compliant protection systems. Note the radial path may be comprised of parallel lines that terminate at the BES connection point. In addition, NESCOE believes that a radial path should qualify for exclusion as long as the power flowing into the BES is less than a threshold MVA. NESCOE does not at this point have a recommendation as to this specific threshold but believes it should be developed through the standards-setting process. NESCOE suggests this approach to avoid burdening the development of generation including renewable generation. As New England is working on facilitating the development of renewable resources located in and around the region to serve customers most cost-effectively, this process should take specific care not to impose undue burdens on renewable resources.

No

As noted in Response 1, NESCOE believes exclusion determinations should not require a finding that all four proposed criteria are met. Generally, NESCOE is in agreement with an exception criteria for additional exclusions that takes into account power flows into the system that rarely flows out. However, additional clarity is necessary for criteria 1(c)(i), (ii) and (iv). Specifically, what is meant by "very limited set of conditions" under 1(c)(i) and (ii) and "limited quantity of energy" under 1(c)(i)? Further, is it appropriate to establish a fixed value of X megawatt hours for the maximum amount of energy flowing out of the system? While it is possible that NESCOE could agree upon a uniform value, NESCOE is not in a position to provide specific comment or support when the MWh value is unspecified. In addition, a fixed value may not adequately address varying system configurations throughout ISO-New England and neighboring control areas.

No

As noted in Response 1, NESCOE believes exclusion determinations should not require a finding that all four proposed criteria are met. NESCOE further notes that New England's network has numerous parallel paths operated at voltages less than 200 kV which may parallel 230 kV and 345 kV BES network paths. If flows on a given <200 kV path only exceed 200 MVA under contingency conditions and if these paths are connected to the higher voltage BES elements with suitable NERC compliant protection systems, these paths may be EXCLUDED from the BES. NESCOE suggests the value of 200 MVA based on typical thermal ratings of 115 kV transmission lines but is open to other values that the drafting team may suggest. NESCOE also suggests that the phrase "to some other system" be broadened to include any other higher voltage BES element.

Yes

NESCOE supports the concept of allowing an additional path to justifying an exclusion from the BES. NESCOE could support development of technical criteria such as those proposed, but does not have specific recommendations at this time. As stated earlier, any excluded elements must be connected to the BES using fully NERC compliant protection systems.

Yes

Please refer to comments under item 4., above. If the parallel power flow in a given < 200 kV path only exceed 200 MVA under contingency conditions and if the applicable BES points have fully NERC compliant protection systems, disturbances on this lower voltage path will not adversely affect the reliability of the BES. The exclusion determination process should be flexible enough to recognize that any requirement that may impose substantial new costs on New England transmission owners, and ultimately on consumers, should also provide meaningful reliability benefits

Yes
NESCOE believes that exclusion determinations should be based on clear but flexible criteria that do not result in the unnecessary inclusion of elements into the BES that do not adversely impact the reliability of the BES. The process described here is too limiting in its requirement that an application meet all of those four listed criteria not requiring technical analysis. Applicants and reviewers should have a broader menu of decision criteria available to them. Regarding those criteria related to exclusions based on technical analysis, NESCOE suggests that ranges of values, in recognition of regional differences in network characteristics, be suggested by the drafting team for further consideration. Finally, as discussed above in response to questions 1 through 4, NESCOE believes that additional exclusion determinations should not require a finding that all four proposed criteria are met. Rather, the various criteria set forth under 1(a) through 1(d) should be treated as alternative criteria to qualify for an additional exclusion, and entities seeking additional exclusions to the BES should be allowed to demonstrate that one or more criteria is met, depending on the nature of the element that is the subject of the application.

No
We agree with this concept to allow entities to submit an exception application that does not include extensive technical analysis. Such an option will make the process efficient for all stakeholders, such as entities, Regions, NERC and relevant regulatory authority. However, we believe that an Element's electrical proximity to load is not necessarily a relevant consideration for determining whether the Element is required for reliable operations.
Yes
We agree with this concept. Entities should be allowed to demonstrate the radial characteristics to determine if they are permitted for an exception. However, we believe some further clarification of the meaning of "radial in character" is needed. The example given in (b)I does not clarify the matter. Would a transmission line operated with a normally open point to form two radial lines be considered "radial in character"? Please clarify. The location of the Disturbance needs to be clarified. For example, if the Disturbance (e.g. a fault) occurs at the radial part of the Element, then it is necessary for the Element to have the capability to disconnect itself from the Disturbance to preserve BES reliability but the Element can be by itself a legitimate radial facility that is used solely for supplying load. The phrase "are not included in a regional dispatch" is unclear. We do not understand what this means.
No
There is an inconsistency between the language used in bullet (c) - "rarely flows out", and that used in Exclusion E3(c) of the BES definition - "Power flows only into the LDN". We have commented during the BES Definition comment period that Exclusion E3 needs to be modified to match the Exception Principles. We agree with the criteria set out in 1(c) except for bullets (iv) and (v). We do not believe it is possible to establish a limit on the energy flow out of a system for which an exception has been requested. Further, we suggest that the SDT avoid prescribing set values in the exception criteria since these would only serve to limit the flexibility of the process. As an alternative to the proposed bullet (iv), we suggest that power flow study results could be used to support the exception request. We therefore propose the following wording to replace bullets (iv) and (v). iv. Power flow simulation results to demonstrate that BES reliability is not dependent upon the power flows through the Element(s) for which an exception has been submitted, for the conditions specified in (ii).
Yes

No

The technical analysis path for exclusions and inclusions allows for override of the listed "criterion". It is not clear what will be the basis for overriding, and what process will be followed? Is the "criterion" meant to be all of (1) to (7) in (a), or is it any one of them? This needs to be clarified. We agree that entities should be given an option to conduct an analysis to demonstrate if an element is or is not necessary for the operation of transmission network. However, consistent with our earlier comments, we suggest that the exception criteria avoid prescribing numerical values. A transmission element is not necessary for the reliable operation of an interconnected electric transmission system, if it can be removed without effecting bulk transfer capabilities. In our view, testing in accordance with the TPL standards should be the basis for establishing this. One way of demonstrating that an element is not required for the transfer of bulk power is to show that with the element out of service (and with all elements that received exemptions in the past also out of service) and at the required power transfers: 1. Pre-contingency and post-contingency loadings on all BES elements are within applicable ratings. 2. Pre-contingency and post-contingency voltages on the BES are within established ratings. 3. All units on the BES remain synchronized following contingencies. 4. All voltage declines on the BES are within established limits (if any limits were defined). 5. All steady-state oscillations and oscillations following a contingency are positively damped. 6. Transient voltage dips do not exceed established limits anywhere on the BES (if any limits were defined). 7. Frequency excursions do not exceed established limits anywhere on the BES (if any limits were defined). Our view is that the exception criteria should NOT specify the voltage decline limits, allowable frequency excursion or the allowable transient voltage dip because every region will have different limits depending on the characteristics of their power system. This would be consistent with Requirement R5 of the recently balloted standard TPL-001-2, which requires each Transmission Planner and Planning Coordinator to have criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and the transient voltage response for its System. Required power transfers are the transfers required to meet the "one day in ten year" loss of load expectation criteria. Further, exception criteria for generators must also be defined. A power system is typically planned to be able to service the load under multiple dispatch scenarios and, therefore, multiple generators disconnected from the transmission system will unlikely reduce the ability of the power system to supply the load. In fact, market forces typically determine whether or not a generator is connected. However, transmission lines are built to achieve specific transfer capabilities and, therefore, directly affect the power system's ability to meet the electricity demand. Since, generators and transmission elements contribute to reliability in a very different ways, the criteria exempting generators should be different from the criteria exempting transmission elements.

We do not agree with setting values for this criterion. This should be left to the relevant Transmission Planner and Planning Coordinator. See our comments in response to Q5a.

We do not agree with setting values for this criterion. This should be left to the relevant Transmission Planner and Planning Coordinator. See our comments in response to Q5a.

We do not agree with setting values for this criterion. This should be left to the relevant Transmission Planner and Planning Coordinator. See our comments in response to Q5a.

We do not agree with setting values for this criterion. This should be left to the relevant Transmission Planner and Planning Coordinator. See our comments in response to Q5a. We suggest that the exception criteria could include the following checks to be carried out in the course of the TPL analysis referred to above to ensure system voltage stability for both the pre-contingency period and the steady state post-contingency period: • Properly converged pre- and post-contingency power flows are to be obtained with the critical parameter increased up to 10% with typical generation as applicable; • All of the properly converged cases obtained must represent stable operating points. This is to be determined for each case by carrying out P-V analysis at all critical buses to verify that for each bus the operating point demonstrates acceptable margin on the power transfer as shown in the following section; and • The damping factor must be acceptable (the real part of the eigen values of the reduced Jacobian matrix are positive)."

No
No
We support the concept of technical analysis in support of Inclusions but disagree with the approach that involves setting specific values for criteria. Please refer to our comments on exclusions.

No
We anticipate that entities would be granted access to any required historical operations records and modeling data after signing of non-disclosure agreements as necessary.
Yes
Similar to the BES Exception Procedure, the document "Technical Principles for Demonstrating BES Exceptions" must explicitly recognize the authority of Canadian and Mexican Governmental Entities to adopt the Technical Principles for Demonstrating BES Exceptions in its entirety or in part with their own deviations, while ensuring there will be no adverse impact on the interconnected transmission system. Footnote 2 of the "Procedure for Requesting and Receiving an Exception from the Application of the NERC Definition of Bulk Electric System" should be repeated in the "Technical Principles" document.
Yes
We hold the view that the path to generating facilities need not be always BES contiguous. Generating units should be required to meet a subset of NERC Standards, but should not always require contiguous BES paths. Finally, we reiterate that exception criteria should be crafted at a high-level with key menu items of assessment that can be followed continent-wide by entities to put forward their exception for element(s) that are not necessary for the interconnected transmission network and based on technical assessment, evidence and justification for its unique characteristics, configuration, and utilization.
Group
MRO's NERC Standards Review Forum
Carol Gerou
No
NSRF believes the relevance and rationale for this criterion is unknown. If this criterion is intended to exempt elements, like circuit switchers, that are part of the distribution transformer circuits operated above 100 kV, and located within a mile of the BES interconnection point, then NSRF would expect the wording to be "in close electric proximity to the BES" rather than in "close electric proximity to Load". Otherwise, NSRF requests the SDT explain the relevance and rationale for this criterion before agreeing on its inclusion.
No
Radial in Character – NSRF proposes that this criterion be eliminated because it does not describe any materially different characteristics beyond Exclusion E1 of the bright-line BES definition.
No
NSRF proposes that this criterion be eliminated because it does not describe any materially different characteristics beyond Exclusion E3 of the bright-line BES definition.
No
NSRF proposes that this criterion be eliminated because it does not describe any materially different characteristics beyond Exclusion E3 of the BES definition.
No
NSRF proposes that this technical analysis criterion be replaced by criteria that are more closely tied to the Adequate Level of Reliability (ALR) characteristics. The following alternate criteria are offered as possible examples, "(1) the BES can be controlled to stay within acceptable limits following a fault on or loss of the Element; (2) the BES performs acceptably after credible contingences of the Element; (3) the Element does not limit the impact and scope of instability and cascading outages

when they occur; (4) BES facilities are protected from unacceptable damage by operating the Element within its ratings; (5) the integrity of the BES can be restored promptly following a fault on or loss of the Element; and (6) the BES has the ability to supply the aggregate electric power and energy requirements of the electricity consumers at all times, taking into account scheduled or reasonably expected unscheduled outages of the Element. In addition, NSRF is not aware of any continent-wide appropriate BES performance measures for voltage dip, frequency excursion, voltage deviation, stability, etc. and NSRF speculates that different values are likely for different regions and system characteristics across the continent. As a result, NSRF believes it is not advisable to try to adopt unproven values without reasonable industry investigation and development.

NSRF proposes replacing this factor with those cited above because a distribution factor measurement indicates how much system changes affect the element, not how much a fault or loss of the element would compromise the ALR of the BES. There is no clear correlation between this factor and any of the six characteristics of Adequate Level of Reliability (ALR) of the BES.

NSRF proposes replacing this factor with those cited above because there is presently no established, continent-wide, acceptable transient voltage dip performance level for evaluating whether a fault or loss of the element would not compromise the ALR of the BES. In addition, the appropriate performance level for this factor may vary for different areas and system characteristics across the continent.

NSRF proposes replacing this factor with those cited above because there are established, continent-wide transient frequency performance levels in the PRC-006-1 standard, but the elements that are applicable to the standard do not have to be BES elements and the transient frequency response requirements are not intended to be a criterion for BES classification.

NSRF proposes replacing this factor with those cited above because there is presently no established, continent-wide, acceptable (steady state) voltage deviation performance level for evaluating whether a fault or loss of the element would not compromise the ALR of the BES. In addition, the appropriate performance level for this factor may vary for different areas and system characteristics across the continent.

Yes

A. NSRF recommends this process address the six characteristics of the Definition of Adequate Level of Reliability (ALR) as listed in the comments above in Question #5. B. Recommend municipalities and other small entities having transmission systems designed to serve local load, operated below 200 kV and not having any IROL's or SOL's be excluded from the BES definition. Rational: The standards, especially those for Transmission Operators (TO) aren't written for the smaller utilities. A utility may have over 75 MWs of generation and have installed a 115 kV loop around their city that is used primarily to serve load and get forced into significant compliance requirements that don't enhance the reliability of the BES.

No

NSRF proposes that the technical analysis criterion be replaced by criteria that are more closely tied to the Adequate Level of Reliability (ALR) characteristics. The following alternate criteria are offered as possible examples, "(1) the BES cannot be controlled to stay within acceptable limits following a fault on or loss of the Element; (2) the BES does not perform acceptably after credible contingences of the Element; (3) the Element limits the impact and scope of instability and cascading outages when they occur; (4) BES facilities are not protected from unacceptable damage by operating the Element within its ratings; (5) the integrity of the BES cannot be restored promptly following a fault on or loss of the Element; and (6) the BES does not have the ability to supply the aggregate electric power and energy requirements of the electricity consumers at all times, taking into account scheduled or reasonably expected unscheduled outages of the Element. In addition, NSRF is not aware of any continent-wide appropriate BES performance measures for voltage dip, frequency excursion, voltage deviation, stability, etc. and NSRF speculates that different values are likely for different regions and system characteristics across the continent. As a result, NSRF believes it is not advisable to try to adopt unproven values without reasonable industry investigation and development.

NSRF proposes replacing this factor with those cited above because a distribution factor measurement indicates how much system changes affect the element, not how a fault or loss of the element would compromise the ALR of the BES. There is no clear correlation between this factor and any of the six characteristics of Adequate Level of Reliability (ALR) of the BES.

NSRF proposes replacing this factor with those cited above because there is presently no established,

continent-wide, acceptable transient voltage dip performance level for evaluating whether a fault or loss of the element would compromise the ALR of the BES. In addition, the appropriate performance level for this factor may vary for different areas and system characteristics across the continent.

NSRF proposes replacing this factor with those cited above because there are established, continent-wide transient frequency performance levels in the PRC-006-1 standard, but the elements that are applicable to the standard do not have to be BES elements and the transient frequency response requirements are not intended to be a criterion for BES classification.

NSRF proposes replacing this factor with those cited above because there is presently no established, continent-wide, acceptable (steady state) voltage deviation performance level for evaluating whether a fault or loss of the element would compromise the ALR of the BES. In addition, the appropriate performance level for this factor may vary for different areas and system characteristics across the continent

No

No

Yes

1. NSRF proposes replacing the wording in the Exclusion preface, Exclusion 2 preface, and Inclusion 1 preface of "not necessary to reliably operate the interconnected transmission network" with "necessary to maintain an Adequate Level of Reliability (ALR) of the Bulk Electric System". 2. NSRF has reservations on the following statement made in the introduction of this document: " Due to the importance of Blackstart Resources and their designated blackstart Cranking Paths to restoration efforts, no exceptions will be allowed for those items." This does not allow for a provision to exclude any designated Blackstart Cranking Path (at any voltage) even though there may be technical justification for it. 3. The first page states that "Specific content of this application is spelled out elsewhere in this appendix." NSRF requests the SDT describe where this appendix will be published. Furthermore, is it a compliance document or just technical "guidance"? 4. Having the following statement included for both exclusions and inclusions will create disagreement: "The ERO can override this criterion but would need to provide additional justification to support their finding." NSRF believes any override should have adequate technical justification and not interfere with other statutory requirements. Also, it does not clarify or identify who would make the determination whether NERC has made adequate justification to override the criterion. 5. NSRF believes that the "Inclusion" process should be completely removed from BES Definition. We recommend using bright-line criteria indentifying everything 100 kV and above to be BES and then allow for the "Exception" process to take out facilities that do not impact the reliability of the BES. Selecting BES facilities based on a right-line criteria is what FERC requested in its Order regarding BES Definition. This would streamline the process and remove some unnecessary paperwork.

Kootenai Electric Cooperative
No
We believe that the proximity test may be unnecessary, and if an Element or group of Elements meets the other three tests proposed by the SDT, it should be excluded from the BES, even if it does not meet the proximity test. Secondly, using impedance to benchmark system load proximity would likely not yield clear demarcations. High voltage relative or per-unit impedances are considered typically much lower than low voltage impedances. Hence, in the absence of phase shifting transformers, service compensation, or other mitigation factors, power typically flows over the highest voltage lines, which offer the lowest impedance.
Yes
Kootenai agrees conceptually that systems operating as radials rather than as integrated portions of the integrated bulk transmission system should be excluded from the BES definition. That is because local distribution systems typically operate adjacent to, or at the end of transmission lines, and function operationally to move power from the Transmission Service Provider's point of delivery of bulk power that has moved across the integrated bulk transmission system to end-users located within the local distribution utility's service territory. To be consistent with the draft BES definition, the term "radial in character" should be explicitly defined as a system that may include one or more lines into a load area or referenced as a local distribution network. In addition, we agree that the manner in which a system is operated during BES disturbances may be an indication of whether that system is radial in character. That being said, we are concerned that, to the extent the SDT considers regional disconnect procedures, it should be careful to note that UFLS and UVLS relays are often embedded within local distribution systems and, while it is necessary for the UFLS and UVLS relays to be properly armed to protect the BES in the event of a severe system disturbance, the local distribution system interconnected with those relays should not.
Yes
Kootenai agrees conceptually that one critical characteristic distinguishing local distribution facilities that must be excluded from the BES from transmission facilities that should be included is the manner in which power flows on those facilities. Power on local distribution systems generally flows only from the interconnected transmission source and across the distribution system for delivery to end-use customers. By contrast, power on transmission systems generally flows in two (or multiple, in networked systems) directions and is delivered in bulk to distribution utilities rather than to end-users. Hence, the SDT has properly identified power flows as one important characteristic that distinguishes BES transmission systems from local distribution systems. In order to identify systems that are not necessary for the operation of the BES under this text, we propose that any system where real power flows into the local distribution system 90 percent of the time or more under normal operating conditions.
Yes
Kootenai agrees that the SDT's fourth test, which asks whether power is intentionally transported through a system, identifies a key characteristic of local distribution facilities that distinguishes such facilities from interconnect bulk transmission facilities that are properly considered part of the BES. In fact, we believe this may be the most important and readily identifiable distinction. Accordingly, Kootenai agrees that if power is not intentionally transported through a particular system, that

system is not used for transmission and should not be considered part of the BES. One exception may be for a small embedded generation unit owned by a different party that may be "scheduled" out of an area, but in reality, does not produce any physical flow. These circumstances should not trigger inclusion.

Yes

We agree conceptually with the idea that two different paths to exclusion should be adopted, one relying upon readily identifiable characteristics that are ordinarily associated with local distribution and not BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES. Kootenai supports the technical arguments and the White Paper presented by Snohomish County PUD in their comments. We recommend that the SDT modify its approach to the technical exclusion process to match the approach advocated in the White Paper, which is based upon the approach recommended by the WECC BES Task Force.

The use of distribution factors, such as Power Transfer Distribution Factors ("PTDF") and Outage Transfer Distribution Factor ("OTDF") provide insight into the relative impedance of neighboring systems. However in the Western Interconnection it has never been a definitive indicator of whether a system fault with delayed clearing would impact a neighboring electric system. While we understand that many entities from the Eastern Interconnection support the use of such factors, we believe the approach is unlikely to work in the Western Interconnection.

Specific transient voltage dip thresholds are proposed at page 15 of Snohomish's White Paper. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should produce no more than a 20% voltage drop for no more than 20 cycles in a Category B contingency and no more than a 20% drop for 40 cycles in a Category C contingency. Technical justification for these thresholds is provided at pages 12-16 of the White Paper.

Page 15 of Snohomish's White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided at pages 12-16 of the White Paper.

[Please see our response to Question 5d.]

No

Yes

As a general matter, we agree with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid showing that the Elements contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. We also agree that the SDT has, in general, identified the correct technical approach, although we recommend that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in the Snohomish PUD White Paper, in the WECC BES Task Force Proposal 6, and in our answer to Question 5.

See Exclusion comment.

See Exclusion comment.

See Exclusion comment.

See Exclusion comment.

No

As discussed on page 12 of the Snohomish White Paper, there may be a few isolated cases where additional data will need to be provided to run a valid technical analysis under the criteria set forth in the Exception Procedure. These cases should be exceedingly rare, however, because the starting point for the technical analysis we recommend is the current base case operated by the relevant Regional Entity, and in nearly every case, the base case can be expected to model any Element that conceivably has a material impact on the reliable operation of the bulk system. In those rare cases where it does not, we believe the owner or operator of the subject Element should be able to provide the needed data.

No
As properly constructed Definition and Exceptions process should meet the legal requirements of Section 215.
Yes
Kootenai generally supports the approach to the exclusion process proposed by the SDT, which provides two different paths to exclusion, one based on readily-identifiable operational characteristics of a system, and one based on technical reliability analysis. We believe it is important to provide for the first path, based on operational characteristics, so that systems that are marginally disqualified under the BES Definition (because, for example, generation within the system exceeds demand for a few hours a year) can obtain an exclusion without the large investment of resources that otherwise might be required for a full-scale technical analysis. That being said, we question whether the first subsection of the characteristic test, relating to system proximity, is necessary, and we are concerned that the requirement that a system meet all four requirements of the characteristics test may be overly restrictive. For example, it is easy to imagine a distribution system in a rural area that covers a widely dispersed area, so that load is many miles from the relevant generation/transmission source, and that the system therefore does not meet the electrical proximity element, but meets the other three elements of the characteristics test. Such a system should be excluded because it clearly serves a local distribution function, and not a transmission function, as demonstrated by the fact that the system meets subsections (c) (power flows into the system but rarely flows out ) and (d) (power is not intentionally transported over the system). Accordingly, we recommend that the SDT consider eliminating the first test. In the alternative, the SDT should consider allowing exempting a system from the BES if it, for example, meets three of the four criteria rather than all four.

Southern Company
Antonio Grayson
No
Yes
We agree with the requirement of an element being radial in character as being a qualifier for exclusion thru the non-technical analysis. However, we recommend tha the term "radial in character" be better defined. Item ii.: The intent of this item is not clear, and the term "regional dispatch" is not defined. Recommend the item be clarified.
Yes
No
No
As written, most of this approach makes no sense. The words imply that if you have planned the system properly, you can exclude it from the BES! In TPL studies you make sure that voltage dips, frequency excursions, voltage deviations are acceptable, oscillations are damped, and no cascading outages occur. So if you meet the performance requirements of TPL studies, you can exclude the element from the BES. What good is this?
This is the only part of this technical analysis that may make sense. If the loss of any element of the BES results in a distribution factor of less than X% on the element being considered for exclusion, then exclude it. We suggest a value of 3% for this, since 3% is the threshold typically used in transfer studies.
As stated above, it does not make sense to use this category.
As stated above, it does not make sense to use this category.
As stated above, it does not make sense to use this category.
Yes
No
Southern Company recommends that applications for inclusion of facilities into the BES should include

justification for doing so. However, there should not necessarily be specific criteria that must be met, but the importance of the facility to the BES should be clearly demonstrated

No

No

Yes

The Technical Principles document suggests that no exceptions be allowed for Blackstart Resources and designated Cranking Paths. Southern Company is concerned with the treatment of these facilities and recommends that certain statements be removed. In Project 2010-17 Definition of the BES, Southern Company commented that the proposed inclusion, Inclusion I4, be removed from the BES Definition because an existing NERC Reliability Standard, EOP-005-2 System Restoration from Blackstart Resources, already addresses these facilities regardless of voltage. Further, the proposed inclusion will expand the applicability of some NERC Reliability Standards to facilities below 100 kV. Southern Company believes this position will unnecessarily cause more facilities to become applicable to reliability standards without any benefit to reliability. Therefore, we recommend the following statement be deleted: "Due to the importance of Blackstart Resources and their designated blackstart Cranking Paths to restoration efforts, no exceptions will be allowed for those items."

Tacoma Power

No

Tacoma Power does not believe that a proximity to Load criteria is useful in BES designation when the other 3 exclusion criteria of this path are applied. However, if the SDT retains this item, we suggest an impedance value of < 0.3 ohms on a 100 MVA base.

Yes

Tacoma Power generally agrees that radial elements should be an item in this path and we suggest that radial element operated at below 300 kV should be excluded from the BES. The 300 kV level is linked with NERC CIP's proposed version 4 definition of critical asset and should be applied here with the BES definition.

Yes

Tacoma Power generally agrees that elements primarily serving load, allowing a limited flow out of the local distribution network, should be excluded from the BES. We support an annual limitation of 219,000 MWhs, equivalent to 25 aMW, since a system of elements that primarily serve load under this limit are insignificant to the BES.

Yes

Tacoma Power generally agrees with fourth item (power transport) when not intentionally transporting power through a system. In development of the supporting evidence for this item, we suggest a demonstration by operating studies or the option to demonstrate the criteria by the use of operational procedures.

Yes

Tacoma Power generally agrees with approach used on the technical analysis path for exclusions.

Tacoma Power generally agrees with the distribution factor measurement in the technical analysis path for exclusions. We suggest adopting a distribution factor not exceeding 30% on an adjacent system.

Tacoma Power generally agrees with allowable transient voltage dip measurement in the technical analysis path for exclusions. We suggest adopting an allowable transient voltage dip not exceeding 20% for more than 20 cycles on an adjacent system's bus.

Tacoma Power generally agrees with the allowable transient frequency response in the technical

analysis path for exclusions. We suggest adopting an allowable transient frequency response of not below 59.6 Hz for up to 6 cycles on an adjacent system's bus.
Tacoma Power generally agrees with the voltage deviation measurement in the technical analysis path for exclusions. We suggest adopting a voltage deviation not exceeding 10% on an adjacent system's bus.
No
Tacoma Power is not suggesting any other methods at this time.
Yes
Tacoma Power generally agrees with approach used on the technical analysis path for inclusions.
Tacoma Power generally agrees with the distribution factor measurement in the technical analysis path for inclusions. We suggest adopting a distribution factor of 30%, or more, on an adjacent system.
Tacoma Power generally agrees with allowable transient voltage dip measurement in the technical analysis path for inclusions. We suggest adopting the criteria that includes a transient voltage dip exceeding 20% for more than 20 cycles on an adjacent system's bus.
Tacoma Power generally agrees with the allowable transient frequency response in the technical analysis path for inclusions. We suggest adopting the criteria that includes a transient frequency response that goes below 59.6 Hz for up to 6 cycles on an adjacent system's bus.
Tacoma Power generally agrees with the voltage deviation measurement in the technical analysis path for inclusions. We suggest adopting a voltage deviation that exceeds 10% on an adjacent system's bus. We have an additional concern with how the language is constructed on items d. and e. The inclusion criteria may work for simply inverting the exclusion language but in this initial draft, it does not appear to work as intended. Our suggestions above are describing criteria for defining elements that can be included in the BES. If that is the result to be adopted by the SDT, items d. and e. must be rewritten to state that elements within such criteria can be included in the BES.
No
Tacoma Power has no comment at this time.
No
Tacoma Power is not aware of any conflicts at this time.
Yes
Tacoma Power supports the SDT's efforts to create an acceptable BES definition directly linked to an exception process. We do have a concern about the application of the standards to Elements that change status due to the Exception process. Any Elements that are determined to be newly included in the BES should have a 24-month period before the standards will apply as a BES Elements. Conversely, a determination that removes an Element from the BES should apply as soon as practicable. Please be aware that the WECC has a task force, the Bulk Electric System Definition Task Force(BESDTF), which has done some notable work on this task. See WECC BESDTF Proposal 6, Appendix C ( <a href="http://www.wecc.biz/Standards/Development/BES/default.aspx">http://www.wecc.biz/Standards/Development/BES/default.aspx</a> ). The BES definition is very complex and the BESDTF has already addressed many of the tough issues that have yet to be addressed in this process, such as: <ul style="list-style-type: none"> <li>• Local Distribution Network definition for automatic exemption</li> <li>• Determination of radial facilities</li> <li>• Demarcation of BES and non-BES Elements</li> <li>• Alternate dispute resolution process</li> <li>• Assignment of the burden of proof for the exemption process</li> <li>• Technical approach for the inclusion/exclusion determination</li> </ul> Thank you for consideration of our comments.

Terry Harbour
MidAmerican Energy
No
MidAmerican agrees with the NSRF. The NSRF believes the relevance and rationale for this criterion is unknown. If this criterion is intended to exempt elements, like circuit switchers, that are part of the distribution transformer circuits operated above 100 kV, and located within a mile of the BES interconnection point, then NSRF would expect the wording to be "in close electric proximity to the BES" rather than in "close electric proximity to Load". Otherwise, NSRF requests the SDT explain the relevance and rationale for this criterion before agreeing on its inclusion.
No

MidAmerican supports the NSRF comments. The NSRF proposes that this criterion be eliminated because it does not describe any materially different characteristics beyond Exclusion E1 of the bright-line BES definition. If not eliminated, the IEEE definition of a radial system should be used.
No
MidAmerican supports the NSRF comments. The NSRF proposes that this criterion be eliminated because it does not describe any materially different characteristics beyond Exclusion E3 of the bright-line BES definition.
No
MidAmerican support the NSRF comments. The NSRF proposes that this criterion be eliminated because it does not describe any materially different characteristics beyond Exclusion E3 of the BES definition.
Yes
The concept of using TPL analyses and normalized Transmission Distribution Factors makes basic sense as a way to determine what elements react to system transfers and what elements react primarily to distribution load. In general all facilities below 100 kV should be excluded by default as distribution according to the 2005 Federal Power Act. Transmission Distribution Factors tend to show low bulk power system transfers (less than 2%) based on their inherent high impedance when normalized. Normalizing the transmission impedance means dividing the ohmic value by a base impedance which is dominated by a (kV <sup>2</sup> ) term. Per Unit Impedance = (transmission line ohms / base impedance) where base impedance = (kV <sup>2</sup> / MVA). Using a common MVA base value of 100 MVA, a base impedance at 69kV = 47.6 ohms versus at 161 kV = 259.2 or at 345 kV = 1190.2 ohms. The rapid increase of the denominator as kV goes higher insures that a 69 kV system is high impedance compared to any high kV facilities and therefore nearly insure the 69 kV system is local in nature and reacts primarily to load. Therefore it is distribution. This all supports the conclusion that all facilities below 100 kV should be classified as distribution according to the 2005 FPA and exempted by default. Facilities below 100 kV could be brought into scope if TPL analyses show instability, uncontrolled separation, or cascading as defined in the 2005 FPA.
The Distribution Factor measurement is acceptable and should exclude facilities that show a low distribution factor for bulk power system transfers. An arbitrary low value could be those facilities that show less than a 2% distribution factor.
There isn't a nation wide transient voltage dip measurement.
There isn't a nation wide transient frequency response
Determining a nation wide voltage deviation would be difficult.
Yes
In general all facilities below 100 kV should be excluded by default as distribution according to the 2005 Federal Power Act. Transmission Distribution Factors tend to show low bulk power system transfers (less than 2%) based on their inherent high impedance when normalized. Normalizing the transmission impedance means dividing the ohmic value by a base impedance which is dominated by a (kV <sup>2</sup> ) term. Per Unit Impedance = (transmission line ohms / base impedance) where base impedance = (kV <sup>2</sup> / MVA). Denise Koehn
Yes
BPA suggests that correlation between the size of the Load and the size of an element is needed. BPA would like the word “close” in the description “close electric proximity to load” to be better defined. For example, a line that carries 600 MWs in close electrical proximity to a 20-MW Load may not meet the intent of this characteristic. In planning models, loads are often aggregated to a higher voltage while, in a distribution system model, the loads are explicitly represented along the distribution feeder. Because of this, the criteria should define where the load is located/represented for the measure of electrical proximity.
No
BPA requests clarification on what the SDT considers radial through additional examples of i “the way the connections to the BES are operated” and ii “the way the Element(s) are treated in operations.” BPA emphasizes that this assessment should be conducted using normal system operations.
Yes
BPA generally agrees with the power flow concept, but suggests including language that the assessment should be “based on normal system operating conditions.” A MWh value to replace ‘TBD’ for maximum energy flowing out per year could be determined based on an annual average MW load level of 25 MW average and below with distribution service of 50MVA and below, because 25MW loads can be served by lines under 100kv. The energy flowing out per year would be limited by the size of the load and the ability to import power to the load area (i.e. the export would never be larger than the initial distribution service minus the local area losses and load). BPA requests that the drafting team perform a cross-walk analysis on each of the 4 items to ensure the consistent application of an existing industry process, practice, or standard.
Yes
BPA suggests that the SDT provide a method for assessing power transport based on intake to serve load versus outflow. BPA requests that the SDT clarify that the qualifying statements i-v for the fourth item are “or” statements.
BPA comments on the technical analysis are as follows: 1. Who is responsible for running these studies (the BA, individual utilities....?). 2. The analysis and criteria need to be better defined for the technical analysis. 3. What did SDT mean by “having a distribution factor of TBD% for any other Element”? This should probably reference a specific PTFD for a path or source/sink group. 4. What contingencies are studied to show the elements meet the transient voltage dip, frequency excursion, etc. (i.e. are they 3 phase delayed cleared faults, single phase faults, etc.)? Furthermore, the exclusion criteria needs to be much more specific about how the study is to be conducted in general – i.e.: Regional Entities have established study guidelines and procedures to determine voltage and frequency criteria. Specifically, is it the intent that the element being proposed for exclusion be opened in the study and then the standard contingency list applied to the rest of the system? Presumably, if there is no difference in system performance with the element in or out, then it could be excluded. Alternatively, is it intended that the contingency to be tested is simply the loss of the element proposed for exclusion? 5. What elements and/or flow gates should be monitored for these analyses? 6. In “Other”, the SDT should add “The limiting element for a flow-gate cannot be excluded from the BES”. 7. How will the criteria be set? Will they follow current standards? (i.e. TPL-001)? The technical principles must identify what category(ies) of TPL studies must be run. BPA requests clarification on what the values for the threshold criteria and/or disturbances would be?

No
BPA emphasizes that exclusion criteria and analysis should be based on normal operations. An exclusion should not be unavailable based on temporary system configuration such as load service by a different transmission segment temporarily used to mitigate system operations due to planned maintenance outages, i.e. a system that is operated radially over 90% of the time and closed for maintenance outages for safety and/or reliability purposes, etc. BPA recommends that the SDT consider not only the single-phase faults, also the effect of more severe events such as two- or three-phase faults, with delayed clearing and evaluate the necessity of the element in those cases.
No
Please refer to BPA's comments on Question #5.
No
The owner of the asset should have all the data necessary to perform the analysis for an Exclusion. The Exclusion analysis should use the same data request and sharing requirements of other NERC standards and the owner conducting the Exclusion analysis should consult with other entities as necessary.
No
Under NERC Standard IRO-010, the Transmission Operators are required to obtain information relating to the operation of the bulk power system within their respective areas. Transmission Operators may still need information relating to network facilities that ultimately are determined not to be BES facilities. BPA is concerned that an exclusion could eliminate a requirement that such information be provided.
No

## **Comment Form for 1<sup>st</sup> Draft of Project 2010-17: Definition of BES (BES) Technical Principles for Demonstrating BES Exceptions – City of Redding - Paul Cummings**

---

Please **DO NOT** use this form. Please use the [electronic comment form](#) to submit comments on the first draft of the Project 2010-17: Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions. **Only** submit comments on the first draft Technical Principles for Demonstrating BES Exceptions. The comments must be submitted by **June 10, 2011**.

If you have questions please contact Ed Dobrowolski at [ed.dobrowolski@nerc.net](mailto:ed.dobrowolski@nerc.net) or by telephone at 609-947-3673.

### **Background Information Definition of the BES (Project 2010-17)**

In parallel with the definition project, another stakeholder team outside the standards development process has been set up to develop a change to the NERC Rules of Procedure (ROP) to allow for entities to apply for excluding Elements from the BES that might otherwise be included according to the proposed definition and designations. This same process would be used by Registered Entities to justify including Elements in the BES that might otherwise be excluded according to the proposed definition and designations. This process would also be utilized for those situations where the core definition and designations do not clearly identify whether an Element is BES or not. The ROP team will develop the process for seeking an exception from the definition and designations, but the Definition of the BES Standards Drafting Team (DBESSDT), through the standards development process, has developed the criteria necessary for applying for an exception.

The exclusion exception process has been set up as a choice between two alternative forms of evidence. The first choice is seen as less onerous in nature as it does not require extensive technical analysis. An entity must choose which path it wants to pursue.

The inclusion exception process requires more detailed analysis and only one choice is provided.

The first draft of the criteria that has been posted contains the evidence that must be presented by an entity seeking an exception as well as specific criteria for how that evidence will be evaluated. The SDT is seeking industry feedback not just on the approach being presented but also on the specific numeric thresholds that will be used. Comments received from this posting will help to determine the final criteria that the industry will be required to adhere to. Therefore, industry feedback is vital to the development process.

It should be noted that the actual application process is described in the Rules of Procedure document that has been posted concurrent with the criteria document.

## Comment Form for 1<sup>st</sup> Draft of Project 2010-17: Definition of BES (BES) Technical Principles for Demonstrating BES Exceptions

**You do not have to answer all questions. Enter All Comments in Simple Text Format.**

*Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.*

1. Exclusions - The SDT has set up one path for evidence that does not include extensive technical analysis. It consists of 4 items, all of which must be addressed in order to submit a completed request for exclusion. The first item involves proximity to Load and requests industry feedback on how to measure this variable. Do you agree with this requirement? If you do not support this requirement or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments. In addition, in the comment field, please provide your thoughts on the appropriate impedance value to replace 'TBD,' including technical rationale for your argument.

Yes:

No: x

Comments: This could serve as one characteristic of a distribution system and is generally a good indicator that the facilities have been installed and are operating to serve a distinct geographical area (the end user). The intent should be changed to indicate it is geographical and not electrical. The electrical reference should be removed from this section and moved to the engineering section.

2. Exclusions - The SDT has set up one path for evidence that does not include extensive technical analysis. It consists of 4 items, all of which must be addressed in order to submit a completed request for exclusion. The second item involves Element(s) treated as radial. Do you agree with this requirement? If you do not support this requirement or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments.

Yes: x

No:

Comments: The term Radial could cause confusion. Clarification needs to be added to indicate that the system can have more than one connection to the BES.

3. Exclusions - The SDT has set up one path for evidence that does not include extensive technical analysis. It consists of 4 items, all of which must be addressed in order to submit a completed request for exclusion. The **third item** involves power flow. Do you agree with this requirement? If you do not support this requirement or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments. In addition, in the comment field, please provide your thoughts on the appropriate MWh value to replace 'TBD,' including technical rationale for your argument.

Yes: x

No:

## Comment Form for 1<sup>st</sup> Draft of Project 2010-17: Definition of BES (BES) Technical Principles for Demonstrating BES Exceptions

**Comments:** To be consistent with E2 of the proposed BES Definition a distribution system should be allowed to export at least 75 mw. This would be the same as a commercial retail customer can export into the distribution system.

4. Exclusions - The SDT has set up one path for evidence that does not include extensive technical analysis. It consists of 4 items, all of which must be addressed in order to submit a completed request for exclusion. The **fourth item** involves power transport. Do you agree with this requirement? If you do not support this requirement or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments.

Yes: x

No:

**Comments:** The SDT needs to address renewable energy and customer owned generation. If an aggregator adds up one thousand roof top PV units or the power from plugged in electric cars and sells them to an entity outside of this system it should not affect the ability of the distribution system to qualify for this exclusion, especially if the power is consumed inside of the distribution system.

5. Exclusions - The SDT has set up one path for evidence that includes technical analysis. Do you agree with this requirement? If you do not support this requirement or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments. In addition, in the comment field, please provide your thoughts on the proposed metrics for analysis and the appropriate values to replace 'TBD,' including technical rationale for your argument.

Yes: x

No:

5a. **Comments on approach:** It appears the industry experts have a very difficult time identifying any set of measurement factors that can be applied on a consistent basis to any system and produce similar results, therefore there needs to be geographical variation where the experts in the local systems can make a determination.

5b. Comments on distribution factor measurement:

5c. Comments on allowable transient voltage dip measurement:

5d. Comments on allowable transient frequency response:

5e. Comments on voltage deviation measurement:

6. Exclusions – Do you have other methods that may be appropriate for proving an exclusion claim? Or, other variables/measurements that may be added to the requirements already shown in the posted *Technical Principles for Demonstrating BES Exceptions*? If so, please provide your comments here with technical rationale for why they should be considered.

Yes:

No: x

**Comment Form for 1<sup>st</sup> Draft of Project 2010-17: Definition of BES (BES)**  
**Technical Principles for Demonstrating BES Exceptions**

Comments:

7. Inclusions - The SDT has set up only one path for evidence that includes technical analysis. Do you agree with this requirement? If you do not support this requirement or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments. In addition, in the comment field, please provide your thoughts on the proposed metrics for analysis and the appropriate values to replace 'TBD,' including technical rationale for your argument.

Yes: x

7a. Comments on approach:

7b. Comments on distribution factor measurement:

7c. Comments on allowable transient voltage dip measurement:

7d. Comments on allowable transient frequency response:

7e. Comments on voltage deviation measurement:

8. Do you have concerns about an entity's ability to obtain the data they would need to do the indicated technical analyses? If so, please be specific with your concerns so that the SDT can fully understand the problem and address it in future drafts.

Yes:

No: x

Comments:

9. Are you aware of any conflicts between the proposed approach and any regulatory function, rule order, tariff, rate schedule, legislative requirement or agreement, or jurisdictional issue? If so, please identify them here and provide suggested language changes that may clarify the issue.

Yes: x

No:

Comments: State and court rulings that have defined Transmission and Distribution. One possible solution is to state that the determination made via this methodology is for reliability purposes only and is not intended to redefine established market and rate determinations.

10. Are there any other concerns with this approach that haven't been covered in previous questions and comments? Please be as specific as possible with your comments.

Yes: x

No:

**Comment Form for 1<sup>st</sup> Draft of Project 2010-17: Definition of BES (BES)**  
**Technical Principles for Demonstrating BES Exceptions**

---

Comments: The SDT is encouraged to address generators installed as load modifiers to distribution load. >>>> As additional evidence of distribution line, if there is not an OATT filed on a line then it is not transmission per FERC rules.

## **Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

The Bulk Electric System (BES) Drafting Team thanks all commenters who submitted comments on the first draft of the Project 2010-17: Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions. These standards were posted for a 30-day public comment period from May 11, 2011 through June 10, 2011. The stakeholders were asked to provide feedback on the standards through a special Electronic Comment Form. There were 91 sets of comments, including comments from approximately 182 different people from approximately 124 companies representing all 10 Industry Segments as shown in the table on the following pages.

[http://www.nerc.com/filez/standards/Project2010-17\\_BES.html](http://www.nerc.com/filez/standards/Project2010-17_BES.html)

Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity's characteristics to a defined value and/or limit. It has become apparent that it is not feasible to establish continent-wide values and/or limits due to differences in operational characteristics. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the Rules of Procedure as presently being drafted.

The SDT is recommending that the project be moved to a parallel 45-day posting and ballot.

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herb Schrayshuen, at 404-443-2560 or at [herb.schrayshuen@nerc.net](mailto:herb.schrayshuen@nerc.net). In addition, there is a NERC Reliability Standards Appeals Process.<sup>1</sup>

---

<sup>1</sup> The appeals process is in the Reliability Standards Development Procedures:  
<http://www.nerc.com/standards/newstandardsprocess.html>.

1. **Exclusions - The SDT has set up one path for evidence that does not include extensive technical analysis. It consists of 4 items, all of which must be addressed in order to submit a completed request for exclusion. The first item involves proximity to Load and requests industry feedback on how to measure this variable. Do you agree with this requirement? If you do not support this requirement or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments. In addition, in the comment field, please provide your thoughts on the appropriate impedance value to replace 'TBD,' including technical rationale for your argument.**

**Summary Consideration:** A vast majority of the commenters disagreed with, or had significant questions about the validity of using electrical proximity as a metric to reflect the importance of an element or group of elements to the operation of an interconnected transmission network. Commenters pointed out that the proximity, electrical or otherwise, of an element to Load is not a reliable basis to determine functionality of an element, nor its impact upon the interconnected network.

Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity's characteristics to a defined value and/or limit. It has become apparent that it is impossible to establish values and/or limits that would be valid across all regions and systems. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the draft Rules of Procedure.

Organization	Yes or No	Question 1 Comment
Northeast Power Coordinating Council	No	<p>1.a.i. Electrical Proximity - If impedance is to be used as a measure of electrical proximity, which in turn is a replacement for geographical proximity, then how would the presence of parallel lines, capacitors, phase-angle regulators (PARs), tap-changing transformers, generation and reactors be treated in determining electrical proximity?</p> <p>How does this approach effectively differentiate between transmission and distribution lines of the same voltage and length?</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 1 Comment
		<p>When using impedance, how is “greater than” determined?</p> <p>Sum of the Impedances - Would the filing entity simply add up the in-series impedances for each radial Element to demonstrate its electrical proximity? For example, would the sum of the impedances from this radial path example be equal to the sum of the two feeder and transformer impedances, i.e., measured from a 230 kV bus along a 230 kV feeder, through a 230/138 kV step-down transformer, and an in-series 138 kV feeder to a 138/13.8 kV step-down distribution transformer? What impedance would the SDT apply to a PAR (or tap-changing transformer) and to the overall path if a PAR (or tap-changing transformer) were located in-series with the measured Elements?</p> <p>1.a.ii. Power Flows - What is the meaning of “power flow data” as the term is used here and how is the meaning different from the term when used under 1.c. Power flows into the system, but rarely flows out? Should this sentence use the phrase “impedance data extracted from a load flow study” instead?</p> <p>Entities should be required to identify the significance of the element’s physical characteristics. Such identification can be done through a simple checklist along with any relevant comments.</p> <p>The SDT should revise the exception criteria to seek an alternative language and/or revise exclusion criteria (a), which will require entities to provide the previously stated information for their element.</p>
SERC Planning Standards Subcommittee	No	<p>The PSS disagrees with the assumption that the proximity of a BES facility to Load is indicative of it's importance to BES reliability. Some lower voltage facilities can be quite short and thus have lower impedance but be important to BES reliability. Furthermore, the term "Load centers" is not defined leaving it subject to interpretation. Assuming a load center has many busses, where would the measurement be made - From the most distant load bus in the load center or the nearest? Similarly - does a single facility get measured from it's terminal to the load center or does the presence or lack of breakers need to be considered when selecting the measurement point?</p>
SPP Standards Review Group	No	<p>Physical characteristics as described in 1.a.i. do not capture the true picture of the functionality of an Element. Rather than use impedance perhaps the SDT should use ‘radial’ or ‘having one source’ as the descriptive term.</p>
City of Redding		<p>This could serve as one characteristic of a distribution system and is generally a good indicator that the facilities have been installed and are operating to serve a distinct geographical area (the end user). The intent should be changed to indicate it is geographical and not electrical. The electrical reference should be removed from this section and moved to the engineering section.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 1 Comment
NERC Staff Technical Review	No	Electrical proximity to load is not an informative measure of whether Element(s) are necessary for reliable operation or the potential reliability impact of excluding Element(s) from the BES. Establishing a maximum impedance threshold as proposed would assure only that the excluded Element(s) do not span a large electrical distance. While minimizing impedance may be beneficial for some aspects of reliability, other aspects of BES reliability are improved with higher impedance. For example, higher impedance minimizes through-flow of power and minimizes impacts to BES reliability associated with faults and switching errors.
ISO/RTO Standards Review Committee	No	The SRC fails to see how electrical proximity to load qualifies an element for exclusion from the BES. Such elements may indeed be involved in serving electricity to those loads. If those loads are critical loads, then why should the element be excluded from the BES?
Iberdrola USA	No	<p>We do not agree with this requirement. These exclusion exception criteria should be deleted in their entirety and replaced with criteria that are objective, specific, and repeatable, or preferably not replaced at all.</p> <p>Specific problems with the criteria as stated are: 1. A facility is not BES if all of “a” through “d” below apply:</p> <p>a. “System elements” are in “close electrical proximity to load” - this is vague, and a lower impedance between systems is higher likelihood of interaction between systems. Proximity measured in ohms should be related to the load level itself. A pair of values (ohms, load) is necessary for this purpose. Transient stability is affected by this value-pair. For a load pocket, an equivalent impedance (e.g., a sort of Thevenin impedance) between the network source and the load location could be defined. The impedances within the network source can also affect the assessment. Re-evaluation over time would be necessary if this path were adopted.</p> <p>This path of evidence (i.e., the path of engineering judgment) which does not include extensive technical analysis is an attempt to provide a definitive criteria for exception without going through the other path of evidence (i.e., the analytical path) which includes extensive technical analysis. Unless the analytical path has been clearly defined and sufficient data obtained from/on it, the path of engineering judgment could become difficult to establish. System parameters such as proximity to load, radial (or non-radial) configuration, power flow direction over time (either unintended or intended) will directly influence results of technical analysis evaluated for distribution factors, transient voltage dip and frequency excursions, voltage deviations, transient and steady-state stability, and sequence of events following a disturbance (i.e., either a cascading outage or a controlled outage). The two paths of evidence cannot be in conflict with each other.</p>
Tri-State Generation and Transmission Association	No	A long radial line with a small transformer could have a relatively high impedance. Proximity to load has no real bearing on this procedure. Requirement 1.(a) should be deleted.

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 1 Comment
Hydro One	No	<p>We agree with this concept to allow entities to submit an exception application that does not include extensive technical analysis. Such an option will make the process efficient for all stakeholders, such as entities, Regions, NERC and relevant regulatory authority. However, our opinion is that there is no real relationship between reliability and the proximity of load. If impedance is to be used as a measure of electrical proximity, which in turn is a replacement for geographical proximity, then how would the presence of parallel lines, capacitors, phase-angle regulators (PARs), tap-changing transformers, generation and reactors be treated in determining electrical proximity?</p> <p>Consistent with references in the FERC Order, we feel that it is much more important to identify and ensure if the BES element(s) are serving load pockets associated with large metropolitan load centers, loads of significance to national security and/or as identified by relevant Federal, State or Provincial Regulatory Authority.</p> <p>We urge the SDT to clarify the exception criteria for exclusions, based on the following questions:</p> <ul style="list-style-type: none"> <li>oHow does the proximity impedance approach effectively differentiate between transmission and distribution lines of the same voltage and length?</li> <li>oWhen using impedance, how is “greater than” determined?</li> <li>oWhat impedance would the SDT apply to a PAR (or tap-changing transformer) and to the overall path if a PAR (or tap-changing transformer) were located in-series with the measured Elements?</li> <li>oWhat is the meaning of “power flow data” used here and how is the meaning different from the term when used under “1c) Power flows into the system, but rarely flows out”? Should this sentence use the phrase “impedance data extracted from a load flow study” instead?</li> </ul> <p>Finally we suggest that entities should be required to identify the significance of the element’s physical characteristics. Such identification can be done through a simple checklist along with any relevant comments.</p>
MRO's NERC Standards Review Forum MidAmerican Energy Muscatine Power and Water	No	<p>NSRF believes the relevance and rationale for this criterion is unknown. If this criterion is intended to exempt elements, like circuit switchers, that are part of the distribution transformer circuits operated above 100 kV, and located within a mile of the BES interconnection point, then NSRF would expect the wording to be “in close electric proximity to the BES” rather than in “close electric proximity to Load”. Otherwise, NSRF requests the SDT explain the relevance and rationale for this criterion before agreeing on its inclusion.</p>
ReliabilityFirst	No	it is far too complicated for the smaller entities
New York State Reliability	No	NERC’s Glossary definition of Load is “An end-use device or customer that receives power from the electric

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 1 Comment
Council		<p>system.” which is not specific enough to permit the definition of an appropriate impedance value.</p> <p>It is not clear from the proposed wording whether the exception applies to the Loads or the electrically close System Elements or both. In any case, the concept of a single impedance value as a metric is flawed because it could be a low impedance breaker or a relatively high impedance transformer connecting the BES to a “radial” Load center. This exclusion is superfluous given the radial test in item 2. Suggest dropping this exclusion test.</p> <p>N.B. The proposed criteria in items 1 - 4 must all be met in order for an element to qualify for an exclusion.</p>
New York Power Authority	No	<p>NYPA does not see a need for this requirement. A radial element that specifically serves a load center will perform that task regardless of the electrical distance from the source to the load. Similarly, any loss of load in the load center will result in a corresponding need to reduce generation in the source system, regardless of the proximity of the load.</p>
ITC	No	<p>Please explain the rationale to require electrical proximity. Is it to limit fault exposure? Perhaps 2 miles of line could be shown to typically have few faults, thus limiting the number of voltage sags to nearby buses. At approximately 0.7 ohms per mile 1.5 ohms (for overhead) might be a reasonable number. Does it make a difference if the load is connected via underground cable?</p>
South Carolina Electric and Gas Georgia Transmission Corporation	No	<p>SCE&amp;G disagrees with the assumption that the proximity of a BES facility to Load is indicative of it's importance to BES reliability. Some lower voltage facilities can be quite short and thus have lower impedance but be important to BES reliability.</p> <p>Furthermore, the term "Load centers" is not defined leaving it subject to interpretation. Assuming a load center has many busses, where would the measurement be made - From the most distant load bus in the load center or the nearest? Similarly - does a single facility get measured from it's terminal to the load center or does the presence or lack of breakers need to be considered when selecting the measurement point?</p>
Glacier Electric Cooperative	No	<p>I do not think that the proximity to load should be a factor in determining whether or not an element should be included in the BES. Rather, the purpose of the element should be the important factor. If an element only serves load, then that should be the most important factor and the proximity (electrical or physical) to that load should not matter.</p>
Consolidated Edison Co. of NY, Inc.	No	<p>We generally support this exclusion option concept, to the extent that it is fashioned after the FERC Seven Factor test. However, we have a number of questions as to how it might work in practice.1.a.i. Electrical Proximity - If impedance is to be used as a measure of electrical proximity, which in turn is a replacement for</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 1 Comment
		<p>geographical proximity, then how would the presence of parallel lines, capacitors, phase-angle regulators (PARs), tap-changing transformers, generation and reactors be treated in determining electrical proximity? How does this approach effectively differentiate between transmission and distribution lines of the same voltage and length? When using impedance, how is “greater than” determined?</p> <p>Sum of the Impedances - Would the filing entity simply add up the in-series impedances for each radial Element to demonstrate its electrical proximity? For example, would the sum of the impedances from this example radial path be equal to the sum of the two feeder and transformer impedances, i.e., measured from a 230 kV bus along a 230 kV feeder, through a 230/138 kV step-down transformer, and an in-series 138 kV feeder to a 138/13.8 kV step-down distribution transformer? What impedance would the SDT apply to a PAR (or tap-changing transformer) and to the overall path if a PAR (or tap-changing transformer) were located in-series with the measured Elements?</p> <p>1.a.ii. Power Flows - What is the meaning of “power flow data” as the term is used here and how is the meaning different from the term when used under 1.c. Power flows into the system, but rarely flows out? Should this sentence use the phrase “impedance data extracted from a load flow study” instead?</p>
ISO New England	No	<p>We disagree with this exception and believe that Section 1.a. should be deleted in it’s entirety and replaced with a definition that excludes remote areas of a generally lesser overall value to reliability and includes areas that are heavily networked serving large loads.</p> <p>The premise of the existing section 1.a. seems at odds with overall system reliability and possibly removes large metropolitan areas from the BES definition. How is close electrical proximity to load defined? A maximum number of Ohms? Heavily networked areas will have lower impedance and are more likely to serve larger amounts of demand and are therefore more likely to be impactful on the overall integrity of the BES.</p>
Flathead Electric Cooperative, Inc.	No	<p>agree in principle that one characteristic of local distribution systems is that they are usually confined to a relatively limited geographic area, as opposed to transmission systems, which (especially in the West) tend to cover very large distances. We also believe the proximity test may be a sensible way to identify local distribution facilities. However, we believe that the proximity test may be unnecessary, and if an Element or group of Elements meets other tests proposed by the SDT, it should be excluded from the BES, even if it does not meet the proximity test.</p>
Entergy Services	No	<p>Entergy does not agree with the assumption that the proximity of a BES facility to Load is indicative of it's importance to BES reliability. Some lower voltage facilities can be quite short and thus have lower impedance but be important to BES reliability. Likewise some facilities remote from load centers may have virtually no</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 1 Comment
		<p>impact on BES reliability.</p> <p>There is also insufficient information as to how the impedance would be measured (locations of measurements within and outside of the "Load pockets". This Exemption Criteria should be removed.</p> <p>The term "Load centers" is not defined leaving it subject to interpretation. "Loads" are not BES Elements and therefore can not be exempted from being considered BES Elements.</p> <p>Item 1.a.i - "Loads within the system seeking exception are in close electrical proximity if they are separated by an impedance of no greater than TBD." This sentence needs to be deleted.</p>
BGE	No	BGE is not clear as to why "close electrical proximity to load" is appropriate to use as a factor in determining exclusion.
Spyker	No	<p>We agree with this concept to allow entities to submit an exception application that does not include extensive technical analysis. Such an option will make the process efficient for all stakeholders, such as entities, Regions, NERC and relevant regulatory authority. However, our opinion is that there is no real relation between reliability and the proximity of load. Consistent with references in the FERC Order, we feel that it is much more important to identify and ensure if the element(s) are serving load pockets associated with large metropolitan load centers (e.g. New York City, Washington DC, Toronto), loads of significance to national security and/or as identified by relevant Federal, State or Provincial Regulatory Authority.</p> <p>We believe that entities should be required to identify the significance of the elements' physical characteristics, such as the proximity of element or, being served or impacted by the element to a load of significant interest. Such identification can be done through a simple checklist along with any relevant comments.</p> <p>Therefore, we suggest the SDT to revise the exception criteria to seek an alternative language and/or re-craft exclusion criteria (a), which will require entities to provide the previously stated information for their element.</p>
<p>Benton Rural Electric Association</p> <p>Northern Wasco County PUD</p> <p>United Electric Co-op Inc</p> <p>Oregon Trail Electric Cooperative, Inc.</p>	No	We believe that the proximity test may be unnecessary, and if an Element or group of Elements meets the other three tests proposed by the SDT, it should be excluded from the BES, even if it does not meet the proximity test. Secondly, using impedance to benchmark system load proximity would likely not yield clear demarcations. High voltage relative or per-unit impedances are considered typically much lower than low voltage impedances. Hence, in the absence of phase shifting transformers, service compensation, or other mitigation factors, power typically flows over the highest voltage lines, which offer the lowest impedance.

