Response: The SDT thanks you for your comments. As with a Transmission Owner's determination of its Clearance 1 distances under version 1 of the Standard, Requirement 3 of the revised Standard begins with the MVCD distances (just as Clearance 1 began with IEEE-516 distances) and then requires additional consideration for conductor movement, vegetation growth variables, and the utility's maintenance approach. These are essentially the same considerations required by version 1 of the existing Standard when developing Clearance 1 distances. Therefore, nothing has been "lost" in the revised Standard. In fact, the proposed Standard is better from an auditing perspective because the overall logic and rationale used by the TO in complying with the new Requirement 3 is now subject to an overall test of adequacy, competency and reasonableness. Also, informal polls conducted by the SDT show that many Transmission Owners are unsuccessful in utilizing Clearance 1 as a tool, because it is easily challenged by landowners as being an arbitrary fill-in-the-blank value set by the Transmission Owner. Further, if the Transmission Owner would cut only to Clearance 1 instead of to the full extent of its legal rights, courts could rule against the Transmission Owner for failing to exercise its full legal rights. Thus, in the revised Standard, the Transmission Owner has neither gained nor lost any tool or advantage in dealing with landowners, but the SDT asserts that the bar has been raised with regard to the adequacy of the Transmission Owner's overall vegetation management program.

- FERC Directive - Define rights-of-way to encompass the required clearance areas instead of the corresponding legal rights, and the standards should not require clearing the entire right-of-way when the required clearance for an existing line does not take up the entire right-of-way.

  NERC Comment – NERC staff believes this directive was met and is addressed in question 1 of the comment form.

Response: The SDT thanks you for your comments.

- FERC Directive – NERC should address the proposed modifications through its Reliability Standards development process.

  NERC Comment – NERC staff believes this directive was met in preparing this draft standard.

Response: The SDT thanks you for your comments.

- FERC Directive - Collect outage data for transmission outages, analyze it, and use the results of this analysis and information in the development of the Reliability Standard.

  NERC Comment – NERC staff believes more work needs to be done in this area. NERC staff believes the drafting team should consider modifying the Periodic Data Submittal to include if outages occur on Federal land.

Response: The SDT thanks you for your comments. After discussion with NERC staff, NERC has agreed to address this issue outside the work of the SDT. The SDT recommends that NERC staff consider adding a field to the TADS data to capture vegetation outages on applicable lines on federal lands.

Other Draft 5 Issues

- Removal of a formal transmission vegetation management program, of Clearance 1 and of a documented vegetation management plan.

NERC Comment – NERC does not support the removal of these items. NERC does not believe these changes represent an improvement to the standard and does not believe this existing requirement is overly burdensome to utilities. NERC does not understand why industry would not be willing to be held accountable to their vegetation management plans. NERC is concerned that the removal of these items could make it difficult for utilities to obtain permissions needed to maintain clearances between inspection cycles which are prudent for reliability and safety due to intervener or landowners exercising their rights and then pointing to this new standard as a the basis for smaller clearances. . Requirement 3 in this draft needs to include a documented plan and to clearly identify the specifics to be included in the plan and provide clarity of expectations. The SDT may not support such specifics as not being consistent with results-based standards development but NERC staff believes otherwise.

Response: The SDT thanks you for your comments. The existing series of items in Requirement R3 along with R3.2 are collectively with the balance of the standard equivalent to the term TVMP. These combined items in R3 are the defense in depth approach that require the TO to maintain vegetation so that it does not enter into the MVCD before the next planned vegetation work, thus accomplishing the equivalent of a C1 without a fill-in-the-blank issue.

- Objectives**:** A qualifier in the standard Objective that it should apply to preventing the risk of vegetation related outages *that could lead to cascading outages.*

  NERC Comment – This qualifier limits the purpose of the standard, which should be to prevent vegetation related outages, not cascading outages. The more outages there are, the less the overall system reliability. An outage does not necessarily have to lead to a cascading outage to be significant and represent a reasonable risk to the BES. References to cascading outages should be removed.

Response: The SDT thanks you for your comments. The SDT has thoughtfully considered every aspect of this version of the Standard to ensure that the pieces are consistent, aligned, and support each other. The SDT added the phrase “with Cascading” not to limit the Standard, but rather to recognize that the 200 kV bright-line for applicability (which is not in question) is founded on the very notion that the 200 kV serves as a proxy for "The Big Three": Cascading, Separation, and Instability. The SDT considered adding all of these conditions to the Purpose statement. However, given the focus of this Standard is on vegetation, and vegetation was deemed to be related to Cascading (i.e. 2003 Blackout report), rather than the other two undesirable system conditions, it seemed more logical and consistent to include the likely outcome of an unmanaged vegetation condition on a Transmission Owner's system. If NERC Staff has evidence that other two are likely related to vegetation, it has not yet been provided to the SDT.

Unlike other types of outages on lines (such as those caused by failed insulators, broken cross-arms, rotten poles and lightning flashover), vegetation outages uniquely affect lines when they are heavily loaded and thus susceptible to a cascading event.

- Background**:** This section excludes vegetations fall-ins and blow-ins from outside the ROW on the basis that they are not preventable.

  NERC Comment – Many fall-ins and blow-ins from outside the ROW are preventable. Trees outside the ROW must be managed adequately to prevent outages on the BES. The work to remove and/or prune trees outside the ROW may be more difficult and costly than such work inside the ROW, but that is not sufficient reason to exclude this work. In addition, utilities wishing to perform such work might be prevented from doing so by regulatory bodies based upon the lack of a specific requirement in this standard.

Response: The SDT thanks you for your comments and has reworded the Background by removing the term non-preventable.

- Requirement 1 & 2: These requirements discuss preventing encroachments into the MVCD of an applicable line that is operating within its Rating.

  NERC Comments –NERC staff would like confirmation that “Rating” is intended to include all published ratings issued by the facility owner, such as Normal, Emergency, etc.

Response: The SDT thanks you for your response. The glossary term "Rating" is adequate to address the issues you raise.

- Requirement 4: R4 states that "Each Transmission Owner, without any intentional time delay, shall notify…"

  NERC Comments: The previous version of the standard included a time limit of 15 minutes once communications became available. This should be reinstated.

Response: The SDT thanks you for your response. The SDT is not aware any posting with a 15 minute rule included.

- Requirement 7: R7 sets the requirement for each Transmission Owner to complete 100 percent of its annual vegetation work plan.

  NERC Comments – NERC is concerned that the draft doesn't have a requirement for a Transmission Owner to have a documented annual plan making Requirement 7 unenforceable. In addition, Requirement 7 has a number of other qualifiers that would seem to allow manipulation of the annual plan to ensure compliance.

Response: The SDT thanks you for your comments. The SDT asserts that a fundamental precept of results-based standards is that having a requirement to complete any particularly activity also presupposes that the elements required to complete the activity are included in the requirement, even if unstated.

- Draft 5 document quality

  NERC Comments – this draft has some typographical errors which need to be fixed. For example, on page 28, reference to use of Table 5 versus Table 7 based on knowledge of maximum transient over-voltage factor is reversed. These edits could probably be handled through a recirculation ballet.

Response: The SDT thanks you for your comments. We agree with the typo you found and we have changed the language in the draft standard.

- Previously raised NERC issues

  NERC Comments – NERC staff posted several comments on the Draft 4 version of this standard in July 2010. NERC believes most of the concerns it raised in those comments are not addressed in Draft 5 and continue to be a concern for NERC.

Response: The SDT thanks you for your comments; however there are not enough specifics for the SDT to respond.

- General compliance and audit issues

  NERC Comments –

  - The whole "sustained outage" concept in R1 (for fall ins and blow ins) is unworkable from an enforcement perspective.
  - The difference between a violation and a non-violation in Draft 5 is whether the registered entity was fortunate with regard to an encroachment. This part should be rewritten to say that any tree contact is a violation. VRFs and VSLs could then be used to address whether the violation was minor or serious.
  - There could be a lot of litigation over whether "circumstances" were really "beyond the control" of the TO. NERC had previously objected to the implementation of a force majeure clause in the standard. If an entity failed to carry out its annual plan, that should be treated as a violation, and any excuses for failing to do so or for changing the plan mid-year all go to whether the penalty should be $0 or substantial.
  - For the evidence retention period, the entity really should retain evidence of compliance until the next compliance audit. Since some TOs may be on a 6 year audit schedule, the 3 year retention period is not sufficient.

Response: The SDT thanks you for your comments.

- The SDT does not understand your comment. The violations under the existing standards are largely due to sustained outages.
- Version 2 has a violation for every known and confirmed encroachment. The Penalty for those encroachments that do no cause Faults is up to $30,000 per violation per day
- The SDT thanks you for your comments. The SDT believes this language is appropriate for this standard due to the many factors related to vegetation that are truly outside the TO's control. Unlike the vast majority of other NERC standards, implementation of FAC-003 is not under

the absolute control of the utilities. These influences range from landowner and agency obstacles to weather events, and as such the SDT believes the force majeure provisions should be applicable. The recognition of this provision is also supported by 90% of the industry. An attempt at similar language is contained in version 1 but it is ambiguous and lacks clarity. This language adds clarity and reduces the opportunity for misapplication. Further, TO's must have supporting evidence for claims that situations are "beyond their control".

- The SDT thanks you for your comments, and will use the NERC approved retention times.

NERC
NORTH AMERICAN ELECTRIC
RELIABILITY CORPORATION

Non-binding Poll of VRFs and VSLs for FAC-003-2 (February 18-28, 2011) Consideration of Comments Report

Project 2007-07 Vegetation Management — September 30, 2011

Summary Consideration:

Some entities expressed concern regarding the use of the MVCD. The SDT explained that the MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions, and that R3 requires that a Transmission Owner to consider the MVCD distances, as well as variables of conductor movement and the variables associated with vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD.

Other entities questioned if the intent of the standard is to "manage vegetation" or to "prevent outages. The STD responded that In Order 693, FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation**" (emphasis added).

If you feel that the drafting team overlooked your comments, please let us know immediately. Our goal is to give every comment serious consideration in this process. If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herb Schrayshuen, at 404-446-2563 or via email at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedure: http://www.nerc.com/files/RSDP_V6_1_12Mar07.pdf.

Voter	Entity	Segment	Vote	Comment
Gregory S Miller	Baltimore Gas & Electric Company	1	Affirmative	VRFs and VSLs seem reasonable.
Response: The SDT thanks you for your comments.				
Joseph S. Stonecipher	Beaches Energy Services	1	Negative	(See comments for 2007-07.)
Response: The SDT responded in the Successive Ballot Consideration of Comments document.				
Donald S. Watkins	Bonneville Power Administration	1	Affirmative	In R1 and R2 and their associated VSLs, the SDT added the phrase "in order of increasing severity" and added the sentence, "The types of encroachments are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a TO's vegetation maintenance program." to the Rationale boxes for R1/R2. Do you agree? If answer is no, please explain. BPA prefers the stratified levels of violation severity presented in the table for R1 and R2. Foot note # 2 on page 8 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. Foot note # 4 on page 12 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. In response to comments received that requirement R3 is unclear with respect to intent, the SDT added "maintenance strategies." Do you agree this clarifies the intent? If answer is no, please offer alternative language.