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 1 Comment
<p>Salem Electric Grant County PUD No. 2 (Grant) Big Bend Electric Cooperative, Inc. Big Bend Electric Cooperative, Inc. Kootenai Electric Cooperative</p>		
<p>Orange and Rockland Utilities, Inc.</p>	No	<p>The approach does not differentiate between transmission and distribution. There is no direct relation between impedance and load. A study of the particular system should be performed to assess impact on BES.</p>
<p>Pepco Holdings Inc</p>	No	<p>A specific impedance value would not be appropriate for all regions and all configurations.</p>
<p>Consumers Energy Company</p>	No	<p>Consumers Energy Company (CECo) proposes that this criterion be eliminated, as it is not a definitive BES criterion. There is no correlation between the proximity of Elements that are 100kV and above to load.</p>
<p>Central Lincoln</p>	No	<p>Central Lincoln agrees in principle that one characteristic of local distribution systems is that they are usually confined to a relatively limited geographic area, as opposed to transmission systems, which (especially in the West) tend to cover very large distances. We also believe the proximity test may be a sensible way to identify local distribution facilities. However, as explained in more detail in our response to Question 10, we believe that the proximity test may be unnecessary, and if an Element or group of Elements meets the other three tests proposed by the SDT, it should be excluded from the BES, even if it does not meet the proximity test. Secondly, using impedance to benchmark system load proximity would likely not yield consistent demarcations. High voltage relative or per-unit impedances are typically much lower than low voltage impedances. Hence, in the absence of phase shifting transformers, service compensation, or other mitigation factors, power typically flows over the highest voltage lines, which offer the lowest impedance. Central Lincoln proposes that “proximity” be determined in the dictionary manner with units of distance.</p>
<p>Duke Energy</p>	No	<p>Duke Energy does not agree that this characteristic materially demonstrates that an Element is not necessary for operating an interconnected electric transmission network. There is no correlation between the electrical proximity of an element to load and its necessity for operating an interconnected transmission network. In general, the path that does not include extensive technical analysis is not adequate to distinguish between the</p>

Organization	Yes or No	Question 1 Comment
		Elements that are and that are not necessary for said operation.
Hydro-Quebec TransEnergie	No	Close electrical proximity to load does not appear to be an appropriate criteria. There is no reason that this criteria would prevent exclusion of a radial system with long lines feeding far away loads. Instead of considering proximity to load, it would be better to consider the way the Element is connected to the BES and the function of the excluded part of the system, mainly to deserve loads or integrate some generation, but not to transfer power to another Balancing Authority. Those are covered by criteria b., c. and d., so we believe that criteria a. should not be maintained.
American Transmission Company, LLC	No	ATC believes the relevance and rationale for this criterion is unknown. If this criterion is intended to exempt elements, like circuit switchers, that are part of the distribution transformer circuits operated above 100 kV, and located within a mile of the BES interconnection point, then ATC would expect the wording to be “in close electric proximity to the BES” rather than in “close electric proximity to Load”. Otherwise, ATC requests the SDT explain the relevance and rationale for this criterion before agreeing on its inclusion.
Manitoba Hydro	No	The purpose of this exception is unclear. It would be possible that a large transmission station with many network connections, which is close to a load (irrespective of size), would be excluded from the BES definition. Similarly, a reduction of system impedance, by transmission line re-conductoring for example, could remove assets out of the scope of the BES definition. The listed proposed criteria suggest values yet to be determined. It is unclear how this exception would support BES reliability.
NESCOE	No	<p>The New England States Committee on Electricity (“NESCOE”) appreciates the work of NERC’s standard drafting team as well as the opportunity to provide comments on this matter. NESCOE is New England’s Regional State Committee and the comments provided herein reflect the collective views of the six New England states. NESCOE’s comments below reflect its general perspective that any new costs imposed as a result of the BES and its implementation, which costs ultimately fall on consumers, should provide meaningful reliability benefits. NESCOE questions the concept as presented and seeks further clarification.</p> <p>As a general matter, NESCOE believes the requirement that a proposed exception must meet all four criteria is overly restrictive and will result in only a narrow category of elements qualifying for exclusion from the BES. NESCOE suggests that a better approach would allow exclusions to be based on one or more criteria, depending on the nature of the element that is the subject of the application.</p> <p>With respect to the proposal, NESCOE does not believe it is possible to obtain agreement on the “proximity to load” criterion for additional exclusions from the BES when the underlying impedance value has not been determined and may be the subject of significant debate.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 1 Comment
		<p>While it is possible that NESCOE could support a single impedance value that would govern exclusion determinations, it notes that a uniform value may not adequately address varying system configurations throughout ISO-New England and neighboring control areas. NESCOE suggests that the standards setting process allow for further deliberation on possible proposed values.</p> <p>Other terms, such as “load center,” also need definition.</p>
Independent Electricity System Operator	No	We agree with this concept to allow entities to submit an exception application that does not include extensive technical analysis. Such an option will make the process efficient for all stakeholders, such as entities, Regions, NERC and relevant regulatory authority. However, we believe that an Element’s electrical proximity to load is not necessarily a relevant consideration for determining whether the Element is required for reliable operations.
Tacoma Power	No	Tacoma Power does not believe that a proximity to Load criteria is useful in BES designation when the other 3 exclusion criteria of this path are applied. However, if the SDT retains this item, we suggest an impedance value of < 0.3 ohms on a 100 MVA base.
Georgia System Operations Corporation		The concept of “Load centers” is vague and needs more specificity for this to be clear.
ACES	Yes	This seems like a reasonable approach although we have no recommendations for impedance thresholds. Some analysis of various load pockets might provide data to consider for the threshold.
Clark Public Utilities	Yes	Clark believes the proximity test should be considered be a valid factor in determining whether a facility is part of the BES or not. Just as this factor is used in the consideration on whether a facility is part of a Local Distribution Network. Clark is not convinced that “proximity” and “impedance” are interchangeable. While impedance will be lower for shorter distances it will also be affected by other factors that are not indicative of close proximity. Distance seems more appropriate to use since it would complement a literal interpretation of the term proximity.
Blachly Lane Electric Cooperative Central Electric Cooperative Clearwater Power Electric	Yes	First, thank you for the opportunity to comment on the Technical Principles for Demonstrating BES Exceptions. We appreciate the work that NERC has done on these principles and the other related efforts to revise the definition of the BES. In response to question #1, we note only that using impedance to benchmark system load proximity would likely not yield clear demarcations. High voltage relative or per-unit impedances are considered typically much lower than low voltage impedances. Hence, in the absence of phase shifting transformers, service compensation, or other mitigation factors, power typically flows over the highest voltage

Coos-Curry Electric Cooperative Douglas Electric Cooperative Fall River Electric Cooperative Lane Electric Cooperative Lincoln Electric Cooperative Lost River Electric Cooperative Northern Lights Electric Cooperative Okanogan Electric Cooperative Raft River Rural Electric Cooperative Salmon River Electric Cooperative Umatilla Electric Cooperative West Oregon Electric Cooperative Pacific Northwest Generating Cooperative		lines, which offer the lowest impedance.
Long Island Power Authority	Yes	Agree with close proximity to load concept but further direction (define suggested methodology) is required for how to calculate impedance value. In addition to impedance value suggest consideration of adding mileage or relative phase angle differences between locations be also an allowable criteria.
American Electric Power	Yes	Using "proximity to load" is a reasonable metric, but would require further consideration given the impedance value eventually chosen to replace "TBD".

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 1 Comment
Oregon Public Utility Commission Staff	Yes	Use of the 100 kV brightline and the core BES definition as proposed is an overreach into local distribution systems and an overreach of FERC’s authority as set out in the FPA 215. A full engineering technical analysis - required every 2 years - is too onerous and not necessary for identifying most local distribution elements miss-identified as BES Elements. A simple screening methodology consistent with the 7-Factor Test (from FERC Order 888) is needed as the first stage of the exception process.
Harney Electric Cooperative, Inc.	Yes	I don't have a suggestion for an appropriate impedance.
Bonneville Power Administration	Yes	BPA suggests that correlation between the size of the Load and the size of an element is needed. BPA would like the word “close” in the description “close electric proximity to load” to be better defined. For example, a line that carries 600 MWs in close electrical proximity to a 20-MW Load may not meet the intent of this characteristic. In planning models, loads are often aggregated to a higher voltage while, in a distribution system model, the loads are explicitly represented along the distribution feeder. Because of this, the criteria should define where the load is located/represented for the measure of electrical proximity.
Western Electricity Coordinating Council	Yes	<p>As long as this remains an “AND” statement, WECC supports this concept. It helps to support the concept that the element is used as distribution to serve Load, rather than to transfer bulk power. However, some correlation between the size of the Load and the size of an element may be needed. For example, a line that can carry 600 MW in close electrical proximity a 20-MW Load may not meet the intent of this characteristic.</p> <p>Furthermore, the criteria must define where the load is located for the measure of electrical proximity. In planning models, loads are often aggregated to a higher voltage substation bus, while in a distribution system model they are typically modeled along a distribution feeder.</p> <p>The SDT should clarify how it intends for the load to be modeled for this analysis of close proximity.</p>
Electricity Consumers Resource Council (ELCON)	Yes	We recommend that this item be added to the BES definition.
Occidental Energy Ventures Corp.	Yes	
Xcel Energy	Yes	
Oncor Electric Delivery	Yes	Oncor Electric Delivery agrees with the proposed language as it is stated, related to load proximity.

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 1 Comment
<p><b>Response:</b> The SDT appreciates the suggestions for alternate language or clarifications to the proposed language for the characteristic associated with the system Element being located in close electrical proximity of Load and the use of impedance as qualifying criteria. Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity’s characteristics to a defined value and/or limit. It has become apparent that it is impossible to establish values and/or limits that would be valid across all regions and systems. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the draft Rules of Procedure.</p>		
Edison Electric Institute	No	<p>We do not believe that a meaningful “not to exceed” impedance value can be proffered which would be appropriately useful across all regions. EEI recommends that Exclusion benchmarks should directly correlate to the BES definition exclusions as written. Although the “4 Item” approach was obviously intended to provide a simple approach, the outcome suggested in the draft was less than satisfactory and we submit it does not hold true to the exclusions provided by the Drafting Committee in their proposed BES Definition. (see additional comments provided at the end of the Comment form)</p>
PacifiCorp	No	<p>All of PacifiCorp’s responses are based on the application of these items to a given interconnection and not on a continental basis. See comments on question 10. Setting a standard for close electrical proximity using an impedance measurement does not address a proper measurement in all interconnections. A better, more accurate measurement would be to utilize fault duty. Low fault duties provide a good measurement of impact on the BES. Fault Duty at adjacent BES substations should not exceed 5,000 MVA.</p>
for Snohomish County PUD	No	<p>Snohomish agrees in principle that one characteristic of local distribution systems is that they are usually confined to a relatively limited geographic area, as opposed to transmission systems, which (especially in the West) tend to cover very large distances. We also believe the proximity test may be a sensible way to identify local distribution facilities. However, as explained in more detail in our response to Question 10, we believe that the proximity test may be unnecessary, and if an Element or group of Elements meets the other three tests proposed by the SDT, it should be excluded from the BES, even if it does not meet the proximity test.</p> <p>Further, using impedance to benchmark system load proximity would likely not yield clear demarcations. High voltage relative or per-unit impedances are considered typically much lower than low voltage impedances. Hence, in the absence of phase shifting transformers, service compensation, or other mitigation factors, power typically flows over the highest voltage lines, which offer the lowest impedance.</p>

		<p>system Element being located in close electrical proximity of Load and the use of impedance as qualifying criteria. Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity’s characteristics to a defined value and/or limit. It has become apparent that it is impossible to establish values and/or limits that would be valid across all regions and systems. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the draft Rules of Procedure.</p> <p>Also see response to Question 10.</p>
<p>Florida Municipal Power Agency Transmission Access Policy Study Group</p>	<p>No</p>	<p>Impedance is a function of a line’s length; it does not measure whether a line serves a BES function. A very long line can exist only to serve load, and a short line in an urban area (where the load is physically close to the grid) could be needed for transmission but would have low impedance. This proposed metric is thus both over- and under-inclusive, and should be discarded.</p> <p>Transfer distribution factor is a more appropriate metric, as described in FMPA’ response to Question 4.</p> <p>FMPA supports having two paths for exclusions, one that includes extensive technical analysis and another that does not. The path with less technical analysis is appropriate for Elements that a relatively high-level examination shows to be not relevant to the reliability of the grid. This opportunity should be available in the context of exclusions to reduce the burden on small entities. Reliability will not be impaired by this option; all exception requests will be reviewed by NERC, and in any case where NERC is less than certain that an exception is appropriate, NERC can perform any or all of the analyses that would be required for a more technical exclusion or inclusion, and a positive result on any one of the analyses would be sufficient justification to deny the exclusion request.</p>
<p><b>Response:</b> The SDT appreciates the suggestions for alternate language or clarifications to the proposed language for the characteristic associated with the system Element being located in close electrical proximity of Load and the use of impedance as qualifying criteria. Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. Organization	Yes or No	Question 1 Comment
<p>Also see response to Question 4.</p> <p>In regards to a two-path approach, the SDT has broadened the exception methodology to allow an entity to submit the characteristics of the Facilities in question without supplying engineering evidence if they feel there is ample supporting documentation for the exception being sought.</p>		
Idaho Falls Power	No	<p>We do not agree that all four criteria under exclusion #1 need be applied in combination to an element to determine its material impact. Assets satisfying all four defining criteria would seem exceedingly small and likely already excluded by the BES definition. This exception criteria appears redundant to, and shadows the NERC BES definition draft’s language excluding radial elements and local distribution networks, and as such add little value to the exclusions built into the BES definitions.</p> <p>Further, the language of the exception criteria addresses transmission elements and doesn’t provide exclusion criteria for generation assets. We would hope that NERC could develop criteria to exempt certain generation, especially those small resources on local distribution networks wherein the generation is completely allocated to local load. Language in section 215 of the FPA excludes distribution “elements.” We assert that generation on a distribution network serving only load on that network is an “element” of the network and deserves exclusionary defining criteria.</p>
<p><b>Response:</b> The SDT appreciates the comments associated with the Element characteristics and the suggestions for language or clarifications to the proposed language for technical exception criterion associated with generation. Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity’s characteristics to a defined value and/or limit. It has become apparent that it is impossible to establish values and/or limits that would be valid across all regions and systems. **Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 1 Comment
The United Illuminating Company	No	
<p><b>Response:</b> Thank you for your response but without specific comments there is nothing that the SDT can do to address your opinion. However, based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES.. The initial proposal was dependent on a comparison of an entity’s characteristics to a defined value and/or limit. It has become apparent that it is impossible to establish values and/or limits that would be valid across all regions and systems. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the draft Rules of Procedure.</p>		
National Grid	No	<p>We feel that there is no relation between the proximity to load and system reliability. The impedance is technically irrelevant, and we suggest that this criteria be dropped.</p> <p>If the criteria is not dropped, there should be clarification on what is meant by “Load”. For instance are you really referring to “major load centers”? In many areas of the country Load is connected all along a 100kV line and hence much of a line is in close proximity to Load - but it could be small industrial loads and not significant load centers. If significant Load Centers is what the drafting team was driving at then, we believe it should be explicit.</p> <p>We also believe that if the drafting team is defining some technical criteria, then it should not be in the exception process. It should be included as part of the core definition. The exception process should be strictly limited to the procedures for application and approval and should not include substantive elements.</p>
<p><b>Response:</b> The SDT appreciates the suggestions for alternate language or clarifications to the proposed language for the characteristic associated with the system Element being located in close electrical proximity of Load and the use of impedance as qualifying criteria. Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. Organization	Yes or No	Question 1 Comment
		Rules of Procedure is strictly focused on the process that entities shall use to seek and be granted or denied exceptions.
Exelon	No	The term “close proximity” is ambiguous and open ended. Exelon believes that all facilities used in local distribution of electric energy that are presently under state jurisdiction should be excluded from the BES regardless of system impedance.
<p><b>Response:</b> The SDT appreciates your comments. Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity’s characteristics to a defined value and/or limit. It has become apparent that it is impossible to establish values and/or limits that would be valid across all regions and systems. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the draft Rules of Procedure.</p> <p>In regards to the facilities used in local distribution that are presently under state jurisdiction the SDT has added language to the core BES definition that addresses the exclusion of distribution facilities.</p>		

**2. Exclusions - The SDT has set up one path for evidence that does not include extensive technical analysis. It consists of 4 items, all of which must be addressed in order to submit a completed request for exclusion. The second item involves Element(s) treated as radial. Do you agree with this requirement? If you do not support this requirement or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments.**

**Summary Consideration:** A significant portion of the comments disagreed with, or had significant concerns about using various undefined terms such as “regional dispatch”, “disconnection procedures”, and “radial in character”. Comments also indicated that the example was not clear and many comments indicated that the entire wording of this exception should be abandoned. Several comments indicated that assessments, studies, and drawings/diagrams should be allowed as evidence to provide the validity of the exception.

Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity’s characteristics to a defined value and/or limit. It has become apparent that it is impossible to establish values and/or limits that would be valid across all regions and systems. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the draft Rules of Procedure.

Organization	Yes or No	Question 2 Comment
Northeast Power Coordinating Council	No	<p>The term “regional dispatch” is not defined. Provide a definition or reference to a definition to be used in making this determination. Recommend adoption of the alternate term “operational control.”</p> <p>1.b.ii, Operational Control - The SDT should consider using the terms “under the operational control of a Balancing Authority.” It is instructive that the overarching requirement for a finding of transmission system integration in Mansfield was that the facilities be under operational control of the Independent System Operator (ISO).** Southern Cal. Edison Co., 92 FERC ¶ 61,070 at 61,255 (2000), reh’g denied 108 FERC ¶ 61,085 (2004).</p> <p>Replace the example in 1.b.i. with a clearer example.</p> <p>Entities should be allowed to demonstrate the radial characteristics to determine if they are permitted for an exception, and demonstrate compliance with radial defining criteria.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 2 Comment
SPP Standards Review Group	No	<p>Could the SDT clarify what is meant by ‘disconnection procedures’ in 1.b.ii? It appears that the SDT is okay with excluding an element that can be switched out of service without removing another element. How are automatic breaker operations or manual switching factored into disconnection procedures? We need clarification on this.</p> <p>More and better examples, including the type of connectivity to the grid, would be helpful.</p>
Transmission Access Policy Study Group	No	<p>We believe that this criterion is intended, like those in 1(a) and (d), to determine whether an Element is planned and operated to function as part of the interconnected grid. It is, however, too vague to be useful and should be discarded.</p>
Florida Municipal Power Agency		<p>We believe that this criterion is intended, like those in 1(a) and (d), to determine whether an Element is planned and operated to function as part of the interconnected grid. It is, however, too vague to be useful and should be discarded.</p>
ISO/RTO Standards Review Committee	No	<p>The SRC generally agrees that radial elements likely may be excluded from the BES. However, there is insufficient information given as to what it means to be “not operated as part of the BES with disconnection procedures for when a Disturbance occurs”.</p> <p>Further, is it possible that such radial elements are serving a remote “critical” load? One would think that, normally, critical loads would have arrangements for multiple sources, but could those multiple sources be individually considered to be radial?</p>
Iberdrola USA	No	<p>We do not agree with this requirement. These exclusion exception criteria should be deleted in their entirety and replaced with criteria that are objective, specific, and repeatable, or preferably not replaced at all.</p> <p>Specific problems with the criteria as stated are: 1. A facility is not BES if all of “a” through “d” below apply:</p> <p>b. “System elements” are “treated as” radial “in character” - this is also vague, and based on operating procedures... what does “treated” involve? What is “character” in the context of system elements?</p>
Tri-State Generation and Transmission Association	No	<p>While we generally agree, 1.(b) should be changed to “normally radial.” “Radial” should not be defined differently in the Rule of Procedure than in the BES Definition.</p>
Hydro One	No	<p>Entities should be allowed to demonstrate the radial characteristics to determine if they are permitted for an exception, and demonstrate compliance with radial defining criteria.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 2 Comment
		<p>The term “regional dispatch” is not defined. Therefore we suggest the SDT to provide a definition or reference to clarify regional dispatch in 1 b) II.</p> <p>We recommend adoption of the alternate term “operational control” and suggest that the SDT consider using the terms “under the operational control of a Balancing Authority” (It is instructive that the overarching requirement for a finding of transmission system integration in Mansfield was that the facilities be under operational control of the Independent System Operator.)* Southern Cal. Edison Co., 92 FERC ¶ 61,070 at 61,255 (2000), reh'g denied 108 FERC ¶ 61,085 (2004).</p>
MRO's NERC Standards Review Forum	No	Radial in Character - NSRF proposes that this criterion be eliminated because it does not describe any materially different characteristics beyond Exclusion E1 of the bright-line BES definition.
MidAmerican Energy	No	MidAmerican supports the NSRF comments. The NSRF proposes that this criterion be eliminated because it does not describe any materially different characteristics beyond Exclusion E1 of the bright-line BES definition. If not eliminated, the IEEE definition of a radial system should be used.
Bonneville Power Administration	No	<p>BPA requests clarification on what the SDT considers radial through additional examples of i “the way the connections to the BES are operated” and ii “the way the Element(s) are treated in operations.”</p> <p>BPA emphasizes that this assessment should be conducted using normal system operations.</p>
Muscatine Power and Water	No	Radial in Character -propose that this criterion be removed for the reason that it does not illustrate any materially different characteristics beyond Exclusion E1 of the bright-line BES definition.
Exelon	No	<p>The term “rarely” is ambiguous and should be removed or quantified.</p> <p>Furthermore, the requirement for power flow analysis will be viewed by many entities as extensive technical analysis.</p>
Consolidated Edison Co. of NY, Inc.	No	<p>We generally support this exclusion option concept, to the extent that it is fashioned after the FERC Seven Factor test. However, we have a number of questions as to how it might work in practice. For example, the term “regional dispatch” is not defined. Please provide a definition or reference to a definition to be used in making this determination.</p> <p>Below we recommend adoption of the alternate term “operational control.”1.b.ii, Operational Control - The SDT should consider using the terms “under the operational control of a Balancing Authority.” It is instructive that the overarching requirement for a finding of transmission system integration in Mansfield was that the</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 2 Comment
		<p>facilities be under operational control of the Independent System Operator (ISO).** Southern Cal. Edison Co., 92 FERC ¶ 61,070 at 61,255 (2000), reh'g denied 108 FERC ¶ 61,085 (2004).</p> <p>Replace the example in 1.b.i. with a clearer example.</p>
ISO New England	No	<p>This three part definition of radial presented in section 1.b. appears cumbersome and requires more definition.</p> <p>With regard to b.i - Where is the disturbance? Is sending a person to the field to perform manual disconnection a requirement of this exception? This item is so vague that we have difficulty providing replacement language as we do not understand its intent.</p> <p>With regard to b.ii - Elements (Excluding generators) are not dispatched in operations. If this approach were to be taken, what would be the criteria for the way the Element is treated in Operations? Again, this item is so vague that we have difficulty providing replacement language.</p> <p>The existing definition appears to require a good deal of technical scrutiny and be at odds with the goal of having a path for evidence that does not include extensive technical analysis. Overall it seems simpler to replace section b with a simpler definition of radial such as - all load served from a single substation at a single voltage level.</p>
The United Illuminating Company	No	
Pepco Holdings Inc	No	<p>Radial system is already an explicit Exclusion by definition (E1). Does this imply that ALL radial systems require a request to be submitted for the RE and NERC approval that the elements are in fact radial?</p> <p>There may not be internal written procedures describing the radial system operation. The evidence that an entity can provide should include a description or justification of the radial operation and non impact to the BES.</p>
Duke Energy	No	<p>This second characteristic does not add clarity to the E1 Exclusion in the proposed BES definition. And in general, the path that does not include extensive technical analysis is not adequate to distinguish between the Elements that are and that are not necessary for operating an interconnected electric transmission network.</p>
American Transmission Company, LLC	No	<p>Radial in Character - ATC proposes that this criterion be eliminated because it does not describe any materially different characteristics beyond Exclusion E1 of the bright-line BES definition.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 2 Comment
Manitoba Hydro	No	<p>The proposed criteria to substantiate a request for an exception should be removed as it does not introduce anything different than what is already proposed under the exclusions in the bright line BES definition. Specifically, radial systems are already excluded in the bright line definition E1.</p>
NESCOE	No	<p>As noted in Response 1, NESCOE believes exclusion determinations should not require a finding that all four proposed criteria are met.</p> <p>In addition, NESCOE believes that the criterion proposed here is overly complex and that developing the evidence may be overly burdensome to the applicant. Radial paths should have a simple definition related to how the path is connected from a topological perspective. NESCOE suggests that a radial path be defined simply as a path having only one connection point to the BES, thereby presenting no opportunity for power flows parallel to the BES network. Under fault situations, these excluded paths can be isolated from the BES with suitable NERC compliant protection systems. Note the radial path may be comprised of parallel lines that terminate at the BES connection point.</p> <p>In addition, NESCOE believes that a radial path should qualify for exclusion as long as the power flowing into the BES is less than a threshold MVA.</p> <p>NESCOE does not at this point have a recommendation as to this specific threshold but believes it should be developed through the standards-setting process. NESCOE suggests this approach to avoid burdening the development of generation including renewable generation. As New England is working on facilitating the development of renewable resources located in and around the region to serve customers most cost-effectively, this process should take specific care not to impose undue burdens on renewable resources.</p>
Idaho Falls Power		<p>Using these criteria assumes that every asset must be radial in nature in order to receive consideration that it may not be material to the BES. This then implies that the BES is a contiguous connected system as only radial off-shoots could receive exemption consideration. We disagree. Our assertion is that the BES is comprised of assets that due to their size or location are vital to a sound BES but may or may not necessarily be connected to each other. This defining criteria in the exception could be a stand-alone criteria or stricken.</p>
Blachly Lane Electric Cooperative Flathead Electric Cooperative, Inc. Central Electric Cooperative Clearwater Power Electric	Yes	<p>We agree conceptually that facilities operating as radials rather than as integrated portions of the integrated bulk transmission system should be excluded from the BES definition. However, to be consistent with the draft BES definition, the term “radial in character” should be explicitly defined as facilities that may include one or more lines into a load area or referenced as a local distribution network.</p> <p>In addition, we agree that the manner in which a system is operated during BES disturbances may be an indication of whether that facility is radial in character. That being said, we are concerned that, to the extent</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 2 Comment
Cooperative Consumer's Power Inc. Coos-Curry Electric Cooperative Douglas Electric Cooperative Fall River Electric Cooperative Lane Electric Cooperative Lincoln Electric Cooperative Lost River Electric Cooperative Northern Lights Electric Cooperative Okanogan Electric Cooperative Raft River Rural Electric Cooperative Salmon River Electric Cooperative Umatilla Electric Cooperative West Oregon Electric Cooperative Pacific Northwest Generating Cooperative Consumer's Power Inc.		the SDT considers regional disconnect procedures, it should be careful to note that UFLS and UVLS relays are often embedded within local distribution facilities and, while it is necessary for the UFLS and UVLS relays to be properly armed to protect the BES in the event of a severe system disturbance, the local distribution facilities interconnected with those relays should not, and cannot legally, be classified as BES.
South Carolina Electric and Gas Georgia Transmission Corporation	Yes	SCE&G agrees with the requirement of an element being radial in character as being a qualifier for exclusion thru the non-technical analysis.  However, we recommend that the term "radial in character" be better defined.  In addition, the language is confusing and we would like to recommend the following: i.: suggest replacing

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 2 Comment
		<p>“disconnection procedures” with “automatic disconnection devices”</p> <p>ii.: The intent of this item is not clear, and the term "regional dispatch" is not defined. Recommend the item be clarified or deleted.</p>
Springfield Utility Board	Yes	<p>SUB agrees with providing an exclusion exception for System Elements that are treated as “radial in character”, but feels this should be part of the core definition in NERC’s Proposed Continent-wide Definition of Bulk Electric System rather than requiring an exclusion/exemption application process.</p> <p>In SUB’s May 27, 2011 BES definition comments SUB expressed concern that there still appears to be inconsistencies in both definition and application of “radial.” SUB encourages NERC to develop a concise definition. For example, if a system is normally operated as radial, but could be operated closed (for example, by manually closing a breaker), would it be considered a radial or close-looped system?</p>
Entergy Services	Yes	<p>Entergy agrees that radial facilities should be excluded directly. However, the "radial in character" language is nebulous. A simpler approach could be to allow exceptions for facilities which become radial as a consequence of a normal system response to a disturbance (breakers opening during normal clearing of a fault).</p>
<p>Clark Public Utilities</p> <p>Benton Rural Electric Association</p> <p>Northern Wasco County PUD</p> <p>United Electric Co-op Inc</p> <p>Oregon Trail Electric Cooperative, Inc.</p> <p>Central Lincoln</p> <p>Salem Electric</p> <p>Grant County PUD No. 2 (Grant) for Snohomish County PUD</p> <p>Northwest Public Power Association (NWPPA)</p> <p>Big Bend Electric Cooperative,</p>	Yes	<p>Clark agrees conceptually that systems operating as radials rather than as integrated portions of the integrated bulk transmission system should be excluded from the BES definition. That is because local distribution systems typically operate adjacent to, or at the end of transmission lines, and function operationally to move power from the Transmission Service Provider’s point of delivery of bulk power that has moved across the integrated bulk transmission system to end-users located within the local distribution utility’s service territory.</p> <p>To be consistent with the draft BES definition, the term “radial in character” should be explicitly defined as a system that may include one or more lines into a load area or referenced as a local distribution network. In addition, Clark agrees that the manner in which a system is operated during BES disturbances may be an indication of whether that system is radial in character. That being said, we are concerned that, to the extent the SDT considers regional disconnect procedures, it should be careful to note that UFLS and UVLS relays are often embedded within local distribution systems and, while it is necessary for the UFLS and UVLS relays to be properly armed to protect the BES in the event of a severe system disturbance, the local distribution system interconnected with those relays should not.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 2 Comment
Inc. Kootenai Electric Cooperative		
Oregon Public Utility Commission Staff	Yes	<p>Use of the 100 kV brightline and the core BES definition as proposed is an overreach into local distribution systems and an overreach of FERC’s authority as set out in the FPA 215.</p> <p>A full engineering technical analysis - required every 2 years - is too onerous and not necessary for identifying most local distribution elements miss-identified as BES Elements. A simple screening methodology consistent with the 7-Factor Test (from FERC Order 888) is needed as the first stage of the exception process.</p>
Hydro-Quebec TransEnergie	Yes	<p>However, the point B.i. is hard to understand and would need clarification. Here is a proposal: "For an Element to be excluded from BES, its should be demonstrated that there are a proper disconnection procedure when facing a disturbance that would prevent this Element to impact the BES" ?.</p> <p>The point should be to make sure a fault on the Element will be isolated effectively without adverse impact on the BES, even when we have a second transmission source for the syb system seeking exclusion.</p> <p>Also, for point B. ii., it should be explained what is meant by the expression "regional dispatch". Is it an alternate way of transfer of power outside the Balancing Authority ?</p>
PacifiCorp	Yes	<p>All of PacifiCorp’s responses are based on the application of these items to a given interconnection and not on a continental basis. See comments on question 10. If this requirement is added to the four requirements to capture local distribution networks, which are often operated in a looped configuration, which may still be included in the BES by the proposed BES bright-line due to generator inclusions, then this requirement has merit. Otherwise, exclusion E1 in the proposed BES bright-line definition already covers this item and it becomes redundant.</p>
Independent Electricity System Operator	Yes	<p>We agree with this concept. Entities should be allowed to demonstrate the radial characteristics to determine if they are permitted for an exception. However, we believe some further clarification of the meaning of “radial in character” is needed. The example given in (b)I does not clarify the matter. Would a transmission line operated with a normally open point to form two radial lines be considered “radial in character”? Please clarify.</p> <p>The location of the Disturbance needs to be clarified. For example, if the Disturbance (e.g. a fault) occurs at the radial part of the Element, then it is necessary for the Element to have the capability to disconnect itself from the Disturbance to preserve BES reliability but the Element can be by itself a legitimate radial facility that</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 2 Comment
		is used solely for supplying load. The phrase “are not included in a regional dispatch” is unclear. We do not understand what this means.
Tacoma Power	Yes	Tacoma Power generally agrees that radial elements should be an item in this path and we suggest that radial element operated at below 300 kV should be excluded from the BES. The 300 kV level is linked with NERC CIP’s proposed version 4 definition of critical asset and should be applied here with the BES definition.
SERC Planning Standards Subcommittee	Yes	<p>The PSS agrees with the requirement of an element being radial in character as being a qualifier for exclusion thru the non-technical analysis. However, the PSS recommends that the term "radial in character" needs to be better defined.</p> <p>In addition, the language is confusing and the PSS would like to recommend the following:i.: suggest replacing “disconnection procedures” with “automatic disconnection devices”ii.: The intent of this item is not clear, and the term "regional dispatch" is not defined. Recommend the item be clarified or deleted.</p>
Tennessee Valley Authority	Yes	<p>We agree with the requirement of an element being radial in character as being a qualifier for exclusion thru the non-technical analysis. However, we recommend that the term "radial in character" needs to be better defined.</p> <p>In addition, the language is confusing and we recommend the following:i.: suggest replacing “disconnection procedures” with “automatic disconnection devices”</p> <p>ii.: The intent of this item is not clear, and the term "regional dispatch" is not defined.</p> <p>Recommend the item be clarified or deleted.</p>
New York State Reliability Council	Yes	It should be clarified that radial Element(s) include all system elements in load pockets.
Electricity Consumers Resource Council (ELCON)	Yes	We recommend that that the item be added to the BES definition.
New York Power Authority	Yes	The definition of radial systems needs to be modified to include radials that are connected to a single transmission source by more than one automatic interruption devices, such as occurs with a “breaker and a half” arrangement.
Southern Company	Yes	We agree with the requirement of an element being radial in character as being a qualifier for exclusion thru

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 2 Comment
		<p>the non-technical analysis. However, we recommend tha the term "radial in character" be better defined.</p> <p>Item ii.: The intent of this item is not clear, and the term "regional dispatch" is not defined. Recommend the item be clarified.</p>
ITC	Yes	<p>ITC is in agreement if we are correct in assuming that any one of the three ways ( i, ii, or iii ) can be used to satisfy the exclusion.</p> <p>We would also like to request additional clarification as to what "disconnection procedures" would be valid for consideration in this requirement.</p>
National Grid	Yes	<p>We agree that elements that are treated as radial should be allowed to request an exception.</p> <p>We would like more clarification about what is meant by “regional dispatch”. To the extent definitions of terms such as “regional dispatch” are necessary; they should be addressed in the core definition development process. The exception process should be strictly limited to the procedures for application and approval and should not include substantive elements.</p> <p>We would also like clarification on whether all three criteria under bullet b are required to show if the element is treated as radial, or if meeting one is enough.</p>
Harney Electric Cooperative, Inc.	Yes	
Oncor Electric Delivery	Yes	<p>Oncor Electric Delivery agrees with the proposed language that describes the exclusion criteria for system Elements that are radial in character.</p>
Xcel Energy	Yes	
Consumers Energy Company	Yes	
Long Island Power Authority	Yes	<p>Elements could be included in a regional dispatch such as a large regional ISO, but still serve only local load and therefore should still be treated as radial.</p>
American Electric Power	Yes	<p>Considering whether or not the element is treated as radial is a reasonable approach.</p>
Orange and Rockland Utilities, Inc.	Yes	

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 2 Comment
BGE	Yes	No comment.
Spyker	Yes	We agree with this concept. Entities should be allowed to demonstrate the radial characteristics to determine if they are permitted for an exception.
Occidental Energy Ventures Corp.	Yes	
ReliabilityFirst	Yes	yes only true radial without any impact should be excluded otherwise include it
Electric Market Policy	Yes	
ACES	Yes	We agree with this path.
<p><b>Response:</b> The SDT appreciates the suggestions for alternate language or clarifications to the proposed language for the characteristic associated with the system Element being treated as radial in character as qualifying criteria. Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity’s characteristics to a defined value and/or limit. It has become apparent that it is not feasible to establish continent-wide values and/or limits due to differences in operational characteristics. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the Rules of Procedure as presently being drafted.</p>		
NERC Staff Technical Review	No	<p>We believe that restating this measure as “System performance impacts are similar to radial systems” would be more in-line with the SDT intent and a better measure of whether Element(s) are necessary for reliable operation.</p> <p>We also believe that the best measure of whether Element(s) affect system performance in a manner similar to radial systems is through distribution factor analysis. Such analysis, when limited to this purpose, does not require extensive technical analysis. Analysis for a limited number of stressed transfer conditions, and contingencies involving the Element(s) under consideration and in the area of the Element(s) under consideration, is sufficient to demonstrate whether the system performance impacts are similar to radial systems.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 2 Comment
Western Electricity Coordinating Council	No	This characteristic is vague and subjective. It is unclear what “radial in character” means, and the methods for demonstration do not appropriately clarify the meaning. WECC recommends that the SDT determine what it is looking for to show “radial in character” and clearly identify that concept in the methods for demonstration. It is not clear how Operating Procedures can demonstrate that an element is “radial in character” nor is it clear how a re-evaluation might be processed if such Operating Procedures, ownership, or operations change. WECC believes that BES inclusion or exclusion should be based on physical, technical characteristics of the element, and requests a justification for use of procedural or contractual documentation as evidence of a technical principle.
Edison Electric Institute	Yes	<p>The verbiage used in the BES Principles document does not closely match the verbiage used in the NERC Bright-line Exclusion. For that reason, we submit the following alternative language.</p> <p>System Elements and Facilities treated in total as a radial system shall have the following characteristics:1. Shall be separated from the BES with an Automatic Interrupting Device, AND2. Only load serving and must be isolated from other radial systems through a normally open switching device, OR3. Only include generation resources but cannot include any of the Inclusions (i.e., I2, I3, I4 and I5) identified in the BES Definition, OR4. Is a combination of Load and Generation but cannot include any of the Inclusions (i.e., I2, I3, I4 and I5) identified in the BES</p> <p>DefinitionEvidences to be supplied shall include:</p> <ul style="list-style-type: none"> <li>o One-line Diagram clearly showing all demarcations between BES Facilities and the Radial System (including the Automatic Interrupting Device, AND</li> <li>o Operating procedures or interconnection agreements that indicate Generating Units contained within the Radial System are not dispatchable (if applicable), AND/OR</li> <li>o Operating procedures that show that the Radial System is not operated as part of the BES</li> </ul>

**Response:** The SDT appreciates the suggestions for alternate language or clarifications to the proposed language for the characteristic associated with the system Element being treated as radial in character as qualifying criteria.

The new proposed process allows an entity to submit a specified and consistent list of studies that should support the entity’s request and that can then be utilized by the ERO panel judging the request in making their decision.

Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity’s characteristics to a defined value and/or limit. It has become apparent that it is not feasible to establish continent-wide values and/or limits due to differences in operational characteristics. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support

Organization	Yes or No	Question 2 Comment
the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the Rules of Procedure as presently being drafted.		
PPL Supply	No	See comments in Questions 9 and 10
<b>Response:</b> See response to Q9 & Q10.		
Glacier Electric Cooperative	No	I do agree that radial elements should definitely be excluded. However, I believe that non-radial elements should be able to be excluded by Path 1 as well. If a small local distribution system is operated non-radially for the purpose of improving reliability for its loads, then that system should be eligible for exclusion from the BES. I also believe that language needs to be included that makes the provision for radial elements that can be temporarily and briefly looped together during switching to prevent an outage (e.g. for transformer maintenance) to also be excluded from the BES.
City of Redding	Yes	The term Radial could cause confusion. Clarification needs to be added to indicate that the system can have more than one connection to the BES.
<p><b>Response:</b> Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity’s characteristics to a defined value and/or limit. **3. Exclusions - The SDT has set up one path for evidence that does not include extensive technical analysis. It consists of 4 items, all of which must be addressed in order to submit a completed request for exclusion. The third item involves power flow. Do you agree with this requirement? If you do not support this requirement or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments. In addition, in the comment field, please provide your thoughts on the appropriate MWh value to replace 'TBD,' including technical rationale for your argument.**

**Summary Consideration:** Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity's characteristics to a defined value and/or limit. It has become apparent that it is not feasible to establish continent-wide values and/or limits due to differences in operational characteristics. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the Rules of Procedure as presently being drafted.

Organization	Yes or No	Question 3 Comment
Northeast Power Coordinating Council	No	<p>If an entity provides hourly MWh power flow data on a radial for a 12-month period (under v.) showing no power flow reversals, would transaction data (under i. through iv.) still be required?</p> <p>Could the entity just say "no transactional records?"</p> <p>If there were power flow reversals, wouldn't the power flow data (provided under v.) also show those, e.g., the amount and duration?</p> <p>Isn't this request redundant?</p> <p>If reversing power flows on a feeder caused it to fail one of the criteria, could the radial still be excluded, or is it necessary for the Element to pass all requirements?</p> <p>Alternatively, could the entity choose to file for Exclusion of that Element under the technical analysis option? What happens and what are the implications when the two approaches produce different outcomes?</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 3 Comment
		<p>Recommend that “iv. The maximum amount of energy flowing out” limit be set to no more than 24 hours of reverse power flows within any rolling 12-month period.</p> <p>Consider avoiding prescribing values and eliminate bullet (iv). The intended performance outcome should be described, but without setting values.</p> <p>This should not have any impact on the reliability of the transmission network if items 1, 2 and 3 are satisfied.</p>
SPP Standards Review Group	No	<p>Rather than combining two conflicting criterion - ‘rarely’ and the number of MWh of backflow allowed annually - we would suggest the following. 1) That the maximum outflow doesn’t create an issue on the BES. This would be determined by study of the system and conditions. Or 2) when the condition exists, be able to mitigate the condition within a prescribed time relevant to the prevailing system conditions.</p>
NERC Staff Technical Review	No	<p>Requiring that power flows into, and rarely out of, the Element(s) considered for exclusion is an appropriate measure, as is requiring an entity to define the conditions under which power will flow out.</p> <p>In addition to information such as specified contingencies in item (ii), details on the conditions should include other relevant information such as the system load level, generation dispatch, system transfer levels, etc., and the number of hours per year these conditions are expected.</p> <p>An exception request also should include the maximum flow expected. E.g., the following information would be useful in evaluating a request for exception: “Power will flow out only when line A is out of service, system load is at or below X percent of peak load, and generator B is on-line; based on the load duration curve for this area and the number of hours generator B is dispatched at these load levels, the exposure to power flow out for this contingency is limited to N hours per year and the maximum flow if the contingency occurred during these hours would be Y MW.” This type of information will be far more informative than a pass/fail test as to whether a MWh threshold is expected to be exceeded. While a MWh threshold may be useful for evaluating requests, it is unlikely that a one-size-fits-all threshold could be established for evaluating exception requests.</p>
ISO/RTO Standards Review Committee	No	<p>The SRC believes that, if power EVER flows out, then the area is either not radial or it includes generation resources. There is insufficient information to determine whether this “limited quantity of energy” is indeed small. There could be very large amounts of load and generation resources within that area. Such large quantities could represent a significant potential for sudden increases in load or unexpected energy injections.</p>
Iberdrola USA	No	<p>We do not agree with this requirement. These exclusion exception criteria should be deleted in their entirety and replaced with criteria that are objective, specific, and repeatable, or preferably not replaced at all.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 3 Comment
		Specific problems with the criteria as stated are: 1. A facility is not BES if all of “a” through “d” below apply: c. Power flows into “the system” most of the time - this is vague and covers much of the 115 kV system.
Hydro One	No	We agree with the criteria set out in 1(c), but suggest the SDT to avoid prescribing values and eliminate bullet (IV).  The SDT should also consider allowing: a) Power flow-out up to 20% of the minimum forecasted load for the element(s) over a 12 month period; or b) Maximum amount of energy flowing out be set to no more than 24 hours of reverse power flows within any rolling 12-month period. The intended performance outcome should be described, but without setting values. This should not have any impact on the reliability of the transmission network if items 1, 2 and 3 are satisfied.
MRO's NERC Standards Review Forum	No	NSRF proposes that this criterion be eliminated because it does not describe any materially different characteristics beyond Exclusion E3 of the bright-line BES definition.
MidAmerican Energy	No	MidAmerican supports the NSRF comments. The NSRF proposes that this criterion be eliminated because it does not describe any materially different characteristics beyond Exclusion E3 of the bright-line BES definition.
ReliabilityFirst	No	All power flow studies can be don eto show a small impact, this is how the system is planned. This will only cause more confusion and debate between the FERC, NERC the Regions and registered entities
Idaho Falls Power	No	We agree in general, however believe there is little distinction between the defining criteria in this exception and the local distribution network exclusion already provided for in the BES definition.  We would like to see added language that provides an exclusion for all elements on such a system, to include generation regardless of MVA rating, wherein the power flows are generally into the system.  We would agree that a number of MWh of annual outflow needs to be established as a limitation to the size and amount of generation under consideration. This exclusion should be geared towards smaller municipal or like sized systems having no material impact upon a BA much less the region.
Muscatine Power and Water	No	Proposing that this criterion be eliminated because it does not describe any materially different characteristics beyond Exclusion E3 of the bright-line BES definition.
Glacier Electric Cooperative	No	Regarding using power flow into and out of a system as a criterion fro BES exclusion, I do not think that

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 3 Comment
		<p>establishing a hard MWh per year is the proper approach to take. Once again, I believe that the purpose of the system should be the most important factor. If the purpose of a system is to serve load or transport non-essential generation (i.e. wind power), then that system should be able to be excluded.</p>
<p>Consolidated Edison Co. of NY, Inc.</p>	<p>No</p>	<p>We generally support this exclusion option concept, to the extent that it is fashioned after the FERC Seven Factor test. However, we have a number of questions as to how it might work in practice. For example:</p> <ul style="list-style-type: none"> <li>o If an entity provides hourly MWh power flow data on a radial for a 12-month period (under v.) showing no power flow reversals, would transaction data (under i. through iv.) still be required? Couldn't the entity just say "no operating records?"</li> <li>o If there were power flow reversals, wouldn't the power flow data (provided under v.) also show those, e.g., the amount and duration? Isn't this request redundant? If not, why not? Please explain.</li> <li>o If reversing power flows on a feeder caused it to fail one of the criteria, could the radial still be excluded, or is it necessary for the Element to pass all requirements? Alternatively, could the entity choose to file for Exclusion of that Element under the technical analysis option? What happens and what are the implications when the two approaches produce different outcomes?</li> </ul> <p>We recommend that "iv. The maximum amount of energy flowing out" limit be set to no more than 24 hours of reverse power flows within any rolling 12-month period. Replace "transactional records" with "operating records."</p>
<p>ISO New England</p>	<p>No</p>	<p>Section 1.c again appears to allow the exclusion of large portions of the system in metropolitan areas. How does this differ from the LDN exclusion already presented in the definition?</p> <p>Section c should simply be deleted.</p>
<p>The United Illuminating Company</p>	<p>No</p>	<p>What does rarely mean? How is maintenance conditions considered? This is simply worded but conceptually extremely complicated.</p>
<p>Entergy Services</p>	<p>No</p>	<p>Power flows into or out of a portion of the BES may characterize BES facilities less important to BES reliability but without limits to the size of the area, it would be difficult to show compliance. An entire state could be excluded from the BES.</p> <p>Additionally, there is no process specified to review the characteristics as transmission topology and resources change over time.</p>
<p>BGE</p>	<p>No</p>	<p>BGE is generally opposed to this requirement because the MWh factor is too variable and/or may be utilized</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 3 Comment
		in a way contrary to reliable system operation.
Pepco Holdings Inc	No	The characteristic statement should be reworded to say: “Power flow is generally load serving.”The criteria as written have very burdensome MWh record requirements. Yearly totals for flows in and out and an overall description or justification for this exception should be allowable.
Duke Energy	No	This third characteristic does not add clarity to the E3 Exclusion in the proposed BES definition. And in general, the path that does not include extensive technical analysis is not adequate to distinguish between the Elements that are and that are not necessary for operating an interconnected electric transmission network.
American Transmission Company, LLC	No	ATC proposes that this criterion be eliminated because it does not describe any materially different characteristics beyond Exclusion E3 of the bright-line BES definition.
Manitoba Hydro	No	Vague language such as “rarely” or “not intentionally” does not support a “bright line” approach, and is not measureable or auditable. Also, the sample evidence should not be included as part of the criteria. In addition, the proposed criteria to substantiate a request for an exception should be removed as it does not introduce anything different than what is already proposed under the exclusions in the bright line BES definition. Specifically, this item is already excluded in the bright line definition E3.
NESCOE	No	<p>As noted in Response 1, NESCOE believes exclusion determinations should not require a finding that all four proposed criteria are met. Generally, NESCOE is in agreement with an exception criteria for additional exclusions that takes into account power flows into the system that rarely flows out. However, additional clarity is necessary for criteria 1(c)(i),(ii) and (iv). Specifically, what is meant by “very limited set of conditions” under 1(c)(i) and (ii) and “limited quantity of energy” under 1(c)(i)?</p> <p>Further, is it appropriate to establish a fixed value of X megawatt hours for the maximum amount of energy flowing out of the system?</p> <p>While it is possible that NESCOE could agree upon a uniform value, NESCOE is not in a position to provide specific comment or support when the MWh value is unspecified. In addition, a fixed value may not adequately address varying system configurations throughout ISO-New England and neighboring control areas.</p>
Independent Electricity System Operator	No	There is an inconsistency between the language used in bullet (c) - “rarely flows out”, and that used in Exclusion E3(c) of the BES definition - “Power flows only into the LDN”. We have commented during the BES Definition comment period that Exclusion E3 needs to be modified to match the Exception Principles.