Voter	Entity	Segment	Vote	Comment
				The TO procedures / policies and specifications shall demonstrate the TO's ability to manage the system at all rated conditions to maintain reliability. BPA believes that the intent is clear, but the fundamental approach of using the MVCD (table 2) to manage a vegetation program is still problematic. These values are flashover distances and are way too close. This is acknowledged in a footnote to table 2 but no identification of allowable buffers/distances between energized phase conductors at rated temperatures and vegetation is discussed (this is left up the transmission owners). Clarity is needed on this topic. Setting a finite distance limit based on recognized standards, good science and risk avoidance should be done for the industry. BPA has previously made this comment during the drafting of the standard. It was not addressed then, nor has it been addressed now.
Response: The SDT thanks you for your comments. The footnotes were changed to conform with your suggestions. With respect to comments about the MVCD, R3 does not suggest the MVCD be used as a distance to manage vegetation. The MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD. In a performance based standard, requirements are focused on "what" needs to be accomplished to achieve desired results and avoids prescriptive requirements of "how" to achieve that result. TO's are in the best position to determine the appropriate management approach suited for their system, rather than a "one size fits all" or "fill in the blank" requirement that could suppress best practices for vegetation management.				
Randall McCamish	City of Vero Beach	1	Negative	Vero Beach's concern is that entities may not be able prove compliance with the standard. R1 and R2 say that: "Each

Voter	Entity	Segment	Vote	Comment
				Transmission Owner shall manage vegetation to prevent encroachments ...". If the requirements were interpreted such that "manage" is the operative word, then, we are OK because we can provide evidence of managing a program, such as a vegetation management plan and evidence of executing that plan (which does not align with the Measures). However, that 1) would cause the standard to not be performance based, and 2) it would be duplicative of the other requirements of the standard. If the requirements were interpreted with "prevent encroachment" as the operative phrase (which would be an incorrect interpretation from the construct of the sentence) there is no way to provide sufficient evidence that encroachment was prevented during the audit-period. The suggested Measures are not sufficient evidence to prove compliance with that interpretation of the requirement. For instance, most encroachments do not result in outages; hence, lack of outages cannot prove that there were no encroachments, and real time observations are insufficient because it is a spot-check that does not cover the audit period. There are other weaknesses in the standard, such as R4 being un-measurable therefore unenforceable. However, in the guilty until proven innocent paradigm we live in, FMPA's primary concern is that industry could be put into a no-win situation of not being able to prove compliance with the standard if R1 and R2 are interpreted as "prevent encroachment", and if R1 and R2 are interpreted as "manage" then it is not a performance based standard as advertised. Vero Beach suggests one of two approaches: 1. Performance based focused on preventing vegetation

Voter	Entity	Segment	Vote	Comment
				related outages. For instance: "Each Transmission Owner shall prevent vegetation related outages (except as noted in Footnote 2) of any of its applicable line(s) ..." Evidence of outages is practical to gather and provide, evidence of encroachment is not. 2. Modify the standard to be similar to the currently mandatory non-results based standard and focus on the word "manage". This would essentially mean eliminating R1 and R2 since the rest of the standard focuses on having a plan and managing to that plan..
Response: The SDT thanks you for your comments. In Order 693, FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation**" (emphasis added). The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct inspections in which clearances are evaluated.				
Christopher L de Graffenried	Consolidated Edison Co. of New York	1	Affirmative	The VSLs in R6 and R7 should be consistent with each other: R6 says '...TO failed to inspect 5% or less.....' and R7 says '...TO failed to complete up to 5%....' They both should use the same verbiage in each VSL whether it is 'x% or less' or 'up to and including x%.'
Response: The SDT thanks you for your comments. The SDT has changed the verbiage in the VSLs in R6 and R7 such that it addresses you suggestion.				
Michael Gammon	Kansas City Power & Light Co.	1	Negative	The VSL for Requirement 7 should be clear and specifically state this specifically addresses only "all applicable lines".
Response: The SDT thanks you for your comments. The team has added the phrase, "applicable lines" as proposed to all the VSLs for R7.				
Stan T.	Keys Energy	1	Negative	Concern is that entities may not be able prove compliance with the standard. R1 and R2 say that: "Each Transmission

Voter	Entity	Segment	Vote	Comment
Rzad	Services			Owner shall manage vegetation to prevent encroachments ...". If the requirements were interpreted such that "manage" is the operative word, then, we are OK because we can provide evidence of managing a program, such as a vegetation management plan and evidence of executing that plan (which does not align with the Measures). However, that 1) would cause the standard to not be performance based, and 2) it would be duplicative of the other requirements of the standard. If the requirements were interpreted with "prevent encroachment" as the operative phrase (which would be an incorrect interpretation from the construct of the sentence) there is no way to provide sufficient evidence that encroachment was prevented during the audit-period. The suggested Measures are not sufficient evidence to prove compliance with that interpretation of the requirement. However, we do have one major disagreement with the STD and cannot support this standard as drafted.</td></tr>
</table>

Voter	Entity	Segment	Vote	Comment
				We disagree with the use of the Minimum Vegetation Clearance Distance (MVCD) developed by the drafting team for Requirements R1 and R2. These distances are not the design distances used for designing and constructing transmission facilities as stated in the document for minimum distances between conductors and grounded objects. The proposed Table 2 provides a distance of 3.12 feet as the acceptable distance for an alternate current 345kV line at sea level. This distance is considerably less than the distance used for line design to separate the grounded tower structure from the energized conductor. If the distance in Table 2 is acceptable to prevent energized portions of a transmission line from grounding to a tree why then is this distance not the design criteria used for tower design to prevent flashover from conductor to tower? The STD needs to explain why a ground tree should have a different standard that a grounded steel tower or wood pole structure. The STD erroneously viewed the possibility of transient over voltage as only occurring during re-energizing and not from natural events such as a lightning strike that can occur and does occur to energized operating lines. Secondly, the proposed distances in Table 2 are considerably less than the distances specified in OSHA requirements for air gap clearance required by tree workers to safely remove trees or limbs from conductors energized at the voltages specified. A transmission owner/operator could let a tree grow to within 3.5 feet of a 345 kV line and not be in violation of this proposed standard. To remove the tree, the line would have to be de-energized, tagged, tested de-energized, and grounded. Working clearance would have to be established by the operating entity and then the tree crew could remove the

Voter	Entity	Segment	Vote	Comment
				tree. The net result is the loss of the capacity of the line because an outage was forced on the line in order to remove the tree that did not trigger a violation of FAC-003-2. This situation, in our opinion, is a violation of the intent of the standard, which is to ensure the continued operation of the line. Therefore, the minimum distance any tree should be able to approach a conductor is more than the minimum requirement for air gap distance between the tree and conductor as required by OSHA worker standards. The STD did not like referring to another standard to provide the distance requirements for R1 and R2. This can be alleviated by putting in a table with the IEEE 516 distances but not reference it as the IEEE 516 standard. The distances provided in the current draft do not adequately provide or ensure the continued safe operation of the transmission facilities in the United States and the reasoning for the distances provided is unfounded and not based on current design practices.

Response: The SDT thanks you for your comments. You are correct that these distances do not represent complete design specifications for towers, nor define and describe safe worker approach distances. These practices are correctly specified in the other standards you referenced. The SDT feels the standard is clear in that regard.   The footnote associated with the Table 2 distances clearly states that these are only distances to prevent flashover under appropriate conditions. The SDT would also like to point out that the transient overvoltage factors used to derive these distances are the maximums normally seen with a transmission line in steady state service. Thus, a tower design would have to account for the larger overvoltage factors that are possible while taking lines out of service.

As has been stated before, these distances were derived using a known set of line design equations and only represent distances that will prevent spark-over from the transmission line to a grounded object. These are not distances to be managed to – they have been established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions.

R3 requires that a Transmission Owner' consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach.   The net result of this

Voter	Entity	Segment	Vote	Comment
"building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD. These distances are smaller than safety standard distances that have many other factors involved in the determination, such as inadvertent human movement and larger safety factors. In regard to the over-voltages caused by lightning, even the maximum overvoltage factors contained in the IEEE-516 tables do not account for these.				
Russell A Noble	Cowlitz County PUD	3	Negative	Referring back to Cowlitz' negative vote made on the 7/9-19/2010 ballot, Cowlitz tried to convey the problem that the statement in R4 "without intentional time delay" will require subjective judgment on the part of the auditor. In other words, maintaining equal auditing standard throughout the interconnection will be impossible with this verbiage in a requirement. Cowlitz agrees with the SDT that establishing an equitable time frame is very difficult (it may be impossible!); however leaving it to the judgment of the auditor to determine whether an intentional delay was made is most disagreeable. Cowlitz respectfully points out that the SDT did not adequately address the subjective nature the auditor is forced into with this requirement. If establishing "[t]he time required by the to report an issue is subject to many variables..." and "[f]or this reason it is difficult to establish a time period which would fairly apply to all TO's," how does leaving this to the auditor to decide going to make it any better?
Response: The SDT thanks you for your comments. The SDT believes that it was not prudent to suggest a quantitative time element for notification in R4. The technical reference offers examples of acceptable unintentional delays for your review. The SDT notes that this language is already embodied in at least one other FERC-approved, in-force Standard.				
Charles Locke	Kansas City Power & Light Co.	3	Negative	The VSL for Requirement 7 should be clear and specifically state this specifically addresses only "all applicable lines".

Voter	Entity	Segment	Vote	Comment
Response: The SDT thanks you for your comments. The team has added the phrase, "applicable lines" as proposed to all the VSLs for R7.				
Mace Hunter	Lakeland Electric	3	Affirmative	R1. Each Transmission Owner shall manage vegetation to prevent encroachments of the types shown below, ---------------- and all Rated Electrical Operating Conditions.2 1. An encroachment into the MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage, that is not corrected within 5 working days of discovery, Make the same change to R2 Type 1 encroachment and reflect the changes in Table 1. Rational: This condition would enable a entity to discover an encroachment and clear it without having to self report a possible violation as long as the conditions was corrected within 5 working days. The change should encourage extra inspections for problem areas more often than annually as required in R6. There should be no negative consequences for diligent inspection of lines as long as the problem is clear with a defined time such as 5 or 10 working days.
Response: The SDT thanks you for your comment. As a general rule, a revised standards should not be less stringent than the existing standard it replaces. In the existing standard, a violation occurs when the encroachment occurs. A 'find and fix' of five days would be viewed as a lowering the level of performance required by the current standard.				
Rick Syring	Cowlitz County PUD	4	Negative	Referring back to Cowlitz' negative vote made on the 7/9-19/2010 ballot, Cowlitz tried to convey the problem that the statement in R4 "without intentional time delay" will require subjective judgment on the part of the auditor. In other words, maintaining equal auditing standard throughout the interconnection will be impossible with this verbiage in a requirement. Cowlitz agrees with the SDT that establishing an equitable time frame is very difficult (it may be impossible!); however leaving it to the judgment of the

Voter	Entity	Segment	Vote	Comment
				auditor to determine whether an intentional delay was made is most disagreeable. Cowlitz respectfully points out that the SDT did not adequately address the subjective nature the auditor is forced into with this requirement. If “[t]he time required by the entity to report an issue is subject to many variables...” and “[f]or this reason it is difficult to establish a time period which would fairly apply to all TO’s,” how does leaving this to the auditor to decide going to make it any better? You will be forcing the audited entity to "prove the negative."
Response: The SDT thanks you for your comments. The SDT believes that it was not prudent to suggest a quantitative time element for notification in R4. The technical reference offers examples of acceptable unintentional delays for your review. The SDT notes that this language is already embodied in at least one other FERC-approved, in-force Standard.				
Frank Gaffney	Florida Municipal Power Agency	4	Negative	R1 and R2 requirement reads: "Each Transmission Owner shall manage to prevent encroachment ....". The results of manage would be invoices of tree trimming actually performed, documentation of a vegetation management program that would be managed to, etc. However, the Measures proposed are all actual outages which are neither evidence of management nor evidence of encroachment since there can be encroachment without an outage, and in fact, many if not most encroachments do not result in outages. Hence, the Measures are inconsistent with the requirements. Further, there is ambiguity of the action required in requirements R1 and R2 - e.g., do entities need evidence that they: 1) "manage", or 2) "prevent encroachment"; or 3) as implied by the Measures, prevent vegetation related outages?. In other words, what needs to be proven through evidence? Certainly the third, prevent vegetation related outages, is not in the Requirement; yet, that us what is proposed for the Measures, highlighting the