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 3 Comment
		<p>We agree with the criteria set out in 1(c) except for bullets (iv) and (v). We do not believe it is possible to establish a limit on the energy flow out of a system for which an exception has been requested.</p> <p>Further, we suggest that the SDT avoid prescribing set values in the exception criteria since these would only serve to limit the flexibility of the process.</p> <p>As an alternative to the proposed bullet (iv), we suggest that power flow study results could be used to support the exception request. We therefore propose the following wording to replace bullets (iv) and (v).iv. Power flow simulation results to demonstrate that BES reliability is not dependent upon the power flows through the Element(s) for which an exception has been submitted, for the conditions specified in (ii).</p>
Georgia System Operations Corporation		<p>If the BES Definition itself is clarified to allow for some de minimis amount of power flow out of a customarily radial line that is excluded by definition, this justification for an exclusion may not be necessary. We encourage the Drafting Team to pursue that approach because we believe it is technically justified and could significantly reduce the need for exceptions.</p>
Florida Municipal Power Agency Transmission Access Policy Study Group		<p>The third item is “power flows into the system, but rarely flows out.” This criterion is vague. FMPA suggests instead the following language, which is consistent with FMPA’ comments on Exclusion E3 of the BES definition: “Neither the Element, nor any Elements that it connects to the grid (in aggregate), includes more than 75 MVA of generation used to meet the resource-adequacy requirements of electric utilities.”</p>
ACES	Yes	<p>We agree with this path although iii and v may be in conflict. One requires 24 months data and the other requires 12 months of data.</p>
National Grid	Yes	<p>We agree with this requirement, but feel that assigning a specific value to the energy flowing out of the system in MWh is unnecessary. The energy flowing out of a system depends on the size of the area, and thus could vary widely.</p> <p>Another concern is about non-wires alternatives (NWA). One type of non-wires alternative that is considered during planning studies is to reduce the amount of load on our system by paying customers to not operate during peak hours. One scenario to consider is a generator connected on a radial line that qualifies as BES, and will need upgrades if the generator runs frequently. If this generator produces power close to the MWh threshold in the specified time frame per NERC criteria, does it mean the utility company will have to consider paying the <i>generator</i> owner money to shut down in order to keep total MWh generation below the threshold and avoid BES criteria required radial line upgrades? This is another reason assigning a specific value to the energy flowing out of the system is unnecessary.</p> <p>We would like clarification on whether all criteria (i,ii,iii,iv,v) need to be met, or if just meeting one criteria is</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 3 Comment
		<p>sufficient. We feel that meeting criteria 1.c.1, 1.c.ii OR 1.c.iii is sufficient in showing that power rarely flows out of the system. Criteria 1.c.iv and 1.c.v should be removed.</p> <p>The exception process should be strictly limited to the procedures for application and approval and should not include substantive elements.</p>
<p>Blachly Lane Electric Cooperative            Flathead Electric Cooperative, Inc            Central Electric Cooperative            Clearwater Power Electric Cooperative            Consumer's Power Inc            Coos-Curry Electric Cooperative            Douglas Electric Cooperative            Fall River Electric Cooperative            Lane Electric Cooperative            Lincoln Electric Cooperative            Lost River Electric Cooperative            Northern Lights Electric Cooperative            Okanogan Electric Cooperative            Raft River Rural Electric Cooperative            Salmon River Electric Cooperative            Umatilla Electric Cooperative            West Oregon Electric</p>	<p>Yes</p>	<p>We agree conceptually that one critical characteristic distinguishing facilities that must be excluded from the BES from facilities that should be included is the manner in which power flows on those facilities. Hence, the SDT has properly identified power flows as one important characteristic that identifies BES facilities. We also agree conceptually that the fact that power may flow out of facilities onto the grid during a few hours in a year or during extreme contingencies should not change the characterization of the facilities in question as excluded from the BES. Accordingly, we support inclusion of power flow analysis as one element of characteristics that can be used to exclude facilities from the BES even if the facilities do not pass each of the bright-line thresholds laid down in the BES definition.</p> <p>We also agree that transactional and hourly generation records are an appropriate basis for making the determination since these can be used to demonstrate that demand within a system exceeds generation within that system in most hours and that power therefore does not flow onto the grid, and also to determine the number of hours where this is not the case and the amount by which generation within the system exceeds demand. In order to identify facilities that are not necessary for the operation of the BES under this text, we propose that any facility where real power flows in 90 percent of the time or more under normal ("N-0" or All Lines in Service) operating conditions should be held to meet this test. That facilities meet this test could be demonstrated using metering or supervisory control and data acquisition ("SCADA") data records over the course on two years.</p> <p>While we agree with the SDT's view that power should flow predominantly in the direction of load for excluded facilities, we are concerned that this characteristic may no longer be a defining characteristic as the electric industry evolves in the future. If distributed generation becomes the future norm for new power generation facilities, it may no longer make sense to look at power flow as a defining characteristic. That is, even if a sufficient number of small distributed generation facilities were constructed on certain facilities to cause power to flow out of those facilities more than ten percent of the time, the fundamental character of those facilities will not have changed.</p> <p>Finally, we believe that power flow analysis under this item should consider actual power flow, not scheduled power flow.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 3 Comment
Cooperative Pacific Northwest Generating Cooperative		
Clark Public Utilities Benton Rural Electric Association Northern Wasco County PUD United Electric Co-op Inc Oregon Trail Electric Cooperative, Inc. Salem Electric Grant County PUD No. 2 (Grant) Northwest Public Power Association (NWPPA) Big Bend Electric Cooperative, Inc Kootenai Electric Cooperative	Yes	Clark agrees conceptually that one critical characteristic distinguishing local distribution facilities that must be excluded from the BES from transmission facilities that should be included is the manner in which power flows on those facilities. Power on local distribution systems generally flows only from the interconnected transmission source and across the distribution system for delivery to end-use customers. By contrast, power on transmission systems generally flows in two (or multiple, in networked systems) directions and is delivered in bulk to distribution utilities rather than to end-users. Hence, the SDT has properly identified power flows as one important characteristic that distinguishes BES transmission systems from local distribution systems. In order to identify systems that are not necessary for the operation of the BES under this text, we propose that any system where real power flows into the local distribution system 90 percent of the time or more under normal operating conditions.
Spyker	Yes	We agree with the criteria set out in 1(c), but suggest the SDT to avoid prescribing values and eliminate bullet (iv). The SDT should describe the intended performance outcome but avoid setting values. This should have little, if any impact on reliability of the transmission network if the items 1, 2 and 3 are satisfied.
American Electric Power	Yes	Requiring that “power flows into the system, but rarely flows out” is a reasonable approach, but would require further consideration given the MWh value eventually chosen to replace “TBD”.
Orange and Rockland Utilities, Inc.	Yes	The “TBD” value should be reasonable and well justified.

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 3 Comment
Central Lincoln	Yes	<p>Central Lincoln agrees that one critical characteristic distinguishing local distribution facilities that must be excluded from the BES from transmission facilities that should be included is the manner in which power flows on those facilities. Power on local distribution systems generally flows only from the interconnected transmission source and across the distribution system for delivery to end-use customers. By contrast, power on transmission systems generally flows in two (or multiple, in networked systems) directions and is delivered in bulk to distribution utilities rather than to end-users. Hence, the SDT has properly identified power flows as one important characteristic that distinguishes BES transmission systems from local distribution systems. Central Lincoln also agrees that the fact that power may flow out of a local distribution system onto the grid during a few hours in a year or during extreme contingencies should not change the characterization of the system as local distribution. Accordingly, we support inclusion of power flow analysis as one element of characteristics that can be used to exclude local distribution facilities from the BES even if the facilities do not pass each of the bright-line thresholds laid down in the BES definition.</p> <p>We also agree that transactional and hourly generation records are an appropriate basis for making the determination since these can be used to demonstrate that demand within a local distribution system exceeds generation within that system in most hours and that power therefore does not flow onto the grid, and also to determine the number of hours where this is not the case and the amount by which generation within the system exceeds demand. In order to identify systems that are not necessary for the operation of the BES under this test, we propose that any system where real power flows into the local distribution system 90 percent of the time or more under normal ("N-0" or All Lines in Service) operating conditions should be held to meet this test. That a system meets this test could be demonstrated using metering or supervisory control and data acquisition ("SCADA") data records over the course of two years. In addition, the presence of generation within a local distribution system that only modifies the level of the load served by the bulk system, but does not result in power being injection into the bulk system, does not change the reliability effect of the local network and therefore should not require the local network to be classified as BES.</p>
Oregon Public Utility Commission Staff	Yes	<p>Use of the 100 kV brightline and the core BES definition as proposed is an overreach into local distribution systems and an overreach of FERC's authority as set out in the FPA 215. A full engineering technical analysis - required every 2 years - is too onerous and not necessary for identifying most local distribution elements miss-identified as BES Elements. A simple screening methodology consistent with the 7-Factor Test (from FERC Order 888) is needed as the first stage of the exception process.</p>
Hydro-Quebec TransEnergie	Yes	<p>However, this is only part of an exclusion.</p> <p>The point c. iv and v, MWh is not relevant for real-time operation. It would be more simple to put a time reference, such as a total number of days or a % of the time.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 3 Comment
		<p>In number iii, do you mean the first self certification ? In fact, the evidence for exclusion will be done once, but ROP suppose that the self certification will be done many times (every two years).</p>
for Snohomish County PUD	Yes	<p>Snohomish agrees conceptually that one critical characteristic distinguishing local distribution facilities that must be excluded from the BES from transmission facilities that should be included is the manner in which power flows on those facilities. Power on local distribution systems generally flows only from the interconnected transmission source and across the distribution system for delivery to end-use customers. By contrast, power on transmission systems generally flows in two (or multiple, in networked systems) directions and is delivered in bulk to distribution utilities rather than to end-users. Hence, the SDT has properly identified power flows as one important characteristic that distinguishes BES transmission systems from local distribution systems.</p> <p>Snohomish also agrees conceptually that the fact that power may flow out of a local distribution system onto the grid during a few hours in a year or during extreme contingencies should not change the characterization of the system as local distribution. Accordingly, we support inclusion of power flow analysis as one element of characteristics that can be used to exclude local distribution facilities from the BES even if the facilities do not pass each of the bright-line thresholds laid down in the BES definition.</p> <p>We also agree that transactional and hourly generation records are an appropriate basis for making the determination since these can be used to demonstrate that demand within a local distribution system exceeds generation within that system in most hours and that power therefore does not flow onto the grid, and also to determine the number of hours where this is not the case and the amount by which generation within the system exceeds demand. In order to identify systems that are not necessary for the operation of the BES under this test, we propose that any system where real power flows into the local distribution system 90 percent of the time or more under normal ("N-0" or All Lines in Service) operating conditions should be held to meet this test. That a system meets this test could be demonstrated using metering or supervisory control and data acquisition ("SCADA") data records over the course on two years.</p> <p>In addition, the presence of generation within a local distribution system that only modifies the level of the load served by the bulk system, but does not result in power being injection into the bulk system, does not change the reliability effect of the local network and therefore should not require the local network to be classified as BES.</p>
New York Power Authority	Yes	<p>NYPA generally agrees with this item. However, the term "system" needs to be better defined.</p> <p>It is not clear how power could flow out of a load only system. If reversing power flows on a feeder caused it to fail one of the criteria, could the radial still be excluded, or is it necessary for the Element to pass all requirements? Alternatively, could the entity choose to file for Exclusion of that Element under the technical</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 3 Comment
		<p>analysis option?</p> <p>What happens and what are the implications when the two approaches produce different outcomes?</p> <p>An example of revised wording for “iv. The maximum amount of energy flowing out” would be no more than 24 hours of reverse power flows within any rolling 12-month period.</p> <p>Consider avoiding prescribing values and eliminate bullet (iv). The intended performance outcome should be described, but without setting values. This should not have any impact on the reliability of the transmission network if items 1, 2 and 3 are satisfied.</p>
New York State Reliability Council	Yes	It should be clarified that this exclusion should not apply to inter-regional transfers, which clearly are candidates for inclusion as BES.
Western Electricity Coordinating Council	Yes	<p>WECC agrees in concept with this characteristic, but it needs to be clarified whether the items i-v are “AND” statements</p> <p>WECC also suggests that i and ii be switched and re-worded. Suggested language for ii would be “A limited set of conditions where power flows out must be identified; for example, only under specified Contingency events.” Then i can become a sub-bullet of ii. It must also be clarified that the specified conditions must have a technical justification to show that the element is not “necessary for reliable operation.” Otherwise it is not clear that the “limited conditions” are truly a justification for exclusion.</p> <p>Any non-zero MWh limit must have a technical justification, otherwise zero should be used. In addition to the imports/exports from the system, the size of the system (in MW) should also be defined.</p>
Bonneville Power Administration	Yes	<p>BPA generally agrees with the power flow concept, but suggests including language that the assessment should be “based on normal system operating conditions.”</p> <p>A MWh value to replace ‘TBD’ for maximum energy flowing out per year could be determined based on an annual average MW load level of 25 MW average and below with distribution service of 50MVA and below, because 25MW loads can be served by lines under 100kv. The energy flowing out per year would be limited by the size of the load and the ability to import power to the load area (i.e. the export would never be larger than the initial distribution service minus the local area losses and load).</p> <p>BPA requests that the drafting team perform a cross-walk analysis on each of the 4 items to ensure the consistent application of an existing industry process, practice, or standard.</p>
Tri-State Generation and	Yes	It may be more appropriate to use a threshold based on maximum power rather than on an annual energy

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 3 Comment
Transmission Association		threshold.
Electric Market Policy	Yes	The word rarely should be struck from this item. It is meaningless in the context for which it is used and offers little to characterize an element or connection since it does not contain a measure.
Harney Electric Cooperative, Inc.	Yes	
Oncor Electric Delivery	Yes	Oncor Electric Delivery agrees with the proposed language that describes the exclusion criteria based upon power flows.
Southern Company	Yes	
Occidental Energy Ventures Corp.	Yes	
Consumers Energy Company	Yes	
<p><b>Response:</b> The SDT appreciates the suggestions for alternate language or clarifications to the proposed language for the characteristic associated with the magnitude, direction and time duration of power flow on a system Element as qualifying criterion. Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity's characteristics to a defined value and/or limit. It has become apparent that it is not feasible to establish continent-wide values and/or limits due to differences in operational characteristics. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the Rules of Procedure as presently being drafted.</p>		
Edison Electric Institute	Yes	<p>Although EEI agrees in principle to the exclusion, we feel the current language has some problems which need to be addresses. Note the following: The word “rarely should be struck. It is meaningless in the context for which it is used and offers little to characterize an element or connection since it does not contain a measure. A more appropriate statement to broadly characterize a Non-BES element or connection would be the following: “Power flows are broadly characterized as Load Serving.”</p> <p>Items i. and iii. are excessive requirements which do not aide in defining what is “necessary for operating an interconnected electric transmission network”. What might be more a more useful measure is a comparison of total MW hours of load consumed vs. MW hours fed back into the BES as measured on an annual</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 3 Comment
		basis.Item v. - Hourly energy data (MWh) for the most recent 12 month period for every excluded BES element is an excessive requirement. Annual records indicating that MW hours consumed annually verses MW hours that flow through the non-BES element would be a better indicator in line with the definition.
SERC Planning Standards Subcommittee Tennessee Valley Authority	Yes	One possible starting point for selecting a MWh threshold: Generators of 20 MVA or less are typically exempt from detailed modeling requirements. Suggest that reverse flows of this level or less, for a period of 24 hours or less would be an acceptable threshold. Therefore, this would provide a basis for selecting a threshold MWh level for reverse flows into the system under part iv. of 20 MW x 24 hours = 480 MWh per year.
<p><b>Response:</b> The SDT appreciates your comments and your suggestions for the amount of power flow allowed to still be eligible for an exclusion. However, based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity’s characteristics to a defined value and/or limit. It has become apparent that it is not feasible to establish continent-wide values and/or limits due to differences in operational characteristics. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the Rules of Procedure as presently being drafted.</p>		
PPL Supply	No	See comments in Questions 9 and 10
<p><b>Response:</b> See responses to Q9 &amp; Q10.</p>		
City of Redding	Yes	To be consistent with E2 of the proposed BES Definition a distribution system should be allowed to export at least 75 mw. This would be the same as a commercial retail customer can export into the distribution system.
Electricity Consumers Resource Council (ELCON)	Yes	The thresholds for power flows out of the system should be made consistent with Exclusion E2 in the definition.We recommend that this item be added to the BES definition.
<p><b>Response:</b> The SDT has responded to comments on the BES definition in the Consideration of Comments form for the BES definition posting.</p>		
South Carolina Electric and Gas Georgia Transmission Corporation	Yes	<p>One possible starting point for selecting a MWh threshold: Generators of 20 MVA or less are typically exempt from detailed modeling requirements.</p> <p>Suggest that reverse flows of this level or less, for a period of 24 hours or less would be an acceptable threshold. Therefore, this would provide a basis for selecting a threshold MWh level for reverse flows into the</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 3 Comment
		system under part iv. of 20 MW x 24 hours = 480 MWh per year
Long Island Power Authority	Yes	Item iv. The maximum amount of energy flowing out is (TBD-1,752,000) MWh per year. Another measure that may be more appropriate is a percent % of total energy requirements in the area.
Xcel Energy	Yes	Regarding the question on MWH, one possible approach is to use 175,000 MWH/ year which would be just under the annual hourly output from the smallest generator (not at a plant) that must be registered under the registry criteria.
Tacoma Power	Yes	Tacoma Power generally agrees that elements primarily serving load, allowing a limited flow out of the local distribution network, should be excluded from the BES.  We support an annual limitation of 219,000 MWhs, equivalent to 25 aMW, since a system of elements that primarily serve load under this limit are insignificant to the BES.
PacifiCorp	Yes	All of PacifiCorp's responses are based on the application of these items to a given interconnection and not on a continental basis. See comments on question 10. This criterion is very similar to a part of exclusion 3 of the proposed bright-line, which requires that power flows into the system. If the intent of this requirement is to capture local distribution networks that may be included under the proposed bright-line definition, then this requirement has merit. PacifiCorp proposes that instead of using a measure of energy, that the SDT utilize a measure of time and recommends that flow out of the system be limited to 15% on an annual basis. PacifiCorp does not have a technical justification for 15%, nor does it believe that a technical justification can be provided for any reasonable percent of time used, or MWh used to be applied equally to all interconnections.

**Response:** The SDT appreciates your comments and your suggestions to fill in some of the gaps in the first posting. However, based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity's characteristics to a defined value and/or limit. It has become apparent that it is not feasible to establish continent-wide values and/or limits due to differences in operational characteristics. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the Rules of Procedure as presently being [drafted](#).

**4. Exclusions - The SDT has set up one path for evidence that does not include extensive technical analysis. It consists of 4 items, all of which must be addressed in order to submit a completed request for exclusion. The fourth item involves power transport. Do you agree with this requirement? If you do not support this requirement or you agree in general but feel that alternative language would be more appropriate, please provide specific suggestions in your comments.**

**Summary Consideration:** Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity's characteristics to a defined value and/or limit. It has become apparent that it is not feasible to establish continent-wide values and/or limits due to differences in operational characteristics. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the Rules of Procedure as presently being drafted.

Organization	Yes or No	Question 4 Comment
SERC Planning Standards Subcommittee Tennessee Valley Authority	No	There is not sufficient evidence provided by the SDT to distinguish between this fourth item for exclusion and the third item for exclusion. They both seem to fall in line with what is excluded per the bright line exclusion E3 (or Local Distribution Networks), but as written, it would be difficult to measure what is meant by “is not intentionally transported through” in this fourth item just as it would be difficult to measure what’s meant by “flows into the system, but rarely flows out” for the third item.  Such an exclusion should be required to include some technical analysis, but not extensive technical analysis (at least the inclusion of power flow base case as a minimum).
SPP Standards Review Group	No	It may be better to focus on the purpose, or need, of a facility, the functionality of the facility, rather than how electric flows impacted the facility during a given situation. Therefore, we would suggest moving away from the term ‘intent’.
NERC Staff Technical Review	No	Limitations on through-flow of power is an appropriate consideration; however, whether the power flow is intentional should not be a primary consideration. Intent is not measurable and most major disturbances are the result of unintentionally placing the system in an unreliable operating condition. The main clause in item

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 4 Comment
		(d) should be modified to reflect that transporting power to another system through the Element(s) to be excluded is prevented (such as by system configuration and/or impedance) or restricted (such as by Operating Procedures). Sub-items (i) and (ii) already are consistent with this revision to the main clause.
ISO/RTO Standards Review Committee	No	Hasn't the reliability concern associated with "loop flows" been related to the unintentional flow of power through parts of the system?
Iberdrola USA	No	<p>We do not agree with this requirement. These exclusion exception criteria should be deleted in their entirety and replaced with criteria that are objective, specific, and repeatable, or preferably not replaced at all.</p> <p>Specific problems with the criteria as stated are: 1. A facility is not BES if all of "a" through "d" below apply:  d. Power "entering" "the system" does not "intentionally" flow into another "system" - what does intentionally versus unintentionally mean?</p>
MRO's NERC Standards Review Forum Muscatine Power and Water	No	NSRF proposes that this criterion be eliminated because it does not describe any materially different characteristics beyond Exclusion E3 of the BES definition.
MidAmerican Energy	No	MidAmerican support the NSRF comments. The NSRF proposes that this criterion be eliminated because it does not describe any materially different characteristics beyond Exclusion E3 of the BES definition.
ReliabilityFirst	No	no one knows when some event will occur, putting this limitation will only cause debate. Any impact is an impact and should be included
Idaho Falls Power	No	We generally agree with this requirement. If a system has redundant transmission to move power that is normally wheeled through, the question of materiality could be addressed by technical analysis.
Southern Company	No	
National Grid	No	<p>We feel that this requirement is not specific enough. "System" is too general. It should be clear what is intended by "system". Also, we would like more clarification about what is meant by "intentionally transport". Is the intent to mean there is a contract between a generator and load?</p> <p>The exception process should be strictly limited to the procedures for application and approval and should not include substantive elements.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 4 Comment
South Carolina Electric and Gas	No	<p>There is not sufficient evidence provided by the SDT to distinguish between this fourth item for exclusion and the third item for exclusion. They both seem to fall in line with what is excluded per the bright line exclusion E3 (or Local Distribution Networks), but as written, it would be difficult to measure what is meant by “is not intentionally transported through” in this fourth item just as it would be difficult to measure what’s meant by “flows into the system, but rarely flows out” for the third item.</p> <p>Such an exclusion should be required to include some technical analysis, but not extensive technical analysis (at least the inclusion of power flow base case as a minimum).</p>
Glacier Electric Cooperative	No	<p>I believe that there should be a provision for systems that intentionally transport variable, non-essential generation (such as systems that transport wind power) to be excluded from the BES. By nature, these types of systems cannot be essential to the BES due to the variability of the generation, and, therefore, should be able to be excluded from the BES.</p>
Springfield Utility Board	No	<p>NERC’s Proposed Continent-wide Definition of Bulk Electric System contains Exclusion E3 (LDNs) as part of the BES core definition. Why would this fourth item be necessary in demonstrating BES Exceptions if LDNs are already excluded as part of NERC’s core BES definition?</p>
ISO New England	No	<p>This appears to be the same as section 1.c and again possibly allows for the exclusion of large portions of the system in metropolitan areas. Section 1.d. should simply be deleted.</p>
The United Illuminating Company	No	<p>The wording is ambiguous. What is meant by system? Different voltage levels, Owners?</p>
Entergy Services	No	<p>There is not sufficient evidence provided by the SDT to distinguish between this fourth item for exclusion and the third item for exclusion. They both seem to fall in line with what is excluded per the bright line exclusion E3 (or Local Distribution Networks), but as written, it would be difficult to measure what is meant by “is not intentionally transported through” in this fourth item just as it would be difficult to measure what’s meant by “flows into the system, but rarely flows out” for the third item.</p> <p>Such an exclusion should be required to include some technical analysis, but not extensive technical analysis (at least the inclusion of power flow base case as a minimum).</p>
Pepco Holdings Inc	No	<p>This criterion is very similar to the third item. Written operating procedures may not exist. The entity should be allowed to submit a description and justification.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 4 Comment
Central Lincoln	No	<p>Central Lincoln agrees that the SDT’s fourth test, which asks whether power is intentionally transported through a system, identifies a key characteristic of local distribution facilities that distinguishes such facilities from interconnect bulk transmission facilities that are properly considered part of the BES. In fact, we believe this may be the most important and readily identifiable distinction. As a matter of operation, power is scheduled across transmission lines. Further, transmission lines in the Western Interconnection (either individually or as part of a transmission path) are rated for total transmission capacity and available transmission capacity, and transmission rights can be purchased on such lines, if available, on an OASIS. Local distribution systems do not share any of these operational characteristics. Accordingly, Central Lincoln agrees that if power is not intentionally transported through a particular system, that system is not used for transmission and should not be considered part of the BES.</p> <p>We also agree that examining the Operating Procedures applicable to a particular system will provide a ready guide to whether power is intentionally scheduled across that system.</p> <p>We suggest, however, that the SDT look beyond those protocols that fall within the NERC Glossary’s definition of Operating Procedure. For example, in the West, transmission paths are almost all listed in the WECC Path Rating Catalog. Similarly, it is not clear whether scheduling protocols, OASIS operations, and the other factors listed above qualify as Operating Procedures. Hence, we urge the SDT to list such specific operational characteristics as part of this test.</p>
Duke Energy	No	<p>This fourth characteristic does not add clarity to the E3 Exclusion in the proposed BES definition. And in general, the path that does not include extensive technical analysis is not adequate to distinguish between the Elements that are and that are not necessary for operating an interconnected electric transmission network.</p>
American Transmission Company, LLC	No	<p>ATC proposes that this criterion be eliminated because it does not describe any materially different characteristics beyond Exclusion E3 of the BES definition.</p>
Manitoba Hydro	No	<p>Vague language such as “rarely” or “not intentionally” does not support a “bright line” approach, and is not measureable or auditable. Also, the sample evidence should not be included as part of the criteria.</p> <p>In addition, the proposed criteria to substantiate a request for an exception should be removed as it does not introduce anything different than what is already proposed under the exclusions in the bright line BES definition. Specifically, this item is already excluded in the bright line definition E3.</p>
NESCOE	No	<p>As noted in Response 1, NESCOE believes exclusion determinations should not require a finding that all four proposed criteria are met. NESCOE further notes that New England’s network has numerous parallel paths operated at voltages less than 200 kV which may parallel 230 kV and 345 kV BES network paths. If flows on</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 4 Comment
		<p>a given &lt;200 kV path only exceed 200 MVA under contingency conditions and if these paths are connected to the higher voltage BES elements with suitable NERC compliant protection systems, these paths may be EXCLUDED from the BES. NESCOE suggests the value of 200 MVA based on typical thermal ratings of 115 kV transmission lines but is open to other values that the drafting team may suggest. NESCOE also suggests that the phrase “to some other system” be broadened to include any other higher voltage BES element.</p>
City of Redding	Yes	<p>The SDT needs to address renewable energy and customer owned generation. If an aggregator adds up one thousand roof top PV units or the power from plugged in electric cars and sells them to an entity outside of this system it should not affect the ability of the distribution system to qualify for this exclusion, especially if the power is consumed inside of the distribution system.</p>
<p>Blachly Lane Electric Cooperative  Flathead Electric Cooperative, Inc.  Central Electric Cooperative  Clearwater Power Electric Cooperative  Consumer's Power Inc.  Coos-Curry Electric Cooperative  Douglas Electric Cooperative  Fall River Electric Cooperative  Lane Electric Cooperative  Lincoln Electric Cooperative  Lost River Electric Cooperative  Northern Lights Electric Cooperative  Okanogan Electric Cooperative  Raft River Rural Electric</p>	Yes	<p>As a matter of operation, power is scheduled across transmission lines. Further, transmission lines in the Western Interconnection (either individually or as part of a transmission path) are rated for total transmission capacity and available transmission capacity, and transmission rights can be purchased on such lines, if available, on an OASIS. Facilities that do not share any of these operational characteristics should not be part of the BES.</p> <p>Accordingly, we agree that if power is not intentionally transported through particular facilities, those facilities should not be considered part of the BES.</p> <p>We also agree that examining the Operating Procedures applicable to particular facilities will provide a ready guide to whether power is intentionally scheduled across those facilities.</p> <p>We suggest, however, that the SDT look beyond those protocols that fall within the NERC Glossary's definition of Operating Procedure. For example, in the West, transmission paths are almost all listed in the WECC Path Rating Catalog. Similarly, it is not clear whether scheduling protocols, OASIS operations, and the other factors listed above qualify as Operating Procedures. Hence, we urge the SDT to list such specific operational characteristics as part of this test.</p> <p>Finally, as noted in our answer to Question 3, we are concerned that, if distributed generation advances significantly, power transport may cease to be a meaningful measure for determining whether a facility is part of the BES, and we believe that power flow analysis should consider actual power flow, not scheduled power flow.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 4 Comment
Cooperative Salmon River Electric Umatilla Electric Cooperative West Oregon Electric Cooperative Pacific Northwest Generating Cooperative Consumer's Power Inc		
Clark Public Utilities	Yes	Clark agrees that the SDT's fourth test, which asks whether power is intentionally transported through a system, identifies a key characteristic of local distribution facilities that distinguishes such facilities from interconnect bulk transmission facilities that are properly considered part of the BES. Clark believes this may be the most important and readily identifiable distinction. Accordingly, Clark agrees that if power is not intentionally transported through a particular system, that system is not used for transmission and should not be considered part of the BES.
BGE	Yes	BGE generally agrees with this requirement, but believes that the term "system" should be clarified.
Benton Rural Electric Association Northern Wasco County PUD United Electric Co-op Inc. Oregon Trail Electric Salem Electric Grant County PUD No. 2 (Grant) Northwest Public Power Association (NWPPA) Big Bend Electric Cooperative, Inc Kootenai Electric Cooperative	Yes	Benton REA agrees that the SDT's fourth test, which asks whether power is intentionally transported through a system, identifies a key characteristic of local distribution facilities that distinguishes such facilities from interconnect bulk transmission facilities that are properly considered part of the BES. In fact, we believe this may be the most important and readily identifiable distinction.  Accordingly, Benton REA agrees that if power is not intentionally transported through a particular system, that system is not used for transmission and should not be considered part of the BES. One exception may be for a small embedded generation unit owned by a different party that may be "scheduled" out of an area, but in reality, does not produce any physical flow. These circumstances should not trigger inclusion.

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 4 Comment
Long Island Power Authority	Yes	In addition to Operating Procedures, electrical elements that restrict or control flow over the line should be allowed to be used as evidence.
Xcel Energy	Yes	It is not clear what ‘some other system’ would be. Is this another point on the BES in general?
for Snohomish County PUD	Yes	<p>Snohomish agrees that the SDT’s fourth test, which asks whether power is intentionally transported through a system, identifies a key characteristic of local distribution facilities that distinguishes such facilities from interconnect bulk transmission facilities that are properly considered part of the BES. In fact, we believe this may be the most important and readily identifiable distinction. As a matter of operation, power is scheduled across transmission lines. Further, transmission lines in the Western Interconnection (either individually or as part of a transmission path) are rated for total transmission capacity and available transmission capacity, and transmission rights can be purchased on such lines, if available, on an OASIS. Local distribution systems do not share any of these operational characteristics. Accordingly, Snohomish agrees that if power is not intentionally transported through a particular system, that system is not used for transmission and should not be considered part of the BES.</p> <p>We also agree that examining the Operating Procedures applicable to a particular system will provide a ready guide to whether power is intentionally scheduled across that system. We suggest, however, that the SDT look beyond those protocols that fall within the NERC Glossary’s definition of Operating Procedure. For example, in the West, transmission paths are almost all listed in the WECC Path Rating Catalog.</p> <p>Similarly, it is not clear whether scheduling protocols, OASIS operations, and the other factors listed above qualify as Operating Procedures.</p> <p>Hence, we urge the SDT to list such specific operational characteristics as part of this test.</p>
Independent Electricity System Operator	Yes	<p>There is an inconsistency between the language used in bullet (c) - “rarely flows out”, and that used in Exclusion E3(c) of the BES definition - “Power flows only into the LDN”. We have commented during the BES Definition comment period that Exclusion E3 needs to be modified to match the Exception Principles.</p> <p>We agree with the criteria set out in 1(c) except for bullets (iv) and (v). We do not believe it is possible to establish a limit on the energy flow out of a system for which an exception has been requested. Further, we suggest that the SDT avoid prescribing set values in the exception criteria since these would only serve to limit the flexibility of the process.</p> <p>As an alternative to the proposed bullet (iv), we suggest that power flow study results could be used to support the exception request. We therefore propose the following wording to replace bullets (iv) and (v).iv. Power flow simulation results to demonstrate that BES reliability is not dependent upon the power flows</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 4 Comment
		through the Element(s) for which an exception has been submitted, for the conditions specified in (ii).
Tacoma Power	Yes	Tacoma Power generally agrees with fourth item (power transport) when not intentionally transporting power through a system. In development of the supporting evidence for this item, we suggest a demonstration by operating studies or the option to demonstrate the criteria by the use of operational procedures.
Tri-State Generation and Transmission Association	Yes	While we generally agree, "system" needs to be clarified, and should be changed to "transmission system." It may also need to be qualified by indicating a change in ownership of transmission systems.  We also wonder if the concept of scheduling should be addressed rather than using the word "intentionally?"
Florida Municipal Power Agency	Yes	FMFA supports the criterion in concept, but "intention[]" is a vague term and not relevant to an Element's impact on the grid. We suggest instead that to obtain an exclusion for such a quasi-radial Element, the owner be required to demonstrate that the Element has no more than a 5% transfer distribution factor on any BES Element for transfers that could be curtailed through the NAESB TLR procedure (e.g., interchange transactions, or generator to load distribution factors (GLDF) for BES generators). Transfer distribution factor (or GLDF) is a good measure of an Element's impact on the grid and is not subject to varying interpretations. In addition, NAESB standards are also approved by FERC and mandatory to jurisdictional entities. Hence, the 5% TDF "Curtailed Threshold" has already been approved by FERC as indicating an insufficient impact on the BES to be considered for TLR. And, it shows consistency between NERC and NEASB standards.
Transmission Access Policy Study Group	Yes	TAPS supports the criterion in concept, but "intention[]" is a vague term and not relevant to an Element's impact on the grid. We suggest instead that to obtain an exclusion for such a quasi-radial Element, the owner be required to demonstrate that energy transfers subject to NAESB TLR procedures (Interchange Transactions or BES generator to load) have no more than a 5% transfer distribution factor (TDF) on the Element that is a candidate for exception. Transfer distribution factor is a good measure of an Element's impact on the grid and is not subject to varying interpretations.
Edison Electric Institute	Yes	A radial system by definition transports power from the BES System to a Distribution System, similarly an LDN operates in a like manner. A strict reading of the above criteria would exclude both from consideration yet the definition allows both. We believe that in an attempt to develop a set of criteria useful for all situations, the outcome has weakened the original intent as set in the Definition. Although much of the criteria used is largely appropriate, a stricter adherence to the BES definition criteria would substantially help to avoid confusion between what was developed as principles and what was developed as the BES Definition.
Bonneville Power Administration	Yes	BPA suggests that the SDT provide a method for assessing power transport based on intake to serve load

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 4 Comment
		versus outflow. BPA requests that the SDT clarify that the qualifying statements i-v for the fourth item are “or” statements.
PacifiCorp	Yes	All of PacifiCorp’s responses are based on the application of these items to a given interconnection and not on a continental basis. See comments on question 10. This criterion is very similar to parts of exclusion 3 of the proposed bright-line, which states “d) Not used to transfer bulk power: The LDN is not used to transfer energy originating outside the LDN for delivery through the LDN; and e) Not part of a Flowgate or transfer path: The LDN does not contain a monitored Facility of a permanent flowgate in the Eastern Interconnection, a major transfer path within the Western Interconnection as defined by the Regional Entity, or a comparable monitored Facility in the Quebec Interconnection, and is not a monitored Facility included in an Interconnection Reliability Operating Limit (IROL).”If the intent of this requirement is to capture local distribution networks that may be included under the proposed bright-line definition, then this requirement has merit.
Western Electricity Coordinating Council	Yes	WECC agrees in concept with this characteristic, but believes that there needs to be more clarity of what constitutes the evidence. Since flow data is used for characteristic c, it seems that the same sort of data (but separated into hourly flow in and hourly flow out) could be used to demonstrate this. Otherwise, a simple procedure that claims “power entering this system is not intentionally transported through the system to some other system” would meet the letter of the law, but gives no description of how this is achieved. If Operating Procedures are allowed, more clarity must be provided on what those procedures must entail.
<p><b>Response:</b> The SDT appreciates the suggestions for alternate language or clarifications to the proposed language for the characteristic associated with the unintentional transporting of power through a system Element with delivery to another system Element as qualifying criterion. Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity’s characteristics to a defined value and/or limit. It has become apparent that it is not feasible to establish continent-wide values and/or limits due to differences in operational characteristics. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the Rules of Procedure as presently being drafted.</p>		
Electricity Consumers Resource Council (ELCON)	Yes	This requirement should be further relaxed to allow for intentional flows that are provided as a courtesy to the local distribution company. In such cases, private, customer-owned facilities may be used to deliver power from a DP to a small number of the DP’s retail customers who are unaffiliated with the owner/operator of the private network. These flows are generally de minimis.

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 4 Comment
		We also recommend that this item (with our qualification) be added to the BES definition.
Oregon Public Utility Commission Staff	Yes	Use of the 100 kV brightline and the core BES definition as proposed is an overreach into local distribution systems and an overreach of FERC’s authority as set out in the FPA 215. A full engineering technical analysis - required every 2 years - is too onerous and not necessary for identifying most local distribution elements miss-identified as BES Elements. A simple screening methodology consistent with the 7-Factor Test (from FERC Order 888) is needed as the first stage of the exception process.
<p><b>Response:</b> The SDT has responded to comments on the BES definition in the Consideration of Comments form for the BES definition posting.</p> <p>The SDT appreciates your comments. Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity’s characteristics to a defined value and/or limit. <p><b>Response:</b> Thank you for your response.</p>		

5a. Comments on approach:

**Summary Consideration:** Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the draft Rules of Procedure.

Organization	Yes or No	Question 5a Comment
Northeast Power Coordinating Council		<p>This method may allow an entity to exclude Elements which perform a transmission function, but that are not the most limiting Element. “</p> <p>Not being necessary for reliability operation” needs definition.</p> <p>The SDT should consider developing a Guidance Document to provide examples and insights to guide prospective filing entities.</p> <p>The TPL Reliability Standards already describe the full set of requirements for a reliable system. Why are added requirements necessary? Why would any such added criteria not conflict with the TPL Reliability Standards to the extent that they were either more or less restrictive?</p> <p>Entities should be given an option to conduct an analysis to demonstrate if an element is necessary for the operation of a transmission network. NERC should specify all the relevant criteria categories to be listed as under 2 (a). NERC should avoid prescribing numerical values, but instead establish a range of values (or reference industry standards) that would be consistent with industry/ regional standards or practices without compromising the reliability of the transmission network.</p>
SERC Planning Standards Subcommittee Tennessee Valley Authority Southern Company		<p>As written, most of this approach makes no sense. The words imply that if you have planned the system properly, you can exclude it from the BES! In TPL studies you make sure that voltage dips, frequency excursions, voltage deviations are acceptable, oscillations are damped, and no cascading outages occur. So if you meet the performance requirements of TPL studies, you can exclude the element from the BES. What good is this?</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 5a Comment
Georgia Transmission Corporation		
City of Redding		<p>It appears the industry experts have a very difficult time identifying any set of measurement factors that can be applied on a consistent basis to any system and produce similar results, therefore there needs to be geographical variation where the experts in the local systems can make a determination.</p>
NERC Staff Technical Review		<p>NERC staff is not opposed to development of evidence based on technical analysis; however, the type of analysis included in this exception criterion requires extensive resources and lacks sufficient detail to allow for consistent and repeatable application. Concerns with this approach include (1) the ability to provide sufficient guidance on the system conditions and contingencies necessary to support an exception request,</p> <p>(2) difficulty with identifying thresholds for items iv-1 through iv-4, and</p> <p>(3) the ability to address interdependencies among exception requests.</p> <p>These concerns can be addressed by deleting this second path for evidence and including technical analysis on a limited basis to assess performance as described in our response to Question 2. If the SDT elects to retain this second path for evidence, then our three concerns must be addressed. In particular with regard to our third concern, the ERO must be able to deny requests for exception based on the cumulative impact of all previously approved exceptions.</p>
ACES		<p>Overall, the approach is reasonable. However, we disagree with 2.b which states that the ERO can override the criteria. Once criteria is established, the ERO should not be able to override the determination. The ability of the ERO to override implies the criteria is not sufficient and needs to be modified. Rather than override, the ERO should seek to modify the criteria if it is not sufficient.</p>
Edison Electric Institute		<p>In general, we agree that an alternative path allowing a technical analysis to demonstrate that a Facility (or Element) should not be considered part of the BES is appropriate. However, we disagree with the measures offered and suggest an alignment with efforts already being developed within NERC's Event Analysis Working Group. EEI proposes that the technical analysis criterion which has been proposed is too complicated, inconsistent with what is currently being done across the regions and submits that a better approach would be to align reliability impacts with the Event Analysis Criteria being developed by NERC's EAWG.</p> <p>These criteria would be a better benchmark as to whether a Facility or Element should be excluded from the BES. The proposed alternate criteria are as follows:(1) The loss of the Facility (or Element) would not interfere or negatively impact the BES from staying within acceptable limits (i.e., frequency, voltage and</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 5a Comment
		<p>System Operating limits) following a fault on or loss of that Facility (or Element);</p> <p>(2) The loss of the Facility (or Element) would not interfere or negatively impact the BES from performing acceptably after credible contingences;</p> <p>(3) Facility (or Element) faults, failures, or trips do not push the system to a point of Instability or otherwise initiate cascading outages;</p> <p>(4) BES facilities are protected from unacceptable damage by operating the Facility (or Element) within its ratings; and</p> <p>(5) The unexpected loss of the Facility (or Element) does not negatively impact the BES from achieving its mission of to supply the aggregate electric power and energy requirements of its customers.</p>
Florida Municipal Power Agency		<p>FMPA supports including specific technical criteria that Elements must meet to obtain an exclusion through the exception process. This approach will facilitate uniform application of the exception process. FMPA responds to the first five proposed criteria in response to 5b-5e below. In the sixth proposed criterion, “steady state stability” is ambiguous, does the SDT mean voltage stability, power angle curve stability, or small signal stability?</p> <p>The seventh proposed criterion, “No cascading outages,” is insufficiently granular and should be discarded. The criteria are intended to measure whether, among other things, a particular Element can cause a cascading outage. They need to set out how decision-makers will determine whether an Element can cause a cascading outage, not simply state that an Element that can cause a cascading outage cannot be excluded from the BES.</p>
Transmission Access Policy Study Group		<p>TAPS supports including specific technical criteria that Elements must meet to obtain an exclusion through the exception process. This approach will facilitate uniform application of the exception process. TAPS responds to the first five proposed criteria in response to 5b-5e below. The seventh proposed criterion, “No cascading outages,” is insufficiently granular and should be discarded. The criteria are intended to measure whether, among other things, a particular Element can cause a cascading outage. They need to set out how decision-makers will determine whether an Element can cause a cascading outage, not simply state that an Element that can cause a cascading outage cannot be excluded from the BES.</p>
ISO/RTO Standards Review Committee		<p>Predictive analysis of an accurate model is useful in determining the importance of various elements of the system.</p>
Iberdrola USA		<p>A facility is not BES if it is not necessary for reliable system operation, based on a TPL-type analysis similar to</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 5a Comment
		<p>NPCC Document A-10 “Classification of Bulk Power System Elements” - this type of analysis was rejected by FERC. Besides, at 115kV, calculated distribution factors for interfaces between areas (where higher voltage lines, e.g., at 230kV and 345kV, are included as part of the interface definition) tend to be small and inaccurate. The method used to calculate distribution factors is an approximate method which must be re-evaluated for small values of distribution factors.</p>
Tri-State Generation and Transmission Association		<p>This appears very similar to the “material impact” proposal that FERC has previously disallowed, so we recommend removing 2.</p> <p>If retained, remove 2.(b) because allowing the ERO to override the technical justification and analysis devalues such analysis to the point of it being meaningless.</p>
Hydro One		<p>We agree that entities should be given an option to conduct an analysis to demonstrate whether or not an element is necessary for the operation of the transmission network.</p> <p>We also support that NERC should specify the entire relevant criteria category to be listed under exclusion criteria 2 (a). However, we suggest that NERC should avoid prescribing numerical values but establish a range of value (or reference industry standard) that would be consistent with industry/ regional standards or practices without compromising the reliability of the transmission network.</p>
MRO's NERC Standards Review Forum		<p>NSRF proposes that this technical analysis criterion be replaced by criteria that are more closely tied to the Adequate Level of Reliability (ALR) characteristics.</p> <p>The following alternate criteria are offered as possible examples, “(1) the BES can be controlled to stay within acceptable limits following a fault on or loss of the Element; (2) the BES performs acceptably after credible contingences of the Element; (3) the Element does not limit the impact and scope of instability and cascading outages when they occur; (4) BES facilities are protected from unacceptable damage by operating the Element within its ratings; (5) the integrity of the BES can be restored promptly following a fault on or loss of the Element; and (6) the BES has the ability to supply the aggregate electric power and energy requirements of the electricity consumers at all times, taking into account scheduled or reasonably expected unscheduled outages of the Element.</p> <p>In addition, NSRF is not aware of any continent-wide appropriate BES performance measures for voltage dip, frequency excursion, voltage deviation, stability, etc. and NSRF speculates that different values are likely for different regions and system characteristics across the continent. As a result, NSRF believes it is not advisable to try to adopt unproven values without reasonable industry investigation and development.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 5a Comment
Bonneville Power Administration		<p>BPA comments on the technical analysis are as follows:</p> <ol style="list-style-type: none"> <li>1. Who is responsible for running these studies (the BA, individual utilities....?)</li> <li>.2. The analysis and criteria need to be better defined for the technical analysis.</li> <li>3. What did SDT mean by “having a distribution factor of TBD% for any other Element”? This should probably reference a specific PTDF for a path or source/sink group.</li> <li>4. What contingencies are studied to show the elements meet the transient voltage dip, frequency excursion, etc. (i.e. are they 3 phase delayed cleared faults, single phase faults, etc.)? Furthermore, the exclusion criteria needs to be much more specific about how the study is to be conducted in general - i.e.: Regional Entities have established study guidelines and procedures to determine voltage and frequency criteria. Specifically, is it the intent that the element being proposed for exclusion be opened in the study and then the standard contingency list applied to the rest of the system? Presumably, if there is no difference in system performance with the element in or out, then it could be excluded. Alternatively, is it intended that the contingency to be tested is simply the loss of the element proposed for exclusion?</li> <li>5. What elements and/or flow gates should be monitored for these analyses?</li> <li>6. In “Other”, the SDT should add “The limiting element for a flow-gate cannot be excluded from the BES”.</li> <li>7. How will the criteria be set? Will they follow current standards? (i.e. TPL-001)? The technical principles must identify what category(ies) of TPL studies must be run. BPA requests clarification on what the values for the threshold criteria and/or disturbances would be?</li> </ol>
PacifiCorp		<p>5a. Comments on approach: All of PacifiCorp’s responses are based on a given interconnection and not on a continental basis. See comments on question 10. Using any technical criteria will allow many elements to be excluded from the BES regardless of the element’s criticality to the interconnected system.</p> <p>Whatever technical criteria is established should only be applied to elements under 200 kV and any radial elements above 200 kV</p>
ReliabilityFirst		to complicated and will only raise debate between FERC, NERC, the Regions and the Registered Entities
Western Electricity Coordinating Council		WECC agrees in concept that a technical analysis can be used and should be allowed to show that an element is not necessary for reliable operation. However, the technical analysis must be based on sound reasoning and a justification must be given as to why the analysis makes a showing that the element is not necessary for reliable operation. Furthermore, the technical principles must identify what category(ies) of TPL

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 5a Comment
		<p>studies must be run.</p> <p>Finally, the values used for the threshold criteria and/or disturbances must be more stringent than the applicable TPL criteria/disturbances. Otherwise the argument becomes circular because all BES elements must meet the TPL criteria, so by meeting them all elements could be excluded.</p>
New York State Reliability Council		<p>A single threshold value for performance based testing does not recognize differences in regional system characteristics. Therefore, regional approaches for at least generation exclusions should be used, like NPCC's A-10 criterion.</p>
National Grid		<p>We do not agree with all the criteria listed in point 2.a.iv. For example we believe that the term in 2.a.vi.6 “Steady-state Stability - positively damped” does not relate to the concept of steady-state stability. We believe an acceptable measure of steady-state stability would be an angle difference across the transmission line. That difference can vary depending on the line; however, a rule of thumb is typically 45 degrees which provides a 30% steady state stability margin. As mentioned previously, the exception process should be strictly limited to the procedures for application and approval and should not include substantive elements.</p>
Muscatine Power and Water		<p>Would like to propose that this technical analysis criterion be changed to criteria that are more closely tied to the Adequate Level of Reliability (ALR) characteristics.</p> <p>Would like to offer the following alternate criteria as possible examples, “(1) the BES can be controlled to stay within acceptable limits following a fault on or loss of the Element;</p> <p>(2) the BES performs acceptably subsequent to credible contingences of the Element;</p> <p>(3) the Element does not limit the impact and scope of instability and cascading outages once they occur;</p> <p>(4) BES Facilities are protected from undesirable damage by operating the Element within its ratings;</p> <p>(5) the reliability of the BES can be restored promptly subsequent to a fault on or loss of the Element; and</p> <p>(6) the BES has the ability to supply the aggregate electric power and energy requirements of the electricity consumers at all times, taking into account scheduled or reasonably expected unscheduled outages of the Element.</p> <p>Currently not aware of any continent-wide appropriate BES performance metrics for voltage dip, frequency excursion, voltage deviation, stability, etc. and would speculate that different values are likely for the different regions and system characteristics across the continent. Thus, it is not advisable to try to adopt unproven values without reasonable industry investigation and development.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 5a Comment
<p>Blachly Lane Electric Cooperative  Flathead Electric Cooperative, Inc  United Electric Co-op Inc.  Oregon Trail Electric Cooperative, Inc.  Central Lincoln  Salem Electric  Grant County PUD No. 2 (Grant) for Snohomish County PUD  Northwest Public Power Association (NWPPA)  Big Bend Electric Cooperative, Inc.  Kootenai Electric Cooperative</p>		<p>We agree conceptually with the idea that two different paths to exclusion should be adopted, one relying upon readily identifiable characteristics that are ordinarily associated with non-BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES.</p> <p>Snohomish Public Utility District has prepared a White Paper proposing a performance-based approach to support the technical determination whether Elements should be excluded from the BES, which we commend to the SDT for study.</p> <p>We also commend the work of the WECC BES Task Force and the WECC Technical Studies Subcommittee, both of which have devoted substantial time and resources to developing a workable and technically defensible process for excluding Elements classified as BES based upon their electrical characteristics. See WECC BES Task Force Proposal 6, App. A at 3-9 &amp; App. B at pp. B-4 to B-7 (posted Feb. 18, 2011) (available at: <a href="http://www.wecc.biz/Standards/Development/BES/default.aspx">http://www.wecc.biz/Standards/Development/BES/default.aspx</a>).</p> <p>We recommend that the SDT modify its approach to the technical exclusion process to match the approach advocated in Snohomish’s White Paper, which is based upon the approach recommended by the WECC BES Task Force.</p>
<p>South Carolina Electric and Gas</p>		<p>As written, most of this approach makes no sense. The words imply that if you have planned the system properly, you can exclude it from the BES! In TPL studies you make sure that voltage dips, frequency excursions, voltage deviations are acceptable, oscillations are damped, and no cascading outages occur. So if you meet the performance requirements of TPL studies, you can exclude the element from the BES. This does not seem to be what was intended.</p>
<p>Glacier Electric Cooperative</p>		<p>I strongly agree that there should be a way for elements to be excluded from the BES based on a technical analysis. However, the current approach only provides one technical avenue for exclusion and that is through a transmission planning study. Performing and analyzing such a study could be very, very difficult for a small entity to do. If this is the approach that NERC continues with, then I believe there needs to be some extra language outlining who is responsible for performing and analyzing these transmission planning studies. The question is should the RRO (WECC, etc.) be responsible for performing the study and determining through the technical criteria what elements are included and excluded in the BES, or should that responsibility fall on</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 5a Comment
		<p>control area operators within an RRO, or should that responsibility fall on individual entities? I believe it should fall on either the RROs or the control area operators within the RROs.</p> <p>Perhaps an alternative approach could be to establish a few technical checks that could be evaluated first before a transmission planning study is required. For example, a max fault MVA value could be established and if the available fault MVA at an element is less than the established value, then that element and could be excluded without having to go through a transmission planning study. If the available fault MVA at the element is above the established value, then the study would have to be done for determination.</p>
Exelon		<p>This item calls for the use of criteria in order to prove that a facility should be excluded the BES. First of all, the items 5b - 5e do indeed require extensive technical analysis which will be outside of the capabilities of many users of the BES.</p> <p>Furthermore, it is not clear who's criteria will be used? The user's? The Transmission Owner's? The Planning Authority's? This question of ownership needs to be resolved and in itself poses a problem for this process. If differing criteria levels are used across the continent, there remains the possibility that similarly-situated facilities in different Regions will not be treated consistently.</p>
Consolidated Edison Co. of NY, Inc.		<p>The technical analysis approach may have merit. However, we have a number of questions about how it would be implemented in practice. We are concerned that this method may allow an entity to exclude Elements simply because they are not the most limiting Element in a particular TPL analysis. What does "not being necessary for reliability operation" mean? Please define.</p> <p>The SDT should consider developing a Guidance Document to provide examples and insights to guide prospective filing entities.</p> <p>The TPL Reliability Standards already describe the full set of requirements for a reliable system. Why are added requirements necessary? Why would any such added criteria not conflict with the TPL Reliability Standards to the extent that they were either more or less restrictive?</p>
ISO New England		<p>The use of distribution factors is a significant concern. The term distribution factor is used a number of ways in the industry. Is this determined using the percentage pickup on the element in question following the loss of another element, or is this the percentage of a transfer that is picked up on the element in question, or a combination of both?</p> <p>Item 2.a.ii states that the TPL studies have to be run if the model is updated. The distribution factor is not required to be calculated as part of the TPLs and therefore will require additional analysis in all circumstances, not just when the model is updated.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 5a Comment
The United Illuminating Company		This is not very different from trying to demonstrate no adverse impact outside the local area.
Georgia System Operations Corporation		It would be helpful to specify which TPL Standard(s) the referenced studies are usually prescribed for.
Entergy Services		The entire approach seems overly complex and difficult to document.
Clark Public Utilities Central Electric Cooperative Clearwater Power Electric Cooperative Consumer's Power Inc. Coos-Curry Electric Cooperative Douglas Electric Cooperative Fall River Electric Cooperative Lane Electric Cooperative Lincoln Electric Cooperative Lost Rive Electric Cooperative Northern Lights Electric Cooperative Okanogan Electric Cooperative Raft River Rural Electric Cooperative Salmon River Electric Cooperative Umatilla Electric Cooperative West Oregon Electric		<p>Clark agrees conceptually with the idea that two different paths to exclusion should be adopted, one relying upon readily identifiable characteristics that are ordinarily associated with local distribution and not BES transmission facilities, and one relying on technical analysis to determine whether or not an Element or group of Elements has a measurable impact on the threat of cascading outages, separation events, or instability on the interconnected bulk system. If technical analysis demonstrates that Elements create no material threat of such reliability events, they should properly be excluded from the BES.</p> <p>Clark supports the technical arguments and the White Paper presented by Snohomish County PUD in their comments. Clark recommends that the SDT modify its approach to the technical exclusion process to match the approach advocated in the White Paper, which is based upon the approach recommended by the WECC BES Task Force.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 5a Comment
Cooperative Pacific Northwest Generating Cooperative Consumer's Power Inc Benton Rural Electric Association Northern Wasco County PUD		
BGE		BGE believes that there is value in allowing for exclusions through a technical analysis path.  Because multiple entities may perform “planning assessments” using different models, the phrase, “*the* most recent *applicable* planning assessment” should be clarified to avoid ambiguity as to which model(s) are acceptable. It may be useful to designate the models used in the Planning Authority analyses as acceptable.
Spyker		We agree that entities should be given an option to conduct an analysis to demonstrate if an element is necessary or not for the operation of transmission network. We also support that NERC should specify all the relevant criteria category to be listed as under 2 (a). However, we suggest that NERC should avoid prescribing numerical values but establish a range of value (or reference industry standard) that would be consistent with industry/ regional standards or practices without compromising the reliability of transmission network.
Long Island Power Authority		Exclusion under this criteria would require that the analysis be performed by the registered TP. Criteria identified is based on interconnection to neighboring utilities.
Orange and Rockland Utilities, Inc.		This approach is not necessary since NERC TPL Reliability Standards already addressed how to maintain a reliable electric system.
Pepco Holdings Inc		Generally agree that a specific technical analysis approach (power flow studies) showing no impact on BES is appropriate, but don't know how to define specific criteria on which to base decision.
Duke Energy		Duke Energy agrees with the approach of using a technical analysis based on transmission system modeling but the specific criteria do not need to be specified here - they should be consistent with the latest revision of

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 5a Comment
		<p>the TPL-001. R5 of TPL-001-2, Transmission System Planning Performance Requirements states that each Transmission Planner and Planning Coordinator shall have criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and the transient voltage response for its System. The technical analysis required for exclusion of an Element from the BES should evaluate the loss of the Element against a more conservative set of criteria than that specified by the Transmission Planner and Planning Coordinator responsible for that Element. There are currently no continent-wide performance levels defined for these evaluations, and there is no technical basis for developing performance levels that would be applicable continent wide.</p>
American Transmission Company, LLC		<p>ATC proposes that this technical analysis criterion be replaced by criteria that are more closely tied to the Adequate Level of Reliability (ALR) characteristics. The following alternate criteria are offered as possible examples, "(1) the BES can be controlled to stay within acceptable limits following a fault on or loss of the Element;</p> <p>(2) the BES performs acceptably after credible contingences of the Element;</p> <p>(3) the Element does not limit the impact and scope of instability and cascading outages when they occur;</p> <p>(4) BES facilities are protected from unacceptable damage by operating the Element within its ratings; and</p> <p>(5) the BES has the ability to supply the aggregate electric power and energy requirements of the electricity consumers at all times, taking into account scheduled or reasonably expected unscheduled outages of the Element. In addition, ATC is not aware of any continent-wide appropriate BES performance measures for voltage dip, frequency excursion, voltage deviation, stability, etc. and ATC speculates that different values are likely for different regions and system characteristics across the continent.</p> <p>As a result, ATC believes it is not advisable to try to adopt unproven values without reasonable industry investigation and development.</p>
Manitoba Hydro		<p>Manitoba Hydro does not agree with an impact based approach to establishing BES elements as we believe it will result in regional differences in the application of the BES definition.</p> <p>In addition, the resources required to verify the assumptions made in the models used to substantiate a BES exception would be substantial with no benefit to reliability.</p> <p>As well, this section appears to be an incomplete process. As currently worded, if the model was not updated in step ii, then there is no requirement to run the TPL studies indicated in the remainder of step ii.</p>
NESCOE		<p>NESCOE supports the concept of allowing an additional path to justifying an exclusion from the BES.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 5a Comment
		<p>NESCOE could support development of technical criteria such as those proposed, but does not have specific recommendations at this time.</p> <p>As stated earlier, any excluded elements must be connected to the BES using fully NERC compliant protection systems.</p>
Independent Electricity System Operator		<p>The technical analysis path for exclusions and inclusions allows for override of the listed “criterion”. It is not clear what will be the basis for overriding, and what process will be followed? Is the “criterion” meant to be all of (1) to (7) in (a), or is it any one of them? This needs to be clarified.</p> <p>We agree that entities should be given an option to conduct an analysis to demonstrate if an element is or is not necessary for the operation of transmission network. However, consistent with our earlier comments, we suggest that the exception criteria avoid prescribing numerical values.</p> <p>A transmission element is not necessary for the reliable operation of an interconnected electric transmission system, if it can be removed without effecting bulk transfer capabilities. In our view, testing in accordance with the TPL standards should be the basis for establishing this. One way of demonstrating that an element is not required for the transfer of bulk power is to show that with the element out of service (and with all elements that received exemptions in the past also out of service) and at the required power transfers:1. Pre-contingency and post-contingency loadings on all BES elements are within applicable ratings.2. Pre-contingency and post-contingency voltages on the BES are within established ratings.3. All units on the BES remain synchronized following contingencies.4. All voltage declines on the BES are within established limits (if any limits were defined).5. All steady-state oscillations and oscillations following a contingency are positively damped.6. Transient voltage dips do not exceed established limits anywhere on the BES (if any limits were defined).7. Frequency excursions do not exceed established limits anywhere on the BES (if any limits were defined). Our view is that the exception criteria should NOT specify the voltage decline limits, allowable frequency excursion or the allowable transient voltage dip because every region will have different limits depending on the characteristics of their power system. This would be consistent with Requirement R5 of the recently balloted standard TPL-001-2, which requires each Transmission Planner and Planning Coordinator to have criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and the transient voltage response for its System. Required power transfers are the transfers required to meet the “one day in ten year” loss of load expectation criteria.</p> <p>Further, exception criteria for generators must also be defined. A power system is typically planned to be able to service the load under multiple dispatch scenarios and, therefore, multiple generators disconnected from the transmission system will unlikely reduce the ability of the power system to supply the load. In fact, market forces typically determine whether or not a generator is connected. However, transmission lines are built to achieve specific transfer capabilities and, therefore, directly affect the power system’s ability to meet the</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 5a Comment
		electricity demand. Since, generators and transmission elements contribute to reliability in a very different ways, the criteria exempting generators should be different from the criteria exempting transmission elements.
MidAmerican Energy		<p>The concept of using TPL analyses and normalized Transmission Distribution Factors makes basic sense as a way to determine what elements react to system transfers and what elements react primarily to distribution load. In general all facilities below 100 kV should be excluded by default as distribution according to the 2005 Federal Power Act.</p> <p>Transmission Distribution Factors tend to show low bulk power system transfers (less than 2%) based on their inherent high impedance when normalized. Normalizing the transmission impedance means dividing the ohmic value by a base impedance which is dominated by a (kV<sup>2</sup>) term. Per Unit Impedance = (transmission line ohms / base impedance) where base impedance = (kV<sup>2</sup> / MVA). Using a common MVA base value of 100 MVA, a base impedance at 69kV = 47.6 ohms versus at 161 kV = 259.2 or at 345 kV = 1190.2 ohms. The rapid increase of the denominator as kV goes higher insures that a 69 kV system is high impedance compared to any high kV facilities and therefore nearly insure the 69 kV system is local in nature and reacts primarily to load. Therefore it is distribution.</p> <p>This all supports the conclusion that all facilities below 100 kV should be classified as distribution according to the 2005 FPA and exempted by default. Facilities below 100 kV could be brought into scope if TPL analyses show instability, uncontrolled separation, or cascading as defined in the 2005 FPA.</p>
<p><b>Response:</b> The SDT appreciates the suggestions for alternate language or clarifications to the proposed language and application of the study parameters utilized to analyze system Elements for potential exclusion from the BES. Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity's characteristics to a defined value and/or limit. It has become apparent that it is impossible to establish values and/or limits that would be valid across all regions and systems. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the draft Rules of Procedure.</p>		
PPL Supply		See comments in Questions 9 and 10
<p><b>Response:</b> See response to Q9 &amp; Q10.</p>		
Tacoma Power		Tacoma Power generally agrees with approach used on the technical analysis path for exclusions.

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

---

Organization	Yes or No	Question 5a Comment
Idaho Falls Power		We generally agree with having two paths towards exclusion.
New York Power Authority		In general, NYPA agrees with this approach except as noted below.
Springfield Utility Board		In general, SUB supports a technical analysis approach as a secondary/ alternative option for qualifying to apply for BES Element exclusions.
Consumers Energy Company		Generally, this approach seems sound.
Oncor Electric Delivery		Oncor Electric Delivery agrees with the proposed language that describes the exclusion criteria based technical analysis.
<p><b>Response:</b> The SDT appreciates your support. However, based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity’s characteristics to a defined value and/or limit. It has become apparent that it is impossible to establish values and/or limits that would be valid across all regions and systems. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the draft Rules of Procedure.</p>		

**5b. Comments on distribution factor measurement:**

**Summary Consideration:** Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the draft Rules of Procedure.

Organization	Yes or No	Question 5b Comment
		be excluded from the BES. However, if we use the TDF as a factor the radial line would be included in the BES since the TDFs would be high.
Edison Electric Institute		In general, we do not agree this is a relevant factor for consideration and should be excluded.
Florida Municipal Power Agency		The first proposed criterion, “Having a distribution factor of 5% for any other Element,” should instead be “Having a distribution factor of 5% for Interchange Transactions or BES generator to load curtailable in Transmission Loading Relief stages one through five.”
Transmission Access Policy Study Group		<p>The first proposed criterion, “Having a distribution factor of 5% for any other Element,” should instead be “Having a distribution factor of 5% for curtailable Interchange Transactions or BES generator to load identified in Transmission Loading Relief stages one through five.”</p> <p>An Element with a higher distribution factor only on a non-BES Element should not be considered part of the BES on that account.</p>
ACES	Yes	The IDC uses 5% as a distribution factor cutoff so this might be a reasonable value. “Transmission Transfer Capability” which was published by NERC in 1995 recommends using 3% on page 18 for transfer capability studies.
ISO/RTO Standards Review Committee		Distribution factors by themselves are not sufficient evidence that elements are not important to the system. Multiple elements may have significant distribution factors related to various portions of the system, but that doesn’t necessarily mean that loss of those elements will result in a reliability risk to the system.
Tri-State Generation and Transmission Association		If this approach is used, then there needs to be a clear technical rationale for defining the metric and for determining the threshold value.
Hydro One		Distribution Factor is an estimate of what feeder power flow participation level material is and what non-material is. While TDF and OTDF analysis is an indication of contributions from the element, hence the SDT should avoid setting values and instead describe the intended performance outcome from a distribution factor measurement. Note that ultimately NERC as an ERO or relevant regulatory authority will approve the application and can assess the performance outcome in their decision making presented in an entity’s application.
MRO's NERC Standards Review		NSRF proposes replacing this factor with those cited above because a distribution factor measurement indicates how much system changes affect the element, not how much a fault or loss of the element would

Forum		<p>compromise the ALR of the BES.</p> <p>There is no clear correlation between this factor and any of the six characteristics of Adequate Level of Reliability (ALR) of the BES.</p>
PacifiCorp		<p>5b.Comments on distribution factor measurement: All of PacifiCorp’s responses are based on a given interconnection and not on a continental basis. See comments on question 10. Distribution factor has little to no bearing on entities in the Western Interconnection.</p>
ReliabilityFirst		<p>any impact is an impact, even generation is re-dispatched at 0% in some cases.</p>
New York Power Authority		<p>NYPA does not agree with this measurement. Distribution factors are dependent on the number of radial transmission lines that connect a single source to a load. For example, if two lines connect a single source to a load, and one line trips, the distribution factor provides a 100% increase in flow on the remaining line. If three lines connect the source to the load, and one line trips, the distribution factor for the remaining lines would be 50%. The SDT should avoid setting values and instead describe the intended performance outcome from a distribution factor measurement. Note that ultimately NERC as an ERO or relevant regulatory authority will approve the application and can assess the performance outcome in their decision making presented in an entity’s application.</p>
National Grid		<p>We don’t think this measurement is necessarily relevant in determining whether an element is necessary to system reliability. This criterion can be removed from the list.</p> <p>The exception process should be strictly limited to the procedures for application and approval and should not include substantive elements.</p>
Muscatine Power and Water		<p>Suggest replacing this aspect with those cited above because a distribution factor measurement indicates how much system changes influence the element, not how much a loss of the element would compromise the ALR of the BES.</p> <p>Currently unable to establish a clear correlation between this factor and any of the six characteristics of Adequate Level of Reliability (ALR) of the BES.</p>
Blachly Lane Electric Cooperative Flathead Electric Cooperative, Inc		<p>The use of distribution factors, such as Power Transfer Distribution Factors (“PTDF”) and Outage Transfer Distribution Factor (“OTDF”) provide insight into the relative impedance of neighboring systems. Central Lincoln  for Snohomish County PUD</p>		<p>Eastern Interconnection support the use of such factors, we believe the approach is unlikely to work in the Western Interconnection.</p> <p>Based on the significant differences between the four major interconnections in North America, we suggest that a detailed technical exemption process be allowed on an interconnections wide basis. The Western Interconnection is a "hub and spoke system" where loads are very remote from large generation plants, with margins that are based on stability limits. By contrast, the Eastern Interconnection is a tightly meshed system with loads and generation in close proximity, often creating margins that are based on thermal limitations. These differences manifest themselves in a variety of ways for various operations. For example, the Western Interconnection uses a rated-paths methodology while the Eastern Interconnection uses transmission load relief mechanisms.</p> <p>Consistent with FERC order 743-A, we support exemption criteria for individual frequency independent regions, or interconnections.</p>

Organization	Yes or No	Question 5b Comment
Kootenai Electric Cooperative		
BGE		BGE requests that it be made clear that the 2(a) iv.1 criteria refers to the of the distribution factor for the loss of any other facility on the subject Element, whereas criteria 2 through 7 refer to the performance following the loss of the subject Element.
Spyker		The SDT should avoid setting values and instead describe the intended performance outcomes from the measurement
Consumers Energy Company		This criterion raises concerns. If based on transfer distribution factor it may have some merit, depending on the TBD value. However, the criteria should not be based on outage transfer distribution factor, as Draft 1 implies, since loss of certain local distribution facilities can result in local distribution load being transferred to other local distribution facilities. Distribution facilities should not be prevented from exclusion from BES.
Duke Energy		This should be removed - there is no correlation between distribution factor and whether or not an element is necessary for reliable operation of the interconnected transmission network.
Hydro-Quebec TransEnergie		Comments on distribution factor measurement: The choice of the maximum distribution factor could be difficult to establish. For this point, the comparison of the distribution factor prior and after the events could be considered.
American Transmission Company, LLC		ATC proposes replacing this factor with those cited above in 5a because a distribution factor measurement indicates how much system changes affect the element, not how much a fault or loss of the element would compromise the ALR of the BES. There is no clear correlation between this factor and any of the six characteristics of Adequate Level of Reliability (ALR) of the BES.
Independent Electricity System Operator		We do not agree with setting values for this criterion. This should be left to the relevant Transmission Planner and Planning Coordinator. See our comments in response to Q5a.
Tacoma Power		Tacoma Power generally agrees with the distribution factor measurement in the technical analysis path for exclusions. We suggest adopting a distribution factor not exceeding 30% on an adjacent system.
MidAmerican Energy		The Distribution Factor measurement is acceptable and should exclude facilities that show a low distribution factor for bulk power system transfers. An arbitrary low value could be those facilities that show less than a 2% distribution factor.

5c. Comments on allowable transient voltage dip measurement:

**Summary Consideration:** Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the draft Rules of Procedure.

Organization	Yes or No	Question 5c Comment
Northeast Power Coordinating Council		Voltage dip is specified in terms of duration and retained voltage, usually expressed in percentage. Suggest that either the SDT avoid using voltage dip as a criteria, or clearly specify that the transient voltage not exceed the X limit of Y cycles (time). References to relevant industry standards such as IEEE standard 1346-1998 should be made.
SERC Planning Standards Subcommittee Tennessee Valley Authority Southern Company South Carolina Electric and Gas Georgia Transmission Corporation		As stated above, it does not make sense to use this category.
Edison Electric Institute		Presently no regional standards exist for allowable transient voltage dip beyond WECC. It is also doubtful a useful standard could be developed for all regions or interconnections.
Florida Municipal Power Agency Transmission Access Policy		The second criterion, "Allowable transient voltage dip - criteria TBD," should specify where the transient voltage dip is, i.e. "Allowable transient voltage dip on another BES Element for events on the Element that is a candidate of the Exception Request-criteria TBD."

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 5c Comment
Study Group		
ISO/RTO Standards Review Committee		These “transient” and “voltage deviation” analyses are highly dependent upon sound and accurate dynamic system models. Much has been said in recent days about the suspicions that many such models are not truly accurate enough to predict system response that is close to what actually occurs.
Tri-State Generation and Transmission Association		If this approach is used, then there needs to be a clear technical rationale for defining the metric and for determining the threshold value.
Hydro One		Voltage dip is specified in terms of duration and retained voltage, usually expressed in percentage. We advise against prescribing limits by the SDT, and instead suggest that either the SDT avoid relating voltage dip altogether or clearly specify that the transient voltage not exceed the X limit of Y cycles (time). We suggest SDT to make references to relevant industry standard such as IEEE standard 1346-1998. For example, a document effective in 2007 titled Ontario Resource and Transmission Assessment Criteria Issue 5.0 mentions that: “The minimum post-fault positive sequence voltage sag must remain above 70% of nominal voltage and must not remain below 80% of nominal voltage for more than 250 milliseconds within 10 seconds following a fault. Specific locations or grandfathered agreements may stipulate minimum post-fault positive sequence voltage sag criteria higher than 80%. IEEE standard 1346-1998 supports these limits.”
MRO's NERC Standards Review Forum		NSRF proposes replacing this factor with those cited above because there is presently no established, continent-wide, acceptable transient voltage dip performance level for evaluating whether a fault or loss of the element would not compromise the ALR of the BES.  In addition, the appropriate performance level for this factor may vary for different areas and system characteristics across the continent.
ReliabilityFirst		any impact is an impact, planning criteria between 3 & 5 % is often used and not allowed, why inject this into what define the BES. the criteria is applied it should be included
New York Power Authority		Suggest that either the SDT avoid using voltage dip as a criteria, or clearly specify that the transient voltage not exceed the X limit of Y cycles (time).  References to relevant industry standards such as IEEE standard 1346-1998 should be made.

ISO New England		Is the requirement to evaluate the voltage dip on the element or is the test to evaluate the voltage dip on the BES due to a contingency on the element? Under the draft TPL standards, this will have to be tested and investigated anyway, so it is unclear as to what is being added or evaluated here.
The United Illuminating Company		Measured where on the BES?
BGE		For PJM members, this figure is set at 5%. BGE suggests a lower figure such as 2-3%.
Spyker		We suggest SDT to make references to relevant industry standard such as IEEE standards

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 5c Comment
Consumers Energy Company		The criterion related to Transient Voltage Deviations should be removed. This criterion, regardless of value TBD, would be impossible to achieve, and would render this process meaningless. A fault on non-BES elements will cause significant transient voltage dips on nearby BES elements until the fault is cleared. If the non-BES element is at the same voltage level, the dip will result in near-zero voltages; if at different voltage levels, the dip magnitude will be determined by the ratio of the system Thévenin impedance at the BES to the intervening transformer impedance - if the system Thévenin impedance is 2% and the transformer impedance is 18%, the voltage on the BES will dip to 10%.
Central Lincoln		Fault induced transient voltage measurements will always be low if taken at a point electrically close to the fault during the fault. The question should be about voltage recovery following the clearing of the fault as in the TPL standards. The Technical Principles do not make this distinction, and the resulting effect would be the exclusion of elements that should be included and the inclusion of elements that should be excluded.
Duke Energy		See general comment on approach.
Hydro-Quebec TransEnergie		Comments on allowable transient voltage dip measurement: The TPL-001 to 004 do not specify any reference measurement for stability (such as Allowable transient voltage, frequency excursion, voltage deviation, etc.). Instead, it request that the system shall remain stable, without cascading or uncontrolled islanding. Also, it is requested that the Planning Entities shall define and document the criteria or methodology used in the analysis to identify System instability for conditions such as Cascading, voltage instability, or uncontrolled islanding. This is exactly what should be requested in the analysis and demonstration of Element seeking exclusion from BES. The analysis and burden of proof should be left to the Entity as is done in the TPL, considering that there are no common values with the different interconnection.
American Transmission Company, LLC		<p>ATC proposes replacing this factor with those cited above in 5a because there is presently no established, continent-wide, acceptable transient voltage dip performance level for evaluating whether a fault or loss of the element would not compromise the ALR of the BES.</p> <p>In addition, the appropriate performance level for this factor may vary for different areas and system characteristics across the continent.</p>
Independent Electricity System Operator		We do not agree with setting values for this criterion. This should be left to the relevant Transmission Planner and Planning Coordinator. See our comments in response to Q5a.

Northeast Power Coordinating Council		Suggest that for assigning a value for transient frequency response, entities conduct and submit to the SDT their quantitative and qualitative technical assessment based on the conditions of the element(s) under the application. Do not establish a fixed binary value within the exception criteria but rather focus on the performance outcome. See 5 (a) above.
SERC Planning Standards Subcommittee Tennessee Valley Authority Southern Company South Carolina Electric and Gas		As stated above, it does not make sense to use this category.

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 5d Comment
Georgia Transmission Corporation		
Edison Electric Institute		Presently no regional standards exist for allowable transient frequency response beyond WECC. It is also doubtful a useful standard could be developed for all regions or interconnections.
Florida Municipal Power Agency Transmission Access Policy Study Group		The third proposed criterion, “Allowable transient frequency excursion - criteria TBD,” should be rephrased like the second: “Allowable transient frequency excursion on another BES Element for events on the Element that is a candidate of the Exception Request - criteria TBD.”
Tri-State Generation and Transmission Association		If this approach is used, then there needs to be a clear technical rationale for defining the metric and for determining the threshold value.
Hydro One		<p>We suggest that, in terms of assigning a value for transient frequency response, entities conduct and submit to the SDT their quantitative and qualitative technical assessment based on the conditions of the element(s) under the application.</p> <p>We suggest not to establish a fixed binary value within the exception criteria but rather focus on the performance outcome. See 5 (a)</p>
MRO's NERC Standards Review Forum		NSRF proposes replacing this factor with those cited above because there are established, continent-wide transient frequency performance levels in the PRC-006-1 standard, but the elements that are applicable to the standard do not have to be BES elements and the transient frequency response requirements are not intended to be a criterion for BES classification.
ReliabilityFirst		any impact is an impact, planning criteria between 5 & 10 % is often used and restricted to guard against these changes, why inject this into what define the BES. the criteria is applied it should be included
New York Power Authority		<p>Suggest that for assigning a value for transient frequency response, entities conduct and submit to the SDT their quantitative and qualitative technical assessment based on the conditions of the element(s) under the application.</p> <p>Do not establish a fixed binary value within the exception criteria but rather focus on the performance outcome.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 5d Comment
Muscatine Power and Water		Suggest replacing this factor with those cited above. There are recognized, continent-wide transient frequency performance levels in the PRC-006-1 standard; however, the elements that are applicable to this standard are not necessarily BES elements and the transient frequency response requirements are not intended to be a criterion for BES classification.
Blachly Lane Electric Cooperative Flathead Electric Cooperative, Inc Clark Public Utilities Central Electric Cooperative Clearwater Power Electric Cooperative Consumer's Power Inc. Coos-Curry Electric Cooperative Douglas Electric Cooperative Fall River Electric Cooperative Lane Electric Cooperative Lincoln Electric Cooperative Lost River Electric Cooperative Northern Lights Electric Cooperative Okanogan Electric Cooperative Raft River Rural Electric Cooperative Salmon River Electric Cooperative Umatilla Electric Cooperative		Page 15 of Snohomish's White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided on pages 12-16 of the White Paper.

Spyker		The SDT should avoid setting values and instead describe the intended performance outcomes from the measurement
Consumers Energy Company		The criterion relative to frequency response should be removed. Frequency deviations can result from large changes in distribution load.  Distribution facilities should not be prevented from being excluded from BES.
Duke Energy		See general comment on approach.

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 5d Comment
American Transmission Company, LLC		ATC proposes replacing this factor with those cited above in 5a because there are established, continent-wide transient frequency performance levels in the PRC-006-1 standard, but the elements that are applicable to the standard do not have to be BES elements and the transient frequency response requirements are not intended to be a criterion for BES classification.
Independent Electricity System Operator		We do not agree with setting values for this criterion. This should be left to the relevant Transmission Planner and Planning Coordinator. See our comments in response to Q5a.
Tacoma Power		Tacoma Power generally agrees with the allowable transient frequency response in the technical analysis path for exclusions. We suggest adopting an allowable transient frequency response of not below 59.6 Hz for up to 6 cycles on an adjacent system's bus.
MidAmerican Energy		There isn't a nation wide transient frequency response
<p><b>Response:</b> The SDT appreciates the suggestions for alternate language or clarifications to the proposed language and application of the study parameters utilized to analyze system Elements for potential exclusion from the BES.. Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity's characteristics to a defined value and/or limit. It has become apparent that it is impossible to establish values and/or limits that would be valid across all regions and systems. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the draft Rules of Procedure.</p>		

**5e. Comments on voltage deviation measurement:**

**Summary Consideration:** Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the draft Rules of Procedure.

Northeast Power Coordinating Council Hydro One		<p>Voltage deviation is generally expressed as a percentage, between the voltage at a given instant at a point in the system. Do not establish a fixed binary value within the exception criteria but rather focus on the performance outcome.</p> <p>Adequate voltage performance does not guarantee system voltage stability. Steady state stability is the ability of the grid to remain in synchronism during relatively slow or normal load or generation changes, and to damp out oscillations caused by such changes. The requirement should suggest that following checks are carried out to ensure system voltage stability for both the pre-contingency period and the steady state post-contingency period:</p> <ul style="list-style-type: none"> <li>o Properly converged pre- and post-contingency power flows are to be obtained with the critical parameter increased up to 10% with typical generation as applicable;</li> <li>o All of the properly converged cases obtained must represent stable operating points. This is to be determined for each case by carrying out P-V analysis at all critical buses to verify that for each bus the operating point demonstrates acceptable margin on the power transfer; and</li> <li>o The damping factor must be acceptable (the real part of the eigen values of the reduced Jacobian matrix are positive).</li> </ul>
SERC Planning Standards Subcommittee Tennessee Valley Authority Southern Company South Carolina Electric and Gas Georgia Transmission		As stated above, it does not make sense to use this category.

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 5e Comment
Corporation		
Edison Electric Institute		Presently no regional standards exist for allowable voltage deviation beyond WECC. It is also doubtful a useful standard could be developed for all regions or interconnections.
Florida Municipal Power Agency Transmission Access Policy Study Group		The fourth proposed criterion should be revised in the same way as the second and third: “Voltage deviation on another BES Element for events on the Element that is a candidate of the Exception Request - criteria TBD.”The fifth proposed criterion should be similarly revised: “Transient Stability on another BES Element for events on the Element that is a candidate of the Exception Request - positively damped.”
Tri-State Generation and Transmission Association		If this approach is used, then there needs to be a clear technical rationale for defining the metric and for determining the threshold value.
MRO's NERC Standards Review Forum		NSRF proposes replacing this factor with those cited above because there is presently no established, continent-wide, acceptable (steady state) voltage deviation performance level for evaluating whether a fault or loss of the element would not compromise the ALR of the BES.  In addition, the appropriate performance level for this factor may vary for different areas and system characteristics across the continent.
ReliabilityFirst		any impact is an impact, planning criteria is often used and restricted to guard against these changes, why inject this into what define the BES. If the criteria is applied to the facility as a BES element it should be included
New York Power Authority		Voltage deviation is generally expressed as a percentage, between the voltage at a given instant at a point in the system. Do not establish a fixed binary value within the exception criteria but rather focus on the performance outcome.
Muscatine Power and Water		Requesting the STD replace this factor with those cited above. At this time there is no established, continent-wide, acceptable (steady state) voltage deviation performance level for evaluating whether a fault or loss of the element would not compromise the ALR of the BES.  Moreover, the appropriate performance level for this factor may vary for different areas and system characteristics across the continent.
Consolidated Edison Co. of NY,		The NYISO uses a 0.95 to 1.05 p.u. as the acceptable range for post-transient system conditions.

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 5e Comment
Inc.		
ISO New England		Is the requirement to evaluate the voltage dip on the element or is the test to evaluate the voltage dip on the BES due to a contingency on the element? Under the draft TPL standards, this will have to be tested and investigated anyway, so it is unclear as to what is being added or evaluated here.
The United Illuminating Company		Measured where on BES?
BGE		BGE believe the loss of the facility in question should cause only a small voltage deviation to the BES (on the order of 1%).
Spyker		The SDT should avoid setting values and instead describe the intended performance outcomes from the measurement
Northern Wasco County PUD		Page 15 of Snohomish’s White Paper also sets forth recommended thresholds for transient frequency response. For example, we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more. Technical justification for these thresholds is provided at pages 12-16 of the White Paper.
Flathead Electric Cooperative, Inc.		we propose that, if an Element is to be excluded from the BES, removal of that Element should not cause any load bus to drop below 59.6 Hz for 6 cycles or more.
Consumers Energy Company		This criterion may be reasonable, depending on the TBD value. The TBD value may need to vary for different voltage levels or system configurations. The criteria needs to recognize that loss of multiple capacitors at the distribution level could result in significant voltage deviation at the BES and this must not prevent distribution facilities from being excluded from BES.
Duke Energy		See general comment on approach.
American Transmission Company, LLC		<p>ATC proposes replacing this factor with those cited above in 5a because there is presently no established, continent-wide, acceptable (steady state) voltage deviation performance level for evaluating whether a fault or loss of the element would not compromise the ALR of the BES.</p> <p>In addition, the appropriate performance level for this factor may vary for different areas and system characteristics across the continent.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 5e Comment
Independent Electricity System Operator		<p>We do not agree with setting values for this criterion. This should be left to the relevant Transmission Planner and Planning Coordinator. See our comments in response to Q5a.</p> <p>We suggest that the exception criteria could include the following checks to be carried out in the course of the TPL analysis referred to above to ensure system voltage stability for both the pre-contingency period and the steady state post-contingency period:</p> <ul style="list-style-type: none"> <li>o Properly converged pre- and post-contingency power flows are to be obtained with the critical parameter increased up to 10% with typical generation as applicable;</li> <li>o All of the properly converged cases obtained must represent stable operating points. This is to be determined for each case by carrying out P-V analysis at all critical buses to verify that for each bus the operating point demonstrates acceptable margin on the power transfer as shown in the following section; and</li> <li>o The damping factor must be acceptable (the real part of the eigen values of the reduced Jacobian matrix are positive)."</li> </ul>
Tacoma Power		Tacoma Power generally agrees with the voltage deviation measurement in the technical analysis path for exclusions. We suggest adopting a voltage deviation not exceeding 10% on an adjacent system's bus.
MidAmerican Energy		Determining a nation wide voltage deviation would be difficult.
<p><b>Response:</b> The SDT appreciates the suggestions for alternate language or clarifications to the proposed language and application of the study parameters utilized to analyze system Elements for potential exclusion from the BES. Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity's characteristics to a defined value and/or limit. Flathead Electric Cooperative, Inc. for Snohomish County PUD	No	supports the exemption of generation interconnected to local distribution networks if the generation is less than 300 MW capacity and where the power generated is consumed within the LDN and rarely flows out of the LDN consistent with the section III.c.4 [Exclusion] of the NERC Statement of Compliance Registry Criteria as well as the Load modifiers used in the Eastern Interconnection. "Load Modifiers" (small generators that only affect load at the distribution level)."
<b>Response:</b> The SDT has responded to comments on the BES definition in the Consideration of Comments form for the BES definition posting.		

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 6 Comment
The United Illuminating Company	No	Procees is complicated and fraught with interpretations.
Bonneville Power Administration	No	<p>BPA emphasizes that exclusion criteria and analysis should be based on normal operations. An exclusion should not be unavailable based on temporary system configuration such as load service by a different transmission segment temporarily used to mitigate system operations due to planned maintenance outages, i.e. a system that is operated radially over 90% of the time and closed for maintenance outages for safety and/or reliability purposes, etc.</p> <p>BPA recommends that the SDT consider not only the single-phase faults, also the effect of more severe events such as two- or three-phase faults, with delayed clearing and evaluate the necessity of the element in those cases.</p>
ISO/RTO Standards Review Committee		Very small elements may be candidates for exclusion because such a small loss cannot cause reliability risk. An exception to this statement may be that, though small, the element is important to the service of a critical load.
SERC Planning Standards Subcommittee Tennessee Valley Authority South Carolina Electric and Gas Georgia Transmission Corporation Entergy Services	Yes	<p>Revise second paragraph to read “Due to the importance of designated Blackstart Resources and their Cranking Paths to restore efforts, no exceptions will be allowed for those items that are included in a system restoration plan.”Technical rationale: Multiple Blackstart Resources and Cranking Paths are frequently available but are not included in a system restoration plan. System restoration plans describe the Blackstart resources and cranking paths thar are deemed to be necessary for system restoration.</p> <p>Section “Exception Criteria - Exclusions”:Add 1.e. “Generation that is inoperable and not planned to be placed back into service but not yet officially decommissioned.”Technical rationale: These facilities are not relied on to insure the reliability of the BES.</p>
Florida Municipal Power Agency Transmission Access Policy Study Group	Yes	<p>TAPS proposes a simpler set of exclusion exception criteria:1. Having a distribution factor of 5% for curtailable Interchange Transactions or BES generator - load identified in Transmission Loading Relief stages one through five, and</p> <p>2. Category B and C contingencies on the Element that is the subject of the Exception Request meet the TPL-002 criteria for other BES Elements. (With the new TPL-001-3 standard recently approved by ballot, Category P0 through P7 contingencies on the Element that is subject of the Exception Request meets the criteria of P0 through P3 for other BES Elements)</p> <p>3. The Element that is the subject of the Exception Request is not: (1) part of an IROL, (ii) part of a blackstart or cranking path used in a TOP’s restoration plan, and (iii) is not used in NUC-001 to provide service to a</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 6 Comment
		nuclear plant.TAPS believes these three criteria meet the intent of all of the criteria presented by the SDT.
Hydro One	Yes	<p>Technical Analysis must fundamentally use NERC - TPL methodology and testing requirements.</p> <p>We believe that an element may “not be necessary for the operation of the interconnected transmission system” if the remaining system can be operated without the element(s) for over 30 days and during peak load conditions. This assumption considers that loss of element(s) may result in outage to the connected load or generation during this period but will not have any adverse impact on the operation of the interconnected transmission network.</p> <p>Following are technical assessment categories that entities could be required when filing for exception:</p> <ul style="list-style-type: none"> <li>1.Power flow <ul style="list-style-type: none"> <li>oPrimarily unidirectional (less than 20% of min load)</li> </ul> </li> <li>2.TPL Assessment <ul style="list-style-type: none"> <li>oLoad Flows Analysis</li> <li>oThermal and Voltage Stability</li> <li>oTransient Stability</li> </ul> </li> <li>3.TDF and OTDF assessment</li> </ul> <p>For entities filing an exception:[Step 1]Entities should undertake relevant and detailed technical assessment/analysis and describe their findings under each of the technical categories. Finally, the findings and conclusions should be listed in the form of maximum 6 bullets.</p> <p>[Step 2]Findings and conclusions from each of the technical categories should be presented in a spreadsheet including the categories that may not be relevant to the element(s). If a category is not relevant, it should be explained why.</p> <p>[Step 3]The final conclusion should be presented by taking the overall assessment in Step 2 by assessing contributions of each item and demonstrating that the element(s) is or is not necessary for the operation of interconnected transmission network.</p> <p>We suggest the above method and request entities to complete the table below, as this will allow entities to present their assessment of the element(s) that are under the consideration of exception.</p> <p>Measured Value===== Load    Critical Load Affected? [yes][No]----- -----</p> <ul style="list-style-type: none"> <li>oRadial oLocal supply, e.g. distribution in nature</li> <li>oLarge load center, critical load, national security Generation Characteristics    Critical Load Affected? [yes][No]-----</li> <li>oLocal load modifier, peak shaver oBehind meter or industrial load displacement</li> <li>oMust Run</li> </ul>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 6 Comment
		<p>oFlow contribution outside of the elements under exception</p> <p>Cascading Outage    Critical Load Affected? [yes][No]-----</p> <p>Measured Value =====Max Dip [Voltage] Applicable Industry Practice (IEEE/CSA,Market Rules,etc.)Acceptable Level [in cycles]</p> <p>Assessment Results [in cycles]Does the assessment confirm successful recovery? [Yes] [No]</p> <p>Transient Voltage Dip [voltage]</p> <p>Transient Frequency Excursion [Hertz]Voltage deviation [Voltage]</p> <p>Transient Stability Steady State Stability</p>
MRO's NERC Standards Review Forum	Yes	<p>A. NSRF recommends this process address the six characteristics of the Definition of Adequate Level of Reliability (ALR) as listed in the comments above in Question #5.</p> <p>B. Recommend municipalities and other small entities having transmission systems designed to serve local load, operated below 200 kV and not having any IROL's or SOL's be excluded from the BES definition. Rational: The standards, especially those for Transmission Operators (TO) aren't written for the smaller utilities. A utility may have over 75 MWs of generation and have installed a 115 kV loop around their city that is used primarily to serve load and get forced into significant compliance requirements that don't enhance the reliability of the BES.</p>
PacifiCorp	Yes	All of PacifiCorp's responses are based on a given interconnection and not on a continental basis. Fault duty may be appropriate for certain interconnections only.
Western Electricity Coordinating Council	Yes	WECC recommends that the SDT consider not only the single-phase faults used in the TPL standards, but also the effect of more severe events such as two- or three-phase faults, with delayed clearing and the necessity of the element in those cases.
Electricity Consumers Resource Council (ELCON)	Yes	We recommend an additional method (or alternatively this be added to the BES Definition Exception E1): System Elements are part of facilities, generally radial in nature, supplying a retail customers from the point of delivery to the load regardless of voltage. Evidence to support this position could be an interconnection agreement indicating the point of delivery, a one-line diagram showing the point of delivery and load etc. The technical rationale is that protection of the BES for facilities serving load is the responsibility of the service

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 6 Comment
		provider (e.g., TO/TOP). These facilities are distribution facilities and are not now part of the BPS.
National Grid	Yes	<p>The NERC process could potentially be very lengthy and could interfere with the timely completion of our studies. In the technical paths for exclusions, bullet v states “If within the criteria in all cases, then the Elements can be excluded.” This could lead to a very high number of studies that need to be done to prove an element should be excluded. For this reason, National Grid endorses a more streamlined process. We propose a process where entities would only need to submit a short form that briefly describes what they would like to exempt and the reason why, along with a one-line diagram. The entity who is requesting the exception would have to maintain records that show why the elements can be exempted until NERC performs an audit. At the audit, the entity can show the proof of why the element should be granted an exception. This process also allows for the application to remain public and reduces documentation burdens, because the non-public, CEIL, or NERC CIP protected supporting documentation is maintained by the applicant. In this process, the entity first submits the application to their RE, and if approved by the RE, the application is submitted to NERC. The entity should be able to appeal if either the RE or NERC denies the application; however, it should be clear that for the second appeal to NERC, the decision is made by a different group than whoever decided on the first appeal. The appeal process in this exception procedure could be similar to the appeal process set by CMEP (compliance, monitoring and enforcement program). For entities that don’t wish to wait until the next audit, there can be an optional process by which the proposed exception can be reviewed to provide an immediate ruling. Also, there should be a grace period after the audit is performed if audit staff concludes that an exception or inclusion granted by the initial application is not supported by adequate evidence. NERC’s approval of an exception during this initial application process should stand until an Entity is audited and a final audit report is issued. There should also be an implementation period included in the audit report for the entity to come into compliance if the audit report disagrees with the initial exception approval. Absent evidence of fraud or intentional misrepresentation by the entity, there should be no non-compliance assessed for the period from initial exception approval to the final audit report. This process would need to allow participation or comments by Regional Entities, Reliability Coordinators, and/or Balancing Authorities in the application process, but should not allow participation by other third parties.</p>
Muscatine Power and Water	Yes	<p>Recommending that this process address the six characteristics of the Definition of Adequate Level of Reliability (ALR) as listed in the comments above in Question #5.</p> <p>Also recommend that municipalities and other small entities having transmission systems designed to serve local load only, operated below 200 kV and not having any IROL’s or SOL’s be excluded from the BES definition. Rationale: this could affect smaller registered entities within a BA. The standards, especially those for Transmission Operators, aren’t written for the smaller utilities. A small, municipal utility could have 75 MW of generation and operate a 115 kV looped system around their service area that is used primarily to serve their own load. Subsequently, they get forced into significant compliance requirements that does not enhance</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 6 Comment
		the reliability of the BES whatsoever.
Glacier Electric Cooperative	Yes	Perhaps using an element's available fault MVA as a "quick screening" method to quickly determine if an element should be included or excluded. If an element's available fault MVA exceeds a properly established value, then a more detailed technical analysis can be done to determine whether or not the element truly should be included in the BES. But if the element's available fault MVA is less than the established value, then that element could quickly be excluded.
Orange and Rockland Utilities, Inc.	Yes	FERC Order No. 888 - Seven Factor Test.
Xcel Energy	Yes	Xcel Energy would like the SDT to consider a Capacity Factor exclusion for generating resources that are rarely used. For example, at least two standards that are currently being drafted exempt generators that have an average Capacity Factor of 5% or less over a three year period.
American Transmission Company, LLC	Yes	ATC recommends this process address the five characteristics of the Definition of Adequate Level of Reliability (ALR) as listed in the comments above in Question #5a.
NESCOE	Yes	Please refer to comments under item 4., above. If the parallel power flow in a given < 200 kV path only exceed 200 MVA under contingency conditions and if the applicable BES points have fully NERC compliant protection systems, disturbances on this lower voltage path will not adversely affect the reliability of the BES. The exclusion determination process should be flexible enough to recognize that any requirement that may impose substantial new costs on New England transmission owners, and ultimately on consumers, should also provide meaningful reliability benefits
<p><b>Response:</b> The SDT appreciates the suggestions for alternate language or clarifications to the proposed language for the technical exception criterion. Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity's characteristics to a defined value and/or limit. It has become apparent that it is not feasible to establish continent-wide values and/or limits due to differences in operational characteristics. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the Rules of Procedure as presently being drafted.</p>		
Northeast Power Coordinating	Yes	An impact-based method should be available for entities seeking Exclusions and Inclusions. The method

Council		<p>should not allow excess regional discretion and unintended continent-wide variation. Recommend the power Transfer Distribution Factor (power TDF) approach mentioned in the reply to Question 5 above. If the Transmission Planner (TP) or Planning Authority (PA), were tasked with performing such analyses using standardized assumptions, then regional discretion could be minimized.</p> <p>Technical Analysis must fundamentally use NERC - TPL methodology and testing requirements.</p>
Consolidated Edison Co. of NY, Inc.	Yes	<p>An impact-based method should be available for entities seeking Exclusions and Inclusions. The method should not allow excess regional discretion and unintended continent-wide variation. We recommend the power Transfer Distribution Factor (power TDF) approach mentioned in the reply to Question 6 above.</p> <p>If the Transmission Planner (TP) or Planning Authority (PA), e.g., the NYISO, were tasked with performing such analyses, using standardized assumptions, then regional discretion could be minimized.</p>
Spyker	Yes	<p>Technical Analysis must fundamentally use NERC - TPL methodology and testing requirements.</p>
Hydro-Quebec TransEnergie	Yes	<p>Technical demonstration should not be limited to technical principles stated in the "Technical Principles for Demonstrating BES Exceptions". Entities should be allowed to do their own demonstration with their own technical arguments. As an example, an Entity could consider a few level of application for the standards. As an example, the level #1 being the most important level, all standards would apply to this level, including more stringent criteria than the TPL standards. This would bring BES level #1 very robust and reliable, ensuring the reliability of the main system. A second BES level #2 could be define for local transmission to which would be applied most standards but excluding some of the C section of TPL. Attention would be given to proper reliable operation of the BES level #2, but with smaller level of investment on the design aspect, those regional transmission part of the system being able to face higher risk for loss of continuity of service. Finally, for generation or Load Facility that would be excluded from both level of BES, minimum standards would still apply such as in protection or for generation. Through its own technical principles, the Entity could demonstrate that the highest level of BES is more reliable than what is expected by NERC's standard, but that in regional transmission part of the system, the C TPL standard would not apply with the only risk of lower continuity of service.</p>
<p><b>Response:</b> The SDT appreciates your comments. Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity's characteristics to a defined value and/or limit. It has become apparent that it is not feasible to establish continent-wide values and/or limits due to differences in operational characteristics. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the</p>

<p><b>Response:</b> See response to 5a.</p>		
Occidental Energy Ventures Corp.	Yes	<p>Suggested additional method. The Element(s) meet all the following characteristics: 1) generally radial in nature, and</p> <p>2) used to supply a retail customer from the point of delivery to the load regardless of voltage.</p> <p>Evidence to support this position could be an interconnection agreement indicating the point of delivery, a one-line diagram showing the point of delivery and load, etc. The technical rationale is that protection of the BES for facilities serving a retail customer is the responsibility of the service provider (e.g., transmission owner/operator). These facilities are distribution facilities and are not now part of the BPS. Alternatively, this could be an Exclusion in the BES Definition as it is in the current definition.</p>
MidAmerican Energy	Yes	<p>In general all facilities below 100 kV should be excluded by default as distribution according to the 2005 Federal Power Act. Transmission Distribution Factors tend to show low bulk power system transfers (less than 2%) based on their inherent high impedance when normalized. Normalizing the transmission impedance means dividing the ohmic value by a base impedance which is dominated by a (kV<sup>2</sup>) term. Per Unit Impedance = (transmission line ohms / base impedance) where base impedance = (kV<sup>2</sup> / MVA). Using a common MVA base value of 100 MVA, a base impedance at 69kV = 47.6 ohms versus at 161 kV = 259.2 or at 345 kV = 1190.2 ohms. The rapid increase of the denominator as kV goes higher insures that a 69 kV</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 6 Comment
		<p>system is high impedance compared to any high kV facilities and therefore nearly insure the 69 kV system is local in nature and reacts primarily to load. Therefore it is distribution. This all supports the conclusion that all facilities below 100 kV should be classified as distribution according to the 2005 FPA and exempted by default. Facilities below 100 kV could be brought into scope if TPL analyses show instability, uncontrolled separation, or cascading as defined in the 2005 FPA.</p>
<p><b>Response:</b> The SDT appreciates your comments. Your specific concerns will be accommodated under the revised process.</p> <p>Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity's characteristics to a defined value and/or limit. 		inclusion, and then file the request and recommendation with the ERO as established in the draft Rules of Procedure.

7a. Comments on approach:

**Summary Consideration:** Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the draft Rules of Procedure.

Organization	Yes or No	Question 7a Comment
Northeast Power Coordinating Council		Inclusions criteria should mirror the Exclusion criteria, and that consistent values should be employed for Inclusions here and for Exclusions above. That is, for example, if 0.95 to 1.05 (+/- 5%) p.u. is adopted as an acceptable voltage deviation range for Exclusions, then Elements resulting in post-transient system voltage deviations outside that range should be candidates for Inclusion. Further, all assumptions should also be fully documented for any proposed Inclusions. Also refer to comments on exclusions.
SERC Planning Standards Subcommittee Tennessee Valley Authority Southern Company South Carolina Electric and Gas Georgia Transmission Corporation		The PSS recommends that applications for inclusion of facilities into the BES should include justification for doing so. However, there should not necessarily be specific criteria that must be met, but the importance of the facility to the BES should be clearly demonstrated.
NERC Staff Technical Review		NERC staff is not opposed to development of evidence based on technical analysis; however, we have the same concerns with the exception criterion for including Element(s) as with exception criterion 1 for excluding Element(s). The type of analysis included in this exception criterion requires extensive resources and lacks sufficient detail to allow for consistent and repeatable application.  Additional concerns with this approach include (1) the ability to provide sufficient guidance on the system

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 7a Comment
		<p>conditions and contingencies necessary to support an exception request,</p> <p>(2) difficulty with identifying thresholds for items iv-1 through iv-4, and</p> <p>(3) the ability to address interdependencies among exception requests.</p>
Independent Electricity System Operator		<p>We support the concept of technical analysis in support of Inclusions but disagree with the approach that involves setting specific values for criteria. Please refer to our comments on exclusions.</p>
Florida Municipal Power Agency		<p>FMPA supports using a uniform set of technical criteria to decide inclusion exceptions. Such an approach will facilitate uniform application of the criteria. In addition to having clear and uniform criteria, the technical analysis for inclusions and exclusions should use the same criteria (though one should of course be the inverse of the other). We note that the steps laid out for Inclusions do not quite track those in Exclusions 2(a). For example, Inclusions 1(b) states, confusingly, “Monitor the contribution of the disputed Element(s),” but there is no corresponding step in Exclusions 2(a). FMPA suggests that Inclusions 1 be revised to mirror Exclusions 2.</p>
Transmission Access Policy Study Group		<p>TAPS supports using a uniform set of technical criteria to decide inclusion exceptions. Such an approach will facilitate uniform application of the criteria. It is appropriate for there to be only one path, using technical analysis, for inclusions, because the analysis for inclusions should be performed by Regional Entities and NERC (see TAPS comments on the BES Exception Process, also submitted today), which have more resources available than do the small entities that TAPS believes are likely to request exclusions based on the path for exclusions that does not include extensive technical analysis. In addition to having clear and uniform criteria, the technical analysis for inclusions and exclusions should use the same criteria (though one should of course be the inverse of the other). We note that the steps laid out for Inclusions do not quite track those in Exclusions 2(a). For example, Inclusions 1(b) states, confusingly, “Monitor the contribution of the disputed Element(s),” but there is no corresponding step in Exclusions 2(a). TAPS suggests that Inclusions 1 be revised to mirror Exclusions 2.</p>
ISO/RTO Standards Review Committee		<p>The SRC generally agrees with the technical analysis approach to determining whether an element should be included in the BES. However, consideration should also be given to valid and supported evidence given by RCs and PCs, and, possibly TOPs and BAs to actual historical events that indicate significant importance of elements which, when lost, have resulted in reliability risk to the system.</p>
Iberdrola USA		<p>A facility is BES if it is necessary for reliable system operation, based on a TPL-type analysis similar to NPCC Document A-10 “Classification of Bulk Power System Elements” - this type of analysis was rejected by FERC. In addition, applicable threshold values for these parameters could differ from one system to another, and</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 7a Comment
		would require extensive analysis.
Tri-State Generation and Transmission Association		<p>This appears very similar to the “material impact” proposal that FERC has previously disallowed, so we recommend removing it, but allowing elements that are included in Regional Entity defined bulk transfer paths that are not already included in the BES definition.</p> <p>If retained, remove 1.(f) because allowing the ERO to override the technical justification and analysis devalues such analysis to the point of it being meaningless.</p>
Hydro One		Inclusions criteria should mirror the Exclusion criteria, and that consistent values should be employed for Inclusions here and for Exclusions above. [See our comments on exclusions]
MRO's NERC Standards Review Forum		<p>NSRF proposes that the technical analysis criterion be replaced by criteria that are more closely tied to the Adequate Level of Reliability (ALR) characteristics.</p> <p>The following alternate criteria are offered as possible examples, “(1) the BES cannot be controlled to stay within acceptable limits following a fault on or loss of the Element;</p> <p>(2) the BES does not perform acceptably after credible contingences of the Element;</p> <p>(3) the Element limits the impact and scope of instability and cascading outages when they occur;</p> <p>(4) BES facilities are not protected from unacceptable damage by operating the Element within its ratings;</p> <p>(5) the integrity of the BES cannot be restored promptly following a fault on or loss of the Element; and</p> <p>(6) the BES does not have the ability to supply the aggregate electric power and energy requirements of the electricity consumers at all times, taking into account scheduled or reasonably expected unscheduled outages of the Element.</p> <p>In addition, NSRF is not aware of any continent-wide appropriate BES performance measures for voltage dip, frequency excursion, voltage deviation, stability, etc. and NSRF speculates that different values are likely for different regions and system characteristics across the continent. As a result, NSRF believes it is not advisable to try to adopt unproven values without reasonable industry investigation and development.</p>
ReliabilityFirst		to complicated and will only raise debate between FERC, NERC, the Regions and the Registered Entities
New York Power Authority		In general, NYPA agrees with this approach except as noted below. Inclusions criteria should mirror the Exclusion criteria, and that consistent values should be employed for Inclusions here and for Exclusions

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 7a Comment
		above.
National Grid		There should be a non-technical process for inclusions similar to the exclusions process.
Muscatine Power and Water		<p>Would like to propose that the technical analysis criterion be replaced by criteria that are more closely tied to the Adequate Level of Reliability (ALR) characteristics. The following alternate criteria are offered as possible examples, “(1) the BES cannot be controlled to stay within acceptable limits following a fault on or loss of the Element;</p> <p>(2) the BES does not perform acceptably after credible contingences of the Element;</p> <p>(3) the Element limits the impact and scope of instability and cascading outages when they occur;</p> <p>(4) BES facilities are not protected from unacceptable damage by operating the Element within its ratings;</p> <p>(5) the integrity of the BES cannot be restored promptly following a fault on or loss of the Element; and</p> <p>(6) the BES does not have the ability to supply the aggregate electric power and energy requirements of the electricity consumers at all times, taking into account scheduled or reasonably expected unscheduled outages of the Element. Currently not aware of any continent-wide appropriate BES performance measures for voltage dip, frequency excursion, voltage deviation, stability, etc. and would speculate that different values are likely for different regions and system characteristics across the continent.</p> <p>Therefore, would like to state that it is not advisable to try to adopt unproven values without reasonable industry investigation and development.</p>
Blachly Lane Electric Cooperative Central Electric Cooperative Clearwater Power Electric Cooperative Consumer's Power Inc Coos-Curry Electric Cooperative Douglas Electric Cooperative Fall River Electric Cooperative Lane Electric Cooperative		<p>As a general matter, we agree with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid justification showing that the Elements in question contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. We also agree that the SDT has, in general, identified the correct technical approach, although we recommend that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in Snohomish’s White Paper, in the WECC BES Task Force Proposal 6, and in our answer to Question 5.</p> <p>While we support the SDT’s overall approach, we believe subsection (f) of the proposed inclusion criteria, which would allow NERC to “override this criterion” if it provides “additional justification” for doing so is both unnecessary and creates confusion and uncertainty in what is otherwise a clear and concise process. Subsection (f) is unnecessary because if the technical process laid out in subsections (a) through (e) fails to provide any evidence that the contested Element(s) create a material impact on the reliability of the bulk</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 7a Comment
Lincoln Electric Cooperative Lost River Electric Cooperative Northern Lights Electric Cooperative Okanogan Electric Cooperative Raft River Rural Electric Cooperative Salmon River Electric Cooperative Umatilla Electric Cooperative West Oregon Electric Cooperative Pacific Northwest Generating Cooperative Consumer's Power Inc. Central Lincoln for Snohomish County PUD		interconnected transmission network, there is no reason to classify those Element(s) as BES, and that should be the end of the question. Subsection (f) creates needless uncertainty because it allows NERC to override the technical criteria laid out in subsections (a) through (e) if "additional justification" is provided, but there is no suggestion as to what this additional justification might be. Nor is there any explanation as to why additional justification might be necessary after the criteria in subsections (a) through (e) have been exhausted.
Glacier Electric Cooperative		I do strongly agree that there should be an avenue for elements to be included or excluded from the BES based on technical analysis.  I do believe who's responsibility it will be to perform and analyze the transmission planning studies needs to be clarified.
Exelon		: Exelon points out that most of the Regions don't have Region-wide criteria for distribution factor measurement, voltage excursions, or transient frequency response for use in this proposed Inclusion Process.  In addition, most of the Regions do not have region-wide criteria developed for these attributes. If differing criteria levels are used across the continent, there remains the possibility that similarly-situated facilities in different Regions will not be treated consistently.