Voter	Entity	Segment	Vote	Comment
				inconsistency between Requirements and Measures. But, how would the ambiguity between "manage" and "prevent encroachment" be resolved? One auditor could interpret that the requirement is to "manage" and accept a vegetation management program and plan and proof that the plan was executed as appropriate evidence. Another auditor could interpret that "prevent" is the key word and look for evidence proving that there was never a vegetation encroachment. How would evidence be produced to provide the auditor that vegetation never encroached? Would video cameras and other surveillance measures need to operate 24 hours a day? Would we cause an entity to survey the lines periodically? One can easily see that "prevent encroachment" is inappropriate here since it is infeasible to create evidence of compliance. FMPA suggests one of two approaches: Eliminate the word manage, but do not focus on encroachment and instead focus on outages. For instance: "Each Transmission Owner shall prevent vegetation related outages (except as noted in Footnote 2) of any of its applicable line(s) ..." Evidence of outages is practical to gather and provide, evidence of encroachment is not. Focus on the word "manage", similar to the existing FAC-003 standard, and move R3 to a new R1 to develop a management plan, and then the existing R1 and R2 become R2 an R3 and require execution of that plan in the words of R7, which would in turn enables elimination of R7.
Response: The SDT thanks you for your comments. In Order 693 FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation"** (emphasis added). The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct				

Voter	Entity	Segment	Vote	Comment
inspections in which clearances are evaluated.				
Douglas Hohlbaugh	Ohio Edison Company	4	Affirmative	For the Requirement R1 and R2 VSLs, we suggest that the proposed Moderate (fall-ins) and High (blowing together) VSL be interchanged. We believe that fall-ins are more severe encroachments than blowing together and the categories listed in the compliance section support this point. Category 1 (grow-ins) is most severe, followed by Category 2 & 3 (fall-ins) and Category 4 (blowing together. If the team elects to not make the suggested VSL changes then a change in the category listing within the compliance section is warranted. Either way they should be consistent.
Response: The SDT believes that there is consensus that "blowing-together" events are more indicative of a program failure than are "fall-in" events. Further, the risk to the transmission system from blowing-together events is greater than for fall-ins; partly because blowing-together events are more likely to repeat themselves, whereas fall-ins generally end on the spot. The SDT agrees with you that the ordering of the categories seems to convey a different message; however, re-sequencing the categories in order of severity would have led to a clash with the existing categories in Version 1 and thus would have provoked widespread confusion.				
Francis J. Halpin	Bonneville Power Administration	5	Affirmative	In R1 and R2 and their associated VSLs, the SDT added the phrase "in order of increasing severity" and added the sentence, "The types of encroachments are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a TO's vegetation maintenance program." to the Rationale boxes for R1/R2. Do you agree? If answer is no, please explain. BPA prefers the stratified levels of violation severity presented in the table for R1 and R2. Foot note # 2 on page 8 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities.

Voter	Entity	Segment	Vote	Comment
				Foot note # 4 on page 12 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. In response to comments received that requirement R3 is unclear with respect to intent, the SDT added “maintenance strategies.” Do you agree this clarifies the intent? If answer is no, please offer alternative language. The TO procedures / policies and specifications shall demonstrate the TO’s ability to manage the system at all rated conditions to maintain reliability. BPA believes that the intent is clear, but the fundamental approach of using the MVCD (table 2) to manage a vegetation program is still problematic. These values are flashover distances and are way too close. This is acknowledged in a footnote to table 2 but no identification of allowable buffers/distances between energized phase conductors at rated temperatures and vegetation is discussed (this is left up the transmission owners). Clarity is needed on this topic. Setting a finite distance limit based on recognized standards, good science and risk avoidance should be done for the industry. BPA has previously made this comment during the drafting of the standard. It was not addressed then, nor has it been addressed now.
Response: The SDT thanks you for your comments. The footnotes were changed to conform with your suggestions. With respect to comments about the MVCD, R3 does not suggest the MVCD be used as a distance to manage vegetation. The MVCD was established as a beginning of a series of “building blocks” for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and				

Voter	Entity	Segment	Vote	Comment
vegetation growth, when designing the Transmission Owner’s overall vegetation management approach. The net result of this “building block” approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD distances. In a performance based standard, requirements are focused on “what” needs to be accomplished to achieve desired results and avoids prescriptive requirements of “how” to achieve that result. TO’s are in the best position to determine the appropriate management approach suited for their system rather than a “one size fits all” requirements that could suppress best practices for vegetation management.				
James B Lewis	Consumers Energy	5	Negative	See comments on the Standard.
Response: The SDT thanks you for your comments that were made during the formal comment period for the Standard; the SDT’s responses to those comments are available there.				
Bob Essex	Cowlitz County PUD	5	Negative	Referring back to Cowlitz’ negative vote made on the 7/9-19/2010 ballot, Cowlitz tried to convey the problem that the statement in R4 “without intentional time delay” will require subjective judgment on the part of the auditor. In other words, maintaining equal auditing standard throughout the interconnection will be impossible with this verbiage in a requirement. Response: The SDT thanks you for your comments. The footnotes were changed to conform with your suggestions. With respect to comments about the MVCD, R3 does not suggest the MVCD be used as a distance to manage vegetation. The MVCD				