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 7a Comment
Consolidated Edison Co. of NY, Inc.		<p>We believe that Inclusions criteria should mirror the Exclusion criteria, and that consistent values should be employed for Inclusions here and for Exclusions above. That is, for example, if 0.95 to 1.05 (+/- 5%) p.u. is adopted as an acceptable voltage deviation range for Exclusions, then Elements resulting in post-transient system voltage deviations outside that range should be candidates for Inclusion.</p> <p>Further, all assumptions should also be fully documented for any proposed Inclusions.</p>
Springfield Utility Board		<p>NERC’s Exception Criteria for Inclusions states that, “Entities can submit an application to see an exception for an inclusion in the BES...”, but SUB would ask NERC to clarify whether an entity can 1) seek an inclusion exception for them only, or</p> <p>2) can an entity seek an inclusion exception for another entity? SUB would not support another entity having the ability to file for another entity.</p>
Flathead Electric Cooperative, Inc.		<p>Elements otherwise excluded from the BES should be included only upon a technically valid showing that the Elements contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system.</p>
Entergy Services		<p>It is unclear why an inclusion process should be necessary. Including facilities not otherwise included in the basic definition should be at the discretion of the TO.</p>
Clark Public Utilities Benton Rural Electric Association Northern Wasco County PUD United Electric Co-op Inc Oregon Trail Electric Cooperative, Inc Salem Electric Grant County PUD No. 2 (Grant) Northwest Public Power Association (NWPPA) Big Bend Electric Cooperative,		<p>As a general matter, Clark agrees with the SDT that Elements otherwise excluded from the BES should be included only upon a technically valid showing that the Elements contribute substantially to the potential for cascading outages, separation events, or instability on the interconnection bulk transmission system. Clark also agrees that the SDT has, in general, identified the correct technical approach, although Clark recommends that the inclusion analysis (which mirrors the technical exclusion analysis) be modified as discussed in the Snohomish PUD White Paper, in the WECC BES Task Force Proposal 6, and in Clark’s answer to Question 5.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 7a Comment
Inc Kootenai Electric Cooperative		
BGE		BGE believes that there is a value in allowing for inclusions through a technical analysis path; however, it is critical that such a path does not allow for unreasonable inclusion of facilities that do not warrant BES status.
Spyker		We agree that entities should be allowed to conduct an analysis to demonstrate if an element is necessary or not for the operation of transmission network. We also support that NERC should specify all the relevant criteria category to be listed as under 2 (a). However, we suggest that NERC should avoid prescribing numerical values but establish a range of value (or reference industry standard) that would be consistent with industry/ regional standards or practices without compromising the reliability of transmission network.
Consumers Energy Company		We believe all of the Inclusion criteria should be replaced by a single criterion, which would include any element that could cause cascading outages of greater than 1,000 MW.
Oncor Electric Delivery		Oncor Electric Delivery agrees with the proposed language that describes the inclusion criteria based technical analysis.
Tacoma Power		Tacoma Power generally agrees with approach used on the technical analysis path for inclusions.
Duke Energy		The approach and evaluation values should be consistent with those for the Exclusions.
American Transmission Company, LLC		<p>ATC proposes that the technical analysis criterion be replaced by criteria that are more closely tied to the Adequate Level of Reliability (ALR) characteristics. The following alternate criteria are offered as possible examples, “(1) the BES cannot be controlled to stay within acceptable limits following a fault on or loss of the Element;</p> <p>(2) the BES does not perform acceptably after credible contingences of the Element;</p> <p>(3) the Element limits the impact and scope of instability and cascading outages when they occur;</p> <p>(4) BES facilities are not protected from unacceptable damage by operating the Element within its ratings; and</p> <p>(5) the BES does not have the ability to supply the aggregate electric power and energy requirements of the electricity consumers at all times, taking into account scheduled or reasonably expected unscheduled outages of the Element.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 7a Comment
		In addition, ATC is not aware of any continent-wide appropriate BES performance measures for voltage dip, frequency excursion, voltage deviation, stability, etc. and ATC speculates that different values are likely for different regions and system characteristics across the continent. As a result, ATC believes it is not advisable to try to adopt unproven values without reasonable industry investigation and development.
Manitoba Hydro		Manitoba Hydro does not agree with an impact based approach to establishing BES elements as we believe it will result in regional differences in the application of the BES definition. In addition, the resources required to verify the assumptions made in the models used to substantiate a BES exception would be substantial with no benefit to reliability.
<p><b>Response:</b> The SDT appreciates the suggestions for alternate language or clarifications to the proposed language and application of the study parameters utilized to analyze system Elements for potential inclusion in the BES. Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity's characteristics to a defined value and/or limit. It has become apparent that it is impossible to establish values and/or limits that would be valid across all regions and systems. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the draft Rules of Procedure.</p>

Independent Electricity System Operator		[See Comment 7a]
<b>Response:</b> See response to Q7a.		
Tri-State Generation and Transmission Association		If this approach is used, then there needs to be a clear technical rationale for defining the metric and for determining the threshold value.
MRO's NERC Standards Review Forum		NSRF proposes replacing this factor with those cited above because a distribution factor measurement indicates how much system changes affect the element, not how a fault or loss of the element would compromise the ALR of the BES. There is no clear correlation between this factor and any of the six characteristics of Adequate Level of Reliability (ALR) of the BES.
ReliabilityFirst		any impact is an impact, even generation is re-dispatched at 0% in some cases
New York Power Authority		NYPA does not agree with this measurement. Distribution factors are dependent on the number of radial transmission lines that connect a single source to a load. For example, if two lines connect a single source to a load, and one line trips, the distribution factor provides a 100% increase in flow on the remaining line. If three lines connect the source to the load, and one line trips, the distribution factor for the remaining lines would be 50%.
Muscatine Power and Water		Proposing to replace this factor with those cited above because a distribution factor measurement indicates how much system changes affect the element, not how a fault or loss of the element would compromise the ALR of the BES. There is no clear correlation between this factor and any of the six characteristics of Adequate Level of Reliability (ALR) of the BES.
Consumers Energy Company		If our suggestion in 7a is not adopted, we propose the following: If based on transfer distribution factor this criterion may have some merit, depending on the TBD value. However, the criterion should not be based on

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 7b Comment
		outage transfer distribution factor, as Draft 1 implies since loss of certain distribution facilities can result in distribution load being transferred to other interconnection points. Distribution facilities should not be classified as BES.
American Transmission Company, LLC		ATC proposes replacing this factor with those cited above in 7a because a distribution factor measurement indicates how much system changes affect the element, not how a fault or loss of the element would compromise the ALR of the BES. There is no clear correlation between this factor and any of the six characteristics of Adequate Level of Reliability (ALR) of the BES.
Tacoma Power		<p>Tacoma Power generally agrees with the distribution factor measurement in the technical analysis path for inclusions.</p> <p>We suggest adopting a distribution factor of 30%, or more, on an adjacent system.</p>

**Response:** The SDT appreciates the suggestions for alternate language or clarifications to the proposed language and application of the study parameters utilized to analyze system Elements for potential inclusion in the BES. Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity's characteristics to a defined value and/or limit. It has become apparent that it is impossible to establish values and/or limits that would be valid across all regions and systems. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the draft Rules of Procedure.

**7c. Comments on allowable transient voltage dip measurement:**

**Summary Consideration:** Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. Organization	Yes or No	Question 7c Comment
MRO's NERC Standards Review Forum		NSRF proposes replacing this factor with those cited above because there is presently no established, continent-wide, acceptable transient voltage dip performance level for evaluating whether a fault or loss of the element would compromise the ALR of the BES. In addition, the appropriate performance level for this factor may vary for different areas and system characteristics across the continent.
<p><b>Response:</b> The SDT appreciates the suggestions for alternate language or clarifications to the proposed language and application of the study parameters utilized to analyze system Elements for potential inclusion in the BES. Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity's characteristics to a defined value and/or limit. It has become apparent that it is impossible to establish values and/or limits that would be valid across all regions and systems. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. ReliabilityFirst		any impact is an impact, planning criteria between 3 & 5 % is often used and not allowed, why inject this into what define the BES. the criteria is applied it should be included
Muscatine Power and Water		Propose replacing this factor with those cited above because there is presently no established, continent-wide, acceptable transient voltage dip performance level for evaluating whether a fault or loss of the element would compromise the ALR of the BES. In addition, the appropriate performance level for this factor may vary for different areas and system characteristics across the continent.
Consumers Energy Company		If our suggestion in 7a is not adopted, we propose the following: The criterion related to Transient Voltage Deviations should be removed from the Inclusion Process. This criterion, regardless of value TBD, would cause any element, perhaps even including radial Primary Distribution Facilities (8.2 kV, etc.) to be sequentially included as BES. A fault on non-BES elements will cause significant transient voltage dips on nearby BES elements until the fault is cleared. If the non-BES element is at the same voltage level, the dip will result in near-zero voltages; if at different voltage levels, the dip magnitude will be determined by the ratio of the system Thevenin impedance at the BES to the intervening transformer impedance - if the system Thevenin impedance is 2% and the transformer impedance is 18%, the voltage on the BES will dip to 10%.
American Transmission Company, LLC		ATC proposes replacing this factor with those cited above in 7a because there is presently no established, continent-wide, acceptable transient voltage dip performance level for evaluating whether a fault or loss of the element would compromise the ALR of the BES. In addition, the appropriate performance level for this factor

Operator		
<b>Response:</b> See response to Q7a.		
Tri-State Generation and Transmission Association		If this approach is used, then there needs to be a clear technical rationale for defining the metric and for determining the threshold value.
MRO's NERC Standards Review Forum		NSRF proposes replacing this factor with those cited above because there is presently no established, continent-wide, acceptable (steady state) voltage deviation performance level for evaluating whether a fault or loss of the element would compromise the ALR of the BES. In addition, the appropriate performance level for this factor may vary for different areas and system characteristics across the continent
ReliabilityFirst		any impact is an impact, planning criteria is often used and restricted to guard against these changes, why inject this into what define the BES. the criteria is applied to the facility as a BES element it should be included
Muscatine Power and Water		Propose replacing this factor with those cited above because there is presently no established, continent-wide, acceptable (steady state) voltage deviation performance level for evaluating whether a fault or loss of the element would compromise the ALR of the BES.  In addition, the appropriate performance level for this factor may vary for different areas and system characteristics across the continent.
Consumers Energy Company		If our suggestion in 7a is not adopted, we propose the following: This criterion may be reasonable, depending on the TBD value. The TBD value may need to vary for different voltage levels or system configurations. Loss of multiple capacitors at the distribution level could result in significant voltage deviation at the BES and the criterion should be developed so as not to result in Distribution facilities being classified as BES.
for Snohomish County PUD		Please see our response to Question 5d.
<b>Response:</b> See response to Q5d.		
American Transmission Company, LLC		ATC proposes replacing this factor with those cited above in 7a because there is presently no established, continent-wide, acceptable (steady state) voltage deviation performance level for evaluating whether a fault or loss of the element would compromise the ALR of the BES.

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 7e Comment
		In addition, the appropriate performance level for this factor may vary for different areas and system characteristics across the continent
Tacoma Power		<p>Tacoma Power generally agrees with the voltage deviation measurement in the technical analysis path for inclusions. We suggest adopting a voltage deviation that exceeds 10% on an adjacent system's bus.</p> <p>We have an additional concern with how the language is constructed on items d. and e. The inclusion criteria may work for simply inverting the exclusion language but in this initial draft, it does not appear to work as intended. Our suggestions above are describing criteria for defining elements that can be included in the BES. If that is the result to be adopted by the SDT, items d. and e. must be rewritten to state that elements within such criteria can be included in the BES.</p>
<p><b>Response:</b> The SDT appreciates the suggestions for alternate language or clarifications to the proposed language and application of the study parameters utilized to analyze system Elements for potential inclusion in the BES. Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity's characteristics to a defined value and/or limit. It has become apparent that it is impossible to establish values and/or limits that would be valid across all regions and systems. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the draft Rules of Procedure.</p>		

**8. Do you have concerns about an entity’s ability to obtain the data they would need to do the indicated technical analyses? If so, please be specific with your concerns so that the SDT can fully understand the problem and address it in future drafts.**

**Summary Consideration:** Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity’s characteristics to a defined value and/or limit. It has become apparent that it is not feasible to establish continent-wide values and/or limits due to differences in operational characteristics. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the Rules of Procedure as presently being drafted.

Duke Energy	No	
Hydro-Quebec TransEnergie	No	
American Transmission Company, LLC	No	
Tacoma Power	No	Tacoma Power has no comment at this time.
MidAmerican Energy	No	
American Electric Power	Yes	Each criterion specified would not be able to be provided, or even applicable, for each exclusion requested. If the criteria provided may be selected from as necessary for each request, then we have no concerns on our ability to provide the data. Our only concern would be if the intent is that each and every criterion specified must be provided for each request made.
Pepco Holdings Inc	Yes	The entity may not have the tools, model or resources to do a full transmission planning study
Flathead Electric Cooperative, Inc.	Yes	Obtaining data creates a cost and should be minimized as possible.
Exelon	Yes	As mentioned above, this process will require extensive technical analysis from users, owners, operators and the Regions. In many cases, the Principles anticipate the use of criteria that is not in existence today. Rather than reinforcing the bright line approach, these Principles have the potential to create processes that will result in high costs with little to no corresponding benefits to reliability.

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 8 Comment
Glacier Electric Cooperative	Yes	It could be very, very difficult and costly for small utilities to perform the necessary transmission planning studies described in the proposal. I think there needs to be language clarifying how smaller utilities should be able to obtain this data.
Electricity Consumers Resource Council (ELCON)	Yes	NERC (and the BES SDT) should not assume that data pursuant to Large Generator Interconnection Agreements (LGIA) or the Large Generator Interconnection Procedures (LGIP) will be forthcoming on a timely basis for the purpose of demonstrating BES exceptions. While such information is generally available from ISOs and RTOs, it is not so forthcoming from vertically-integrated utilities in regions of the country not served by ISOs or RTOs because such utilities are generally hostile to third-party generation in their service territory. They are capable of delaying or otherwise obstructing requests for data and information. We recommend that NERC or the SDT identify mechanisms for requesting and getting the necessary data and information. This process should be included in the NERC Rules of Procedure.
Western Electricity Coordinating Council	Yes	The Owner should have all of the data to perform this analysis for an Exclusion; however, an Inclusion would likely be sought by an entity other than the Owner (i.e., Regional Entity, RC, BA, TOP) that may not have sufficient data. It should be clarified in the Rules of Procedure that such an entity has the right to request such data and that the Owner must provide such data.
ReliabilityFirst	Yes	many smaller entities would require assistance and or consultants to perform this analysis and some data many not be available or be shared etc.
Edison Electric Institute	Yes	<p>Method 2 is largely based on System Planning Criteria developed by WECC. At the present time, we do not believe that any of the other regions have similar planning criteria for which they could use or could easily integrate similar criteria into useable Planning Standards which could be applied in useful manner across all regions. For this reason, it is recommended that a separate Design Committee be created which would include representatives from all regions. It is expected that this effort may be substantial but is necessary before Method 2 or the Inclusion Process as written could be used.</p> <p>We would further caution the use or imposition of such a process since some transmission owners may not have the necessary skills or tools required to conduct studies of this type (in-house) and imposing this level of evidence will likely cause many who cannot meet this requirement to include unnecessary elements diluting the BES as defined and negating the value of the exclusion process.</p>
Electric Market Policy	Yes	Generation Owners and Generation Operators are typically not given access to non-public transmission information, especially that where a NDA or CEII signature is required. It would be virtually impossible for a GO to refute proposed inclusion of an Element owned by the GO unless they procure the services of a

Clark Public Utilities Benton Rural Electric Association Northern Wasco County PUD United Electric Co-op Inc. Oregon Trail Electric Cooperative, Inc Salem Electric Grant County PUD No. 2 (Grant) for Snohomish County PUD Northwest Public Power Association (NWPPA) Big Bend Electric Cooperative, Inc. Kootenai Electric Cooperative	No	As discussed on page 12 of the Snohomish White Paper, there may be a few isolated cases where additional data will need to be provided to run a valid technical analysis under the criteria set forth in the Exception Procedure. These cases should be exceedingly rare, however, because the starting point for the technical analysis Clark recommends is the current base case operated by the relevant Regional Entity, and in nearly every case, the base case can be expected to model any Element that conceivably has a material impact on the reliable operation of the bulk system. In those rare cases where it does not, we believe the owner or operator of the subject Element should be able to provide the needed data.
<p><b>Response:</b> The SDT believes that the technical criteria represent a base line of information to be presented for justification of the exception. If the applicant</p>		

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 8 Comment
<p>believes that additional information is needed to justify their request, the SDT agrees that the entity should be able to provide any additional information it believes necessary. The SDT disagrees that the Regional Entity should assess the adequacy of the application. In order to ensure consistency and uniformity across the continent, the ERO, not the Regional Entity, can be the only institution to conduct this analysis.</p> <p>Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity's characteristics to a defined value and/or limit. It has become apparent that it is impossible to establish values and/or limits that would be valid across all regions and systems. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the draft Rules of Procedure.</p>		
Manitoba Hydro	No	We are concerned however that assumptions could be made to complete the technical analysis to support an exclusion that may not be appropriate.
<p><b>Response:</b> The SDT believes that unwarranted assumptions will be identified in the process and such information will be made available to the industry to prevent others from utilizing similar assumptions.</p>		
Independent Electricity System Operator	No	We anticipate that entities would be granted access to any required historical operations records and modeling data after signing of non-disclosure agreements as necessary.
<p><b>Response:</b> Thank you for your comment.</p>		
Consumers Energy Company	Yes	CECo is not able to formulate detailed comments at this time, as the criteria have not been finalized. There are a number of items that are somewhat open ended, i.e. TBD and Other. Once those gray areas are filled in, we will have a better idea of our ability to obtain the necessary data.
<p><b>Response:</b> The SDT looks forward to your future comments.</p>		
Long Island Power Authority	Yes	The Reliability Coordinator would be required to provide much of the data needed to perform the technical analyses.
<p><b>Response:</b> The SDT believes that the burden of proof for the exception is on the applying entity. The applying entity can utilize any resource including other Registered Entities in presenting their case to the ERO.</p>		

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

---

Organization	Yes or No	Question 8 Comment
PPL Supply	Yes	See comments in Questions 9 and 10
<b>Response:</b> See response to Q9 & Q10.		

**9. Are you aware of any conflicts between the proposed approach and any regulatory function, rule order, tariff, rate schedule, legislative requirement or agreement, or jurisdictional issue? If so, please identify them here and provide suggested language changes that may clarify the issue.**

**Summary Consideration:** Most of the commenters expressed that they were not aware of specific conflicts associated with the BES exception technical principles and regulatory/jurisdictional matters. However, a substantial number of commenters answering “no” and “yes” raised concerns that the BES Definition and the Exception Technical Principles should respect FPA Section 215 authority limitations. Commenters to this question did not provide suggestions for addressing this concern.

Based on the extensive comments received by entities about FPA Section 215 authority excluding local distribution systems, the SDT modified the BES definition to provide additional clarity in this regard. Specifically, the SDT inserted language into the core of the revised BES definition.

WECC and another commenter brought up concerns associated with the applicability of a specific NERC reliability standard (i.e., IRO-010). ReliabilityFirst expressed concerns about the proposed BES definition changing the NERC Statement of Compliance Registry Criteria (SCRC). It should be emphasized that the goal of the SDT is to provide clarity to the BES definition and the technical principles for the NERC Rules of Procedure (RoP) exception process. The SDT’s scope of work does not include potential changes to the SCRC. The SDT has debated this matter extensively and believes that NERC reliability standards may be applied to non-BES Elements.

A few commenters brought up concerns about specific unique situations (e.g., black start Cranking Paths in local distribution systems). The SDT cannot address each and every unique regulatory situation in the BES definition and technical principles for the Rules of Procedure (RoP) exception process. Entities would need to submit relevant regulatory evidence on a case by case basis using the RoP exception process. However, the SDT did delete the reference to Cranking Paths.

**Bulk Electric System (BES):** Unless modified by the lists shown below, all Transmission Elements operated at 100 kV or higher and Real Power and Reactive Power resources connected at 100 kV or higher. This does not include facilities used in the local distribution of electric energy.

**I3** - Blackstart Resources identified in the Transmission Operator’s restoration plan.

Organization	Yes or No	Question 9 Comment
Bonneville Power Administration	No	Under NERC Standard IRO-010, the Transmission Operators are required to obtain information relating to the operation of the bulk power system within their respective areas. Transmission Operators may still need information relating to network facilities that ultimately are determined not to be BES facilities. BPA is concerned that an exclusion could eliminate a requirement that such information be provided.
ReliabilityFirst	Yes	FERC stated that entities registered were not to be taken off the registry without sound reasons and the definition sole intent was not to restrict or remove entities, but put in place a sound definition that everyone

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 9 Comment
		can use. I do not think this is a help, it is very detailed and allot of entities will be confused and lost
Western Electricity Coordinating Council	Yes	It must be clear that under NERC Standard IRO-010, the Reliability Coordinators are required to obtain information relating to the operation of the bulk power system within their respective areas. In light of this requirement, Reliability Coordinators may request the submittal of information for network facilities that ultimately are not determined to be BES facilities. It would be reasonable to also include a requirement that Reliability Coordination staff will explain why they require the requested information from non-BES facilities when seeking such information.
<p><b>Response:</b> The goal of the SDT is to provide clarity to the BES Definition and the technical principles for the Rules of Procedure exception process not to address the NERC Statement of Compliance Criteria Registry (SCRC) and the applicability of specific reliability standards. NERC reliability standards may be applied to non-BES Elements that are necessary for operating the interconnected transmission network.</p>		
City of Redding	Yes	State and court rulings that have defined Transmission and Distribution. One possible solution is to state that the determination made via this methodology is for reliability purposes only and is not intended to redefine established market and rate determinations.
Northeast Power Coordinating Council Hydro One Spyker	Yes	<p>It is imperative to understand that the NERC’s revised definition will have a direct impact on entities across North America and may conflict with regulatory requirements, Codes, and Licenses. FERC in its Orders 743 and 743A has directed NERC to address these concerns. For Ontario, the BES exception criteria shall meet the expectations of Ontario’s regulator (Ontario Energy Board) which has the sole authority and responsibility for the reliability of customer connections and loads within Ontario. Therefore, it will be necessary to accommodate NERC’s proposed definition of BES or the exception process with the Ontario situation.</p> <p>The SDT and RoP teams should:</p> <ul style="list-style-type: none"> <li>o Modify the exception criteria and procedure to provide regulatory flexibility with requirements to conduct basic technical analysis , to allow entities to consistently present their case to the ERO and/or the regulator for a step by step expedited evaluation.</li> <li>o Include provisions in both the NERC exception criteria and exception process for federal, state and provincial jurisdictions. These provisions should provide clear guidance so that, if and when there are deviations from the exception criteria, they are identified with technical and regulatory justifications ensuring there is no adverse impact on the interconnected transmission network.</li> <li>o Understand that the path to generating facilities need not be always BES contiguous. Generating units can/should be required to be planned, designed, and operated in accordance with a subset of NERC Standards, but should not always require contiguous paths.</li> </ul>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 9 Comment
Edison Electric Institute	Yes	EEI is concerned that under the technical principles, some facilities that are local distribution facilities may be included the BES. This is in conflict with the definition of the Bulk Power System in Section 215 which excludes facilities used in local distribution. In particular, EEI is concerned that the provision of the technical principles prohibiting the seeking an Exclusion for a cranking path will include local distribution within the definition of BES.
Consolidated Edison Co. of NY, Inc.	Yes	See the EEI reply to BES Definition and Designations Question 11.
PacifiCorp	Yes	The SDT proposal combined with the ROP proposal may be in conflict with Section 215 of the Federal Power Act, which requires “facilities used in the local distribution of electric energy” be excluded. The processes proposed may be over inclusive and by default require several elements which are not required for the reliable operation of the BES to in fact be included in the definition of “BES.”
Flathead Electric Cooperative, Inc.	No	the proposed BES Definition could conflict with Section 215 of the Federal Power Act if the Definition, the Exception Process, and the Technical Criteria do not effectively exclude facilities used in local distribution from the BES or if the BES definition does not focus on cascading outages, separation events, and instability on the interconnected bulk system. These statutory limits on the scope of the BES and reliability standards are a minimum that must be met.
Electricity Consumers Resource Council (ELCON)	Yes	The proposed technical principles violate the exemption in FPA section 215 against the inclusion in the BES of facilities used in the local distribution of electric energy, given that the BES is a subset of the BPS.
Exelon	Yes	To the extent facilities used in local distribution of electric energy may be included in the BES, the proposed principles are in conflict with the Federal Power Act.
Occidental Energy Ventures Corp.	Yes	The proposed technical principles seem to be in contradiction to the exemption in FPA Section 215 against the inclusion in the BES of facilities used in the local distribution of electric energy.
Central Lincoln for Snohomish County PUD	No	As we explained in our response to Question 1 of the Comment Form on the 1st Draft of Definition of BES, filed on May 27, Central Lincoln believes that the proposed BES Definition could conflict with Section 215 of the Federal Power Act if the Definition, the Exception Process, and the Technical Criteria do not effectively exclude facilities used in local distribution from the BES or if the BES definition does not focus on cascading outages, separation events, and instability on the interconnected bulk system. These statutory limits on the

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 9 Comment
		scope of the BES and reliability standards are a minimum that must be met.
The United Illuminating Company	Yes	under the technical principles, some facilities that are local distribution facilities may be included the BES. This is in conflict with the definition of the Bulk Power System in Section 215 which excludes facilities used in local distribution. In particular, Local distribution facilities can not be included in the BES even if they are part of a cranking path.
Pepco Holdings Inc	Yes	Facilities defined as local distribution facilities should not be forced into BES classification due to this new bright line definition.
Consumers Energy Company	Yes	The Technical Principles for Demonstrating BES Exceptions should not conflict with the seven-factor test provisions of FERC Order 888. In particular, provisions should not be established by the Standard Drafting Team that contradict prior Commission rulings associated with seven-factor test provisions.
Hydro-Quebec TransEnergie	Yes	<p>However, there is a conflict between the proposed approach and the regulatory framework applicable in the Quebec's Interconnexion or at least there are some important differences between both. Paragraph 95 of FERC Order 743 acknowledged the situation of non-FERC jurisdiction. As for the Quebec's Interconnexion, the BES definition and exclusion approach shall meet the expectations of Quebec's regulator, the Régie de l'Énergie du Québec, (Quebec Energy Board) which has the responsibility to ensure that electric power transmission in Quebec is carried out according to the reliability standards it adopts. In a recent order (D-2011-068), the Régie de l'Énergie du Québec has recognized several level of application for the Reliability Standards in Québec. It stated specifically that most reliability standards in Québec shall be applied to the Main Transmission System (MTS). One other level of application recognised by this decision is the NPCC Bulk Power System (BPS) to which the standards related to the protection system (PRC-004-1 and PRC-005-1) and those related to the design of the transmission system (TPL 001-0 to TPL-004-0) will be applicable (including the rest of the standards). The Main Transmission System definition is somewhat different than the Bulk Electric System definition. The Main Transmission System includes elements that impact the reliability of the grid, supply-demand balance and interchanges. It can be described as follows :The transmission system comprised of equipments and lines generally carrying large quantities of energy and of generating facilities of 50 MVA or more controlling reliability parameters:</p> <ul style="list-style-type: none"> <li>o Generation/load balancing</li> <li>o Frequency control</li> <li>o Level of operating reserves</li> <li>o Voltage control of the system and tie lines</li> <li>o Power flows within operating limits</li> <li>o Coordination and monitoring of interchange transactions</li> <li>o Monitoring of special protection systems</li> <li>o System restoration</li> </ul> <p>Therefore, it will be necessary to accommodate NERC's proposed definition of BES or the exception process with the Quebec situation where Entities are under a different jurisdiction. These differences include more</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 9 Comment
		than one level of application for the reliability standards, the Main Transmission System definition being the main one to which most reliability standards apply.
Manitoba Hydro	Yes	Canadian Entities are not under FERC jurisdiction, so the revised BES Definition may not apply.  A number of Canadian Entities have the BES defined within their provincial legislation. This may introduce differences and even contradictions between elements that are included in the BES according to provincial legislation and the NERC definition.
Independent Electricity System Operator	Yes	Similar to the BES Exception Procedure, the document “Technical Principles for Demonstrating BES Exceptions” must explicitly recognize the authority of Canadian and Mexican Governmental Entities to adopt the Technical Principles for Demonstrating BES Exceptions in its entirety or in part with their own deviations, while ensuring there will be no adverse impact on the interconnected transmission system. Footnote 2 of the “Procedure for Requesting and Receiving an Exception from the Application of the NERC Definition of Bulk Electric System” should be repeated in the “Technical Principles” document.
<p><b>Response:</b> The SDT has clarified this position.</p> <p><b>Bulk Electric System (BES):</b> Unless modified by the lists shown below, all Transmission Elements operated at 100 kV or higher and Real Power and Reactive Power resources connected at 100 kV or higher. This does not include facilities used in the local distribution of electric energy.</p>		
Electric Market Policy	Yes	Dominion is concerned that the provision of the proposed technical principles prohibiting the seeking of an exclusion for a cranking path for blackstart resources will include local distribution facilities within the definition of the BES. This conflicts with the definition of “Bulk Power System” in Section 215 of the Federal Power Act, which excludes facilities used in local distribution.
<p><b>Response:</b> The SDT has deleted the reference to Cranking Paths.</p> <p><b>13</b> - Blackstart Resources identified in the Transmission Operator’s restoration plan.</p>		
PPL Supply	Yes	Based on FERC Order 743 paragraph 120, radial and local distribution facilities should be excluded from the definition of the Bulk Electric System (BES). The exclusion of non-networked facilities such as radial lines is further re-enforced with Order 743 paragraph 73 which describes the characteristics of a network and does not include most generator interconnection facilities. In that order, FERC justified its bright-line, 100 kV threshold, explaining that "many facilities operated at 100 kV and above have a significant effect on the overall functioning of the grid" because they share the following characteristics: 1. "operate in parallel with other high voltage and extra high voltage facilities".i. The “bright line” at 100 kV recognizes many 100 kV lines

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 9 Comment
		<p>parallel other HV/EHV lines and can be significantly loaded by failure of the HV/EHV lines. This does not apply to radial lines, even at 100 kV and above.2. "interconnect significant amounts of generation sources" (emphasis added)3. "operate as part of a defined flow gate"4. have a "parallel nature" and are capable of "caus[ing] or contribute[ing] to significant bulk system disturbances".i. Radial lines cannot cause significant BES disturbances since the outage of a radial line is studied in all N-1 planning studies and if the TPL standards are followed, an N-1 should not cause such disturbances.Excluding generator lead lines is very practical because the physical reality of a radial generator lead line is that it cannot be overloaded by outages on parallel paths because there are no parallel paths. Further, the MW flow on a radial line is well known and limited to a known maximum (limited to the larger of the generation or load on the end of the line); clearly these are reasons for excluding radial lines. When and if a generator lead line is tapped by another generator or load, it is possible that the line between the tap point and the original point of interconnection might need to be rolled into the electrical network. However, at that time, it might also be possible for the transmission owner to purchase the line and make the tap point the new point of interconnection.</p>
<p><b>Response:</b> The SDT cannot address each and every unique situation in the technical principles for the Rules of Procedure (RoP) exception process. Entities would need to bring relevant evidence on a case by case basis using the RoP exception process.</p>		
Springfield Utility Board	Yes	<ul style="list-style-type: none"> <li>o The four characteristics defined in the "Exception Criteria - Exclusions" portion of Technical Principles for Demonstrating BES Exceptions appears to be in conflict with, rather than in parallel to, the exceptions which are part of the proposed "core definition" in the Proposed Continent-wide Definition of Bulk Electric System. SUB proposes that NERC postpone work related to Technical Principles for Demonstrating BES Exceptions until a continent-wide BES definition is approved.</li> <li>o FERC Order No. 743 states, "We believe that it would be worthwhile for NERC to consider formalizing the criteria for inclusion of critical facilities operated below 100 kV in developing the exemption process". However, there is no mention of critical facilities operated below 100 kV in NERC's Exception Criteria. SUB would encourage NERC to include critical facilities consideration in their exception criteria.</li> </ul>
<p><b>Response:</b> The SDT is responsible for completing NERC Project 2010-17 (related to the BES Definition process and the exception technical principles process) before year-end. The SDT does not have sufficient time to bifurcate the two processes.</p> <p>The technical principles for the Rules of Procedure exception process as proposed by the SDT allows for presenting exception evidence for including critical Elements energized below 100 kV into the Bulk Electric System.</p>

**10. Are there any other concerns with this approach that haven’t been covered in previous questions and comments? Please be as specific as possible with your comments.**

**Summary Consideration:** Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity’s characteristics to a defined value and/or limit. It has become apparent that it is not feasible to establish continent-wide values and/or limits due to differences in operational characteristics. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the Rules of Procedure as presently being drafted.

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 10 Comment
as established in the Rules of Procedure as presently being drafted.		
BGE	No	<p>It is important to consider that the Technical Principles for Demonstrating BES Exceptions is only one part of the BES definition project. The Technical Principles and the Rule of Procedure Process must be evaluated together with the BES Definition to sufficiently understand the revisions. In the end, the Technical Principles and the BES Definition must coalesce and be clearly coordinated and understood. The BES Definition language must include reference to the role of the associated defining documents. One unambiguous document must not be made ambiguous by an associated document or process.</p> <p>We appreciate the work of the drafting team and support the goal to produce clear definition language so that upwards of 95% of the assets are clearly distinguished as either included or excluded from the BES. We are particularly sensitive to the potential for burdensome processes (e.g. TFEs) to be added to reliability compliance. We appeal to the team for continued, vigilant consideration of the arduousness of the BES determination process.</p>
<p><b>Response:</b> The upcoming posting of the BES definition and the technical principals will be posted simultaneously in order for industry to adequately evaluate the two documents and their relationship to each other.</p>		
Oncor Electric Delivery	No	<p>Although Oncor Electric Delivery understands the need for the ERO to be in a position to override the inclusion criterion,</p> <p>Oncor desires more clarity on what factors contribute to an overriding action.</p>
ACES	Yes	<p>The term interconnected transmission network is used throughout this document. Bulk Electric System should be used in its place. The purpose of the technical principles is to determine if an Element is needed to support the operation of the Bulk Electric System. Using interconnected transmission network adds more uncertainty to the document.</p>
Northeast Power Coordinating Council	Yes	<p>Exception criteria should be crafted at a high-level with key menu items of assessment that can be followed continent-wide by entities to put forward their exception(s) for element(s) that are not necessary for the interconnected transmission network based on technical assessment, evidence and justification for unique characteristics, configuration, and utilization. (Also see suggestions/ comments in Question 6)</p>
SPP Standards Review Group	Yes	<p>In Question 5 regarding the Transient and Steady State Stability criteria, we would suggest establishing criteria for the damping such that the time required to return to normal is limited. Damping in 1-5% range may be sufficient to accomplish this.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 10 Comment
		Also, delete 2.a.iv.8. in the Exclusion Criteria and 1.c.8. in the Inclusion Criteria.
NERC Staff Technical Review	Yes	<p>A criterion should be added for supporting a request for inclusion of an Element. If an Element has been identified as causal or contributory to a Category 2 or higher event as defined in the ERO Event Analysis Process, that should be sufficient evidence that it is necessary for the Element to be planned, designed, maintained, and operated in accordance with NERC Reliability Standards. An assessment of the Element should include consideration of any corrective actions that have been implemented to prevent a reoccurrence.</p> <p>The Exception criteria also should include a list of characteristics of Elements that will not be considered for exclusion, on the basis that this list of characteristics already identifies the importance of such Elements to reliable operation of the interconnected transmission network. Characteristics should include: (1) Elements that are relied on in the determination of an Interconnection Reliability Operating Limit (IROL); (2) Blackstart resources and the designated blackstart Cranking Paths identified in the Transmission Operator’s restoration plan regardless of voltage, (3) Elements subject to Nuclear Plant Interface Requirements (NPIRs) as agreed to by a Nuclear Plant Generator Operator and a Transmission Entity defined in NUC-001, and (4) Elements identified as required to comply with a NERC Reliability Standard by application of criteria defined within the standard (e.g., the test defined in PRC-023 to identify sub-200 kV Elements to which the standard is applicable.)</p>
Florida Municipal Power Agency Transmission Access Policy Study Group	Yes	The third paragraph of the introduction to the Technical Principles is awkwardly worded and might be misconstrued. FMPA suggests the following rewording: “Entities are not required to seek exceptions under the Exception Procedure to exclude from the BES Element(s) that are already excluded under the BES definition and designations.”For the sake of consistency, Exclusions (1) should contain a provision analogous to Exclusions (2)(b) and Inclusions (1)(f) addressing the circumstances under which the ERO can override a demonstration based on these criteria. As noted above, one of those circumstances would be a demonstration by NERC that the Element in question meets the criteria for inclusion in the BES.
Tri-State Generation and Transmission Association	Yes	<p>The proposed principles seem preliminary and immature. In addition as noted in earlier comments they are not fully consistent with the proposed BES definition, particularly with respect to radial elements and local distribution networks. Such consistency should be incorporated before the next posting.</p> <p>We further feel that it is very unlikely that the technical evidence path can be placed on a sound technical foundation and matured by the end of this year as directed by the FERC.</p> <p>Key definitions are lacking and should be added to the document. For instance “distribution factor” is not carefully defined even though such factors can be calculated in a variety of ways.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 10 Comment
Hydro One	Yes	Exception criteria should be crafted at a high-level with key menu items of assessment that can be followed continent-wide by entities to put forward their exception for element(s) that are not necessary for the interconnected transmission network and based on technical assessment, evidence and justification for its unique characteristics, configuration, and utilization. (Also see suggestions/ comments on Question 6)
MRO's NERC Standards Review Forum	Yes	<p>1. NSRF proposes replacing the wording in the Exclusion preface, Exclusion 2 preface, and Inclusion 1 preface of “not necessary to reliably operate the interconnected transmission network” with “necessary to maintain an Adequate Level of Reliability (ALR) of the Bulk Electric System”.</p> <p>2. NSRF has reservations on the following statement made in the introduction of this document:” Due to the importance of Blackstart Resources and their designated blackstart Cranking Paths to restoration efforts, no exceptions will be allowed for those items.” This does not allow for a provision to exclude any designated Blackstart Cranking Path (at any voltage) even though there may be technical justification for it.</p> <p>3. The first page states that “Specific content of this application is spelled out elsewhere in this appendix.” NSRF requests the SDT describe where this appendix will be published. Furthermore, is it a compliance document or just technical “guidance”?</p> <p>4. Having the following statement included for both exclusions and inclusions will create disagreement:”The ERO can override this criterion but would need to provide additional justification to support their finding.” NSRF believes any override should have adequate technical justification and not interfere with other statutory requirements. Also, it does not clarify or identify who would make the determination whether NERC has made adequate justification to override the criterion.</p> <p>5. NSRF believes that the “Inclusion” process should be completely removed from BES Definition. We recommend using bright-line criteria indentifying everything 100 kV and above to be BES and then allow for the “Exception” process to take out facilities that do not impact the reliability of the BES. Selecting BES facilities based on a right-line criteria is what FERC requested in its Order regarding BES Definition. This would streamline the process and remove some unnecessary paperwork.</p>
MidAmerican Energy	Yes	MidAmerican supports the NSRF comments.
PacifiCorp	Yes	The SDT has proposed several technical criteria to be used to determine if an element has an impact on the reliability of the BES. PacifiCorp believes that the majority of non-BES elements can be excluded using a modified proposed bright-line and/or using the non-technical approach. However, in the event an entity requires additional justification to remove non-BES elements from the BES, then PacifiCorp feels the technical criteria should be established on an interconnection basis, not on a continent-wide basis. Because

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 10 Comment
		of the number of operating and geographic differences among the interconnections, to try to establish technical criteria on a continental basis would introduce confusion. PacifiCorp believes it is impossible to establish technical criteria that will allow unique interconnections to be treated in a comparable manner.
Western Electricity Coordinating Council	Yes	<p>The biggest concern is that the Technical Principles and the reasoning behind them need to be fully explained. The SDT has mentioned on calls the possibility of a white paper or resource document, and WECC fully supports the creation of such a document. This white paper should describe the rationale for the criteria as well as how that indicates that the element is necessary for reliable operation.</p> <p>Also, the justification for the ERO to override these criteria should be clarified. It should be clear that the ERO's ability to override these criteria is on a case-by-case basis.</p>
Electricity Consumers Resource Council (ELCON)	Yes	The bright-line tests used in the revised BES definition and technical principles may capture the facilities of hundreds of entities that may not know that NERC exists or the enforceability of NERC Reliability Standards. The technical principles should be supplemented with a technical guide or appendix that provides examples of the steps that may be necessary to demonstrate BES exceptions.
Alabama Public Service Commission	Yes	The second paragraph of the proposed Technical Principles states that “[d]ue to the importance of Blackstart Resources and their designated blackstart Cranking Paths to restoration efforts, no exceptions will be allowed for those items.” This sentence should be deleted from the technical principles. An unintended consequence of subjecting all blackstart cranking pathways to inclusion in the BES by default would be to cause a Registered Entity, in order to minimize costs, to not declare every possible cranking path but instead limit to the minimum required cranking paths in order to comply with the standards, as opposed to designating multiple pathways. This consequence could be avoided by allowing blackstart cranking pathways to be evaluated for exceptions just like any other element.
Southern Company	Yes	<p>The Technical Principles document suggests that no exceptions be allowed for Blackstart Resources and designated Cranking Paths. Southern Company is concerned with the treatment of these facilities and recommends that certain statements be removed. In Project 2010-17 Definition of the BES, Southern Company commented that the proposed inclusion, Inclusion I4, be removed from the BES Definition because an existing NERC Reliability Standard, EOP-005-2 System Restoration from Blackstart Resources, already addresses these facilities regardless of voltage.</p> <p>Further, the proposed inclusion will expand the applicability of some NERC Reliability Standards to facilities below 100 kV. Southern Company believes this position will unnecessarily cause more facilities to become applicable to reliability standards without any benefit to reliability. Therefore, we recommend the following statement be deleted: “Due to the importance of Blackstart Resources and their designated blackstart</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 10 Comment
		Cranking Paths to restoration efforts, no exceptions will be allowed for those items.”
National Grid	Yes	The exception process should be strictly limited to the procedures for application and approval and should not include substantive elements.
Muscatine Power and Water	Yes	<p>1. Propose replacing the wording in the Exclusion preface, Exclusion 2 preface, and Inclusion 1 preface of “not necessary to reliably operate the interconnected transmission network” with “necessary to maintain an Adequate Level of Reliability (ALR) of the Bulk Electric System”.</p> <p>2. Currently having reservations concerning the following statement made in the introduction of this document:” Due to the importance of Blackstart Resources and their designated blackstart Cranking Paths to restoration efforts, no exceptions will be allowed for those items.” This does not allow for a provision to exclude any designated Blackstart Cranking Path (at any voltage) even though there may be technical justification for it.</p> <p>3. The first page states that “Specific content of this application is spelled out elsewhere in this appendix.” Request the SDT describe where this appendix will be published and indicate if this is a compliance document or just technical “guidance”?</p> <p>4. By having the following statement included for both exclusions and inclusions will lead to disagreement:”The ERO can override this criterion but would need to provide additional justification to support their finding.” Suggesting that any override should include adequate technical justification and not interfere with other statutory requirements. Also, it does not clarify or identify who would make the determination whether NERC has made adequate justification to override the criterion.</p> <p>5. Do not believe that the “Inclusion” process should be completely removed from BES Definition. Would like to recommend using bright-line criteria indentifying everything 100 kV and above to be considered BES and then allow for the “Exception” process to take out Facilities that do not have an impact on the reliability of the BES. Selecting BES Facilities based on bright-line criteria is what FERC requested in its Order regarding BES Definition. This would streamline and simplify the process by removing a large quantity of exceedingly unnecessary paperwork.</p>
Blachly Lane Electric Cooperative Central Electric Cooperative Clearwater Power Electric	Yes	In general, , as we discuss above, the Technical Principles for Demonstrating BES Exceptions present a reasonable approach to resolving questions of inclusion and exclusion in the BES that the BES definition itself does not clearly resolve. However, we caution that these principles for demonstrating exceptions cannot, and must not, take the place of a consideration of, and criteria under whether, any specific piece of equipment is subject to FERC, the ERO, and Regional Entity jurisdiction in the first instance. Section 215 of the Federal power Act (FPA) sets out clear limits of jurisdiction of FERC, the ERO, and Regional Entities for purposes of

Organization	Yes or No	Question 10 Comment
Cooperative Consumer's Power Inc Coos-Curry Electric Cooperative Douglas Electric Cooperative Fall River Electric Cooperative Lane Electric Cooperative Lincoln Electric Cooperative Lost River Electric Cooperative Northern Lights Electric Cooperative Okanogan Electric Cooperative Raft River Rural Electric Cooperative Salmon River Electric Cooperative Umatilla Electric Cooperative West Oregon Electric Cooperative Pacific Northwest Generating Cooperative Consumer's Power Inc		<p>developing and enforcing reliability standards. Specifically, Section 215(i) provides that the ERO “shall have authority to develop and enforce compliance with reliability standards for only the Bulk-Power System.” 16 U.S.C. Â§ 824o(a)(1) (emphasis added). Section 215(a)(1) of the statute defines the term “Bulk-Power System” or “BPS” as: (A) facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof); and (B) electric energy from generation facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy.” Id. As we have explained in our comments on the BES definition, that definition should expressly account for these jurisdictional limitations up front. This would allow for the jurisdictional limitation consideration as the very first step in determining whether or not a particular piece of equipment is part of the BES.</p> <p>The Technical Principles for Demonstrating BES Exceptions, on the other hand, provides a completely separate set of criteria for exclusion from the BES and would come into play only after application of the full BES definition to a particular piece of equipment and determination that the BES definition does not provide a satisfactory answer as to whether that piece of equipment is or is not part of the BES. This is acceptable insofar as it goes, but, because (1) the criteria in the Technical Principles are distinct from the jurisdictional limits of Section 215 of the FPA, and (2) consideration of the Technical Principles would essentially be the last, or one of the last, steps in the process, the Technical Principles cannot substitute for, in any way, consideration of the jurisdictional limitations of the FPA. Again, we cannot overemphasize enough how important it is to have the jurisdictional consideration be the very first step in the process of determining whether a particular piece of equipment is or is not part of the BES. Again, thank you for the opportunity to comment. We look forward to continuing to work with NERC and stakeholders to develop a BES definition that is both workable and lawful.</p>
New York State Department of Public Service		<p>The core BES definition based on a 100 kV brightline is an overreach of bulk system designation under the provisions of the Federal Power Act; a properly specified BES core definition would avoid the extensive analysis required under the exceptions procedure. That said, the proposed principles for use in the exceptions process are consistent with previous FERC efforts to distinguish between transmission and local distribution.</p> <p>The upfront exclusion of applying the proposed principles to blackstart cranking path facilities is a potential</p>

Organization	Yes or No	Question 10 Comment
		<p>overreach into the local distribution system and can be counter productive reliability. Mandating compliance of NERC standards to cranking paths will result in the specification of only one cranking path by host utilities to minimize costs, where designating multiple paths in restoration paths would provide the flexibility needed to minimize customer outage duration.</p>
Springfield Utility Board	Yes	<p>SUB has the following concerns regarding NERC’s Technical Principles for Demonstrating BES Exceptions:</p> <ul style="list-style-type: none"> <li>o Clear Definition of Radial - As previously addressed in our BES Definition comments, SUB would encourage a more clear definition of a “radial” versus “closed-loop” system. Because there still appears to be inconsistencies in both definition and application, SUB encourages NERC to develop a concise definition of a radial system. For example, if a system is normally operated as radial, but could be operated as closed (by manually closing a breaker), would it be considered a radial or close-looped system? If the answer is close-looped, then is this in all cases, or are there exceptions?</li> <li>o Approval of Exceptions - SUB would like for NERC to clarify the process for receiving, reviewing, and accepting or rejecting exception applications. The Technical Principles for Demonstrating BES Exceptions states that, “...will be subject to review and remand by the ERO itself, or by any agency having regulatory or statutory oversight of NERC as the ERO.” During NERC’s presentation at APPA’s BES Definition webinar, it was explained that the exception process would look like the following:1. Entity applies for expemption,2. Region receives application, verifies received, and forward to NERC with recommendation(s), and 3. NERC makes final determination (decision is appealable by entity).For consistent application of the expemption procedure, SUB would encourage NERC to adopt the process as it was communicated during the APPA webinar, with regions making recommendations, but NERC making the final decision.</li> <li>o Duration of Approved Exclusions/Inclusions - The Technical Principles for Demonstrating BES Exceptions does not indicate the duration for approved exclusions or inclusions. How long are granted exclusions/inclusions? Permanent? Annual? Other?</li> <li>o Publication of Exceptions - For consistent application, as well as transparency and accountability, SUB would request that all exceptions be published ; those applied for, as well as whether they were rejected or accepted, as well as decision rationale.</li> </ul>
ISO New England	Yes	<p>Any generator that is studied individually will not be shown as material since the electric system is designed to allow the outage of any individual generator. Generators must be studied within the context of the electric system to assess materiality. The generator and its interconnecting transmission facilities would likely be able to be excluded based on this process although they meet the Registry Criteria thresholds requiring inclusion.</p>
The United Illuminating	Yes	<p>UI is concerned that the method used to characterize exclusions in Method 1 did not follow the proposed BES</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 10 Comment
Company		<p>Definition and believe the process developed for Method 2 (and reused for Sub-100kV Inclusions) is overly complicated, lacks necessary regional standards to support the process and may prove too difficult for some companies to fully comply with thereby discouraging a consistent and uniform application of the definition across all regions and affected BES element owners.</p> <p>These Principles are not technical Principles. Further the use of these Planning criteria and impact assessments is not very different from the NPCC functional test that drew the ire of FERC. The Drafting Team is attempting to develop definitions and identifiers for the fringes of the bulk power system, but they are replacing one set of ambiguities with a set of technical ambiguity. This product is poor because given the very first term, that is the first principle to be met, is those facilities necessary for the reliable operation of an interconnected transmission system, is full of undefined concepts such that anything attempting to define it in a subtle manner is immediately lost in the ether.</p> <p>Recognizing that these technical principles will be permanent, UI suggests excluding them and sticking with the bright line exclusions and inclusions in the proposed definition.</p>
Occidental Energy Ventures Corp.	Yes	<p>The Technical Principles and the new BES Definition seem to include a significant number of retail customers as proposed. Surely this is not the intent of these changes.</p> <p>There should be an exclusion along the lines of Comment 6.</p>
Flathead Electric Cooperative, Inc. Benton Rural Electric Association Northern Wasco County PUD United Electric Co-op Inc Oregon Trail Electric Cooperative, Inc Central Lincoln Salem Electric Grant County PUD No. 2 (Grant) Big Bend Electric Cooperative,	Yes	<p>supports the approach to the exclusion process proposed by the SDT, which provides two different paths to exclusion, one based on readily-identifiable operational characteristics of a system, and one based on technical reliability analysis. We believe it is important to provide for the first path, based on operational characteristics, so that systems that are marginally disqualified under the BES Definition (because, for example, generation within the system exceeds demand for a few hours a year) can obtain an exclusion without the large investment of resources that otherwise might be required for a full-scale technical analysis. we question whether the first subsection of the characteristic test, relating to system proximity, is necessary, and we are concerned that the requirement that a system meet all four requirements of the characteristics test may be overly restrictive. For example, it is easy to imagine a distribution system in a rural area that covers a widely dispersed area, so that load is many miles from the relevant generation/transmission source, and that the system therefore does not meet the electrical proximity element, but meets the other three elements of the characteristics test. Such a system should be excluded because it clearly serves a local distribution function, and not a transmission function, as demonstrated by the fact that the system meets subsections (c) (power flows into the system but rarely flows out ) and (d) (power is not intentionally transported over the system). Accordingly, we recommend that the SDT consider eliminating the first test.</p> <p>In the alternative, the SDT should consider allowing exempting a system from the BES if it, for example,</p>

Organization	Yes or No	Question 10 Comment
Inc Northwest Public Power Association (NWPPA) Kootenai Electric Cooperative		meets three of the four criteria rather than all four.
Spyker	Yes	Exception criteria should be crafted at a high-level with key menu items of assessment that can be followed continent-wide by entities to put forward their exception for element(s) that are not necessary for the interconnected transmission network and based on technical assessment, evidence and justification for its unique characteristics, configuration, and utilization.
American Electric Power	Yes	<p>AEP appreciates the work that the drafting teams have done within the various deliverables related to the BES definition, technical principles for demonstrating BES exceptions, and the BES definition exception process. AEP acknowledges the benefits of agreeing to a BES definition and exception process, and appreciates the drafting teams' requests for industry involvement.</p> <p>Due to the interrelated nature of the deliverables currently out for review regarding the BES definition and exception processes, it is difficult if not impossible, to comment "in isolation" on any individual facet of the project. For example, there needs to be a defined relationship between an approved definition of BES, the technical principles for demonstrating BES exception, and the exception process itself. When closely related projects such as these are done simultaneously, no individual deliverable can rely on the completed work of another. As a result, we risk having conflicting decision making across these projects. As a result, AEP is not in the position to make further comments at this time beyond those recently and concurrently made regarding the BES definition and technical principles for demonstrating BES exceptions. We suggest that further work on these efforts, when appropriate, become more consolidated and that care be taken to not undertake concurrent efforts before sufficient progress has been made on important aspects of the project. AEP appreciates the drafting teams' requests for industry input, and looks forward to its future involvement after additional progress has been made on these issues.</p>
Consumers Energy Company	Yes	<p>In addition to the owner, only those with jurisdictional authority, such as the ERO and RRO, should be permitted to register Exception Requests. A third party may have a business reason for wishing to encumber another entity with regulatory compliance risk and responsibility. In addition, this could create an additional strain on the Exception Request process due to an excessive number of requests from third parties.</p> <p>We do want to ensure that the term "Other", used in Exclusion Section 2.a.iv.8., and Inclusion Section 1.c.8., not remain in the final Technical Principles document.</p>

Organization	Yes or No	Question 10 Comment
for Snohomish County PUD	Yes	<p>Snohomish County PUD generally supports the approach to the exclusion process proposed by the SDT, which provides two different paths to exclusion, one based on readily-identifiable operational characteristics of a system, and one based on technical reliability analysis.</p> <p>We believe it is important to provide for the first path, based on operational characteristics, so that systems that are marginally disqualified under the BES Definition (because, for example, generation within the system exceeds demand for a few hours a year) can obtain an exclusion without the large investment of resources that otherwise might be required for a full-scale technical analysis.</p> <p>That being said, we question whether the first subsection of the characteristic test, relating to system proximity, is necessary, and we are concerned that the requirement that a system meet all four requirements of the characteristics test may be overly restrictive. For example, it is easy to imagine a distribution system in a rural area that covers a widely dispersed area, so that load is many miles from the relevant generation/transmission source, and that the system therefore does not meet the electrical proximity element, but meets the other three elements of the characteristics test. Such a system should be excluded because it clearly serves a local distribution function, and not a transmission function, as demonstrated by the fact that the system meets subsections (c) (power flows into the system but rarely flows out ) and (d) (power is not intentionally transported over the system). Accordingly, we recommend that the SDT consider eliminating the first test.</p> <p>In the alternative, the SDT should consider allowing exempting a system from the BES if it, for example, meets three of the four criteria rather than all four. We have pasted in the text of our White Paper below. Please contact us for a more readable version of the White Paper. White Paper A Performance-Based Exemption Process to Exclude Local Distribution Facilities from the Bulk Electric System April 2011 This White Paper proposes a transmission planning (“TPL”) “performance-based” process to determine the local distribution facilities the North American Electric Reliability Corporation (“NERC”) must exclude from the Bulk Electric System (“BES”) pursuant to Section 215(a)(1) of the Federal Power Act (“FPA”).</p> <p>This process would apply to those local distribution facilities that are not automatically excluded under a bright-line BES definition. Consistent with Federal Energy Regulatory Commission (“FERC”) Order Nos. 743 and 743-A, a performance-based exemption process would be objective, consistent, and transparent, and would adequately differentiate between local distribution and transmission, i.e., BES, facilities.</p> <p>I. What Is Reliability? FPA Section 215 authorizes NERC to promulgate “reliability standards,” subject to FERC approval. Section 215 defines “reliability standard” to mean a properly-approved requirement “to provide for the reliable operation of the bulk-power system.” The statute, in turn, defines “reliable operation” to mean “operating the elements of the bulk-power system within equipment and electric system thermal, voltage, and stability limits so that instability, uncontrolled separation, or cascading failures of such system will</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 10 Comment
		<p>not occur as a result of sudden disturbances, including . . . unanticipated failure of system elements.”</p> <p>II. What Is “Customer Service” or “Level of Service” (“LOS”)? Local customer service or LOS relates to service failures on local utility systems that are wholly internalized rather than spilling onto the interconnected regional grid. These types of service failures relate to local customer service and LOS standards. The customers of those utilities will bear the full cost of complying with internal LOS standards and will obtain the full benefit of compliance to the extent that service levels on those systems improve. Accordingly, state public utility commissions (for regulated utilities) and independent boards (for non-regulated utilities) can fully and accurately weigh whether the benefits of compliance with such standards are justified by the costs they will pay. Intervention by NERC and a Regional Entity is not needed because a utility’s actions related to level of service on its own system will neither unduly burden the customers of other systems, threaten the reliable delivery of power to those customers, nor create incidental benefits to those remote customers. In the absence of the need to protect customers of systems remote from the consequences of decisions made by an individual utility, there is no warrant for NERC or a Regional Entity to interfere with a utility’s internal decision-making about the appropriate LOS to its own customers, and the costs that will be borne by those customers to achieve any particular level of service. In fact, in the “Savings Provisions” of Section 215, Congress specifically included language prohibiting NERC and Regional Entities from enforcing “compliance with standards for adequacy” of electric service. By law, these remain the exclusive province of local decision-makers.</p> <p>III. The Need for a Material Impact Test In Order No. 743-A, FERC clarified that a material impact test is appropriate in the reliability context if the test can be shown to identify facilities needed for reliable operation. The following example of an outage demonstrates the need for an impact test to distinguish between LOS and Reliability, i.e., local distribution facilities and BES facilities.</p> <p>A. Pre-Event Facts Local Utility Administration (“LUA”) owns a 115 kV system that moves power from two points of delivery (“POD”) and serves 1000 MW of load. A DC battery rack had an unexpected failure a few days after it was routinely inspected and LUA has not implemented Supervisory Control and Data Acquisition (“SCADA”) so the DC battery voltage is not continuously monitored. The LUA system interconnects with BES Company’s system which consists of 230 kV and 500 kV lines.</p> <p>B. Event Facts A fault occurs and the breakers in substation 2 fail to operate due to a battery failure (Figure 1). This results in an outage for customers served by substations 1, 2, and 3 on the LUA system. Figure 1</p> <p>C. Post-Event Facts Immediately after the outage, LUA customer service receives numerous customer calls followed by a call from its Public Utility Commission/Local Utility Board (“/PUC/LUB”). LUA dispatches crews immediately after being informed of the outage to identify and resolve the problem. Within 45 minutes, the fault is sectionalized and the all load is restored. The PUC/LUB receives complaints from LUA customers who identify economic and other adverse impacts of the outage. The PUC/LUB demands a report from the</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 10 Comment
		<p>LUA that describes the event and restoration, as well as potential solutions. LUA submits a report which finds that the main solution to this problem involves the implementation of a SCADA system. The SCADA system scope of work includes battery voltage telemetry and would have identified the DC system issue and prevented the protection system failure, resulting in only the loss of substation 3. The SCADA plan cost estimate is \$30 million and was presented three years earlier. The PUC/LUB evaluated the costs and benefits of the new SCADA system, but did not approve the project in order to reduce the budget and/or provide rate stability for the struggling local economy. LUA, the PUC/LUB, and customers will re-evaluate the merits of adding SCADA as well as other solutions such as increasing substation inspection runs, updating the batter fleet, and further investigating battery manufacture reliability records. Based on the LUA report, the battery bank failure rate immediately after routine inspections is expected to occur once every 3,500 years. Seventy battery banks are used on the LUA system, so a bank failure should be expected every 50 years. BES Company's neighboring 230kV and 500kV system does not experience an adverse system impact. Subsequently, BES Company identifies that one of its breakers operated at the LUA South POD. BES Company and LUA coordinate a review of the system protection scheme and BES Company determines that it operated correctly. BES Company verifies that the LUA outage did not create any thermal, voltage, or transient stability limit violations on the BES Company system. The Regional Entity, NERC, and FERC treat the outage as a Reliability Standards issue. The LUA System (highlighted in yellow) is considered part of the BES because it meets the "bright line" 20 MVA and 100 kV thresholds under the current BES definition and the NERC Statement of Compliance Registry Criteria ("SCRC"). The event would most likely be considered a TPL-003 category C event specifically C8 SLG Fault, with delayed clearing that may include a stuck breaker or protection system failure. The LUA Substation Department reviews its inspection records and has adequate documentation for the battery banks involved in the outage. As a result, LUA avoids substantial fines. However, during the inspection review, LUA notices that the battery bank in a similar distribution substation inspection schedule was completed three days late. Upon following further internal procedures, LUA finds that the battery bank was inspected three days late due to restorations efforts after a major wind storm. Although there were no LOS impacts, and the inspection schedule was unrelated to the outage, the Reliability Standards triggered a LUA self report to its Regional Entity which ultimately resulted in a \$50,000 penalty.</p> <p>D. Summary This example identifies that in addition to a "bright line" BES exclusion process a more refined process such as a "performance based" reliability assessment is needed to distinguish BES facilities from distribution facilities if the NERC Statement of Compliance Registry Criteria ("SCRC") continues to be the benchmark for assessing BES facilities. It is clear from this example that the current 100 kV and 20 MVA thresholds cannot accurately classify what is and is not considered part of the BES. Defining BES facilities is important from the "Reliability Standard" and "LOS" perspectives as well as from a local and regional jurisdictional standpoint. There are multiple agencies identifying and approving what facilities should and should not be built, what programs should and should not be implemented, and if a fine should be paid by</p>

Organization	Yes or No	Question 10 Comment
		<p>customers experiencing an outage without determining if it could have had an adverse impact on neighboring electric systems. Without a performance-based process, many small and medium electric utilities would be unnecessarily burdened. ¶</p> <p>IV. Neighboring System Rule It is important but not always easy to distinguish the difference between “reliability” and “LOS” impacts. One way to resolve this is to use the “neighboring system rule.” Simplistically, if events on the host system’s facilities can create an “adverse” or “material” impact on a neighboring electric (TO, TOP, BA) system, those facilities should be considered part of the BES as they are creating a reliability impact. If not, these facilities should not be considered part of the BES.</p> <p>V. “Adverse” or “Material” Impact A key question in applying the “neighboring system rule” is what is an “adverse” or “material” impact, and what “performance based” assessment should be used to benchmark adverse or material. Because the electric system within an interconnection is frequency interdependent, theoretically every system change impacts the interconnected system to some degree. Turning on a light-switch that is connected to an operational 20 watt CFL (light bulb) theoretically impacts frequency, although to an undetectable degree. Therefore the term “material” or “adverse” impacts must be defined to distinguish observable impacts that affect reliability from minutia. A number of performance based exclusion examples have been proposed that use, Power Transfer Distribution Factors (“PTDF”), Line Outage Distribution Factors (“LODF”), fault duty or short circuit levels, reactive margin studies (P-V and Q-V), abbreviated or focused powerflow and transient stability analysis, as well as complete TPL assessment using multiple seasonal base cases, loading conditions, transfer levels. These methods demonstrate various metrics, they rank system strength (both real and reactive), the ability of power to flow through system under normal and outage conditions, and they determine steady state, voltage stability and transient (angular) stability performance. Although there may be advantages to a multi-step “performance based” approach that includes the exclusion examples above, this paper proposes a TPL-based assessment that is consistent with BES performance benchmarks used in assessing transmission system performance in North America. The Western Electricity Coordinating Council (“WECC”) BES Exclusion/Inclusion Assessment - 2-16-11 version provides a sound metrics in assessing the performance of a system as well as determining if a system can materially impact a neighboring system (Figure 2). It would be envisioned that each interconnection would develop a “Disturbance Performance Table of Allocable Effects on Other System”. This table is necessary because the NERC TPL Performance Table does not provide actual performance details on acceptable transient and post transient voltage perturbations or minimum transient voltage frequencies. Figure 2 show the approved TPL-001 through TPL-004 performance tables. Figure 3 - Table 1 from the NERC TPL Reliability Standards¶</p> <p>VI. Performance Based Assessment Process The “performance based” methodology below is based on the “neighboring system rule” and the WECC BES Exclusion/Inclusion Assessment - 2-16-11 that was developed by the WECC Bulk Electric System Definition Task Force (“BESDTF”). The process focuses on exclusions rather than inclusion and specific response times, schedules, and process details have been removed as this</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 10 Comment
		<p>will likely need to be determined by each, Regional Entity Representing the Interconnection (“RERI”)</p> <p>A. Purpose The purpose of this document is to set forth a “performance based” technical process for assessing whether elements with a nominal operating voltage greater than 100 kV and outside the NERC SCRC based excursion process should be excluded from the Bulk Electric System. An element is necessary to reliably operate an interconnected transmission system if it significantly affects neighboring Transmission Owners, Operators, and Balancing Authorities as described in Table 1 below. This paper proposes a method for assessing whether an element is necessary to support the reliability of an interconnected transmission system or if the element is limited to supporting local customer service levels.</p> <p>B. TermsExclusion Assessment (EA) An assessment of whether a Subject Element or System has a material impact on neighboring Transmission Owners, Operators, and Balancing Authorities as described in Table 1 below and conducted in accordance with the process set forth in this document.EA Base Case The interconnection approved, Base Case as modified to include the Subject Element, used to perform the assessment described in this document.Regional Entity Representing the Interconnection The regional entity representing the interconnectionRegistered Entity The entity registered to comply with mandatory reliability standards for a Registered Function.Responsible Entity The entity responsible for performing the EA and verifying the results of the EA to the interconnection.Subject System or Element of a System The System or Element of a System that is being examined by the EA.</p> <p>C. Applicabilitya. An EA may be performed:i. By a registered entity, or by a third party on behalf of a registered entity, to assess whether a Subject Element or system has a material impact on neighboring Transmission Owners, Operators, and Balancing Authorities as described in Table 1 may be excluded from the BES as set forth by the RERI. ii. The RERI, or by a third party on behalf of the RERI, to assess whether a Subject Element or system has a material impact on neighboring Transmission Owners, Operators, and Balancing Authorities as described in Table 1 should be included as part of the BES as set by the RERI.b. Frequency of analysis. The confirmed findings of an EA are valid until reversed by a subsequent EA. A new EA is required if:i. Significant changes are made to the network topology in the vicinity of the Subject Element; orii. RERI staff requests a new EA. Such request shall be provided in writing and shall include reasonable justification for the request.</p> <p>D. Notifying the RERI of the Responsible Entity’s intent to submit an EA finding or to perform an EA.The Responsible Entity shall notify the RERI in writing of its intent to submit such a finding. Such notice shall include:a. A general description of the Subject Element(s);b. One-line diagrams representing the Subject Element and applicable neighboring Elements; andc. A description of the base case that will be used in performing the EA and how that case will be stressed for the analysis.</p> <p>E. Performing the Analysis Base Case The base case(s) used for the studies shall be developed from current interconnection Operating Cases and shall simulate stressed conditions in the area of the element to be</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 10 Comment
		<p>analyzed which (1) are reasonably expected to be achieved, consistent with the study period selected (e.g., hydro generation shall reflect seasonal water availability patterns) and (2) are expected to provide “worst-case” results (i.e., the greatest impact on voltage, flow, or transfer capability) during the upcoming operating year. The base case(s) shall be “stressed” by committing or de-committing generating units and adjusting generating unit output to increase the flow on the candidate element and the electrically nearest rated interconnection transfer path to the greatest extent possible, but not beyond their continuous ratings, for the initial set of conditions. To help minimize the possibility of dispute as to whether the base case(s) are suitably stressed, entities are encouraged to solicit input from subregional planning groups or other planning entities as the suitability of the base case(s) before undertaking the analyses described below.</p> <p>i. Non-represented Elements. If the Subject Element is not represented in the EA Base case:</p> <ol style="list-style-type: none"> <li>1. The Responsible Entity shall provide to the RERI a written request to add the Responsible Entities data to the cases:</li> <li>o all data reasonably necessary to accurately and completely model the Subject Element in the EA Base case;</li> <li>and o A one-line diagram showing this element and other nearby Elements. If the nearest connected Element is not found to be necessary for the operation of an interconnected transmission system, the RERI shall notify the Responsible Entity to take no further action.</li> </ol> <p>F. Performance Based Methodology The impact an System or Element has on neighboring Transmission Owners, Operators, and Balancing Authorities as described in Table 1 shall be determined by assessing the performance of key measures of BES reliability through power flow, post-transient, and transient stability analysis with (1) the system, and the Subject Element, operating at reasonably stressed conditions that replicate expected system conditions under which the loss of the Subject Element would have the greatest impact on the key measures of reliability, and (2) the Subject Element removed from service, but without allowing for system readjustment. For the purposes of this analysis, “Elements” may be: (1) lines; (2) transformers; (3) buses or bus sections; (4) generating units; (5) shunt devices .</p> <p>i. Simulation 1: Requirement: Meet applicable NERC Reliability Standard (TPL-002 and TPL-003) and the RERI Disturbance Performance Table of Allocable Effects on Other System” Criteria performance for NERC TPL-002 and TPL-003 disturbances.</p> <p>Step 1: Run appropriate TPL-002 (N-1 contingency) studies of elements in the electrical vicinity of and including the Candidate Element (i.e., simulate primary protection operates as intended)</p> <p>Step 2: Run appropriate TPL-003 (N-2 contingency) studies of elements in the electrical vicinity of and including the Candidate Element. This would include both N-2 contingencies in which the Candidate Element would simultaneously be lost as part of a common mode failure, as well as contingencies in which the Candidate Element’s primary protection fails.</p> <p>Automatic Remedial Action Schemes (“RAS”) or Special Protection Schemes (“SPS”) that are fully redundant (i.e., their failure is not credible) may be triggered during this simulation. If the failure of the RAS/SPS is a credible event, it should be considered as part of the N-2 analysis.</p> <p>ii. Simulation 2: Requirement: Remove the Candidate Element. Do not allow for system adjustment, and re-solve the base case. Then conduct applicable NERC Reliability Standard (TPL-002 and TPL-003) contingencies. Step 1: Remove Candidate Element (i.e., simulate unplanned opening of</p>

Voltage Performance Parameters RERI TPL criteria related to reactive power resources:1. For transfer paths, voltage stability is required with the pre-contingency path flow modeled at a minimum of 105% of the path rating for system normal conditions (Category A) and for single contingencies (Category B). For multiple contingencies (Category C), post-transient voltage stability is required with the pre-contingency transfer path flow modeled at a minimum of 102.5% of the path rating.2. For load areas, voltage stability is required for the area modeled at a minimum of 105% of the reference load level for system normal conditions (Category A) and for single contingencies (Category B). For multiple contingencies (Category C), post-transient voltage stability is required with the area modeled at a minimum of 102.5% of the reference load level. For this criterion, the reference load level is the maximum established planned load limit for the area under study.3. Specific requirements that exceed the minimums specified in 1 and 2 may be established, to be adhered to by others, provided that technical justification has been approved by the RERI.4. Item 3 applies to internal interconnection Systems.Submitting a Proposed Finding of Exclusion to the Regional EntityInformation required. Once the analysis has been performed and the Subject Element/System has been determined to not have a material impact on neighboring Transmission Owners, Operators, and Balancing Authorities as described in Table 1, and is unnecessary for the operation of an interconnected transmission system, the Responsible Entity shall submit the findings to the RERI.RERI Review of Proposed Findings The RERI operational/planning staff with technical expertise in powerflow studies shall review Proposed Findings of Exclusion submittals and shall determine if the assessment is deficient or agrees with the finding of exclusion. The RERI shall exempt the system elements from the BES, if the elements are approved for exclusion. If the exclusion of the BES elements change the Responsible Entities NERC functional registrations the Region shall support the Responsible Entity through the NERC deregistration process.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 10 Comment
		<p>Dispute Resolution A Responsible Entity or Registered Entity or Owner may appeal a Disputed Finding of Exclusion with the RERI to NERC.</p> <p>Ongoing Responsibilitiesa. Logging. The RERI shall create and maintain a comprehensive list, available for public review, of:i. All Elements with nominal operating voltages at or above 100 kV that have Confirmed Findings of Exclusion, or, through other aspects of the BES definition, have been excluded from the BES including an explanation of how the element was excluded through the definition;ii. All Elements with nominal operating voltages below 100 kV that have Findings of Inclusion; andiii. The status of all EAs in dispute.iv. The Responsible Entity would continue to provide system data to the neighboring Balancing Authorities and Transmission Owners and Operators and if applicable continue to coordinate underfrequency load shed and under voltage load shed scheme information.VII. Conclusion NERC should adopt the TPL-based assessment as proposed herein. A bright-line BES test will not exclude all load distribution facilities as required by the FPA. Further, a performance-based exemption process would be objective, consistent, and transparent, and would adequately differentiate between local distribution and transmission, i.e., BES, facilities.</p>
American Transmission Company, LLC	Yes	<ol style="list-style-type: none"> <li>1. ATC proposes replacing the wording in the Exclusion preface, Exclusion 2 preface, and Inclusion 1 preface of “not necessary to reliably operate the interconnected transmission network” with “necessary to maintain an Adequate Level of Reliability (ALR) of the Bulk Electric System”.</li> <li>2. ATC has reservations on the following statement made in the introduction of this document:” Due to the importance of Blackstart Resources and their designated blackstart Cranking Paths to restoration efforts, no exceptions will be allowed for those items.” This does not allow for a provision to exclude any designated Blackstart Cranking Path (at any voltage) even though there may be technical justification for it.</li> <li>3. The first page states that “Specific content of this application is spelled out elsewhere in this appendix.” ATC requests the SDT describe where this appendix will be published. Furthermore, is it a compliance document or just technical “guidance”?</li> <li>4. Having the following statement included for both exclusions and inclusions will create disagreement:”The ERO can override this criterion but would need to provide additional justification to support their finding.” ATC believes any override should have adequate technical justification and not interfere with other statutory requirements. Also, it does not clarify or identify who would make the determination whether NERC has made adequate justification to override the criterion.</li> </ol>
Manitoba Hydro	Yes	<p>The exception procedure is a complicated and resource intensive process. To be most effective, the BES definition should be a stand-alone 100kV bright line with any exception criteria being specified within the definition. Additionally:-FERC Order 743 directed the revision of the Bulk Electric System (BES) definition to improve clarity, to reduce ambiguity, and to establish consistency across all Regions. The proposed impact</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 10 Comment
		<p>based exception procedure undermines all three of these targets. -The Technical Exceptions eliminate the 100kV 'bright-line' definition and introduce regional differences, both of which are contradictory to the goals of the BES revision project. -The commitment for NERC to review and continuously monitor BES exceptions made through this process would be extremely onerous and resource intensive with little benefit to reliability. -To obtain industry consensus on the precise limits to determine if an element has sufficient impact on the BES to be included in the BES is not a reasonable or attainable endeavor.</p>
NESCOE	Yes	<p>NESCOE believes that exclusion determinations should be based on clear but flexible criteria that do not result in the unnecessary inclusion of elements into the BES that do not adversely impact the reliability of the BES. The process described here is too limiting in its requirement that an application meet all of those four listed criteria not requiring technical analysis.</p> <p>Applicants and reviewers should have a broader menu of decision criteria available to them.</p> <p>Regarding those criteria related to exclusions based on technical analysis, NESCOE suggests that ranges of values, in recognition of regional differences in network characteristics, be suggested by the drafting team for further consideration.</p> <p>Finally, as discussed above in response to questions 1 through 4, NESCOE believes that additional exclusion determinations should not require a finding that all four proposed criteria are met. Rather, the various criteria set forth under 1(a) through 1(d) should be treated as alternative criteria to qualify for an additional exclusion, and entities seeking additional exclusions to the BES should be allowed to demonstrate that one or more criteria is met, depending on the nature of the element that is the subject of the application.</p>
<p><b>Response:</b> The SDT appreciates your comments. Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity's characteristics to a defined value and/or limit. It has become apparent that it is not feasible to establish continent-wide values and/or limits due to differences in operational characteristics. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the Rules of Procedure as presently being drafted.</p>		
Edison Electric Institute	Yes	<p>We are concerned that the method used to characterize exclusions in Method 1 did not follow the proposed BES Definition and believe the process developed for Method 2 (and reused for Sub-100kV Inclusions) is overly complicated, lacks necessary regional standards to support the process and may prove too difficult for some companies to fully comply with thereby discouraging a consistent and uniform application of the</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 10 Comment
		<p>definition across all regions and affected BES element owners.</p> <p>In the proposed (BES) definition and accompanying Inclusions and Exclusions, the Drafting Committee went to some effort to clearly and methodically define what was included and what was permissible to exclude. Unfortunately the NERC proposed “Technical Principles for Demonstrating BES Exceptions” did not follow that same clear and concise manner adding some confusion which could lead to inconsistent application of the Exclusion (and Inclusion) Criteria. For example, at no point did the “Principles” ever identify Inclusions I2 through I5 which were liberally used in the exclusion criteria within the BES definition.</p> <p>Additionally within the body of the Proposed BES definition, there are three (3) approved Exclusions (E1 - Radial System; E2 - Small Customer Generator/Generation System and E3 - Local Distribution Networks). Each of the Exclusions have its own set of criteria used to define and characterize the methodology necessary to meet each exclusion, however, the “Principles” contained in this document only loosely follow the criteria provided and in some cases miss that criteria all together.</p> <p>We refer the SDT to the EEI comments previously submitted on the BES Definition regarding the relationship of the BES definition to the statutory exclusion of local distribution facilities.</p>
PPL Supply	Yes	<p>General PPL Supply concerns with draft Technical Principles for exclusion/inclusion:1. It may be premature to work on an exclusion/exemption/inclusion process since the BES definition is not established yet. A lot of work could be done on the Exclusion/Inclusion that is meaningless because there is some chance the exclusion/inclusion process will not complement or might duplicate the BES definition.</p> <p>2. The proposal will result in inclusion of generation facilities that are not significant to BES reliability.</p> <p>3. The exclusion/inclusion drafting team does not appear to have considered the FERC assessment in Order 743-A (17-Mar-11) that “material impact assessments” cannot be unduly subjective and must be technically based as stated in paragraph 47.</p> <p>a. For the material impact tests in the Exclusion/Inclusion Technical Principles to be technically based, it is important that the tests actually measure what FERC states are the characteristics of the BES (see Order 743 paragraph 73), namely 1) operate in parallel, 2) carry significant amounts of generation, 3) operate as part of a defined flowgate, 4) are parallel in nature and 5) are capable of causing or contributing to significant disturbances. The proposed tests do not make these measurements.</p> <p>b. Further, since all facilities already meet the technically based NERC planning and operating standards, any additional measure beyond these standards such as those created by the BES Exclusion/Inclusion drafting team will be unduly subjective, as these new measures go beyond the technical basis of the NERC standards.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 10 Comment
		<p>4. It is unclear how the exclusion/inclusion drafting team considered FERC’s concerns with the use of “material impact assessments,” as described in Order 743, paragraph 85 (“no grounds on which to reasonably assume that the results of the material impact assessment are accurate, consistent, and comprehensive”). Specific comments on Technical Principles paper from NERC DT 20110510A. Please add wording to make complete sentences as needed in order to clarify whether facilities meeting these criteria are included or excluded. For example, the clarifying words are added to the following Exclusion 1 to help the reader better understand the meaning. 1. “The elements that meet all of the following characteristics are not necessary for the reliable operation of the grid and are thus excluded:”a. System elements that are located in close electrical proximity to Load are exempt from inclusion in the BES.B. Notwithstanding the need for complete sentences to assure proper interpretation, the following comments should be considered by the drafting team:</p> <ul style="list-style-type: none"> <li>o Exclusion 1 a) uses an unduly subjective, non-technically based material impact test.</li> <li>o Exclusion 1 b) i and ii attempts to introduce disconnect procedures in the classification as “radial” which may hurt reliability by disconnecting radial equipment that could provide voltage support. The exclusion also introduces commercial (dispatch) considerations which may not be appropriate in a reliability-based document.</li> <li>o Exclusion 1 c) assuming “system” is short for “system elements”, this requirement for exclusion is overly discriminatory to generators which flow power out.</li> <li>o Exclusion 1 d) is too vague to be useful because “system” seems to have more than one meaning in this requirement.</li> <li>o Exclusion 2 and Inclusion 1 in their entirety are unduly subjective, non-technically based material impact tests. We are concerned that the proposed inclusion and exclusion procedures could result in not only significant generation interconnection facilities being included in the BES - but also less significant generation interconnection facilities. Such a result would be inconsistent with FERC Order 743.</li> </ul> <p>Accordingly, PPL Supply respectfully requests NERC to:</p> <ul style="list-style-type: none"> <li>o Exclude radial facilities less than 100 kV and not black start (these facilities are excluded in the latest definition of the BES).</li> <li>o Exclude radial facilities greater than 100 kV but less than 200 MVA (proposed BES now includes generators over 20 MVA)</li> <li>o Exclude local distribution networks (LDNs) with flow into network up to 200 MVA</li> <li>o Currently, LDNs are excluded if they only absorb (not produce) net power (Technical Principles Exclusion 1-c). It is also appropriate to exclude LDNs with less than net 200 MVA flow into the BES electrical network.</li> <li>o Inclusion efforts should not consider such issues as proximity to markets, proximity to load or nuclear facilities, or length of generator lead line.</li> </ul>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 10 Comment
Independent Electricity System Operator	Yes	<p>We hold the view that the path to generating facilities need not be always BES contiguous. Generating units should be required to meet a subset of NERC Standards, but should not always require contiguous BES paths.</p> <p>Finally, we reiterate that exception criteria should be crafted at a high-level with key menu items of assessment that can be followed continent-wide by entities to put forward their exception for element(s) that are not necessary for the interconnected transmission network and based on technical assessment, evidence and justification for its unique characteristics, configuration, and utilization.</p>
<p><b>Response:</b> The SDT has responded to comments on the BES definition in the Consideration of Comments form for the BES definition posting.</p> <p>The SDT appreciates the comments and suggestions for the technical exception criterion. Based on industry response and further analysis, the SDT has abandoned the initial exclusion criteria and developed a new methodology is intended to clarify the technical and operational characteristics that are to be considered in identifying exceptions, and provide greater continuity with the existing definition of BES. The initial proposal was dependent on a comparison of an entity's characteristics to a defined value and/or limit. It has become apparent that it is not feasible to establish continent-wide values and/or limits due to differences in operational characteristics. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of an exception request form along with any other supporting documentation for the exception being sought. Electric Market Policy	Yes	<p>Although Dominion didn't see a specific form to address comments on Appendix 5B to the NERC ROP, Dominion would like to point out a particular area of concern with that Appendix. Dominion requests that NERC include explicit language stating that exclusion or inclusion of an element (for compliance purposes) begins only after approval/disapproval and any associated appeal has been reviewed and a final decision reached. Dominion would also like to point out that it assisted in the preparation of the Edison Electric Institute's comments and therefore agrees with the comments raised by EEI.</p>
<p><b>Response:</b> The SDT has forwarded your comments to the RoP team for their consideration.</p>		
Pepco Holdings Inc	Yes	<p>Concern that as this proposal is written such that each exclusion in the BES definition (E1, E2 and E3) will require a submittal to approve that is an exclusion.</p>
City of Redding	Yes	<p>The SDT is encouraged to address generators installed as load modifiers to distribution load.&gt;&gt;&gt;&gt;</p> <p>As additional evidence of distribution line, if there is not an OATT filed on a line then it is not transmission per FERC rules.</p>

**Consideration of Comments on Definition of the Bulk Electric System (BES) Technical Principles for Demonstrating BES Exceptions — Project 2010-17**

Organization	Yes or No	Question 10 Comment
Tacoma Power	Yes	<p>Tacoma Power supports the SDT’s efforts to create an acceptable BES definition directly linked to an exception process. We do have a concerned about the application of the standards to Elements that change status due to the Exception process. Any Elements that are determined to be newly included in the BES should have a 24-month period before the standards will apply as a BES Elements. Conversely, a determination that removes an Element from the BES should apply as soon as practicable.</p> <p>Please be aware that the WECC has a task force, the Bulk Electric System Definition Task Force(BESDTF), which has done some notable work on this task. See WECC BESDTF Proposal 6, Appendix C (<a href="http://www.wecc.biz/Standards/Development/BES/default.aspx">http://www.wecc.biz/Standards/Development/BES/default.aspx</a>).</p> <p>The BES definition is very complex and the BESDTF has already addressed many of the tough issues that have yet to be addressed in this process, such as:</p> <ul style="list-style-type: none"> <li>o Local Distribution Network definition for automatic exemption</li> <li>o Determination of radial facilities</li> <li>o Demarcation of BES and non-BES Elements</li> <li>o Alternate dispute resolution process</li> <li>o Assignment of the burden of proof for the exemption process</li> <li>o Technical approach for the inclusion/exclusion determination</li> </ul> <p>Thank you for consideration of our comments.</p>
<p><b>Response:</b> The SDT has addressed comments on the BES definition under the Consideration of Comments form for the BES definition posting.</p>		

**END OF REPORT**

## **Detailed Information to Support an Exception Request**

---

Entities that have Element(s) designated as excluded, under the BES definition and designations, do not have to seek exception for those Elements under the Exception Procedure.

### **General Instructions:**

A one-line breaker diagram identifying the facility for which the exception is requested must be supplied with every application. The diagram(s) supplied should also show the Protection Systems at the interface points associated with the Elements for which the exception is being requested.

Entities are required to supply the data and studies needed to support their submittal. Studies should:

- Be based on an Interconnection-wide base case that is suitably complete and detailed to reflect the facility's electrical characteristics and system topology
- Clearly document all assumptions used
- Address key performance measures of BES reliability through steady-state power flow, and transient stability analysis as necessary to support the entity's application, consistent with the methodologies described in the Transmission Planning (TPL) standard and commensurate with the scope of the request

Supporting statements for your position from other entities are encouraged.

List any attached supporting documents:

**Detailed Information to Support an Exception Request**

**For Transmission Facilities:**

1. Is there generation connected to the facility?

Yes     No

If yes, what are the individual gross nameplate values of each unit?

Description/Comments:

2. How does the facility impact permanent Flowgates in the Eastern Interconnection, major transfer paths within the Western Interconnection, or a comparable monitored facility in the ERCOT Interconnection or the Quebec Interconnection?

Please list the Flowgates or paths considered in your analysis along with any studies or assessments that illustrate the degree of impact:

3. Is the facility included in an Interconnection Reliability Operating Limit (IROL) in the Eastern Interconnection, ERCOT Interconnection, or Quebec Interconnection or a major transfer path rating in the Western Interconnection?

Yes     No

Please provide the appropriate list for your operating area:

4. How does an outage of the facility impact the over-all reliability of the BES? Please provide study results that demonstrate the most severe system impact of the outage of the facility and the rationale for your response:

**Detailed Information to Support an Exception Request**

5. Is the facility used for off-site power supply to a nuclear power plant as designated in a mutually agreed upon Nuclear Plant Interface Requirement (NPIR)?

Yes     No

Description/Comments:

6. Is the facility part of a Cranking Path associated with a Blackstart Resource?

Yes     No

Description/Comments:

7. Does power flow through this facility into the BES?

Yes     No

If yes,     under 10% of the calendar year     10% - 25% of the calendar year  
               25% - 50% of the calendar year     More than 50% of the calendar year

If yes, then using metered or SCADA data for the most recent consecutive two calendar year period, what is the minimum and maximum magnitude of the power flow out of the facility and describe the conditions when this could occur?

## Detailed Information to Support an Exception Request

### For Generation Facilities:

1. What is the MW value of the host Balancing Authority's most severe single Contingency and what is the generator's, or generator facility's, percent of this value?

Please provide the values and a reference to supporting documents:

2. Is the generator or generator facility used to provide Ancillary Services?

Yes  No

Describe what Ancillary Services the generator or generator facility is supplying:

3. Is the generator designated as a must run unit?

Yes  No

Please provide the appropriate reference for your operating area:

4. How does an outage of the generator impact the over-all reliability of the BES? Please provide study results that demonstrate the most severe system impact of the outage of the generator and the rationale for your response:

5. Does the generator use the BES to deliver its actual or scheduled output, or a portion of its actual or scheduled output, to Load?

Yes  No

Description/Comments:

## **Comment Form for 2<sup>nd</sup> Draft of Project 2010-17: Definition of BES (BES) Technical Principles for Demonstrating BES Exceptions**

---

Please **DO NOT** use this form to submit comments on the second draft of the Project 2010-17: Definition of the Bulk Electric System (BES) Exception Criteria. Use the [electronic comment form](#) **only** to submit comments on the second draft Exception Criteria. Comments must be submitted by **October 10, 2011**.

### **Background Information Definition of the BES (Project 2010-17) Technical Principles for Demonstrating BES Exceptions**

In parallel with the definition project, another stakeholder team outside the standards development process has been set up to develop a change to the NERC Rules of Procedure (RoP) to allow for entities to apply for excluding Elements from the BES that might otherwise be included according to the proposed definition and designations. This same process would be used by Registered Entities to justify including Elements in the BES that might otherwise be excluded according to the proposed definition and designations. The RoP team will develop the process for seeking an exception from the definition and designations, but the Definition of the BES Standards Drafting Team (DBESSDT), through the standards development process, has developed the criteria necessary for applying for an exception.

The exception process has been set up as a checklist of items that an entity requesting an exception should supply to the Regional Entity as the first step in the process described in the Rules of Procedure. The same checklist will be utilized for exceptions dealing with inclusions or exclusions. The intent of the SDT is to standardize the types of information that must be supplied when seeking an exception to the extent possible. This will allow for the Regional Entities to process the requests based on standardized evidence and for the ERO to make the eventual decision on the request based on this standardized evidence. This is a significant departure from the first posting on this topic. Based on industry response from that posting and further analysis the SDT has abandoned the initial exclusion criteria and developed this new methodology that it believes will provide more clarity and continuity to the process. The initial proposal was dependent on a comparison of an entity's characteristics to a defined value and/or limit. However, it has become apparent that it is not feasible to establish continent-wide values and/or limits due to differences in operational characteristics. The new process requires an entity to clarify the characteristics of the facilities in question and to document the operational performance as appropriate through submittal of the Detailed Information to Support an Exception Request along with any other supporting documentation for the exception being sought. The appropriate Regional Entity will review the submittal to validate information, make a recommendation of whether or not to support the exclusion or inclusion, and then file the request and recommendation with the ERO as established in the Rules of Procedure as presently being drafted and posted for comment. An ERO panel as described in the Rules of Procedure presently being drafted and posted for comment will then make the decision on the exception. At this point, the engineering judgment of the ERO panel will be utilized. Using the request document to dictate the type of supporting material that needs to be supplied plus having a common panel perform the evaluations will result in an open, transparent, and consistent process.

**Comment Form for 2<sup>nd</sup> Draft of Project 2010-17: Definition of BES (BES)**  
**Technical Principles for Demonstrating BES Exceptions**

The SDT is seeking industry feedback on the approach being presented. Comments received from this posting will help to determine the final criteria that the industry will be required to adhere to. Therefore, industry feedback is vital to the development process.

It should be noted that the actual application process is described in the Rules of Procedure document that will be posted separately from the exception criteria document.

## Standards Announcement

### Project 2010-17 BES Definition

Two Ballot Pool Windows Open August 26 – September 26, 2011

Two Formal Comment Periods Open August 26 – October 10, 2011

Two Ballot Windows Open September 30 – October 10, 2011

Available tomorrow at: <https://standards.nerc.net/BallotPool.aspx>

The Definition of Bulk Electric System Standard Drafting Team (DBES SDT) has posted a second draft of the Definition of Bulk Electric System (BES) and associated implementation plan for a formal 45-day comment period, through **8 p.m. Eastern on Monday, October 10, 2011**.

The Definition of Bulk Electric System Standard Drafting Team (DBES SDT) has also posted a draft application form titled *Detailed Information to Support an Exception Request* referenced in the Rules of Procedure Exception Process for a formal 45-day comment period, through **8 p.m. Eastern on Monday, October 10, 2011**. (Note that the information contained in this draft form includes revisions made to the *Technical Principles for Supporting BES Exceptions* that was posted for comment in May and June 2011.)

A separate team is working with NERC to draft a new Appendix 5C to NERC's Rules of Procedure to address the process for requesting BES exceptions. This team will be posting the Rules of Procedure changes for stakeholder comment in September. The comment period for the Rules of Procedure changes will overlap the comment period for the definition and application form, to provide an opportunity for stakeholders to review all three documents to understand how they will work together.

Clean and redline versions of the definition and associated implementation plan, along with a technical justification for the Local Network exclusion and a clean version of the application form titled *Detailed Information to Support an Exception Request* have been posted on the project page at: [http://www.nerc.com/filez/standards/Project2010-17\\_BES.html](http://www.nerc.com/filez/standards/Project2010-17_BES.html). The format of the application form titled *Detailed Information to Support an Exception Request* has changed substantially since the first posting, making a redline impractical, so none has been provided.

The Standards Committee and NERC Board of Trustees have recommended that the drafting team address issues such as generation thresholds in a second phase of this project. This approach will ensure that the drafting team has sufficient time to adequately consider and develop a sound technical basis for an approach, and will allow the drafting team to meet the regulatory deadline in FERC Orders 743 and 743a (filing by January 25, 2012). The drafting team has posted a **draft** Supplemental Standards Authorization Request (SAR) for information purposes only; the SAR will be posted for comment at a future time.

## Ballot Pools Forming

During the first 30 days of the comment period, two separate ballot pools will be formed: one for balloting the Definition of Bulk Electric System, and a second for balloting the application form titled *Detailed Information to Support an Exception Request*. The ballot pool windows will be open from **Friday, August 26 through 8 a.m. Eastern on Monday, September 26, 2011**.

During the final 10 days of the comment period, two separate initial ballots will be conducted, one for the Definition of the Bulk Electric System, and a second for the application form titled *Detailed Information to Support an Exception Request*. The ballot windows will begin on Friday, September 30th and end at 8 p.m. Eastern on Monday, October 10, 2011.

## Instructions for Joining Ballot Pools

Registered Ballot Body members must join each of the ballot pools to be eligible to vote in the upcoming ballots at the following page: <https://standards.nerc.net/BallotPool.aspx>

During the pre-ballot window, members of each ballot pool may communicate with one another by using their “ballot pool list server.” (Once the balloting begins, ballot pool members are prohibited from using the ballot pool list servers.) The list servers for this project are:

- Definition of BES ballot:  
[bp-2010-17\\_BES\\_Def\\_in@nerc.com](mailto:bp-2010-17_BES_Def_in@nerc.com)
- *Detailed Information to Support an Exception Request* form:  
[bp-2010-17\\_TechInfo\\_BES\\_in@nerc.com](mailto:bp-2010-17_TechInfo_BES_in@nerc.com)

## Instructions for Submitting Comments

Please use this [electronic comment form](#) to submit comments on the Definition of Bulk Electric System. Please use this separate [electronic comment form](#) to submit comments on the draft form application form titled *Detailed Information to Support an Exception Request*.

If you experience any difficulties in using either of these electronic forms, please contact Monica Benson at [monica.benson@nerc.net](mailto:monica.benson@nerc.net). An off-line, unofficial copy of each comment form is posted on the project page:

## Background

On November 18, 2010 FERC issued [Order 743 \(amended by Order 743A\)](#) and directed NERC to revise the definition of Bulk Electric System so that the definition encompasses all Elements and Facilities necessary for the reliable operation and planning of the interconnected bulk power system. Additional specificity will reduce ambiguity and establish consistency across all Regions in distinguishing between BES and non-BES Elements and Facilities.

In addition, NERC was directed to develop a process for identifying any Elements or Facilities that should be excluded from the BES. NERC is working to address these directives with two activities – the definition of Bulk Electric System (BES) is being revised through the standard development process and a BES Definition Exception Process is being developed as a proposed modification to the Rules of Procedure. The work of the BES Definition Exception Process has been publicly posted at: [http://www.nerc.com/filez/standards/Rules\\_of\\_Procedure-RF.html](http://www.nerc.com/filez/standards/Rules_of_Procedure-RF.html). The Rules of Procedure team expects to post the next draft of its proposed addition to the Rules of Procedure (Appendix 5C – BES Exception Process) in September.

*For more information or assistance, please contact Monica Benson,  
Standards Process Administrator, at [monica.benson@nerc.net](mailto:monica.benson@nerc.net) or at 404-446-2560.*

## Standards Announcement

### Project 2010-17 BES Definition

Two Ballot Pool Windows Open August 26 – September 26, 2011

Two Formal Comment Periods Open August 26 – October 10, 2011

Two Ballot Windows Open September 30 – October 10, 2011

Available tomorrow at: <https://standards.nerc.net/BallotPool.aspx>

The Definition of Bulk Electric System Standard Drafting Team (DBES SDT) has posted a second draft of the Definition of Bulk Electric System (BES) and associated implementation plan for a formal 45-day comment period, through **8 p.m. Eastern on Monday, October 10, 2011**.

The Definition of Bulk Electric System Standard Drafting Team (DBES SDT) has also posted a draft application form titled *Detailed Information to Support an Exception Request* referenced in the Rules of Procedure Exception Process for a formal 45-day comment period, through **8 p.m. Eastern on Monday, October 10, 2011**. (Note that the information contained in this draft form includes revisions made to the *Technical Principles for Supporting BES Exceptions* that was posted for comment in May and June 2011.)

A separate team is working with NERC to draft a new Appendix 5C to NERC's Rules of Procedure to address the process for requesting BES exceptions. This team will be posting the Rules of Procedure changes for stakeholder comment in September. The comment period for the Rules of Procedure changes will overlap the comment period for the definition and application form, to provide an opportunity for stakeholders to review all three documents to understand how they will work together.

Clean and redline versions of the definition and associated implementation plan, along with a technical justification for the Local Network exclusion and a clean version of the application form titled *Detailed Information to Support an Exception Request* have been posted on the project page at: [http://www.nerc.com/filez/standards/Project2010-17\\_BES.html](http://www.nerc.com/filez/standards/Project2010-17_BES.html). The format of the application form titled *Detailed Information to Support an Exception Request* has changed substantially since the first posting, making a redline impractical, so none has been provided.

The Standards Committee and NERC Board of Trustees have recommended that the drafting team address issues such as generation thresholds in a second phase of this project. This approach will ensure that the drafting team has sufficient time to adequately consider and develop a sound technical basis for an approach, and will allow the drafting team to meet the regulatory deadline in FERC Orders 743 and 743a (filing by January 25, 2012). The drafting team has posted a **draft** Supplemental Standards Authorization Request (SAR) for information purposes only; the SAR will be posted for comment at a future time.

## Ballot Pools Forming

During the first 30 days of the comment period, two separate ballot pools will be formed: one for balloting the Definition of Bulk Electric System, and a second for balloting the application form titled *Detailed Information to Support an Exception Request*. The ballot pool windows will be open from **Friday, August 26 through 8 a.m. Eastern on Monday, September 26, 2011**.

During the final 10 days of the comment period, two separate initial ballots will be conducted, one for the Definition of the Bulk Electric System, and a second for the application form titled *Detailed Information to Support an Exception Request*. The ballot windows will begin on Friday, September 30th and end at 8 p.m. Eastern on Monday, October 10, 2011.

## Instructions for Joining Ballot Pools

Registered Ballot Body members must join each of the ballot pools to be eligible to vote in the upcoming ballots at the following page: <https://standards.nerc.net/BallotPool.aspx>

During the pre-ballot window, members of each ballot pool may communicate with one another by using their “ballot pool list server.” (Once the balloting begins, ballot pool members are prohibited from using the ballot pool list servers.) The list servers for this project are:

- Definition of BES ballot:  
[bp-2010-17\\_BES\\_Def\\_in@nerc.com](mailto:bp-2010-17_BES_Def_in@nerc.com)
- *Detailed Information to Support an Exception Request* form:  
[bp-2010-17\\_TechInfo\\_BES\\_in@nerc.com](mailto:bp-2010-17_TechInfo_BES_in@nerc.com)

## Instructions for Submitting Comments

Please use this [electronic comment form](#) to submit comments on the Definition of Bulk Electric System. Please use this separate [electronic comment form](#) to submit comments on the draft form application form titled *Detailed Information to Support an Exception Request*.

If you experience any difficulties in using either of these electronic forms, please contact Monica Benson at [monica.benson@nerc.net](mailto:monica.benson@nerc.net). An off-line, unofficial copy of each comment form is posted on the project page:

## Background

On November 18, 2010 FERC issued [Order 743 \(amended by Order 743A\)](#) and directed NERC to revise the definition of Bulk Electric System so that the definition encompasses all Elements and Facilities necessary for the reliable operation and planning of the interconnected bulk power system. Additional specificity will reduce ambiguity and establish consistency across all Regions in distinguishing between BES and non-BES Elements and Facilities.

In addition, NERC was directed to develop a process for identifying any Elements or Facilities that should be excluded from the BES. NERC is working to address these directives with two activities – the definition of Bulk Electric System (BES) is being revised through the standard development process and a BES Definition Exception Process is being developed as a proposed modification to the Rules of Procedure. The work of the BES Definition Exception Process has been publicly posted at: [http://www.nerc.com/filez/standards/Rules\\_of\\_Procedure-RF.html](http://www.nerc.com/filez/standards/Rules_of_Procedure-RF.html). The Rules of Procedure team expects to post the next draft of its proposed addition to the Rules of Procedure (Appendix 5C – BES Exception Process) in September.

# Standards Announcement

## Project 2010-17 Definition of Bulk Electric System Initial Ballot Results

[Now available](#)

### Ballot Results for Definition of Bulk Electric System

The two ballots windows for Project 2010-17 Definition of Bulk Electric System (BES): the first for the definition of Bulk Electric System and associated implementation plan, and the second for the draft application form titled Detailed Information to Support an Exception Request referenced in the Rules of Procedure Exception Process closed at 8 p.m. Eastern on Monday, October 10, 2011.

Voting statistics for each ballot are listed below, and the [Ballot Results](#) Web page provides a link to the detailed results.

BES Definition	Technical Criteria to Support a BES Exception Request
Quorum: 92.97%	Quorum: 89.53%
Approval: 71.68%	Approval: 64.03%

### Next Steps

The drafting team will consider all comments received, and decide whether to make additional revisions to the definition of Bulk Electric System, the associated implementation plan, and the application form titled *Detailed Information to Support an Exception Request* referenced in the Rules of Procedure Exception Process. The drafting team is working to meet the regulatory deadline established in FERC Orders 743 and 743A (filing by January 25, 2012).

The Standards Committee and NERC Board of Trustees have recommended that the drafting team address issues such as generation thresholds in a second phase of this project. This approach will ensure that the drafting team has sufficient time to adequately consider and develop a sound technical basis for an approach, and will allow the drafting team to meet the regulatory deadline in FERC Orders 743 and 743A (filing by January 25, 2012). The drafting team has posted a **draft** Supplemental Standards Authorization Request (SAR) for information purposes only; the SAR will be posted for comment at a future time. Additionally, the drafting team has posted a [Fact Sheet](#), which provides an up to date review of the project scope, project plan - phased approach, current status and upcoming events, on the [project webpage](#).

### **Project Background**

On November 18, 2010 FERC issued [Order 743 \(amended by Order 743A\)](#) and directed NERC to revise the definition of Bulk Electric System so that the definition encompasses all Elements and Facilities necessary for the reliable operation and planning of the interconnected bulk power system. Additional specificity will reduce ambiguity and establish consistency across all Regions in distinguishing between BES and non-BES Elements and Facilities.

In addition, NERC was directed to develop a process for identifying any Elements or Facilities that should be excluded from the BES. NERC is working to address these directives with two activities – the definition of Bulk Electric System is being revised through the standard development process and a BES Definition Exception Process is being developed as proposed modifications to the Rules of Procedure. The proposed modifications have been posted for a comment period through October 27, 2011. The work of the BES Definition Exception Process has been publicly posted at: [http://www.nerc.com/filez/standards/Rules\\_of\\_Procedure-RF.html](http://www.nerc.com/filez/standards/Rules_of_Procedure-RF.html).

### **Standards Development Process**

The [Standard Processes Manual](#) contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate. For more information or assistance, please contact Monica Benson at [monica.benson@nerc.net](mailto:monica.benson@nerc.net).

How an exception application will be assessed by the RE and NERC is not addressed in the document. Stakeholders need to know how the exception application will be evaluated and processed. Suggest that the SDT develop a reference or a guidance document as part of the RoP that will provide guidance to Registered Entities, Regional Entities and the ERO on how an exception application will be processed. Of particular concern is the lack of clarity and specificity with respect to what analyses and study results are required under the third bullet on page 1 and under question 4 on both pages 2 and 4. This lack of clarity and specificity will lead to inconsistent application of the Technical Principles by both Registered Entities and Regional Entities. We recommend the following: the impact and performance analyses required by the 3rd bullet on page 1 and by #4 on pages 2 and 4 should be stipulated to be all analyses, scenarios, and contingencies required under NERC Standard TPL-002-1 with the "exception element" removed from the base system model. Entities shall report on all key

performance measures of BES reliability specified in the TPL-002-1 attributable to the removed "exception element". On page 1 under General Instructions, it is stated that: "A one-line breaker diagram identifying the facility for which the exception is requested must be supplied with every application. The diagram(s) supplied should also show the Protection Systems at the interface points associated with the Elements for which the exception is being requested." What is meant by interface points?

No

For question 2 on page 2 For Transmission Facilities: • What standards will define the "impact"? • What is a material impact and a non-material impact? • What kinds and types of impacts are acceptable/unacceptable? • How are impacts determined? Question 6 on page 3 reads "Is the facility part of a Cranking Path associated with a Blackstart Resource?", suggest removing the reference to "Cranking Path" because the Drafting Team does not require that the BES be contiguous, and black start resource Cranking Paths were deleted from Inclusion I3. Question 7 on page 3 asks, "Does power flow through this facility into the BES?" This can only apply to a Local Network with two or more connections to the BES. No power should normally flow through a Local Network (or Radial system) to another portion of the BES. There may be occasional, brief reverse power flows may be acceptable during short periods under abnormal operating conditions. Question 7 also requests "data for the most recent consecutive two calendar year period." Why is two years worth of data necessary? One year of data would be sufficient. From Question 7, "what is the minimum and maximum magnitude of the power flow out of the facility ..." What is intended by the use of magnitude? Suggest that the Drafting Team adopt the FERC Seven Factor test for question 7. Suggest deleting the "% of the calendar year" check boxes in favor of a statement either that power does not flow through the Local Network, or alternatively, a blank space for reporting the net peak MWs and MWHs transferred annually through the facility, and the percentage of these transferred amounts to the peak and annual MWH demands served by the Local Network. Suggest requesting only one year (8,760 hours) of data covering four seasons, including Summer and Winter capability periods.

No

This Application generally applies to traditionally fueled generating facilities. Application form and justifications would be required for non-traditional resources such as solar and wind? Question 2 on page 4 asks, "Is the generator or generator facility used to provide Ancillary Services?" If some of these Generator check list items are market-related and not reliability-related, they should not be present. If the Ancillary Services are reliability-related, please explain their relation to BES reliability. Suggest inserting the word "reliability" before the words "must run" in question 3. Question 5 on page 4 asks, "Does the generator use the BES to deliver its actual or scheduled output, or a portion of its actual or scheduled output, to Load?" This could mean the generator may serve local loads through non-BES facilities. In order to serve these local loads the generator would need to be connected to a Radial system, a Local Network or to local distribution facilities. Is this what is intended? Were there any other possibilities envisioned by the BES SDT?

No

According to the Applicability section, the TPL Reliability Standards are only applicable to the Planning Coordinator (PC) and the Transmission Planner (TP). Was it the BES SDT's assumption that Applicants would have the PC or TP run studies for them, or that all Applicants would gain access to those models and run the models themselves? (Ref. TPL-002-1b, Applicability: Planning Authority, and Transmission Planner.)

Yes

There is no guidance provided as to how the information asked for in this form will be evaluated, and what the decision making process will entail. As such, a reference document should be developed and provide some guidance how to evaluate applications. Suggest that the BES SDT adopt the FERC Seven Factor test.

SNPD agrees generally that the General Instructions set forth the basic information that would be necessary to support an Exception Request. SNPD is concerned, however, that the statement "diagram(s) supplied should also show the Protection Systems at the interface points associated with the Elements for which the exception is being requested" may be subject to differing interpretations. SNPD envisions that at least four different kinds of documents would be responsive to the description: one-line diagrams with breakers and switches (status); identification of relays by their ANSI device numbers; details of the DC control logic for ANSI devices; and, operational scheme descriptions of the type used by system operators. Accordingly, we suggest that the language be refined to identify the specific kinds of diagrams necessary to identify protection systems at the interface with the Elements for which the Exception is sought, including any required details. SNPD suggests that a generic example of a completed form be provided to the industry to help ensure that Exception Requests are supported by consistent and complete information. Such a generic example could be addressed in the Phase 2 BES efforts.
No
SNPD agrees that the checklist of items on pages two and three lists most of the information that would be necessary to determine if an Exceptions Request is justified. We suggest three modifications to the proposed language to ensure consistency with Section 215 of the Federal Power Act, with the BES Definition, and to provide an entity seeking an Exception with the opportunity to submit all relevant information: (1) SNPD suggests that a new question should be added concerning the function of the facility, which would read: "Does the facility function as a local distribution facility rather than a Transmission facility? If yes, please provide a detailed explanation of your answer." Section 215(a)(1) of the FPA makes clear that "facilities used in the local distribution of electric energy" are excluded from the BES, 16 U.S.C. § 824o(a)(1), and the most recent draft of the BES definition incorporates the same language. SNPD believes a question to address the function of the Element or system subject to an Exception Request is necessary to determine whether the Element or system is "used" in local distribution and thereby to ensure that this statutory limit on the BES is observed in the Exceptions process. Further, we believe a variety of information may be relevant to determining whether a particular facility functions as local distribution rather than as part of the BES. For example, if power is not scheduled across the facility or if capacity on the system is not posted on the relevant OASIS, it is likely to function as local distribution, not transmission. Similarly, if power enters the system and is delivered to load within the system rather than moving to load located on another system, its function is local distribution rather than transmission. SNPD proposes the language above as an open-ended question so that the entity submitting the Exceptions Request can provide this and any other information it deems relevant to facility function. (2) SNPD suggests modifying question 6 to "Is the facility part a designated Cranking Path associated with a Blackstart Resource identified in a

Transmission Operator's restoration plan." This language reflects the most recent revision of the BES Definition, which removes the reference to "Cranking Paths," and also helps distinguish between generators which have Blackstart capability and those generators that are designated as a Blackstart Resource in the Transmission Operator's restoration plan. It is only the latter that are included in the BES under the current draft of the definition. (3) A general "catch-all" question should be added that will prompt the entity submitting an Exception Request to submit any information it believes is relevant to the Exception that is not captured in the other questions. We suggest the following language: "Is there additional information not covered in the questions above that supports the Exception Request? If yes, please provide the information and explain why it is relevant to the Exception Request." While SNPD believes the questions set forth in the draft capture the information that generally would be necessary to determine whether an Exception Request should be granted, it is foreseeable that there may be unusual circumstances where the information called for either does not capture the full picture or where studies other than the specific types called for in the draft form support the Exception. An entity seeking an Exception should have the opportunity to present any information it believes is relevant.

Yes

SNPD agrees that the items listed on page 4 of the Detailed Information to Support an Exception Request capture the information that generally would be necessary to make a reasoned determination concerning the BES status of a generation facility. SNPD suggests three refinements to the questions: (1) Question 2 should be modified by adding "necessary for the operation of the interconnected bulk transmission system" to the end of the question, so that it reads: "Is the generator or the generator facility used to provide Ancillary Services necessary for the operation of the interconnected bulk transmission system?" The italicized language is necessary to distinguish between a generator that provides, for example, reactive power or regulating reserves that support operation of the interconnected bulk grid, and, for example, a behind-the-meter generator that provides back-up generation to a specific industrial facility. The former may be necessary for the reliable operation of the interconnected bulk transmission system, but the latter is not. (2) The current draft of the BES Definition contains Exclusions for radials and for Local Networks. To be consistent with these aspects of the revised BES definition, SNPD suggests modifying question 5 by adding "radial, or Local Network" to the question, so that it would read: "Does the generator use the BES, a radial system, or a Local Network to deliver its actual or scheduled output, or a portion of its actual or scheduled output, to Load? (3) For reasons similar to those explained in our response to Question 2, a general "catch-all" question should be added that will prompt an entity submitting an Exception Request for a generator to submit any information it believes is relevant to the Exception that is not captured in the previous questions. We suggest the following language: "Is there additional information not covered in questions 1 through 5 that supports the Exception Request? If yes, please provide the information and explain why it is relevant to the Exception Request." This will allow an entity seeking an Exception for a generator to identify any unusual circumstances or non-standard information that might support its Exception Request. An entity seeking such an Exception should have the opportunity to present any information it believes is relevant.