Voter	Entity	Segment	Vote	Comment
was established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner' consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD distances. In a performance based standard, requirements are focused on "what" needs to be accomplished to achieve desired results and avoids prescriptive requirements of "how" to achieve that result. TO's are in the best position to determine the appropriate management approach suited for their system rather than a "one size fits all" requirement that could suppress best practices for vegetation management.				
Nickesha P Carrol	Consolidated Edison Co. of New York	6	Affirmative	The VSLs in R6 and R7 should be consistent with each other: R6 says '...TO failed to inspect 5% or less.....' and R7 says '...TO failed to complete up to 5%....' They both should use the same verbiage in each VSL whether it is 'x% or less' or 'up to and including x%.'
Response: The SDT thanks you for your comments. The SDT has changed the verbiage in the VSLs in R6 and R7 such that it addresses you suggestion.				
Mark S Travaglianti	FirstEnergy Solutions	6	Affirmative	FirstEnergy supports standard FAC-003-2 and would appreciate consideration of our comments submitted through the formal comment period.
Response: The SDT thanks you for your comments and has reviewed and responded to your comments made during the formal comment period.				
Thomas E Washburn	Florida Municipal Power Pool	6	Negative	The concern is that entities may not be able prove compliance with the standard. R1 and R2 say that: "Each Transmission Owner shall manage vegetation to prevent encroachments ...". If the requirements were interpreted such that "manage" is the operative word, then, we are OK because we can provide evidence of managing a program, such as a vegetation management plan and evidence of

Voter	Entity	Segment	Vote	Comment
				executing that plan (which does not align with the Measures). However, that 1) would cause the standard to not be performance based, and 2) it would be duplicative of the other requirements of the standard. If the requirements were interpreted with "prevent encroachment" as the operative phrase (which would be an incorrect interpretation from the construct of the sentence) there is no way to provide sufficient evidence that encroachment was prevented during the audit-period. The suggested Measures are not sufficient evidence to prove compliance with that interpretation of the requirement. For instance, most encroachments do not result in outages; hence, lack of outages cannot prove that there were no encroachments, and real time observations are insufficient because it is a spot-check that does not cover the audit period. There are other weaknesses in the standard, such as R4 being un-measurable therefore unenforceable. However, in the guilty until proven innocent paradigm we live in, FMPA's primary concern is that industry could be put into a no-win situation of not being able to prove compliance with the standard if R1 and R2 are interpreted as "prevent encroachment", and if R1 and R2 are interpreted as "manage" then it is not a performance based standard as advertised. Performance based focused on preventing vegetation related outages. For instance: "Each Transmission Owner shall prevent vegetation related outages (except as noted in Footnote 2) of any of its applicable line(s) ..." Evidence of outages is practical to gather and provide, evidence of encroachment is not. Modify the standard to be similar to the currently mandatory non-results based standard and focus on the word "manage". This would essentially mean eliminating R1

Voter	Entity	Segment	Vote	Comment
				and R2 since the rest of the standard focuses on having a plan and managing to that plan..
Response: The SDT thanks you for your comments. In Order 693 FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation**" (emphasis added). The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct inspections in which clearances are evaluated.				
Thomas Saitta	Kansas City Power & Light Co.	6	Negative	The VSL for Requirement 7 should be clear and specifically state this specifically addresses only "all applicable lines".
Response: The SDT thanks you for your comments. The team has added the phrase, "applicable lines" as proposed to all the VSLs for R7.				
James Eckelkamp	Progress Energy	6	Affirmative	There needs to be a change in the footnote 2 and footnote 4 to remove the exemption for "arboricultural activities or horticultural or agricultural activities" and replace it with the term "installation of."
Response: The SDT thanks you for your comments. The changes to the footnotes have been made as proposed.				
Guy V. Zito	Northeast Power Coordinating Council, Inc.	10	Affirmative	The use of the term "encroachment", and the lack of clarity in defining clearances is an issue that should be addressed by the Drafting Team.
Response: The SDT thanks you for your comments. With regard to the use of "encroachment" and the clarity in defining clearances as it relates to the VRFs and VSLs, the SDT has taken what was a "gray" area in Version 1 and added more clarity with regard to compliance. In Version 1, it is not actually clear whether experiencing an encroachment or experiencing outage is a violation of the standard. The SDT recognized this concern and has addressed this via the proposed VSLs for R1 and R2. These proposed VSLs are designed such to correlate to the severity level of failure of the Transmission Owner's vegetation management program.				

Voter	Entity	Segment	Vote	Comment
If you refer to the VSLs for R1 and R2, only the "Lower" VSLs apply to an encroachment, and that has been defined as "an encroachment into the MVCD observed in Real-time, absent a Sustained Outage." The "MVCD" clearance distance is clearly defined in Table 2 of the Standard. After the Lower VSL level for these requirements, the Moderate to Severe VSLs are correlated more directly to the severity of failure of the Transmission Owner's vegetation management program associated with a Sustained Outage. The SDT makes this recommendation of VSLs based on this being an improvement for compliance clarity over version 1 of the standard.				
Anthony E Jablonski	ReliabilityFirst Corporation	10	Negative	ReliabilityFirst votes negative and has the following comments regarding the VRFs and VSLs: 1. VRF for R1 and R2 a. The Final Report on the August 14th, 2003 Blackout in the United States and Canada: Causes and Recommendations Blackout Report, highlights the importance of all vegetation management work by identifying inadequate vegetation management as one of the causes of the 2003 Blackout. Based on the Blackout Report there should be no distinction between encroachments of applicable line(s) identified as an element of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path(s) and encroachments of applicable line(s) not identified as an element of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path(s). Therefore, ReliabilityFirst recommends that VRFs should be the same for R1 and R2. 2. VSL for R3 a. Since this requirement has sub-parts associated with it, the associated sub-part number should be referenced in the VSL itself.