Yes

The Standards Drafting Team should consider whether it is necessary to require entities other than the entity filing the Exception Request to provide relevant information, either to the entity filing the Exception Request or to the RE receiving the Exceptions Request. For example, in order to answer Question 1 on page 4, regarding the impact of the generator under the most severe single contingency, it may be necessary for the relevant Balancing Authority to provide its Most Severe Single Contingency ("MSSC") to the registered entity seeking an Exception. Similarly, the relevant Transmission Operator or Balancing Authority may have information that is necessary to determine whether the generator has been designated as reliability-must-run or if it provides ancillary services supporting reliable operation of the interconnected transmission grid.

Yes

As discussed in our responses to Questions 1 through 3, SNPD believes that certain additional questions are necessary to elicit all information that may be relevant to an Exceptions Request. As discussed in our answer to Question 4, we are also concerned that it may be necessary to obtain information that is in the hands of the relevant Balancing Authority, Transmission Provider, or other entity, and not in the hands of the entity submitting an Exceptions Request, to develop a complete record upon which a reasoned decision concerning an Exceptions Request can be based.

Yes
As discussed in more detail in our response to Question 2, SNPD believes it is necessary to address the function of an Element or system that is subject to an Exceptions Request to determine whether it is a "facilit[y] used in the local distribution of electric energy" and therefore excluded from the BES under Section 215(a)(1) of the Federal Power Act.
No
As a general matter, SNPD believes the SDT has provided a reasonable check list that will work in most cases to elicit necessary information from the entity submitting an Exception Request. With the added language suggested in our answers to the previous questions, we believe the proposed form will serve its intended purpose of ensuring that decisions regarding Exception Requests are based upon consistent information and are consistent with the requirements of the Federal Power Act and the BES Definition as developed by the Standards Drafting Team. SNPD also supports the Standards Drafting Team's determination to abandon its initial approach to technical criteria, which would have required adherence to specific numerical thresholds. SNPD agrees that this approach was not workable on a nationwide basis, and that the approach embodied in the current draft of the Technical Principles, which would require specific kinds of information on a generic basis but would leave engineering judgment about the significance of that information to the relevant RE, is more workable and provides appropriate deference to the experience and judgment of the REs.

In question #7 of the form, it would be useful to the analysis for technical exception to include not only the minimum and maximum power flow out of the candidate facility, but also a description or demonstration of the "typical" magnitude or the "average" of such flow. An entity may provide this sort of information anyhow, but a prompt for this type of information could be useful and prevent having to solicit more information during the review.

The first sentence only refers to element(s) designated as excluded. Element(s) designated as included under the BES definition, shouldn't have to go through the exception process either.
No
Q1, Q5 and Q6 have a "Description/Comments" section. What type of information should be included under the Description for each of these questions? Providing more guidance here would help achieve the "standardization, clarity and continuity of process" that we seek. Regarding Q2: A permanent flowgate should not be part of the detailed information to support an exception. First, there is no definition for what constitutes a permanent flowgate. Second, flowgates are often created for a myriad of reasons that have nothing to do with them being necessary to operate the BES. While section c) in E3 attempts to limit the applicability to permanent flowgates, there is no definition for what constitutes a permanent flowgate particularly since no flowgate is truly permanent. The NERC Glossary of Terms definition of flowgate includes flowgates in the IDC. This is a problem because flowgates are included in the IDC for many reasons not just because reliability issues are identified. Flowgates could be included to simply study the impact of schedules on a particular interface as an example. It does not mean the interface is critical. As an example, it could be used to generate evidence that there are no transactional impacts to support exclusion from the BES. Furthermore, the list of flowgates in the IDC is dynamic. The master list of IDC flowgates is updated monthly and IDC users can add temporary flowgates at anytime. While the "permanent" adjective applied to flowgates probably limits the applicability from the "temporary" flowgates, it is not clear which of the monthly flowgates would be included from the IDC since they might be added one month and removed another. Flowgates are created for many reasons that have nothing to do with them being necessary to operate the BES. First, flowgates are created to manage congestion. The IDC is more of a congestion management tool than a reliability tool. FERC recognized this in Order 693, when they directed NERC to make clear in IRO-006 that the IDC should not be relied upon to relieve IROs that have been violated. Rather, other actions such as re-dispatch must be used in conjunction. Second, flowgates are used as a convenient point to calculate flows to sell transmission service. The characteristics of the flowgate make it a good proxy for estimating how much contractual use has

<p>been sold not necessarily how much flow will actually occur. While some flowgates definitely are created for reliability issues such as IROLs, many simply are not. We are unclear about what "an appropriate list" in Q3 is supposed to be. Is it supposed to be a list of all IROLs or only those for which the answer is yes? Why is a list even necessary since the answer to the question answers Exclusion E3.c? If the answer is no, is this asking the submitter to prove the negative?</p>
No
<p>Q5 has a "Description/Comments" section. Further clarification on what type of information to include under the Description would help "standardize" the supporting information and "will provide more clarity and continuity to the process." The definition of ancillary services varies and can be quite broad. It can include reactive power and voltage support for example. All generators provide some reactive power and voltage support. Thus, ancillary services should be further defined or one could construe it to limit any generator from being excepted.</p>
Yes
<p>Some generation owners may not be able to obtain their BA's most severe single Contingency. Many generator owners will not have access to the data necessary to demonstrate the reliability impact to the BES. This is particularly true for transmission dependent utilities.</p>
No
Yes
<p>Some organized markets have a must run concept that has nothing to do with reliability. Thus, Q3 for generation facilities might be confused with these tariff provisions.</p>

<p>The 'Technical Principles for Demonstrating BES Exceptions' process was intended to establish technical exception 'criteria' which would be used by the industry to understand what facilities would qualify for inclusions and exclusions from the BES. What has been produced, however, is essentially a listing of 'electrical system indicators', identified on the form, which may be material to making a decision regarding, 'is it BES or not'. The thresholds (or acceptable values) for the indicators, however, have not been determined. It is understood that in Phase II of the BES Definition development process, the SDT will attempt to address these issues but until that work has been completed, the industry will remain enmeshed in confusion and inefficient application of resources and funding. Without these criteria, it is very difficult to believe that this process can be transparent and consistent. Re: Question 4. (For Transmission Facilities) For the purposes of responding to this question, what constitutes the BES? It would seem that you must exclude the elements you are seeking exceptions for or else the exception request is rendered essentially worthless.</p>
Individual

Chris de Graffenried

Consolidated Edison Co. of NY, Inc.

No

Con Edison's overall concern is the lack of clarity and specificity with respect to what analyses and study results are required under the 3rd bullet on page 1 and under #4 on pages 2 and 4. This lack of clarity and specificity will lead to inconsistent application of the Technical Principles by both Registered Entities and Regional Entities. We recommend the following: the impact and performance analyses required by the 3rd bullet on page 1 and by #4 on pages 2 and 4 should be stipulated to be all analyses, scenarios, and contingencies required under NERC Standard TPL-002-1 with the "exception element" removed from the base system model. Entities shall report on all key performance measures of BES reliability specified in the TPL-002-1 attributable to the removed "exception element". Note that references to NERC Standard TPL-001-2 should not be made in the Technical Principles document as TPL-001-2 has not yet been filed with (nor approved by) FERC. General Instructions One-Line Breaker Diagram questions and comments: Page 1, paragraph 2: Please explain the phrase "at the interface points." Where is this location? Please provide several examples, i.e., for a radial, a local network, a generator, a transformer, a substation buss, and for other Elements (PARs, reactors, UFLS panels, relays and switches).

No

Application Form Page 2 For Transmission Facilities: Impacts: Flowgates: The Application form at 2 states, "How does the facility impact permanent Flowgates in the Eastern Interconnection ..." • What standards for "impact" does the BES SDT envision? • What is a material impact and a non-material impact? • What kinds and types of impacts are acceptable and/or unacceptable? • How are impacts determined, e.g., Power TFD method, short circuit analysis, A-10 method? Impact-Based Studies: Note that the FERC Seven Factor test is a time-tested method and FERC has identified it as an acceptable method for reliability purposes; for gauging the expected impact of an Element on the interconnected transmission grid. The NPCC A-10 method has been used extensively in the Northeastern U.S. and Canada, and is an impact-based approach. The power TDF (transfer distribution factor) method is also used by some to assess the impact of changing power flows on individual Elements within a system. FERC has studied using the 'TIER' method for classifying system Elements based on LBMP impacts. WECC uses a short circuit test. Page 3 Cranking Path Issue: The Application form at 6 asks, "Is the facility part of a Cranking Path associated with a Blackstart Resource?" We understand that: (i) The drafting team does not require that the BES be contiguous, and (ii) Blackstart resource Cranking Paths were deleted from Inclusion I3. Recommendation: Delete the reference to "Cranking Paths" in this Application form. Power Flow Issue: The Application form at 7 asks, "Does power flow through this facility into the BES?" We assume that this can only apply to a Local Network with two or more connections to the BES. We believe that no power should normally flow through a Local Network (or Radial system) to another portion of the BES. Occasional, brief reverse power flows may be acceptable during short periods under abnormal operating conditions, e.g., a switch normally open is briefly closed during a forced maintenance outage. The Application form at 7 requests the following: "data for the most recent consecutive two calendar year period." • Please explain why the BES SDT felt that two years worth of data was necessary, as one year of data would appear sufficient? Our experience has been that one year (8,760 hours) of data covers four seasons, including Summer and Winter capability periods, and is therefore sufficient. Requiring an extra year is perhaps unnecessarily burdensome on filing Entities, whether asset owners or Regional Entities. The Application form at 7 asks, "[W]hat is the minimum and maximum magnitude of the power flow outflow of the facility ..." • Please explain why the BES SDT used the term "magnitude" when requesting power outflow data? Recommendations: 1) We strongly recommend that the BES SDT adopt the FERC Seven Factor test for these purposes. The FERC Seven Factor test states that, • "Power flows into local distribution systems, and rarely, if ever flows out," and • "When power enters a local distribution system, it is not reconsigned or transported on to some other market." 2) We recommend deleting the "% of the calendar year" check boxes in favor of a statement either that power does not flow through the Local Network, or alternatively, a blank space for reporting the net peak MWs and MWH's transferred annually, and the percentage of these transferred amounts to the peak and annual MWH demands served by with the Local Network. 3) We recommend requesting only one year (8,760 hours) of data covering four seasons, including Summer and Winter capability periods.

No

For Generation Facilities: This Application form would appear to generally apply to traditional generating facilities. • What Application form and justifications would be required for non-traditional resources, e.g., solar and wind? • The Application form at 2 asks, "Is the generator or generator facility used to provide Ancillary Services?" If some of these Generator check list items are market-related and not reliability-related, then they should not be present. • If the Ancillary Services are reliability-related, please explain their relation to BES reliability. Recommendation: Insert the word "reliability" before the words "must run" in question 3. The Application form at 5 asks, "Does the generator use the BES to deliver its actual or scheduled output, or a portion of its actual or scheduled output, to Load?" We assume this mean the generator may serve local loads through non-BES facilities. In order to serve these local loads the generator would need to be connected to a Radial system, a Local Network or to local distribution facilities. • Is this meaning above implied and intended by this question? • Were there any other possibilities envisioned by the BES SDT?

Yes

According to the Applicability section, the TPL Reliability Standards are only applicable to the Planning Coordinator (PC) and the Transmission Planner (TP). Was it the BES SDT's assumption that Applicants would have the PC or TP run studies for them, or that all Applicants would somehow gain access to those models and run the models themselves? (Ref. TPL-002-1, Applicability: Planning Coordinator, and Transmission Planner.)

Yes

We strongly recommend that the BES SDT adopt the FERC Seven Factor test for local distribution.

Individual

Thad Ness

American Electric Power

Yes

Though we have no objections to the proposed content, this is contingent on the number and type of elements eventually found included or excluded as a result of the BES definition itself which is still being drafted. Any changes in that definition could in turn cause us concern regarding these general instructions. There needs to some provision for cases where specific elements which are not specifically contained within the studies. It needs to be clear what additional analysis needs to be provided under those circumstances. We recommend that the owner of the asset be identified as part of the general instructions. In the case of wind resources, how is individual gross nameplate information to be reported?

Yes

We recommend capitalizing "facility".

No

It is unclear how the process will work with the interaction among the various NERC Functions. For instance, an exception request from generation might require collaboration among other functional entities, i.e. GOP, TOP, and RC. The question "How does an outage of the generator impact the over-all reliability of the BES" may be subjective and dependent on contingencies at any given time. It would be dependent on what state the BES would be in the area the generator is located. More detail would be needed in describing the study required to have consistent results.

No

As stated in the response to question #3, the question "How does an outage of the generator impact the over-all reliability of the BES" may be subjective and dependent on contingencies at any given time. It would be dependent on what state the BES would be in the area the generator is located. More detail would be needed in describing the study required to have consistent results.

No

As stated in the response to question #3, it is unclear how the process will work with the interaction among the various NERC Functions. For instance, an exception request from generation might require collaboration among other functional entities, i.e. GOP, TOP, and RC. The existence of a must run unit means that unit has a material impact on any configuration of the BES and as such would need a serious waiver to not be considered a BES facility. As such, a must run unit would not receive an

exception. As a result, should question #3 be removed? Criteria for applying for an exception should be outlined before filling out the form.

No

AEP is not aware of any conflicts between the proposed approach and any regulatory function, rule order, tariff, rate schedule, legislative requirement or agreement, or jurisdictional issue.

No

AEP agrees with the overall approach demonstrated by the exception request form; however, its appropriateness will be largely dependent on the process eventually used for its implementation. AEP would like guidance on how moth-balled generation should be treated. Perhaps this could be added to the exception form as well.

Individual

Anthony Jablonski

ReliabilityFirst

No

These instructions are at a very high level and provide no clear guidance on what is required. ReliabilityFirst Staff believes each bulleted item needs to provide clear expectations. As an example in bullet #2 "Clearly document all assumptions used", the document and this bullet should include guidance such as what base case transfers were included, a list of facilities that were assumed out of service, new facilities places in service and system load levels, etc.

No

All generating units, to some degree, affect the transmission elements that make-up the BES. What role will this effect have on the determination? If the systems are planned properly and the day-ahead analysis is done for maintenance work, the outage of any one element is moot. What is the phrase "impact the over-all reliability" getting at? These studies and analysis will need to look at multiple outages and groups of elements being taken out and excluded. Will this be on a first come, first out process? As for the Nuclear Plant Interface Requirement (NPIR) question, ReliabilityFirst Staff believes these facilities should always be included as part of the BES and taken out of the Detailed Information to Support an Exception Request. For question 6 ReliabilityFirst Staff believes the Cranking Path should be included in the BES definition. . ReliabilityFirst Staff feels that without including the Cranking Paths, the reliability of the system could be jeopardized if a restoration is required and the Cranking Paths are unavailable due to non-adherence to Reliability Standards. Omit question 7, E3 (LN) of the definition already talks to power flow and even if there is a small percentage of flow, it makes that entity a user of the BES, which should be included.

No

If the systems are planned properly and the day-ahead analysis is done for maintenance work, the outage of any one unit and even with the most serve outage happening, the system should be capable of withstanding. These studies and analysis will need to look at multiple outages and groups of units being taken out and excluded before any could be exempt. What is the phrase "impact the over-all reliability" getting at? These studies and analysis will need to look at multiple outages and groups of elements being taken out and excluded. Will this be on a first come, first out process? As for the Ancillary Services question, ReliabilityFirst Staff believes that if a unit provides this service, it should be included in the BES. The same applies for the "must run units" in question 3. Omit question 5, E3 (LN) of the definition already talks to power flow and even if there is a small percentage of unit's output flowing onto the BES, it makes that entity a user of the BES, which should be included.

Yes

In some cases, models and even knowledge of the system configurations, operating protocols and procedures may not be well known by all the entities. System adjustments, load levels, topologies, maintenance and outage schedules, which happen daily, will or may be unknown to many entities, including the Regional Entities who may submit a request to include facilities. For cross regional boundaries, the problem becomes even larger. That coupled with generation unit owners/operators not permitted to know transmission information (i.e. Questions 4 and 5); this will put them at a huge disadvantage to participate in the exception request process.

No

Yes
Since the inception of the Open Access Transmission Tariff, transmission models and even knowledge of the systems, operating protocols and procedures may not be well known or known at all by all the entities. System adjustments, load levels, topologies, maintenance and outage schedules (i.e. market sensitive information), which happens daily is not permitted to be known by the generation side of the industry. An unknown at this point and without a common set of criteria to be used by the Regional Entities and NERC Staff and Panels, it will be difficult to make consistent determinations across the ERO Enterprise.
Yes
FERC Order 743-A, paragraph 1, discusses that NERC should "...establish an exemption process and criteria for excluding facilities that are not necessary for operating the interconnected transmission network". It also directed in paragraph 4 that "Order No. 743 also directed the ERO to develop an exemption process that includes clear, objective, transparent and uniformly applicable criteria for exempting facilities that are not necessary for operating the interconnected transmission grid." The SDT proposed a set of questions titled "Detailed Information to Support an Exception Request" to assist in the exemption process but in our mind is not "exception criteria" as stated in the FERC Orders. ReliabilityFirst Staff believes that NERC should develop criteria for which facilities or Elements could be exempted from the core definition; an example being Local Networks as outlined in the current draft of the definition. ReliabilityFirst Staff believes the Local Network exclusion is not "bright line" and could be removed from the core definition and used as criteria for exclusion in the exemption process. Item b of the LN (E3) exclusion would need evidence to support the historical and future power flows. Historical data and future power flow study results would be needed to support this exception. Additionally, another example for exemption criterion for inclusion to the BES could be any 69 kV network facilities that provide a parallel path to the BES. Evidence such as one-line diagrams along with power flow studies would need to be provided through the exemption process for these types of facilities to be included in the BES. ReliabilityFirst Staff believes that any BES facilities should not be candidates for exemption based upon the arbitrary determination of a panel that considers the aspects stated in the document "Detailed Information to Support an Exception Request". Without uniform criteria as stated in the FERC Orders, it will be difficult for the panels to make consistent determinations across the ERO Enterprise.

Yes
Canadian Entities are not under FERC jurisdiction, so the revised BES Definition may not apply. A number of Canadian Entities have the BES defined within their provincial legislation. This may introduce differences and even contradictions between elements that are included in the BES according to provincial legislation and the NERC definition.
Yes
Manitoba Hydro strongly disagrees with the proposed 'Detailed Information to Support an Exception Request' document and associated exception process for the following reasons: -It is not clear what elements or situations beyond what is covered in the core definition and associated inclusions and exclusions that the drafting team is hoping to capture through the exception process. Further, it is unclear what the benefit to reliability would be by allowing an impact based exception process given that entities will be extremely unlikely to use the exception process to include elements in the BES. - The exception process will be extremely resource intensive, particularly in the absence of any

Industry approved threshold criteria. The costs to properly administer and monitor the process to ensure that impact based modeling is done accurately and that it captures the frequent changes on a dynamic system will occupy a wealth of Industry, NERC and Regional Entity time to the detriment of reliability. -It is not reasonable for industry to approve the exception process without knowing what thresholds are required to demonstrate an element as being part of the BES or not. We are concerned that BES determinations would be subjective and would vary from case to case with the particular staff examining the request. BES elements should be established and agreed upon by Industry, not set by a NERC panel. We understand that the drafting team has made this change in the interests of time, but the impact of the BES definition is too broad for this project to be rushed. -The 2010-17 project goals to increase the clarity of the BES definition and establish a 'bright-line' are compromised by the exception process. Changes and alterations to the BES definition should be approved by Industry through the Standards Under Development Process. An interpretation request or SAR should be developed by an entity if they feel that the core definition and associated exceptions and inclusions should be modified. We ask that NERC requests that FERC re-examines the directive to develop an exception process given that the BES definition, which already includes a list of exceptions, is sufficient to standalone without an associated exception process.

Yes

In accordance with WECC's position paper issued on October 5, 2011, AZPS agrees with WECC in that the proposed Technical Principles for Demonstrating BES Exceptions Request does not provide the necessary clarity as to what applying entities must provide to support their request, nor does it provide any criteria for consistency among regions in their assessment of requests.

In the first paragraph "Entities that have Element(s) designated as excluded, under the BES definition and designations, do not have to seek exception for those Elements under the Exception Procedure.", before the "General Instruction" it should have had another sentence saying that "for those who do not clearly meet the Inclusions and Exclusions should use the following instructions". Otherwise, it's still not very clear.
No
Please clarify "facility" and include "N-1" for power-flow studying.

WECC
No
WECC has several concerns with the instructions on the checklist regarding the studies: <ul style="list-style-type: none"> <li>• Study Case – The instructions state the study case that should be used, “Be based on an Interconnection-wide base case that is suitably complete and detailed to reflect the facility’s electrical characteristics and system topology.” The phrase “suitably complete and detailed” is vague. WECC recommends clarification of this phrase and the addition of specific requirements for what will constitute an appropriate case. Allowing the entity requesting an exception to choose any Interconnection-wide case could allow an inappropriate choice of case and could lead to inconsistent study results. If there are no requirements for the chosen case, then it is possible that the most favorable case to an entity’s argument will be chosen. In some instances that choice would likely be appropriate, but in others it would not necessarily be appropriate. At a minimum, there should be further description — and preferably, specific requirements — guiding the determination of which study case is most appropriate. Of particular importance in clarifying what case is an appropriate case, is the timeliness of the case. WECC recommends requiring that a recent case be used. In addition, if each entity is able to chose its own case, without further requirements, there will be no way for the Regional Entity or NERC to ensure consistency of determinations with respect to the elements tested.</li> <li>• The entities are asked to address key performance measures of BES reliability through the studies. This instruction is vague concerning what the study must investigate and it leaves it up to the entity to determine the key performance measures. The “key performance” measures should be consistent with respect to similar elements and there is no way to ensure that if there are no specifications regarding such measures. The exceptions process must be objective and clear as to what performance measures need to be met for the process to be implemented consistently. WECC recommends further clarification and the addition of specific requirements beyond the guidance related to consistency with Transmission Planning (TPL) standards.</li> <li>• The background information on the comment form states: “The same checklist will be utilized for exceptions dealing with inclusions or exclusions.” But there is no mention of this in the document. A note should be added to the checklist instruction to state that the same checklist will be used for exclusions and inclusions.</li> </ul>
Yes
The requested information in the checklist is appropriate. However; the exceptions process as drafted, with no objective criteria defining how to assess the submittals, leaves it to each Regional Entity to develop their own criteria to evaluate the responses to the checklist included in the submittals, leading to inconsistency between Regional Entities. In addition, WECC recommends clarifying Question 7. On its face it is unclear what defines power flowing through a facility in the BES. It should be clear whether a qualitative or quantitative response is required.
Yes
The requested information in the checklist is appropriate. However; the exceptions process as drafted, with no objective criteria defining how to assess the submittals, leaves it to each region to develop their own criteria to evaluate the responses to the checklist included in the submittals, leading to inconsistency between Regional Entities.
Yes
Entities would have a difficult time deciding what data to obtain. Getting the data for their own specific facilities should be relatively simple for the majority of entities. However, it is possible smaller entities may have a higher burden putting together the appropriate information for inclusion in a study case that they currently may not do. In addition, because the instructions state that a case will be “suitably complete and detailed,” WECC believes there is insufficient guidance as to what amount and degree of detail in the data is sufficient for the submittal process. Without thresholds it is difficult to determine whether the entities will have the ability to obtain necessary data to file for an exception. At this time, WECC views the instructions as insufficient for these reasons.
Yes

In order to make a determination of BES status of an element, there should be a listing of effects of the outage on certain facilities, frequencies, voltages, transmission elements, or other information that should be included in the submittal by the entity. Without further specification of requirements for presenting a case it is likely that the Regional Entity will receive inconsistent submittals of data. Leaving open the question of what constitutes a sufficient presentation of a case would likely lead to a wide spectrum of submittals with respect to the amount of data and level of detail in the data.

No

Yes

WECC is very concerned that there are no specific qualifications or requirements, either for the entities or for the Regional Entity, with respect to: • the determination of which studies need to be conducted; • the format of the study data that should be submitted; or • the key performance measures that should be evaluated. This vagueness will lead to inconsistency in studies run, data submitted, and measures of data evaluation. If this inconsistency occurs, it will result in a potentially subjective and discordant process on multiple levels for both the submitting entities and the Regional Entities. It may result in submitting entity having to run multiple studies in order to determine what will be acceptable proof, which is overly burdensome on both the submitting entity requesting the exception and the Regional Entity reviewing the request. It also makes the consistency that FERC has requested difficult to assess and achieve. If the goal of the exceptions process is to result in consistent determinations across the regions, then WECC recommends that to the extent possible, the process be objective, clear, and include detailed instructions. The development of such an objective and detailed process is a difficult task and will require additional time. WECC believes it is better to not have an exceptions process in the interim period than to have an inefficient and overly burdensome process in place. To allow adequate time to complete the task of developing a detailed and consistent process WECC recommends that the Detailed Information to Support BES Exceptions Request be included in Phase II of the BES definition project.

It is unclear what the purpose of submitting diagrams showing the Protection Systems is and we do not feel that it should be a requirement at the onset of the exception process. In the first bullet, we do not feel that the term "Interconnection-wide base case" is required as the phrase "suitably complete and detailed" should provide enough guidance to the submitter that inappropriate equivalent representations would not be accepted. The concern is that one could interpret "Interconnection-wide base case" as the entire Eastern Interconnection model is a requirement.

No

- Question 1 o The use of the words "connected to" is unclear. Some may read this as generation "directly" connected to while others could interpret it more generically. o A generation cut-off should be included in the requirement to list all individual units that may be connected to a facility. A suggestion would be to use a 1 MVA cut-off so that machines such as wind turbines would still be captured but smaller installations would not need to be listed in detail. o When listing individual gross nameplate values, the form should be specific that it is requesting the nameplate MVA value. - Question 3 o It is not clear how a facility could be included in an Interconnection Reliability Operating Limit (IROL) is a limit and not a specific element. Rather, it is clearer to ask if a facility is used to identify an IROL either as a part of the interface itself or as a contingency which relevant to the IROL. - Question 4 o As this question only pertains to the outage of the facility, there may also be a need to show how the outage of another element could impact the facility seeking exception. A new question to add to address this would be "How does an outage of other BES facilities impact flows through this facility and thus, the over-all reliability of the BES?" - Question 6 o This question appears to be inconsistent with the removal of the "Cracking Path" from the BES definition. o If the question is to remain, the question should be clarified to state, "With a Blackstart Resource "material to" and designated as part of a transmission operator entity's restoration plan. - Question 7 o The question should be more specific to whether the flow should be measured under all-lines in conditions or post-contingency. o The question should be more specific as to whether the power flow pertains to Real, Reactive, or Apparent Power. o The use of the word "through" in the question is unclear. This is more

evident when trying to apply this question to facilities which are transmission lines that are not directly connected to the BES.
No
- Question 1 o The question would be better worded as "How many MW are lost following the host Balancing Authority's most severe single Contingency...". o The question becomes difficult to answer when the most severe single Contingency can change on a day-to-day and hour-to-hour basis. o The MVA size of the facility should be requested. - Question 3 o The term "must run unit" is unclear.

Given all of these decisional inputs requested by the Exception Application there needs to be some guidance or clarification here regarding the criteria that will be used to render a yes or no decision other than simply filling out the Application and allowing the Rules of Procedure process to take place. The Application process for Exceptions (inclusions or exclusions) appears to be subjective and lacks the decisional technical criteria for the applicant to be confident of the outcome.

No
What is meant by "key performance measures of BES reliability" in the third bullet? A descriptive list would be helpful.
No
Questions #4 requires an analysis of the "most severe impact" associated an outage of the Element proposed for exception. a. Both the newly Board approved TPL-001-2 standard and the existing TPL-004-1 require that severe contingencies be evaluated, but there are no performance requirements for them. If the team intended the "most-severe impact" analysis to only evaluate TPL outages that incorporate performance requirements, it should make that clear. b. The most-severe-outage impact question does not ask key relevant information such as: i. What is the probability that the "most severe impact "will occur? ii. Could the impact be readily mitigated and service restored? This point is critical because the impact of an outage lasting several minutes before restoration versus several hours before restoration should affect the analysis. What does question #7 ("Does power flow through this facility into the BES?") with check boxes for various % of a calendar year that power flows into the BES) imply with respect to a transmission facility's exception request? Also, is the % of a calendar

year data intended to be forecasted data or historic data? It would seem that forecasted data would need to be supplied that is consistent with the TPL models. Finally, why are historic flows requested – they have no relevance except for perhaps explaining historic and forecasted differences?

No

With regards to question #2 (“Is the generator or generating facility used to provide Ancillary Services”), the answer for most synchronous generators is probably “yes” unless they are in a bid-based market that selects specific generators for Reactive Power delivery. Since most generators (with the exception of those with nuclear prime movers) provide Reactive Power to meet a Transmission Operator-specified voltage, they would provide that Ancillary Service. Other generators (again, with the exception of generators with nuclear prime movers) may be eligible to provide other Ancillary Services such as Spinning Reserve, but may have rarely done so. However, they still may be “used do provide” Spinning Reserve at any time. How would those generators respond to question #2? Questions #4 requires an analysis of the “most severe impact” associated an outage of the Element proposed for exception. a. Both the newly Board approved TPL-001-2 standard and the existing TPL-004-1 require that severe contingencies be evaluated, but there are no performance requirements for them. For consistency, performance requirements for the most-severe-impact analysis needed to be defined by the team. If the team intended the “most-severe impact” analysis to only evaluate TPL outages that incorporate performance requirements, it should make that clear. b. The most-severe-outage impact question does not ask key relevant information such as: i. What is the probability that the “most severe impact “will occur? ii. Could the impact be readily mitigated and service restored? This point is critical because the impact of an outage lasting several minutes before restoration versus several hours before restoration should affect the analysis. What does the answer to the question #5 in the Generator Facilities section (“Does the generator use the BES to deliver its actual or scheduled output, or a portion of its actual or scheduled output, to Load?”) imply with respect to a generator’s exclusion? Also, the phrase “deliver its actual or scheduled output ...to load” needs explanation. The use of “actual output” and “scheduled output” may have several contexts. a. For example, in a market, a generator’s actual output may suddenly go to zero due a forced outage, but the generator has financial obligations that accrue for delivering its scheduled output, which is in fact provided by other sources since the generator is unavailable. Is the question asking about the use of BPS facilities by resources that may be substituted for delivery of a generator’s scheduled output when it differs from its actual output? b. Now assume that a generator’s actual output equals its scheduled output and that several generators are forced out of service in another Balancing Authority, resulting in a frequency decline. Generators within the interconnection with active governors and available spinning capacity will automatically increase their output above their scheduled output, resulting in Inadvertent Interchange. Is the question related to the BES facilities used to deliver such Inadvertent Interchange? c. Again assume that a generator’s actual output equals its scheduled output. Is the question related to the actual BES facilities that may be used to deliver the generator’s power to Load? That would require an analysis of generator and load shift factors to determine what actual facilities carry the power generated from a generator to a specific load for a given set of assumptions on the system topology. In a market, this analysis would not be possible for generators that do not self-schedule for delivery to specific loads.

Yes

It would depend upon the clarifications to the points raised above.

No

No

Yes

An applicant should be able to clearly tell whether or not an exception request will likely be granted before it is submitted. It is nearly impossible to divine the whether a request will be granted from a set of data questions. The team is urged to state the exclusion criteria explicitly; data questions required to evaluate a request should directly reference each criterion. See Order 743, paragraph 115: “NERC should develop an exemption process that includes clear, objective, transparent, and uniformly applicable criteria for exemption of facilities that are not necessary for operating the grid.”

Hydro-Quebec TransEnergie
No
We believe that the new Technical Principles are better than the previous ones, as they allow flexibility for an Entity to make their case with technical justifications. However, without any guide or specific criteria, it does not allow an Entity to identify the real possibility to obtain an exception. It is not clear at all what will guide the Region or ERO to make their decision to grant or not the exception. In order give confidence to the Industry in the procedure, it would be necessary to define the elements that will guide the decision. Will impact base study be accepted? Will the threshold differences with Quebec Interconnection be accepted?
No
No
No
Yes
The general characteristics of the Interconnection (such as frequency or voltage variation), as they may guide the decision for exclusion of specific elements.
Yes
For HQT's system, the proposed BES definition combined with the exception procedure are presently incompatible or at least inconsistent with the regulatory framework applicable in Quebec. The proposed changes have not address this concern, neither the SDT's responses to our previous comments last May (Q.9). We reiterate that the definition and the exception procedure shall be determined by Quebec's regulator, the Régie de l'Énergie du Québec, (Quebec Energy Board) which has the responsibility to ensure that electric power transmission in Quebec is carried out according to the reliability standards it adopts. Per se, it would be necessary that E1 and E3 grant exclusions with much higher level of generation. It would also be necessary to allow for several levels of application for the Reliability Standards, in accordance with the Régie de l'énergie du Québec approach: the Bulk Power System (BPS) as determined using an impact-based methodology, the Main Transmission System (MTS), and other parts of Regional System. Standards related to the protection system (PRC-004-1 and PRC-005-1) and those related to the design of the transmission system (TPL 001-0 to TPL-004-0) shall be applicable to the first level, but all other reliability standards shall be applied to the second level, the MTS. The MTS definition is somewhat different than the Bulk Electric System definition, and it includes elements that impact the reliability of the grid, supply-demand balance and interchanges. We argue that it would be necessary for NERC to address the regulatory issues outside of the present context of the SDT and ROP team.

While the general instruction information outlined is applicable, it lacks sufficient detail to know exactly what is needed to be submitted. More importantly the general instructions and the overall document lacks criteria that if met (through study and other documentation methods) would allow for exclusion from or inclusion to the BES. Something similar to the criteria or concepts used in the Appendix 1 of the Local Network Exclusion justification document is needed. Clear criteria should allow an entity to determine with a reasonable degree of certainty that if the criteria are met as demonstrated by the associated study effort that an exemption can be obtained. Otherwise without that criteria, the process will be not far from where the exemption process is today, which will be costly, time consuming and frustrating for the registered entities as well as the regions and NERC. The process needs to be repeatable and consistent between all regions and entities. Entities need to know what is expected and where the finish line is. As presently written each region and NERC would have to develop their own criteria individually and will be open to opinions which could change as personnel changes occur in a given position or panel.

No
The questions for transmission facilities seem to be appropriate; however, how the answers are to be used by the region or NERC is unclear. Will a given response to a question make exclusion impossible? If so this needs to be known upfront and clearly documented. For example question 4, on page 2 is open for interpretation and debate as to what the impact to the over-all reliability of the BES is. The definition of "impact" is really the key to the whole definition effort. Load flow, voltage, frequency change limits may all be pieces to the puzzle. Are these criteria to be met in normal, N-1, N-2, etc. system configurations?
No
The questions for generation facilities seem to be appropriate; however, how the answers are to be used by the region or NERC is unclear. For example question 4, on page 4 is open for interpretation and debate as to what the impact to the over-all reliability of the BES is. The definition of "impact" is really the key to the whole definition effort. Load flow, voltage, frequency change limits may all be pieces to the puzzle. Are these criteria to be met in normal, N-1, N-2, etc. system configurations?
Yes
The access to the required data would be potentially be a concern especially for smaller entities. Small entities will typically have to outsource the required studies to consultants and obtaining the data may be difficult for the consultants. The entities most likely to obtain exemptions (smaller & lower impact entities) are the ones that probably will have the most difficulty in obtaining the data. Generally larger utilities "upstream" from the smaller ones are hesitant to give information to other entities. Depending on the study requirements and criteria for application, this could be a very costly process.
No
No
Yes
Clear, concise criteria with consistent repeatable results are a must for a successful outcome of the project effort. The included questions are appropriate questions but the use of those questions and the ultimate outcome is unclear with the current version. The background information indicates that continent wide criteria are not feasible. It is understood that this is a very difficult task and will be difficult to achieve (especially in the time allotted). However, if the decisions are left up to a "panel" to decide the results will be inconsistent and will vary region by region, as well as differ over time. The process involved will be very time consuming (i.e. expensive) and will be difficult to control especially during the initial timeframe. History has demonstrated that review and approval processes that pass from the entity to the regions, then to NERC and then on to FERC backup very easily due to limited staff and resources. The drafting team may want to consider moving this topic to Phase 2 of the project. However, Phase 2 needs to have fairly quick time frame in order to provide the needed direction to the industry in a timely manner.
Individual
Bud Tracy
Blachly-Lane Electric Cooperative
Yes
The Blachly-Lane Electric Cooperative (BLEC) agrees generally that the General Instructions set forth the basic information that would be necessary to support an Exception Request. We are concerned, however, that the statement "diagram(s) supplied should also show the Protection Systems at the interface points associated with the Elements for which the exception is being requested" may be subject to differing interpretations. We envision that at least four different kinds of documents could be responsive to the description: one-line diagrams with breakers and switches (status); identification of relays by their ANSI device numbers; details of the DC control logic for ANSI devices; and, operational scheme descriptions of the type used by system operators. Accordingly, we suggest that the language be refined to identify the specific kinds of diagrams necessary to identify protection systems at the interface with the Elements for which the Exception is sought, including any required

details. WE suggest that a generic example of a completed form be available to the industry to help ensure that Exception Requests are supported by consistent and complete information. Such a generic example could be addressed in the Phase 2 BES efforts.

No

BLEC agrees that the checklist of items on pages two and three lists most of the information that would be necessary to determine if an Exceptions Request is justified. We suggest two modifications to the proposed language to ensure consistency with the BES Definition and to provide an entity seeking an Exception with the opportunity to submit all relevant information: (1) We suggest modifying question 6 to "Is the facility part of a designated Cranking Path associated with a Blackstart Resource identified in a Transmission Operator's restoration plan." This language reflects the most recent revision of the BES Definition and also helps distinguish between generators which have Blackstart capability and those generators that are designated as a Blackstart Resource in the Transmission Operator's restoration plan. It is only the latter that are included in the BES under the current draft of the definition. (2) A general "catch-all" question should be added that will prompt the entity submitting an Exception Request to submit any information it believes is relevant to the Exception that is not captured in the other questions. We suggest the following language: Is there additional information not covered in the questions above that supports the Exception Request? If yes, please provide the information and explain why it is relevant to the Exception Request. While we believes the questions set forth in the draft capture the information that generally would be necessary to determine whether an Exception Request should be granted, it is foreseeable that there may be unusual circumstances where the information called for either does not capture the full picture or where studies other than the specific types called for in the draft form support the Exception. An entity seeking an Exception should have the opportunity to present any information it believes is relevant.

Yes

BLEC agrees that the items listed on page 4 of the Detailed Information to Support an Exception Request capture the information that generally would be necessary to make a reasoned determination concerning the BES status of a generation facility. We suggest three refinements to the questions: (1) Question 2 should be modified by adding "necessary for the operation of the interconnected bulk transmission system" to the end of the question, so that it reads: "Is the generator or the generator facility used to provide Ancillary Services necessary for the operation of the interconnected bulk transmission system?" The italicized language is necessary to distinguish between a generator that provides, for example, reactive power or regulating reserves that support operation of the interconnected bulk grid, and, for example, a behind-the-meter generator that provides back-up generation to a specific industrial facility. The former may be necessary for the reliable operation of the interconnected bulk transmission system, but the latter clearly is not. (2) The current draft of the BES Definition contains Exclusions for radials and for Local Networks. To be consistent with these aspects of the revised BES definition, we suggest modifying question 5 by adding "radial, or Local Network" to the question, so that it would read: "Does the generator use the BES, a radial system, or a Local Network to deliver its actual or scheduled output, or a portion of its actual or scheduled output, to Load? (3) For reasons similar to those explained in our response to Question 2, a general "catch-all" question should be added that will prompt an entity submitting an Exception Request for a generator to submit any information it believes is relevant to the Exception that is not captured in the previous questions. We suggest the following language: Is there additional information not covered in questions 1 through 5 that supports the Exception Request? If yes, please provide the information and explain why it is relevant to the Exception Request. This will allow an entity seeking an Exception for a generator to identify any unusual circumstances or non-standard information that might support its Exception Request. An entity seeking such an Exception should have the opportunity to present any information it believes is relevant.

Yes

The Standards Drafting Team should consider whether it is necessary to require entities other than the entity filing the Exception Request to provide relevant information, either to the entity filing the Exception Request or to the Registered Entity receiving the Exceptions Request. For example, in order to answer Question 1 on page 4, regarding the impact of the generator under the most severe single contingency, it may be necessary for the relevant Balancing Authority to provide its Most Severe Single Contingency ("MSSC") to the registered entity seeking an Exception. Similarly, the relevant Transmission Operator or Balancing Authority may have information that is necessary to determine

whether the generator has been designated as reliability-must-run or if it provides ancillary services supporting reliable operation of the interconnected transmission grid.
Yes
As discussed in our responses to Questions 1 through 3, we believe that certain additional questions are necessary to elicit all information that may be relevant to an Exceptions Request. As discussed in our answer to Question 4, we are also concerned that it may be necessary to obtain information that is in the hands of the relevant Balancing Authority, Transmission Provider, or other entity, and not in the hands of the entity submitting an Exceptions Request, to develop a complete record upon which a reasoned decision concerning an Exceptions Request can be based.
No
No
As a general matter, BLEC believes the SDT has provided a reasonable check list that will work in most cases to elicit necessary information from the entity submitting an Exception Request. With the added language suggested in our answers to the previous questions, we believe the proposed form will serve its intended purpose of ensuring that decisions regarding Exception Requests are based upon consistent information and are consistent with the requirements of the Federal Power Act and the BES Definition as developed by the Standards Drafting Team. We also support the Standards Drafting Team's determination to abandon its initial approach to technical criteria, which would have required adherence to specific numerical thresholds. We agree that this approach was not workable on a nationwide basis, and that the approach embodied in the current draft of the Technical Principles, which would require specific kinds of information on a generic basis but would leave engineering judgment about the significance of that information to the relevant RE, is more workable and provides appropriate deference to the experience and judgment of the Registered Entities.

An entity seeking an Exception should have the opportunity to present any information it believes is relevant.

Yes

CEC agrees that the items listed on page 4 of the Detailed Information to Support an Exception Request capture the information that generally would be necessary to make a reasoned determination concerning the BES status of a generation facility. We suggest three refinements to the questions: (1) Question 2 should be modified by adding "necessary for the operation of the interconnected bulk transmission system" to the end of the question, so that it reads: "Is the generator or the generator facility used to provide Ancillary Services necessary for the operation of the interconnected bulk transmission system?" The italicized language is necessary to distinguish between a generator that provides, for example, reactive power or regulating reserves that support operation of the interconnected bulk grid, and, for example, a behind-the-meter generator that provides back-up generation to a specific industrial facility. The former may be necessary for the reliable operation of the interconnected bulk transmission system, but the latter clearly is not. (2) The current draft of the BES Definition contains Exclusions for radials and for Local Networks. To be consistent with these aspects of the revised BES definition, we suggest modifying question 5 by adding "radial, or Local Network" to the question, so that it would read: "Does the generator use the BES, a radial system, or a Local Network to deliver its actual or scheduled output, or a portion of its actual or scheduled output, to Load?" (3) For reasons similar to those explained in our response to Question 2, a general "catch-all" question should be added that will prompt an entity submitting an Exception Request for a generator to submit any information it believes is relevant to the Exception that is not captured in the previous questions. We suggest the following language: Is there additional information not covered in questions 1 through 5 that supports the Exception Request? If yes, please provide the information and explain why it is relevant to the Exception Request. This will allow an entity seeking an Exception for a generator to identify any unusual circumstances or non-standard information that might support its Exception Request. An entity seeking such an Exception should have the opportunity to present any information it believes is relevant.

Yes

The Standards Drafting Team should consider whether it is necessary to require entities other than the entity filing the Exception Request to provide relevant information, either to the entity filing the Exception Request or to the Registered Entity receiving the Exceptions Request. For example, in order to answer Question 1 on page 4, regarding the impact of the generator under the most severe single contingency, it may be necessary for the relevant Balancing Authority to provide its Most Severe Single Contingency ("MSSC") to the registered entity seeking an Exception. Similarly, the relevant Transmission Operator or Balancing Authority may have information that is necessary to determine whether the generator has been designated as reliability-must-run or if it provides ancillary services supporting reliable operation of the interconnected transmission grid.

Yes

As discussed in our responses to Questions 1 through 3, we believe that certain additional questions are necessary to elicit all information that may be relevant to an Exceptions Request. As discussed in our answer to Question 4, we are also concerned that it may be necessary to obtain information that is in the hands of the relevant Balancing Authority, Transmission Provider, or other entity, and not in the hands of the entity submitting an Exceptions Request, to develop a complete record upon which a reasoned decision concerning an Exceptions Request can be based.

No

No

As a general matter, CEC believes the SDT has provided a reasonable check list that will work in most cases to elicit necessary information from the entity submitting an Exception Request. With the added language suggested in our answers to the previous questions, we believe the proposed form will serve its intended purpose of ensuring that decisions regarding Exception Requests are based upon consistent information and are consistent with the requirements of the Federal Power Act and the BES

Definition as developed by the Standards Drafting Team. We also support the Standards Drafting Team's determination to abandon its initial approach to technical criteria, which would have required adherence to specific numerical thresholds. We agree that this approach was not workable on a nationwide basis, and that the approach embodied in the current draft of the Technical Principles, which would require specific kinds of information on a generic basis but would leave engineering judgment about the significance of that information to the relevant RE, is more workable and provides appropriate deference to the experience and judgment of the Registered Entities.

Dave Hagen

Clearwater Power Company (CPC)

Yes

The Clearwater Power Company (CPC) agrees generally that the General Instructions set forth the basic information that would be necessary to support an Exception Request. We are concerned, however, that the statement "diagram(s) supplied should also show the Protection Systems at the interface points associated with the Elements for which the exception is being requested" may be subject to differing interpretations. We envision that at least four different kinds of documents could be responsive to the description: one-line diagrams with breakers and switches (status); identification of relays by their ANSI device numbers; details of the DC control logic for ANSI devices; and, operational scheme descriptions of the type used by system operators. Accordingly, we suggest that the language be refined to identify the specific kinds of diagrams necessary to identify protection systems at the interface with the Elements for which the Exception is sought, including any required details. WE suggest that a generic example of a completed form be available to the industry to help ensure that Exception Requests are supported by consistent and complete information. Such a generic example could be addressed in the Phase 2 BES efforts.

No

CPC agrees that the checklist of items on pages two and three lists most of the information that would be necessary to determine if an Exceptions Request is justified. We suggest two modifications to the proposed language to ensure consistency with the BES Definition and to provide an entity seeking an Exception with the opportunity to submit all relevant information: (1) We suggest modifying question 6 to "Is the facility part of a designated Cranking Path associated with a Blackstart Resource identified in a Transmission Operator's restoration plan." This language reflects the most recent revision of the BES Definition and also helps distinguish between generators which have Blackstart capability and those generators that are designated as a Blackstart Resource in the Transmission Operator's restoration plan. It is only the latter that are included in the BES under the current draft of the definition. (2) A general "catch-all" question should be added that will prompt the entity submitting an Exception Request to submit any information it believes is relevant to the Exception that is not captured in the other questions. We suggest the following language: Is there additional information not covered in the questions above that supports the Exception Request? If yes, please provide the information and explain why it is relevant to the Exception Request. While we believes the questions set forth in the draft capture the information that generally would be necessary to determine whether an Exception Request should be granted, it is foreseeable that there may be unusual circumstances where the information called for either does not capture the full picture or where studies other than the specific types called for in the draft form support the Exception. An entity seeking an Exception should have the opportunity to present any information it believes is relevant.

Yes

CPC agrees that the items listed on page 4 of the Detailed Information to Support an Exception Request capture the information that generally would be necessary to make a reasoned determination concerning the BES status of a generation facility. We suggest three refinements to the questions: (1) Question 2 should be modified by adding "necessary for the operation of the interconnected bulk transmission system" to the end of the question, so that it reads: "Is the generator or the generator facility used to provide Ancillary Services necessary for the operation of the interconnected bulk transmission system?" Lane Electric Cooperative (LEC)

Yes

The Lane Electric Cooperative (LEC) agrees generally that the General Instructions set forth the basic information that would be necessary to support an Exception Request. We are concerned, however, that the statement "diagram(s) supplied should also show the Protection Systems at the interface

points associated with the Elements for which the exception is being requested” may be subject to differing interpretations. We envision that at least four different kinds of documents could be responsive to the description: one-line diagrams with breakers and switches (status); identification of relays by their ANSI device numbers; details of the DC control logic for ANSI devices; and, operational scheme descriptions of the type used by system operators. Accordingly, we suggest that the language be refined to identify the specific kinds of diagrams necessary to identify protection systems at the interface with the Elements for which the Exception is sought, including any required details. WE suggest that a generic example of a completed form be available to the industry to help ensure that Exception Requests are supported by consistent and complete information. Such a generic example could be addressed in the Phase 2 BES efforts.

No

LEC agrees that the checklist of items on pages two and three lists most of the information that would be necessary to determine if an Exceptions Request is justified. We suggest two modifications to the proposed language to ensure consistency with the BES Definition and to provide an entity seeking an Exception with the opportunity to submit all relevant information: (1) We suggest modifying question 6 to “Is the facility part of a designated Cranking Path associated with a Blackstart Resource identified in a Transmission Operator’s restoration plan.” This language reflects the most recent revision of the BES Definition and also helps distinguish between generators which have Blackstart capability and those generators that are designated as a Blackstart Resource in the Transmission Operator’s restoration plan. It is only the latter that are included in the BES under the current draft of the definition. (2) A general “catch-all” question should be added that will prompt the entity submitting an Exception Request to submit any information it believes is relevant to the Exception that is not captured in the other questions. We suggest the following language: Is there additional information not covered in the questions above that supports the Exception Request? If yes, please provide the information and explain why it is relevant to the Exception Request. While we believes the questions set forth in the draft capture the information that generally would be necessary to determine whether an Exception Request should be granted, it is foreseeable that there may be unusual circumstances where the information called for either does not capture the full picture or where studies other than the specific types called for in the draft form support the Exception. An entity seeking an Exception should have the opportunity to present any information it believes is relevant.

Yes

LEC agrees that the items listed on page 4 of the Detailed Information to Support an Exception Request capture the information that generally would be necessary to make a reasoned determination concerning the BES status of a generation facility. We suggest three refinements to the questions: (1) Question 2 should be modified by adding “necessary for the operation of the interconnected bulk transmission system” to the end of the question, so that it reads: “Is the generator or the generator facility used to provide Ancillary Services necessary for the operation of the interconnected bulk transmission system?” The italicized language is necessary to distinguish between a generator that provides, for example, reactive power or regulating reserves that support operation of the interconnected bulk grid, and, for example, a behind-the-meter generator that provides back-up generation to a specific industrial facility. The former may be necessary for the reliable operation of the interconnected bulk transmission system, but the latter clearly is not. (2) The current draft of the BES Definition contains Exclusions for radials and for Local Networks. To be consistent with these aspects of the revised BES definition, we suggest modifying question 5 by adding “radial, or Local Network” to the question, so that it would read: “Does the generator use the BES, a radial system, or a Local Network to deliver its actual or scheduled output, or a portion of its actual or scheduled output, to Load? (3) For reasons similar to those explained in our response to Question 2, a general “catch-all” question should be added that will prompt an entity submitting an Exception Request for a generator to submit any information it believes is relevant to the Exception that is not captured in the previous questions. We suggest the following language: Is there additional information not covered in questions 1 through 5 that supports the Exception Request? If yes, please provide the information and explain why it is relevant to the Exception Request. This will allow an entity seeking an Exception for a generator to identify any unusual circumstances or non-standard information that might support its Exception Request. An entity seeking such an Exception should have the opportunity to present any information it believes is relevant.

Yes

The Standards Drafting Team should consider whether it is necessary to require entities other than

the entity filing the Exception Request to provide relevant information, either to the entity filing the Exception Request or to the Registered Entity receiving the Exceptions Request. For example, in order to answer Question 1 on page 4, regarding the impact of the generator under the most severe single contingency, it may be necessary for the relevant Balancing Authority to provide its Most Severe Single Contingency ("MSSC") to the registered entity seeking an Exception. Similarly, the relevant Transmission Operator or Balancing Authority may have information that is necessary to determine whether the generator has been designated as reliability-must-run or if it provides ancillary services supporting reliable operation of the interconnected transmission grid.

Yes

As discussed in our responses to Questions 1 through 3, we believe that certain additional questions are necessary to elicit all information that may be relevant to an Exceptions Request. As discussed in our answer to Question 4, we are also concerned that it may be necessary to obtain information that is in the hands of the relevant Balancing Authority, Transmission Provider, or other entity, and not in the hands of the entity submitting an Exceptions Request, to develop a complete record upon which a reasoned decision concerning an Exceptions Request can be based.

No

No

As a general matter, LEC believes the SDT has provided a reasonable check list that will work in most cases to elicit necessary information from the entity submitting an Exception Request. With the added language suggested in our answers to the previous questions, we believe the proposed form will serve its intended purpose of ensuring that decisions regarding Exception Requests are based upon consistent information and are consistent with the requirements of the Federal Power Act and the BES Definition as developed by the Standards Drafting Team. We also support the Standards Drafting Team's determination to abandon its initial approach to technical criteria, which would have required adherence to specific numerical thresholds. We agree that this approach was not workable on a nationwide basis, and that the approach embodied in the current draft of the Technical Principles, which would require specific kinds of information on a generic basis but would leave engineering judgment about the significance of that information to the relevant RE, is more workable and provides appropriate deference to the experience and judgment of the Registered Entities.

Independent Electricity System Operator

Yes

Yes

Yes

No

We anticipate that entities will be granted access to the required historical operations records and modeling data after signing of non-disclosure agreements with the providers of the information.

No

No

Yes

We believe that the SDT proposed approach for exception criteria is reasonable recognizing that one method/criteria cannot be applicable to everyone and every situation within the ERO foot print. However, we believe that there is huge gap and lack of any transparency on how the exception application will be evaluated and processed. We strongly suggest that SDT develop a reference or a guidance document as part of the RoP that should provide some guidance to Registered Entities, Regional Entities and the ERO on how an exception application should be processed. The absence of

such guidance will pose a challenge for each entity including the ERO, and may result in discrepancies amongst Regional Entities. The process may be perceived by registered entities as being non-transparency.

Individual

Michael Henry

Lincoln Electric Cooperative (Lincoln)

Yes

The Lincoln Electric Cooperative (Lincoln) agrees generally that the General Instructions set forth the basic information that would be necessary to support an Exception Request. We are concerned, however, that the statement "diagram(s) supplied should also show the Protection Systems at the interface points associated with the Elements for which the exception is being requested" may be subject to differing interpretations. We envision that at least four different kinds of documents could be responsive to the description: one-line diagrams with breakers and switches (status); identification of relays by their ANSI device numbers; details of the DC control logic for ANSI devices; and, operational scheme descriptions of the type used by system operators. Accordingly, we suggest that the language be refined to identify the specific kinds of diagrams necessary to identify protection systems at the interface with the Elements for which the Exception is sought, including any required details. WE suggest that a generic example of a completed form be available to the industry to help ensure that Exception Requests are supported by consistent and complete information. Such a generic example could be addressed in the Phase 2 BES efforts.

No

LINCOLN agrees that the checklist of items on pages two and three lists most of the information that would be necessary to determine if an Exceptions Request is justified. We suggest two modifications to the proposed language to ensure consistency with the BES Definition and to provide an entity seeking an Exception with the opportunity to submit all relevant information: (1) We suggest modifying question 6 to "Is the facility part of a designated Cranking Path associated with a Blackstart Resource identified in a Transmission Operator's restoration plan." This language reflects the most recent revision of the BES Definition and also helps distinguish between generators which have Blackstart capability and those generators that are designated as a Blackstart Resource in the Transmission Operator's restoration plan. It is only the latter that are included in the BES under the current draft of the definition. (2) A general "catch-all" question should be added that will prompt the entity submitting an Exception Request to submit any information it believes is relevant to the Exception that is not captured in the other questions. We suggest the following language: Is there additional information not covered in the questions above that supports the Exception Request? If yes, please provide the information and explain why it is relevant to the Exception Request. While we believes the questions set forth in the draft capture the information that generally would be necessary to determine whether an Exception Request should be granted, it is foreseeable that there may be unusual circumstances where the information called for either does not capture the full picture or where studies other than the specific types called for in the draft form support the Exception. An entity seeking an Exception should have the opportunity to present any information it believes is relevant.

Yes

LINCOLN agrees that the items listed on page 4 of the Detailed Information to Support an Exception Request capture the information that generally would be necessary to make a reasoned determination concerning the BES status of a generation facility. We suggest three refinements to the questions: (1) Question 2 should be modified by adding "necessary for the operation of the interconnected bulk transmission system" to the end of the question, so that it reads: "Is the generator or the generator facility used to provide Ancillary Services necessary for the operation of the interconnected bulk transmission system?" The italicized language is necessary to distinguish between a generator that provides, for example, reactive power or regulating reserves that support operation of the interconnected bulk grid, and, for example, a behind-the-meter generator that provides back-up generation to a specific industrial facility. The former may be necessary for the reliable operation of the interconnected bulk transmission system, but the latter clearly is not. (2) The current draft of the BES Definition contains Exclusions for radials and for Local Networks. To be consistent with these aspects of the revised BES definition, we suggest modifying question 5 by adding "radial, or Local Network" to the question, so that it would read: "Does the generator use the BES, a radial system, or

a Local Network to deliver its actual or scheduled output, or a portion of its actual or scheduled output, to Load? (3) For reasons similar to those explained in our response to Question 2, a general "catch-all" question should be added that will prompt an entity submitting an Exception Request for a generator to submit any information it believes is relevant to the Exception that is not captured in the previous questions. We suggest the following language: Is there additional information not covered in questions 1 through 5 that supports the Exception Request? If yes, please provide the information and explain why it is relevant to the Exception Request. This will allow an entity seeking an Exception for a generator to identify any unusual circumstances or non-standard information that might support its Exception Request. An entity seeking such an Exception should have the opportunity to present any information it believes is relevant.

Yes

The Standards Drafting Team should consider whether it is necessary to require entities other than the entity filing the Exception Request to provide relevant information, either to the entity filing the Exception Request or to the Registered Entity receiving the Exceptions Request. For example, in order to answer Question 1 on page 4, regarding the impact of the generator under the most severe single contingency, it may be necessary for the relevant Balancing Authority to provide its Most Severe Single Contingency ("MSSC") to the registered entity seeking an Exception. Similarly, the relevant Transmission Operator or Balancing Authority may have information that is necessary to determine whether the generator has been designated as reliability-must-run or if it provides ancillary services supporting reliable operation of the interconnected transmission grid.

Yes

As discussed in our responses to Questions 1 through 3, we believe that certain additional questions are necessary to elicit all information that may be relevant to an Exceptions Request. As discussed in our answer to Question 4, we are also concerned that it may be necessary to obtain information that is in the hands of the relevant Balancing Authority, Transmission Provider, or other entity, and not in the hands of the entity submitting an Exceptions Request, to develop a complete record upon which a reasoned decision concerning an Exceptions Request can be based.

No

No

As a general matter, LINCOLN believes the SDT has provided a reasonable check list that will work in most cases to elicit necessary information from the entity submitting an Exception Request. An entity seeking such an Exception should have the opportunity to present any information it believes is relevant.

Yes

The Standards Drafting Team should consider whether it is necessary to require entities other than

the entity filing the Exception Request to provide relevant information, either to the entity filing the Exception Request or to the Registered Entity receiving the Exceptions Request. For example, in order to answer Question 1 on page 4, regarding the impact of the generator under the most severe single contingency, it may be necessary for the relevant Balancing Authority to provide its Most Severe Single Contingency ("MSSC") to the registered entity seeking an Exception. Similarly, the relevant Transmission Operator or Balancing Authority may have information that is necessary to determine whether the generator has been designated as reliability-must-run or if it provides ancillary services supporting reliable operation of the interconnected transmission grid.

Yes

As discussed in our responses to Questions 1 through 3, we believe that certain additional questions are necessary to elicit all information that may be relevant to an Exceptions Request. As discussed in our answer to Question 4, we are also concerned that it may be necessary to obtain information that is in the hands of the relevant Balancing Authority, Transmission Provider, or other entity, and not in the hands of the entity submitting an Exceptions Request, to develop a complete record upon which a reasoned decision concerning an Exceptions Request can be based.

No

No

As a general matter, RAFT believes the SDT has provided a reasonable check list that will work in most cases to elicit necessary information from the entity submitting an Exception Request. With the added language suggested in our answers to the previous questions, we believe the proposed form will serve its intended purpose of ensuring that decisions regarding Exception Requests are based upon consistent information and are consistent with the requirements of the Federal Power Act and the BES Definition as developed by the Standards Drafting Team. We also support the Standards Drafting Team's determination to abandon its initial approach to technical criteria, which would have required adherence to specific numerical thresholds. We agree that this approach was not workable on a nationwide basis, and that the approach embodied in the current draft of the Technical Principles, which would require specific kinds of information on a generic basis but would leave engineering judgment about the significance of that information to the relevant RE, is more workable and provides appropriate deference to the experience and judgment of the Registered Entities.

Individual

Umatilla Electric Cooperative

Yes

The Umatilla Electric Cooperative (UEC) agrees generally that the General Instructions set forth the basic information that would be necessary to support an Exception Request. We are concerned, however, that the statement "diagram(s) supplied should also show the Protection Systems at the interface points associated with the Elements for which the exception is being requested" may be subject to differing interpretations. We envision that at least four different kinds of documents could be responsive to the description: one-line diagrams with breakers and switches (status); identification of relays by their ANSI device numbers; details of the DC control logic for ANSI devices; and, operational scheme descriptions of the type used by system operators. Accordingly, we suggest that the language be refined to identify the specific kinds of diagrams necessary to identify protection systems at the interface with the Elements for which the Exception is sought, including any required details. WE suggest that a generic example of a completed form be available to the industry to help ensure that Exception Requests are supported by consistent and complete information. Such a generic example could be addressed in the Phase 2 BES efforts.

No

UEC agrees that the checklist of items on pages two and three lists most of the information that would be necessary to determine if an Exceptions Request is justified. We suggest two modifications to the proposed language to ensure consistency with the BES Definition and to provide an entity seeking an Exception with the opportunity to submit all relevant information: (1) We suggest modifying question 6 to "Is the facility part of a designated Cranking Path associated with a Blackstart Resource identified in a Transmission Operator's restoration plan." This language reflects the most recent revision of the BES Definition and also helps distinguish between generators which have

Blackstart capability and those generators that are designated as a Blackstart Resource in the Transmission Operator's restoration plan. It is only the latter that are included in the BES under the current draft of the definition. (2) A general "catch-all" question should be added that will prompt the entity submitting an Exception Request to submit any information it believes is relevant to the Exception that is not captured in the other questions. We suggest the following language: Is there additional information not covered in the questions above that supports the Exception Request? If yes, please provide the information and explain why it is relevant to the Exception Request. While we believes the questions set forth in the draft capture the information that generally would be necessary to determine whether an Exception Request should be granted, it is foreseeable that there may be unusual circumstances where the information called for either does not capture the full picture or where studies other than the specific types called for in the draft form support the Exception. An entity seeking an Exception should have the opportunity to present any information it believes is relevant.

Yes

UEC agrees that the items listed on page 4 of the Detailed Information to Support an Exception Request capture the information that generally would be necessary to make a reasoned determination concerning the BES status of a generation facility. We suggest three refinements to the questions: (1) Question 2 should be modified by adding "necessary for the operation of the interconnected bulk transmission system" to the end of the question, so that it reads: "Is the generator or the generator facility used to provide Ancillary Services necessary for the operation of the interconnected bulk transmission system?" The italicized language is necessary to distinguish between a generator that provides, for example, reactive power or regulating reserves that support operation of the interconnected bulk grid, and, for example, a behind-the-meter generator that provides back-up generation to a specific industrial facility. The former may be necessary for the reliable operation of the interconnected bulk transmission system, but the latter clearly is not. (2) The current draft of the BES Definition contains Exclusions for radials and for Local Networks. To be consistent with these aspects of the revised BES definition, we suggest modifying question 5 by adding "radial, or Local Network" to the question, so that it would read: "Does the generator use the BES, a radial system, or a Local Network to deliver its actual or scheduled output, or a portion of its actual or scheduled output, to Load? (3) For reasons similar to those explained in our response to Question 2, a general "catch-all" question should be added that will prompt an entity submitting an Exception Request for a generator to submit any information it believes is relevant to the Exception that is not captured in the previous questions. We suggest the following language: Is there additional information not covered in questions 1 through 5 that supports the Exception Request? If yes, please provide the information and explain why it is relevant to the Exception Request. This will allow an entity seeking an Exception for a generator to identify any unusual circumstances or non-standard information that might support its Exception Request. An entity seeking such an Exception should have the opportunity to present any information it believes is relevant.

Yes

The Standards Drafting Team should consider whether it is necessary to require entities other than the entity filing the Exception Request to provide relevant information, either to the entity filing the Exception Request or to the Registered Entity receiving the Exceptions Request. For example, in order to answer Question 1 on page 4, regarding the impact of the generator under the most severe single contingency, it may be necessary for the relevant Balancing Authority to provide its Most Severe Single Contingency ("MSSC") to the registered entity seeking an Exception. Similarly, the relevant Transmission Operator or Balancing Authority may have information that is necessary to determine whether the generator has been designated as reliability-must-run or if it provides ancillary services supporting reliable operation of the interconnected transmission grid.

Yes

As discussed in our responses to Questions 1 through 3, we believe that certain additional questions are necessary to elicit all information that may be relevant to an Exceptions Request. As discussed in our answer to Question 4, we are also concerned that it may be necessary to obtain information that is in the hands of the relevant Balancing Authority, Transmission Provider, or other entity, and not in the hands of the entity submitting an Exceptions Request, to develop a complete record upon which a reasoned decision concerning an Exceptions Request can be based.

No

No
As a general matter, UEC believes the SDT has provided a reasonable check list that will work in most cases to elicit necessary information from the entity submitting an Exception Request. With the added language suggested in our answers to the previous questions, we believe the proposed form will serve its intended purpose of ensuring that decisions regarding Exception Requests are based upon consistent information and are consistent with the requirements of the Federal Power Act and the BES Definition as developed by the Standards Drafting Team. On the posted document, we did not find how an exception application will be assessed by the RE and NERC. We believe that there is a huge gap and a lack of transparency for all stakeholders on how the exception application will be evaluated and processed. We strongly suggest that the SDT develop a reference or a guidance document as part of the RoP that will provide guidance to Registered Entities, Regional Entities and the ERO on how an exception application would/should be processed.
Yes
We believe that the SDT's proposed approach for exception criteria is reasonable; recognizing that one method/criteria can not be applicable to everyone and every situation within the ERO foot print. See our comment in Q1.
Yes
See comments in Q1.
No
Yes
The general approach, information, data, and assessments proposed seem to be reasonable. However, guidance is not provided as to how this information may be evaluated in the decision making process. As such, a reference document should be developed and provide guidance how applications will be assessed. For example" 1) Does the element(s)? • Would have qualified under one of the exclusions or inclusions but have marginally different threshold as prescribed in the definition; • transfer bulk power within (intra) or between (inter) two Balancing Authority Areas; • monitor facilities included in an Interconnection Reliability Operating Limit (IROL); • are not considered necessary for the operation of interconnected transmission system under normal conditions, contingency or prolonged outage conditions. 2) Are System Element(s) located in close electrical proximity to Load? • Electrical proximity may be a measurement of system impedance between load centers within the system seeking exception. • Other physical characteristics. 3) Are System Elements treated as primarily radial in character? • Smaller deviation from the exclusion E1. • This can be demonstrated by the way the connections to the BES are operated (e.g., the local area is not operated as part of the BES with disconnection procedures when events occur in the local area to separate it.) • This can also be demonstrated by the way resources in the local area are treated in operations, for example, they are not included in a regional dispatch or secured by an ISO/RTO. • Power flows into the system, but rarely flows out. i. This can be demonstrated through transactional records or load flow analysis where it is shown that flow out does not occur or occurs only under a very limited set of conditions and for a limited quantity of energy. a. The limited set of conditions

must clearly state the conditions where power flows out, for example, only under specified contingency events. b. Transactional records provided must be for the same time specified in the Exception Rules of Procedure for performing periodic exception self-certifications (presently two years). c. Power entering the system is not recognized or regularly transported on to some other system. (This can be demonstrated by operational procedures that restrict use of delivered power to that system, e.g., the absence of a wheeling agreement or an agreement that generally restricts wheeling under normal) d. The System Element(s) have a very small Distribution Factor on any other BES Element(s). • System Elements are not necessary for the operation of interconnected transmission under normal, contingency or prolonged outage conditions.

No

We believe, and support that RoP exception procedures are adequately dealing with this issue.

Yes

As mentioned above, we strongly suggest and encourage that SDT to develop a reference or a guidance document that will provide guidance to Registered Entities, Regional Entities and the ERO on how an exception application should/would be processed.

Transmission Reliability Program

Yes

BPA suggests clarifying that the interface point is the point where the entity seeking the exception's facility or facilities interconnect(s) to the Bulk Electric System facility. Page 1 states "Supporting statements for your position from other entities are encouraged." BPA believes coordination with affected systems should be required under the exemption process.

No

Regarding #4 on page 2: BPA believes the impact to the over-all reliability of the BES needs to consider more than just an outage of the facility requesting exclusion. One example is a contingency outage of a parallel facility that could cause an overload. Item 4 needs to include impacts of either the outage of the facility, or with the facility in service. BPA believes that the entity requesting an exception may not have information on impacts of the facility on parallel higher-voltage facilities because the NERC requirements for data sharing for these types of facilities does not necessarily include owners and operators of lower voltage systems. The entity requesting an exemption would likely need to coordinate with affected systems, and this coordination should be required in the exemption process so that affected systems are aware of the possible exclusion.

Yes

Regarding #1 on page 4: BPA Believes seasonality may need to be considered when comparing the generator with the most severe single contingency.

Yes

BPA believes the studies discussed in pages 2-4 would likely need to be completed and the required information supplied by the Transmission Planner/Operator of the Balancing Authority Area since many of the assumptions regarding performance of the BES to delivery under a variety of operating conditions is known only to the TP and TOP of the system.

We agree with the information requested on pages 2 and 3, however we would like more clarification regarding Item 7. When answering what % of the calendar year power flows through the facility into BES, should this be calculated on an hourly basis? We would also like clarification for Item 7 regarding the request for SCADA data from the last 2 years to determine the minimum and maximum magnitude of the power flow out of the facility. What data should be used in situations with new facilities or in situations or where the system configuration (topology) has changed in such a way that the power flows in the area have changed, so the last 2 years of SCADA data is no longer relevant
Not Applicable
No

Yes
We are assuming that "yes" answers on this checklist are not intended to result in automatic rejection of the application. We think the procedure would benefit from a general statement noting that all answers taken together will be considered to make clear that no single answer will necessarily be dispositive of the outcome.

Given that the second sentence in the 1st paragraph of this comment form reads "This same process would be used by Registered Entities to justify including Elements in the BES that might otherwise be excluded according to the proposed definition and designations.", Dominion suggests that the 1st sentence under General Instructions be revised to read "A one-line breaker diagram identifying the facility for which the exception (or inclusion) is requested must be supplied with every application. The diagram(s) supplied should also show the Protection Systems at the interface points associated with the Elements for which the exception (or inclusion) is being requested."
Yes
No
The SDT language specifying services acceptable for inclusion in an exclusion request references ancillary services identified under a Transmission Service Provider's OATT. However, there is great variation in the services that have actually been implemented and posted across North America under those OATTs. There is no consistent description or terminology to characterize those services. In short, Transmission Providers have been permitted to individualize OATT services to fit regional market structures and vernacular. For example, PJM's OATT includes a schedule for Blackstart Service. The FERC pro-forma tariff does not. ISO-NE's tariff includes the following ancillary services (which are performed by the ISO and TSP): • Scheduling, System Control and Dispatch Service • Energy Imbalance Service • Generator Imbalance Service Therefore, Dominion suggests that the SDT provide a specific list of ancillary services that would be eligible for exclusion, rather than rely on OATT references. Examples might include: reactive, voltage control or regulation services, frequency response and blackstart services. Dominion is also aware that the phrase " 'must run" is used in some RTO/ISO market systems to indicate intent to self-schedule the generator. Dominion suggests that question 3 be revised to read "Is the generator designated as a "must run" unit by either the Balancing Authority, Resource Planner or Reliability Coordinator?"
Yes
It has been Dominion's experience that CEII or Code/Standards of Conduct rules may restrict generation entities (GO/GOP) from obtaining some of the information necessary to perform the analysis needed to file the "Detailed Information to Support an Exception Request". Dominion is also aware that, in some cases, generation entities do not have the technical expertise (transmission

planning, power flow and or stability analysis background) to perform such analysis.
No
Yes
Much of the information necessary to perform the analysis required is restricted either by federal and/or state Codes/Standards of Conduct and/or CEII prohibitions.
Yes
The Detailed Information to Support an Exception Request form has 2 sections; one for transmission facilities and another for generation facilities. Yet, the Project 2010-17 Definition of Bulk Electric System document uses other terms such as real and reactive power resources, dispersed power producing resources, static or dynamic devices, blackstart resources, radial systems, local networks (LN), and reactive power devices. Dominion suggests that the Detailed Information to Support an Exception Request form be revised to conform to the Project 2010-17 Definition of Bulk Electric System document through either use of some sort of 'selection' (checkbox, drop down, write in) or revision of transmission facilities and generation facilities to be more inclusive.

This question is actually asking two questions; Tri-State's answers would be No & Yes. There needs to be a better introduction to what and why the exception is being requested.
Again Yes/No is conflicting in the question. The requested information in#2 is too vague and may be subjective. If the information in#7 is requested in the planning stage the data would not be available. What objective criteria would be used to determine the state of the exception request?
Again Yes/No is conflicting in the question. Information requested in #4 is subjective and too vague.
Yes
It may be hard for a GO to get the information requested in #1 or #4.
No
No
Yes
TSGT believes that the proposed "Technical Principles for Demonstrating BES Exceptions Request" does not clearly define the basis for decisions to exclude or include, which will lead to inconsistent application by the Regions. We believe that the checklist items for transmission and generation facilities are appropriate questions that must be answered in considering all requests. However, without objective criteria defining how to assess the materials submitted, the current methodology leaves it to each region to develop their own methodology and criteria for evaluating the submittals. We believe the lack of clarity regarding what studies must be submitted and what must be demonstrated by the studies submitted will be overly burdensome on the submitting entity and the Region, as multiple studies may be required for the two to agree that there is sufficient justification for an exemption request. We believe that additional work is necessary to develop clear, objective methods and criteria for identifying which facilities may be excluded from or should be included in the Bulk Electric System. Clear, objective methods and criteria will enable the submitter of requests to understand what is necessary for submitting an exception request and will provide for consistency among the regions in their initial assessment and recommendations to the ERO.

1)Why must the one-line diagram supplied show the Protection Systems at the interface points associated with the elements for which the exception is being requested? Since Protection Systems are not part of the new bright-line BES definition why would their presence, or absence, on the one-line diagram influence the exception process? 2)The third bullet needs additional detail of what is being requested. The phrase "...key performance measures.." and use of methodologies described in TPS Standards does not provide sufficient direction needed. (see question #4)
No
1) Why is Item 5 (Question pertaining to whether the facility is used for off-site power to a nuclear plant) included, since this criteria is not part of the proposed bright-line BES definition. 2) Similarly, why is Item 6 (Question pertaining to whether the facility is part of a Cranking Path associated with a Black Start Resource) included, since Black Start Cranking Paths were removed from the latest BES definition. Both Items 5 and 6 should be removed from the Exception Request Form.
Yes
No
Not all TOs have the capability to perform the power flow and stability analysis on their own, necessary to meet the exception request. It may be burdensome for the TO to hire a consultant or to have their affiliated TPL perform the rigorous study/analysis as contained in the TPL standards. Additional details should be provided as to what part of the TPL standards apply. Should the Affiliated TPL be required to perform TOs studies for exception requests? If so should that be stated in a related standard as a requirement?

Roger Meader
Coos-Curry Electric Cooperative
Yes
The Coos-Curry Electric Cooperative (CCEC) agrees generally that the General Instructions set forth the basic information that would be necessary to support an Exception Request. We are concerned, however, that the statement "diagram(s) supplied should also show the Protection Systems at the interface points associated with the Elements for which the exception is being requested" may be subject to differing interpretations. We envision that at least four different kinds of documents could be responsive to the description: one-line diagrams with breakers and switches (status); identification of relays by their ANSI device numbers; details of the DC control logic for ANSI devices; and,

operational scheme descriptions of the type used by system operators. Accordingly, we suggest that the language be refined to identify the specific kinds of diagrams necessary to identify protection systems at the interface with the Elements for which the Exception is sought, including any required details. WE suggest that a generic example of a completed form be available to the industry to help ensure that Exception Requests are supported by consistent and complete information. Such a generic example could be addressed in the Phase 2 BES efforts.

No

CCEC agrees that the checklist of items on pages two and three lists most of the information that would be necessary to determine if an Exceptions Request is justified. We suggest two modifications to the proposed language to ensure consistency with the BES Definition and to provide an entity seeking an Exception with the opportunity to submit all relevant information: (1) We suggest modifying question 6 to "Is the facility part of a designated Cranking Path associated with a Blackstart Resource identified in a Transmission Operator's restoration plan." This language reflects the most recent revision of the BES Definition and also helps distinguish between generators which have Blackstart capability and those generators that are designated as a Blackstart Resource in the Transmission Operator's restoration plan. It is only the latter that are included in the BES under the current draft of the definition. (2) A general "catch-all" question should be added that will prompt the entity submitting an Exception Request to submit any information it believes is relevant to the Exception that is not captured in the other questions. We suggest the following language: Is there additional information not covered in the questions above that supports the Exception Request? If yes, please provide the information and explain why it is relevant to the Exception Request. While we believes the questions set forth in the draft capture the information that generally would be necessary to determine whether an Exception Request should be granted, it is foreseeable that there may be unusual circumstances where the information called for either does not capture the full picture or where studies other than the specific types called for in the draft form support the Exception. An entity seeking an Exception should have the opportunity to present any information it believes is relevant.

Yes

CCEC agrees that the items listed on page 4 of the Detailed Information to Support an Exception Request capture the information that generally would be necessary to make a reasoned determination concerning the BES status of a generation facility. We suggest three refinements to the questions: (1) Question 2 should be modified by adding "necessary for the operation of the interconnected bulk transmission system" to the end of the question, so that it reads: "Is the generator or the generator facility used to provide Ancillary Services necessary for the operation of the interconnected bulk transmission system?" The italicized language is necessary to distinguish between a generator that provides, for example, reactive power or regulating reserves that support operation of the interconnected bulk grid, and, for example, a behind-the-meter generator that provides back-up generation to a specific industrial facility. The former may be necessary for the reliable operation of the interconnected bulk transmission system, but the latter clearly is not. (2) The current draft of the BES Definition contains Exclusions for radials and for Local Networks. To be consistent with these aspects of the revised BES definition, we suggest modifying question 5 by adding "radial, or Local Network" to the question, so that it would read: "Does the generator use the BES, a radial system, or a Local Network to deliver its actual or scheduled output, or a portion of its actual or scheduled output, to Load?" (3) For reasons similar to those explained in our response to Question 2, a general "catch-all" question should be added that will prompt an entity submitting an Exception Request for a generator to submit any information it believes is relevant to the Exception that is not captured in the previous questions. We suggest the following language: Is there additional information not covered in questions 1 through 5 that supports the Exception Request? If yes, please provide the information and explain why it is relevant to the Exception Request. This will allow an entity seeking an Exception for a generator to identify any unusual circumstances or non-standard information that might support its Exception Request. An entity seeking such an Exception should have the opportunity to present any information it believes is relevant.

Yes

The Standards Drafting Team should consider whether it is necessary to require entities other than the entity filing the Exception Request to provide relevant information, either to the entity filing the Exception Request or to the Registered Entity receiving the Exceptions Request. For example, in order to answer Question 1 on page 4, regarding the impact of the generator under the most severe single

contingency, it may be necessary for the relevant Balancing Authority to provide its Most Severe Single Contingency ("MSSC") to the registered entity seeking an Exception. Similarly, the relevant Transmission Operator or Balancing Authority may have information that is necessary to determine whether the generator has been designated as reliability-must-run or if it provides ancillary services supporting reliable operation of the interconnected transmission grid.

Yes

As discussed in our responses to Questions 1 through 3, we believe that certain additional questions are necessary to elicit all information that may be relevant to an Exceptions Request. As discussed in our answer to Question 4, we are also concerned that it may be necessary to obtain information that is in the hands of the relevant Balancing Authority, Transmission Provider, or other entity, and not in the hands of the entity submitting an Exceptions Request, to develop a complete record upon which a reasoned decision concerning an Exceptions Request can be based.

No

No

As a general matter, CCEC believes the SDT has provided a reasonable check list that will work in most cases to elicit necessary information from the entity submitting an Exception Request. With the added language suggested in our answers to the previous questions, we believe the proposed form will serve its intended purpose of ensuring that decisions regarding Exception Requests are based upon consistent information and are consistent with the requirements of the Federal Power Act and the BES Definition as developed by the Standards Drafting Team. We also support the Standards Drafting Team's determination to abandon its initial approach to technical criteria, which would have required adherence to specific numerical thresholds. We agree that this approach was not workable on a nationwide basis, and that the approach embodied in the current draft of the Technical Principles, which would require specific kinds of information on a generic basis but would leave engineering judgment about the significance of that information to the relevant RE, is more workable and provides appropriate deference to the experience and judgment of the Registered Entities.

Transmission Access Policy Study Group (please see [www.tapsgroup.org](http://www.tapsgroup.org) for a list of TAPS' more than 40 members)

Glossary terms should be capitalized throughout the document. Lowercase "facility," especially, should not be used. The document should use "Element" instead. The term "interface points," while common, may not have a sufficiently common understanding to be used in this context. "Boundaries of the Element(s) for which the exception is being requested" may express the SDT's meaning more clearly.

Question 7 asks, "[d]oes power flow through this facility into the BES?" As in the rest of the document, the reference should be to an "Element(s)," rather than to a "facility." In addition, we suggest that the meaning of power flowing "through" the Element(s) be clarified, consistent with clarification of the same point in Exclusion E3 of the BES Definition. In TAPS' comments on the BES Definition, also submitted today, TAPS suggests that the first sentence of Exclusion E3 be revised to state: "Power flows only into the LN, that is, at each individual connection at 100 kV or higher, the pre-contingency flow of power is from outside the LN into the LN for all hours of the previous 2 years." We propose that Question 7 in the Detailed Information to Support an Exception Requests be similarly revised: "Does power flow from this facility into the BES, i.e., at any individual connection at 100kV or higher, is the pre-contingency flow of power from the LN to the BES for any hour of the previous 2 years?"

The exception request form should begin with a question asking if the inclusion was triggered by the entity responding to an emergency request by the applicable BA, RC or TOP. The entity's response to support recovery from an emergency may have resulted in (1) power flows through the entity's facility into the BES, and/or (2) power injections to the BES that exceed the 20/75-MVA thresholds. The entity should not be required to provide detailed data and studies (as described in the "General Instructions") if either of those conditions would not have occurred but for an emergency situation.
No
A sub-question should be added to Question 1 asking: (1) Does the generation serve all or a part of retail customer Load, and (2) If so, the maximum net capacity of each unit injected to the BES during non-emergency conditions.
Yes
Our "Yes" response is conditioned on the comments to Questions 1 and 2 above.
Yes
It may be necessary that the exception request form explicitly address this potential problem by allowing the entity seeking an exception to state that for reasons beyond its control it failed to acquire the necessary data, base case or supporting document to enable completion of the filing.

From our perspective, the first question should be "Is the facility connected at 100 kV or above?" The questions should be reordered. Of the questions listed, question #3 should be #1, and questions #1 should be the last question in this section. Regarding the word "permanent" as it is used to describe Flowgates, it is suggested that the word "limiting" or "constrained" be used instead.
No
It is suggested that question #2 be deleted and replaced with "Is the generator designated as a black-start unit in an entity's restoration plan?"

In the third bullet under the list of study attributes, it is very important to specifically list the "key performance indicators of BES reliability". This will assist in pointing the studies to focus on the issues relevant to determining the significance of the exception request.
Yes
We agree with the information being requested.

No
We do not agree completely with the information being requested. For checklist item #2, please specify what is included in "providing Ancillary Services" for a generator. For #4, can the question include a measure of evaluating the "most severe system impact"? Can the specific study that is required to be evaluated be outlined?
Yes
An IPP with no Transmission Planning department may find it very difficult to perform an interconnection wide base case as required in the general instructions.

: The last half of the first sentence should be changed to "do not have to seek an Exclusion Exception under the Exception Procedure for the Element(s)." The use of "Element(s)" relates back to that term at the start of the sentence, and the reference to an "Exclusion Exception" is necessary because an entity (albeit probably not the Owner), still may choose to seek an Inclusion Exception for such an Element(s). In the 3rd bullet, the reference should be to TPL standards (plural).
Yes
No
Item 2 asks about "the generator or generator Facility," but 3, 4 and 5 only refer to the generator. There is no immediately apparent reason for them to be different. The language in Item 2 seems preferable.
No
Throughout the document, because it will be part of a larger Exception Request Form, it should, when possible, use terms consistent with the rest of that form (e.g., "Request" rather than "application"). Similarly, defined terms (even if only defined in the context of the Request Form in which these Principles will be used) such as "Exception," "Request," "Element" or "Facility" should be capitalized; if the use of lower case is intended to convey a different meaning than what is defined, another term should be used to avoid confusion. The Definition and Request Form generally use the term "Element," so it is unclear why this document should so consistently use "facility." For consistency, "Element(s)" or possibly "Element(s) or Facility" should be used.

This question is actually asking two questions; Tri-State's answers would be No & Yes. There needs to be a better introduction to what and why the exception is being requested.
Again Yes/No is conflicting in the question. The requested information in#2 is too vague and may be subjective. If the information in#7 is requested in the planning stage the data would not be available. What objective criteria would be used to determine the state of the exception request?
Again Yes/No is conflicting in the question. Information requested in#4 is subjective and too vague.
Yes
It may be hard for a GO to get the information requested in #1 or #4.

TSGT believes that the proposed "Technical Principles for Demonstrating BES Exceptions Request" does not clearly define the basis for decisions to exclude or include, which will lead to inconsistent application by the Regions. We believe that the checklist items for transmission and generation facilities are appropriate questions that must be answered in considering all requests. However, without objective criteria defining how to assess the materials submitted, the current methodology leaves it to each region to develop their own methodology and criteria for evaluating the submittals. We believe the lack of clarity regarding what studies must be submitted and what must be demonstrated by the studies submitted will be overly burdensome on the submitting entity and the Region, as multiple studies may be required for the two to agree that there is sufficient justification for an exemption request. We believe that additional work is necessary to develop clear, objective methods and criteria for identifying which facilities may be excluded from or should be included in the Bulk Electric System. Clear, objective methods and criteria will enable the submitter of requests to understand what is necessary for submitting an exception request and will provide for consistency among the regions in their initial assessment and recommendations to the ERO.

The requirement to base flow studies on an "interconnection-wide base case" is likely to include many more lines and buses than necessary to model the impact of a facility that is not material to the BES. Holland BPW request the words "or regional reduction of such a case" be added after "interconnection-wide base case" to avoid unnecessary expense and detail if a more limited study set is adequate to demonstrate the lack of material impact of the facility(ies) in question.
Yes

Yes
Yes
On Page 4 Question 1, information on the host Balancing Authority's most severe single contingency may not be publically available and therefore difficult or impossible for a smaller entity to obtain. Even if the data is available, it may not be meaningful in a larger Balancing Authority area such as within MISO where the most severe contingency may be geographically and electrically remote. A more readily available and meaningful measure would be a comparison of the generator's capability as a percent of the peak load for the local Balancing Authority or sub-Balancing Authority, as applicable.
Yes
The following revisions should be made to the procedures: 1. The Technical Review Panel (TRP) provided for in Section 5.3 should not include any staff from the host Regional Entity. 2. The Regional Entity should be required to include an attestation of a qualified individual or individuals to support the factual and technical bases for the decision. This is necessary for purposes of establishing a record in the event of an appeal. If a dispute is appealed, there must be someone at the Regional Entity level that serves as the witness supporting the Regional Entity decision. Currently, there is no accountability for the arguments and suppositions put forth by the Regional Entity; no individuals that stand behind the technical bases proffered in the Regional Entity's written decision. Requiring a qualified individual to attest to the facts and technical arguments relied upon in arriving at the decision will ensure that someone at the Regional Entity level is prepared to take responsibility for reviewing a decision before it is issued, to stand behind the assertions and conclusions reached by the Regional Entity, and whom the Submitting Party may cross examine at hearing. 3. A party seeking an exception should have the right to request a hearing and should not be limited to a paper process. 4. The procedures should not permit the TRP or the Regional Entity to make a decision based upon information that is outside of the record placed before it. That is, the TRP and the Regional Entity may not, on their own, conduct an investigation or seek information independently from what has been presented to it. If the TRP or the Regional Entity requires additional information, it must be requested and provided transparently, and the Submitting Party must have an opportunity to comment upon or challenge that information before the TRP or the Regional Entity relies upon it in any way. This is not currently happening at the Regional Entity and NERC level – decisions have been made based upon documents and information that are not part of the record; the information is not shared with the Submitting Party (the party challenging registration) prior to (or after) a decision is made. 5. Section 5.2.2. should be revised as follows: "Upon Acceptance of the Exception Request, the Regional Entity and Submitting Party (and Owner, if different) shall confer to establish milestones in order to complete the substantive review of the Exception Request within six months after Acceptance of the Exception Request or within an alternative time period under Section 5.0. The Regional Entity and the Submitting Party (and Owner, if different) shall also discuss whether and to what extent a reduced compliance burden is appropriate during the review period. At the conclusion of the review period, the Regional Entity shall issue a notice (in accordance with Sections 5.2.3) stating its Recommendation that the Exception Request be approved or disapproved."

City of Austin dba Austin Energy
Yes
AE agrees generally that the General Instructions set forth the basic information that would be necessary to support an Exception Request. AE is concerned, however, that the statement "diagram(s) supplied should also show the Protection Systems at the interface points associated with the Elements for which the exception is being requested" may be subject to differing interpretations. AE believes that at least four different kinds of documents would respond to the description: (i) one-line diagrams with breakers and switches (status); (ii) identification of relays by their ANSI device numbers; (iii) details of the DC control logic for ANSI devices; and, (iv) operational scheme

descriptions of the type used by system operators. Accordingly, we suggest the language be refined to identify the specific kinds of diagrams necessary to identify protection systems at the interface with the Elements for which the Exception is sought, including any required details, such as breaker settings. AE suggests that a generic example of a completed form be available to the industry to help ensure that Exception Requests are supported by consistent and complete information. Such a generic example could be addressed in the Phase 2 BES efforts.

No

AE agrees that the checklist of items on pages two and three lists most of the information necessary to determine if an Exceptions Request is justified. We suggest three modifications to the proposed language to ensure consistency with Section 215 of the Federal Power Act, with the BES Definition, and to provide an entity seeking an Exception with the opportunity to submit all relevant information: (1) AE suggests that a new question be added concerning the function of the facility, which would read: "Does the facility function as a local distribution facility rather than a Transmission facility? If yes, please provide a detailed explanation of your answer." AE makes this suggestion because Section 215(a)(1) of the FPA makes clear that "facilities used in the local distribution of electric energy" are excluded from the BES (16 U.S.C. § 824o(a)(1)) and the most recent draft of the BES definition incorporates the same language. AE believes a question to address the function of the Element or system subject to an Exception Request is necessary to determine whether the Element or system is "used" in local distribution and thereby to ensure observance of the statutory limit on the BES. Further, we believe a variety of information may be relevant to determining whether a particular facility functions as local distribution rather than as part of the BES. For example, if power is not scheduled across the facility or if capacity on the system is not posted on the relevant OASIS, it is likely to function as local distribution, not transmission. Similarly, if power enters the system and is delivered to load within the system rather than moving to load located on another system, its function is local distribution rather than transmission. AE proposes the language above as an open-ended question so the entity submitting the Exceptions Request can provide this and any other information it deems relevant to facility function. (2) AE suggests modifying question 6 to "Is the facility part of a designated Cranking Path associated with a Blackstart Resource identified in a Transmission Operator's restoration plan." This language reflects the most recent revision of the BES Definition and also helps distinguish between generators which have Blackstart capability and those designated as a Blackstart Resource in the Transmission Operator's restoration plan. It is only the latter that are included in the BES under the current draft of the definition. (3) A general "catch-all" question should be added that will prompt the entity submitting an Exception Request to submit any information it believes is relevant to the Exception that is not captured in the other questions. We suggest the following language: Is there additional information not covered in the questions above that supports the Exception Request? If yes, please provide the information and explain why it is relevant to the Exception Request. While AE believes the questions set forth in the draft capture the information that generally would be necessary to determine whether an Exception Request should be granted, there may be unusual circumstances where the information either does not capture the full picture or where studies other than the specific types called for in the draft form support the Exception. An entity seeking an Exception should have the opportunity to present any information it believes is relevant.

Yes

AE agrees that the items listed on page 4 of the Detailed Information to Support an Exception Request capture the information generally necessary to make a reasoned determination concerning the BES status of a generation facility. AE suggests three refinements to the questions: (1) Modify Question 2 by adding "necessary for the operation of the interconnected bulk transmission system" to the end of the question, so it reads: "Is the generator or the generator facility used to provide Ancillary Services necessary for the operation of the interconnected bulk transmission system?" The italicized language is necessary to distinguish between a generator that provides, for example, reactive power or regulating reserves that support operation of the interconnected bulk grid and, for example, a behind-the-meter generator that provides back-up generation to a specific industrial facility. The former may be necessary for the reliable operation of the interconnected bulk transmission system, but the latter is not. (2) The current draft of the BES Definition contains Exclusions for radials and for Local Networks. To be consistent with these aspects of the revised BES definition, AE suggests modifying question 5 by adding "radial, or Local Network" to the question, so that it would read: "Does the generator use the BES, a radial system, or a Local Network to deliver its actual or scheduled output, or a portion of its actual or scheduled output, to Load?" (3) For reasons

similar to those explained in our response to Question 2, a general “catch-all” question should be added that will prompt an entity submitting an Exception Request for a generator to submit any information it believes relevant to the Exception that is not captured in the previous questions. We suggest the following language: Is there additional information not covered in questions 1 through 5 that supports the Exception Request? If yes, please provide the information and explain why it is relevant to the Exception Request. This will allow an entity seeking an Exception for a generator to identify any unusual circumstances or non-standard information that might support its Exception Request. An entity seeking such an Exception should have the opportunity to present any information it believes is relevant.

Yes

The Standards Drafting Team should consider whether it is necessary to require entities other than the entity filing the Exception Request to provide relevant information, either to the entity filing the Exception Request or to the RE receiving the Exceptions Request. For example, in order to answer Question 1 on page 4, regarding the impact of the generator under the most severe single contingency, it may be necessary for the relevant Balancing Authority to provide its Most Severe Single Contingency (“MSSC”) to the registered entity seeking an Exception. Similarly, the relevant Transmission Operator or Balancing Authority may have information necessary to determine whether the generator has been designated as reliability-must-run or if it provides ancillary services supporting reliable operation of the interconnected transmission grid.

Yes

As discussed in our responses to Questions 1 through 3, AE believes that certain additional questions are necessary to elicit all information relevant to an Exceptions Request. As discussed in our answer to Question 4, we are also concerned that it may be necessary to obtain information in the hands of the relevant Balancing Authority, Transmission Provider or other entity and not in the hands of the entity submitting an Exceptions Request, to develop a complete record upon which a reasoned decision concerning an Exceptions Request can be based.

Yes

As discussed in more detail in our response to Question 2, AE believes it is necessary to address the function of an Element or system subject to an Exceptions Request to determine whether it is a “facilit[y] used in the local distribution of electric energy” and, therefore, excluded from the BES under Section 215(a)(1) of the Federal Power Act.

No

As a general matter, AE believes the SDT has provided a reasonable check list that will work in most cases to elicit necessary information from the entity submitting an Exception Request. With the added language suggested in our answers to the previous questions, we believe the proposed form will serve its intended purpose of ensuring that decisions regarding Exception Requests are based upon consistent information and are consistent with the requirements of the Federal Power Act and the BES Definition as developed by the Standards Drafting Team. AE also supports the Standards Drafting Team’s determination to abandon its initial approach to technical criteria, which would have required adherence to specific numerical thresholds. AE agrees that this approach was not workable on a nationwide basis, and that the approach embodied in the current draft of the Technical Principles, which would require specific kinds of information on a generic basis but would leave engineering judgment about the significance of that information to the relevant RE, is more workable and provides appropriate deference to the experience and judgment of the REs.

ATC LLC

No

Since an Exception Request may be for approval to designate identified Element(s) as either excluded from or included in the BES, the wording of the first sentence should be changed and the request should clearly indicate (e.g. exclusion/inclusion check boxes) whether the request regards exclusion or inclusion of the Element(s). Here is some draft wording for consideration: Entities that have Element(s) that are included under the BES definition and designations, but seek to have them designated as excluded from the BES or that that have Element(s) that are excluded under the BES definition and designations, but seek to have them designated as included in the BES should submit

an Exception Request according to the NERC Exception Procedures and provide detailed information to support the Exception Request as indicated below. In addition, ATC suggests the following clarifying edit. Entities that have BES Element(s) considered as excluded under the BES definition and designations, do not have to seek exception for those Elements under the Exception Procedure.

No

ATC proposes the following changes to Item #7: 7a. Are Firm Power Transfers scheduled to flow out of, or through, this facility into the BES in the operating horizon? [for BES designations applicable to the operating horizon] Note: The consideration for power flowing into the BES should be based on normal operating conditions or base case (n-0 contingency analysis), not on historical real-time telemetry. 7b. Are Firm Power Transfers reserved to flow out of, or through, this facility into the BES in the planning horizon? [for BES designations applicable to the planning horizon)

No

In addition to describing how an outage of the facility under consideration affects the rest of the BES, the Submitting Entity also should be required to provide an assessment of how outages of BES facilities affect the facility under consideration. This could be achieved with powerflow studies or distribution factor analysis.

No

For units designated as must run, the Submitting Entity should be required to describe the reasons for which the unit has been so designated. We believe the general requirement to provide an appropriate reference is too vague, and should be appended with ". . . including a description of why the unit has been designated as must run and if applicable, the contingencies that would result in violation of the NERC Reliability Standards if the unit was not must run."

No

No

No

Yes

At a minimum, we believe there are some facilities which should not be excluded from the BES under any circumstances and a list of such facilities should be documented, including facilities such as (1) Elements that are relied on in the determination of an Interconnection Reliability Operating Limit (IROL); (2) Blackstart resources and the designated blackstart Cranking Paths identified in the Transmission Operator's restoration plan regardless of voltage, (3) Elements subject to Nuclear Plant Interface Requirements (NPIRs) as agreed to by a Nuclear Plant Generator Operator and a Transmission Entity defined in NUC-001, (4) Elements identified as required to comply with a NERC Reliability Standard by application of criteria defined within the standard (e.g., the test defined in

PRC-023 to identify sub-200 kV Elements to which the standard is applicable), and (5) a generating unit that is designated as a must run unit to assure reliability of the BES. Also, to make the process of reviewing exception applications consistent and transparent some high level guidance should be developed as to how the information provided will be assessed by the Regional Entities and NERC. In addition to supporting the objectives of consistency and transparency, this also would provide benefit to entities submitting an exception application by allowing them to understand how the Required Information will be evaluated.

KEC agrees generally that the General Instructions set forth the basic information that would be necessary to support an Exception Request. KEC is concerned, however, that the statement "diagram(s) supplied should also show the Protection Systems at the interface points associated with the Elements for which the exception is being requested" may be subject to differing interpretations. KEC envisions that at least four different kinds of documents would be responsive to the description: one-line diagrams with breakers and switches (status); identification of relays by their ANSI device numbers; details of the DC control logic for ANSI devices; and, operational scheme descriptions of the type used by system operators. Accordingly, we suggest that the language be refined to identify the specific kinds of diagrams necessary to identify protection systems at the interface with the Elements for which the Exception is sought, including any required details. KEC suggests that a generic example of a completed form be provided to the industry to help ensure that Exception Requests are supported by consistent and complete information. Such a generic example could be addressed in the Phase 2 BES efforts.

No

KEC agrees that the checklist of items on pages two and three lists most of the information that would be necessary to determine if an Exceptions Request is justified. We suggest three modifications to the proposed language to ensure consistency with Section 215 of the Federal Power Act, with the BES Definition, and to provide an entity seeking an Exception with the opportunity to submit all relevant information: (1) KEC suggests that a new question should be added concerning the function of the facility, which would read: "Does the facility function as a local distribution facility rather than a Transmission facility? If yes, please provide a detailed explanation of your answer." Section 215(a)(1) of the FPA makes clear that "facilities used in the local distribution of electric energy" are excluded from the BES, 16 U.S.C. § 824o(a)(1), and the most recent draft of the BES definition incorporates the same language. KEC believes a question to address the function of the Element or system subject to an Exception Request is necessary to determine whether the Element or system is "used" in local distribution and thereby to ensure that this statutory limit on the BES is observed in the Exceptions process. Further, we believe a variety of information may be relevant to determining whether a particular facility functions as local distribution rather than as part of the BES. For example, if power is not scheduled across the facility or if capacity on the system is not posted on the relevant OASIS, it is likely to function as local distribution, not transmission. Similarly, if power enters the system and is delivered to load within the system rather than moving to load located on another system, its function is local distribution rather than transmission. KEC proposes the language above as an open-ended question so that the entity submitting the Exceptions Request can provide this and any other information it deems relevant to facility function. (2) KEC suggests modifying question 6 to "Is the facility part of a designated Cranking Path associated with a Blackstart Resource identified in a Transmission Operator's restoration plan." This language reflects the most recent revision of the BES Definition, which removes the reference to "Cranking Paths," and also helps distinguish between generators which have Blackstart capability and those generators that are designated as a Blackstart Resource in the Transmission Operator's restoration plan. It is only the latter that are included in the BES under the current draft of the definition. (3) A general "catch-all" question should be added that will prompt the entity submitting an Exception Request to submit any information it believes is relevant to the Exception that is not captured in the other questions. We suggest the following language: Is there additional information not covered in the questions above that supports the Exception Request? If yes, please provide the information and explain why it is relevant to the Exception Request. While KEC believes the questions set forth in the draft capture the information that generally would be necessary to determine whether an Exception Request should be granted, it is

foreseeable that there may be unusual circumstances where the information called for either does not capture the full picture or where studies other than the specific types called for in the draft form support the Exception. An entity seeking an Exception should have the opportunity to present any information it believes is relevant.

Yes

KEC agrees that the items listed on page 4 of the Detailed Information to Support an Exception Request capture the information that generally would be necessary to make a reasoned determination concerning the BES status of a generation facility. KEC suggests three refinements to the questions: (1) Question 2 should be modified by adding "necessary for the operation of the interconnected bulk transmission system" to the end of the question, so that it reads: "Is the generator or the generator facility used to provide Ancillary Services necessary for the operation of the interconnected bulk transmission system?" The italicized language is necessary to distinguish between a generator that provides, for example, reactive power or regulating reserves that support operation of the interconnected bulk grid, and, for example, a behind-the-meter generator that provides back-up generation to a specific industrial facility. The former may be necessary for the reliable operation of the interconnected bulk transmission system, but the latter is not. (2) The current draft of the BES Definition contains Exclusions for radials and for Local Networks. To be consistent with these aspects of the revised BES definition, KEC suggests modifying question 5 by adding "radial, or Local Network" to the question, so that it would read: "Does the generator use the BES, a radial system, or a Local Network to deliver its actual or scheduled output, or a portion of its actual or scheduled output, to Load? (3) For reasons similar to those explained in our response to Question 2, a general "catch-all" question should be added that will prompt an entity submitting an Exception Request for a generator to submit any information it believes is relevant to the Exception that is not captured in the previous questions. We suggest the following language: Is there additional information not covered in questions 1 through 5 that supports the Exception Request? <p>Redding acknowledges there is an immediate need for a method where an entity can present evidence that their facilities are “not necessary for the Reliable Operation of the interconnected bulk power transmission system” as stated in the NERC Rules of Procedure Section 3.0. “BASIS FOR APPROVAL OF AN EXCEPTION.” Without a process to present the evidence then the RE and the ERO are under no mandate to review facilities in light of any criteria besides the BES definition as NERC clearly pointed out in the City of Holland case where they were forced to register by the RE (RFC). However, Redding also is very concerned that under the proposed Exception process the final evaluation of an element or facility is left to the sole judgment of NERC. The concern is there is no method, criteria, measurement, or standard that NERC will use for the evaluation. It is also a concern that NERC has a predetermined definition of Distribution Facilities and will not evaluate networked distribution facilities fairly. NERC has already stated their predetermined position as to what they determine to be distribution and not distribution facilities in their “MOTION TO INTERVENE AND COMMENTS OF THE NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION” filed in the case of the City of Holland, Michigan (Docket No. RC11-5-000). On page 10 and 11 of this motion, under the section labeled “A. Holland’s 138 kV lines are transmission rather than local distribution facilities” NERC states “Distribution facilities generally are characterized as elements that are designed and can carry electric energy (Watts/MW) in one direction only at any given time from a single source point (distribution substation) to final load centers.” NERC clearly states that only radial facilities are considered distribution facilities and are unwilling to consider that network facilities over 100kV could be classified as Distribution Facilities. Holland’s claim of NERC over reaching their authority appears to have credibility. In conclusion, Redding supports this exception process as it stands because it does allow an entity the right to a process which NERC is currently not obligated to allow, it requires that NERC judge the facilities on the merit of “necessary for the Reliable Operation of the interconnected bulk power transmission system”, and it allows an appeals process that must judge if NERC evaluated facilities on the standard set forth. However, Redding’s vote is conditional on the completion of phase 2 where the term “necessary for the Reliable Operation of the interconnected bulk power transmission system” needs to be defined.</p>

<p>Redding acknowledges there is an immediate need for a method where an entity can present evidence that their facilities are “not necessary for the Reliable Operation of the interconnected bulk power transmission system” as stated in the NERC Rules of Procedure Section 3.0. “BASIS FOR APPROVAL OF AN EXCEPTION.” Without a process to present the evidence then the RE and the ERO are under no mandate to review facilities in light of any criteria besides the BES definition as NERC clearly pointed out in the City of Holland case where Holland was forced to register by the RE (RFC). However, Redding is very concerned that under the proposed Exception process the final evaluation of an element or facility is left to the sole judgment of NERC. The concern is there is no method, criteria, measurement, or standard that NERC will use for the evaluation. It is also a concern that NERC has a</p>

predetermined definition of Distribution Facilities and will not evaluate networked Distribution Facilities fairly. NERC has already stated their predetermined position as to what they determine to be distribution and not distribution facilities in their "MOTION TO INTERVENE AND COMMENTS OF THE NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION" filed in the case of the City of Holland, Michigan (Docket No. RC11-5-000). On page 10 and 11 of this motion, under the section labeled "A. Holland's 138 kV lines are transmission rather than local distribution facilities" NERC states "Distribution facilities generally are characterized as elements that are designed and can carry electric energy (Watts/MW) in one direction only at any given time from a single source point (distribution substation) to final load centers." NERC has clearly stated that only radial facilities are considered distribution facilities and were unwilling to consider that network facilities over 100Kv could be classified as Distribution Facilities in this case. Holland's claim of NERC over-reaching their authority appears to have credibility. In conclusion, Redding supports the proposed exception process as it stands on the grounds that it allows an entity the right to a process which NERC is currently not obligated to allow, it requires that NERC judge the facilities on the merit of "necessary for the Reliable Operation of the interconnected bulk power transmission system", and it allows an appeals process that must judge if NERC evaluated facilities on the standard set forth. However, Redding's vote is conditional on the completion of phase 2 where the term "necessary for the Reliable Operation of the interconnected bulk power transmission system" needs to be defined.

General Comments: Metropolitan Water District of Southern California ("MWDSC") believes that additional work is necessary to explain how this Detailed Information to Support an Exception Request will be used in evaluating whether a transmission facility will be an exception to the BES. In addition, MWDSC agrees WECC that the proposed Technical Principles for Demonstrating BES Exceptions Request is lack of clarity. It does not provide detail information as to what entities must provide to support their requests, nor does it provide any criteria for consistency among regions in their assessment of requests. Lastly, the current proposal leaves it to each region to develop its own methodology and criteria for evaluating the technical studies. MWDSC believes that drafting team should establish a common method and criteria to apply continent-wide in achieving uniformity and consistency among regions in their assessment of exception requests. Comments to Checklist #4: MWDSC recommends the following changes to emphasize facility impact on the interconnection of the BES: "How does an outage of the facility impact the over-all reliability of to the interconnection of the BES?" Comments to Checklist #7: What percentage of power flow through entity's facility into the BES will be considered as an exception to the BES?

We agree with most parts on P.2 and P.3, but question the need for Q6, which asks: "Is the facility part of a Cranking Path associated with a Blackstart Resource?" I3 in the BES definition stipulates that Blackstart Resources identified in the Transmission Operator's restoration plan be included (which we disagree and commented in the BES Definition Comment Form). There is no inclusion of any transmission facilities that are part of the cranking path. We suggest this item (Q6) be removed.

We do not agree with the detailed information requirements for generators. In a deregulated

environment, generators are free to bid into the market or offer their availability, to dispatched based on bid price and resource needs, or overall generation dispatch plans. A generator may be on line but not dispatched, or not on line at all due to maintenance outage or a decision to not start. Its status and generation level have little to do in determining whether or not it needs to be included as a BES facility. Rather, it is the generator's active contribution to the BES performance, namely, its protective relay setting and coordination with those of related facilities and its ability to control voltage, respond to contingencies, ride through frequency and voltage excursion, provide accurate model with verification, etc., are critical to BES reliability performance. There are currently no standards or requirements that mandate a generator to be on line or to attain a specific level of output, and we do not see such a need at all in the future. Whether or not the unit is designed as a MUST RUN will depend on whether the generator is (a) on line and bid into the market or be included in the dispatch plan, and (b) the prevailing system conditions such as flow pattern, potential constraints, etc. A generator may be designated as a MUST RUN one day but not the others. Similar argument applies to a generator bidding in the ancillary service markets, or be dispatched to provide reserve or AGC control capability. In our view, generators' physical characteristics and their response to changes on the BES are important considerations for them to be included in the BES. These characteristics affect the assessment and actual performance of the BES in the following key areas: • Voltage and frequency ride through capability • Voltage control (AVR, etc.) • Underfrequency trip setting • Protection relay setting coordination • Data submission for modeling; verification of capability and model We therefore suggest that the entire P.4 be removed as the information it asks for has nothing to do with a generator's physical characteristics or material impact on BES reliability. Having a threshold by MVA suffices to determine if a generator needs to be included as a BES facility, whose characteristics, expected performance and data provision are important to achieve target BES performance and hence should be governed by reliability standards.

No

Yes

One acid test to determine if a facility needs to be included or can be excluded from a BES facility is to simulate an uncleared fault at that facility. If the simulation shows a stable BES performance, then it suggests that even if the fault is not cleared due to whatever reason, the facility has no adverse impact that can lead to instability, cascading or collapse of the BES.