Voter	Entity	Segment	Vote	Comment
				3. VSL for R4 a. The words in the VLS do not match the language in the requirement. The words "vegetation threat" is not mentioned in Requirement R4. Based on the FERC Guideline #3 "Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement" 4. VSL for R6 a. The following qualifier should be added to the end of each of the four VSLs, "...at least once per calendar year and with no more than 18 months between inspections on the same ROW" to be consistent with the corresponding requirement and in accordance with the FERC Guideline #3. 5. VSL for R7 a. There is no associated VSL dealing with the second part of the requirement which references that "... the Modifications to the work plan... must be documented." Where does an entity fall if they have complete 100% of its annual vegetation work plan, but failed to document any modifications to the work plan? This aspect of the requirement should be addressed in the corresponding VSLs.

Response: The SDT thanks you for your comments.

1) In Order 693 FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation**" (emphasis added). Following that concept, the SDT used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. .

R1 and R2 are dealing with the differentiation between lines that fall into an IROL or WECC Transfer Path definition and those lines that do not. The SDT asserts that different VRF's for IROL and non-IROL lines strengthens the reliability of the standard. Vegetation managers that do not know which lines are IROL or WECC Transfer Paths may be inappropriately limiting resources allocated to vegetation management for an IROL line or a WECC Transfer Path. A vegetation manager must ensure that the

Voter	Entity	Segment	Vote	Comment
IROL lines and WECC transfer paths are absolutely clear. By correctly identifying the risk associated with an IROL line and/or a WECC Transfer Path, the standard helps to assure that appropriate resources are applied. 2) The sub-parts referred to are part of the RBS building block approach to document how a TO prevents encroachment of vegetation into the MVCD. The sub parts are not separate elements but make up the processes, strategies, procedures or specifications to prevent encroachment in to the MVCD. 3) The SDT believes the correlation between R4 and the VSL is appropriate. 4) The SDT believes the correlation between R6 and the VSL is appropriate. 5) The wording in the VSL for R7 has been modified to address modifications to the annual work plan.				

Successive Ballot (February 18-28, 2011) Consideration of Comments Report

Project 2007-07 Vegetation Management — September 30, 2011

Summary Consideration:
In order to be consistent with the latest version of NERC's Results Based Standards template, the heading "Objective" was replaced with "Purpose," and the numbering, headings, and sections were reformatted as necessary.

Several entities expressed concern with the use of the Minimum Vegetation Clearance Distance (MVCD) and elimination of Clearance 1. With respect to comments about the MVCD, R3 does not suggest the MVCD be used as a distance to manage vegetation. The MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD. In a performance-based standard, requirements are focused on "what" needs to be accomplished to achieve desired results and avoids prescriptive requirements of "how" to achieve that result. TO's are in the best position to determine the appropriate management approach suited for their system, rather than a "one size fits all" or "fill in the blank" requirement that could suppress best practices for vegetation management.

Other entities questioned whether the goal of the standard was to "prevent outages" or to "manage vegetation." In Order 693, FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way by maintaining safe clearances between transmission lines and vegetation." The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct inspections in which clearances are evaluated.

Some entities expressed concern with the mandatory inspection intervals proposed in the standard. The SDT recognizes that a number of Transmission Owners in North America may prefer to set their own inspection intervals. Because there is substantial industry support for an annual inspection interval the SDT believes that the industry is best served with this approach.

Several entities suggested making minor changes to clarify the footnotes. The team did so.

If you feel that the drafting team overlooked your comments, please let us know immediately. Our goal is to give every comment serious consideration in this process. If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herb Schrayshuen, at 404-446-2563 or at herb.scrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

Voter	Entity	Segment	Vote	Comment
Paul B. Johnson	American Electric Power	1	Affirmative	American Electric Power believes that the phrase "arboricultural activities or horticultural or agricultural activities" was mistakenly introduced into Footnotes 2 and 4, and should be deleted from both footnotes. If the phrase remains in the Standard, it may empower orchard growers, landowners and others to plant trees on the right of way and challenge Transmission Owners' rights to perform maintenance on the presumption that the standard will exempt the TO from violating the outage or encroachment requirements. For increased clarity, AEP offers the following change to the second paragraph of M1, as well as the second paragraph of M2. The original text "If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation" should be replaced

[1] The appeals process is in the Reliability Standards Development Procedure: http://www.nerc.com/files/RSDP_V6_1_12Mar07.pdf.

Voter	Entity	Segment	Vote	Comment
				with "If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation growing into or blowing together with the conductor within the ROW, this shall be considered the equivalent of a Real-time observation. A brief encroachment caused by falling vegetation passing through the MVCD is not considered an encroachment in this requirement".
Response: Thank you for your comments. The SDT made suggested changes to the footnotes as proposed. Regarding the issue of fall-ins, the SDT is sympathetic to your concern. In fact, the SDT had originally crafted language similar to that which you suggested. However, due to concerns expressed by regulators and others, the exemption for encroachment violations due to falling vegetation from inside the right of way was removed.				
Robert D Smith	Arizona Public Service Co.	1	Negative	Overall comment: The objective, as written, is about outages that can lead to cascading and not about reliability. Recommended change to Standard Objective: To maintain a reliable electric transmission system, implement a defense-in-depth strategy to manage vegetation located on transmission rights of way (ROW) and minimize encroachments from vegetation located adjacent to the ROW.
Response: The SDT thanks you for your comment. With respect to the Purpose as written in the proposed standard, the language clearly states "To improve the reliability of the electric Transmission system…" The SDT made it a point to keep the Purpose as concise as possible without getting into issues that are covered further in the body of the standard.				
John Bussman	Associated Electric Cooperative, Inc.	1	Negative	R1 - "Each Transmission Owner shall manage vegetation to prevent encroachments of the types shown below, into the Minimum Vegetation Clearance Distance (MVCD) of any of its applicable line(s) identified as an element of an Interconnection Reliability Operating Limit (IROL) in the planning horizon by the Planning Coordinator; or Major Western Electricity Coordinating Council (WECC) transfer

Voter	Entity	Segment	Vote	Comment
				path(s); operating within its Rating and all Rated Electrical Operating Conditions...” The following is my preliminary comment on this requirement. R1 - Associated Electric Cooperative Inc wants to thank the SDT for their hard work and all the effort associated with this standard. However we currently disagrees with the inclusion in this requirement of any and all IROLs identified within the entire planning horizon (typically 10 years or more). Associated Electric certainly agrees that in real time and in the near term sub 200 kV elements of an IROL should be subject to R1. It seems unreasonable, however, to include a sub 200 kV transmission line that might become an IROL element 10 years in the future. Perhaps the time frame could be limited to the Transmission Owner’s planned maintenance cycle.
Response: The SDT thanks you for your comment, and has revised the Standard’s effective dates (exceptions) accordingly.				
Gregory S Miller	Baltimore Gas & Electric Company	1	Affirmative	There seems to be a marginal level of improvement over the previous drafts.
Response: The SDT thanks you for your comment.				
Joseph S. Stonecipher	Beaches Energy Services	1	Negative	R1 and R2 Requirement reads: "Each Transmission Owner shall manage to prevent encroachment ....". The results of manage would be invoices of tree trimming actually performed, documentation of a vegetation management program that would be managed to, etc. However, the Measures proposed are all actual outages which are neither

Voter	Entity	Segment	Vote	Comment
				evidence of management nor evidence of encroachment since there can be encroachment without an outage, and in fact, many if not most encroachments do not result in outages. Hence, the Measures are inconsistent with the Requirements. Further, there is ambiguity of the action required in requirements R1 and R2 - e.g., do entities need evidence that they: 1) "manage", or 2) "prevent encroachment"; or 3) as implied by the Measures, prevent vegetation related outages? In other words, what needs to be proven through evidence? Certainly the third, prevent vegetation related outages, is not in the Requirement; yet, that us what is proposed for the Measures, highlighting the inconsistency between Requirements and Measures. But, how would the ambiguity between "manage" and "prevent encroachment" be resolved? One auditor could interpret that the Requirement is to "manage" and accept a vegetation management program and plan and proof that the plan was executed as appropriate evidence. Another auditor could interpret that "prevent" is the key word and look for evidence proving that there was never a vegetation encroachment. How would evidence be produced to provide the auditor that vegetation never encroached? Would video cameras and other surveillance measures need to operate 24 hours a day? Would we cause an entity to survey the lines periodically? One can easily see that "prevent encroachment" is inappropriate here since it is infeasible to create evidence of compliance.

Response: The SDT thanks you for your comments. In Order 693, FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances**

Voter	Entity	Segment	Vote	Comment
between transmission lines and vegetation" (emphasis added). The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct inspections in which clearances are evaluated.				
Donald S. Watkins	Bonneville Power Administration	1	Affirmative	R2. Do you agree? If answer is no, please explain. BPA prefers the stratified levels of violation severity presented in the table for R1 and R2. Foot note # 2 on page 8 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. Foot note # 4 on page 12 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. In response to comments received that requirement R3 is unclear with respect to intent, the SDT added "maintenance strategies." Do you agree this clarifies the intent? If answer is no, please offer alternative language. The TO procedures / policies and specifications shall demonstrate the TO's ability to manage the system at all rated conditions to maintain reliability. BPA believes that the intent is clear, but the fundamental approach of using the MVCD (table 2) to manage a vegetation program is still problematic. These values are flashover distances and are way too close. This is acknowledged in a footnote to table 2 but no identification of allowable buffers/distances between energized phase conductors at rated temperatures and vegetation is discussed (this is left up the transmission owners). Clarity is needed on this topic. Setting a finite distance limit based on recognized standards, good science and risk avoidance should be done for the industry. BPA has previously made this comment during the drafting of the

Voter	Entity	Segment	Vote	Comment
				standard. It was not addressed then, nor has it been addressed now.
Response: The SDT thanks you for your comments. The footnotes were changed to conform with your suggestions. With respect to comments about the MVCD, R3 does not suggest the MVCD be used as a distance to manage vegetation. The MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD In a performance based standard, requirements are focused on "what" needs to be accomplished to achieve desired results and avoids prescriptive requirements of "how" to achieve that result. TO's are in the best position to determine the appropriate management approach suited for their system, rather than a "one size fits all" that could suppress best practices for vegetation management.				
Randall McCamish	City of Vero Beach	1	Negative	Vero Beach's concern is that entities may not be able prove compliance with the standard. R1 and R2 say that: "Each Transmission Owner shall manage vegetation to prevent encroachments ...". If the requirements were interpreted such that "manage" is the operative word, then, we are OK because we can provide evidence of managing a program, such as a vegetation management plan and evidence of executing that plan (which does not align with the Measures). However, that 1) would cause the standard to not be performance based, and 2) it would be duplicative of the other requirements of the standard. If the requirements were interpreted with "prevent encroachment" as the operative phrase (which would be an

Voter	Entity	Segment	Vote	Comment
				incorrect interpretation from the construct of the sentence) there is no way to provide sufficient evidence that encroachment was prevented during the audit-period. The suggested Measures are not sufficient evidence to prove compliance with that interpretation of the requirement. For instance, most encroachments do not result in outages; hence, lack of outages cannot prove that there were no encroachments, and real time observations are insufficient because it is a spot-check that does not cover the audit period. There are other weaknesses in the standard, such as R4 being un-measurable therefore unenforceable. However, in the guilty until proven innocent paradigm we live in, FMPA's primary concern is that industry could be put into a no-win situation of not being able to prove compliance with the standard if R1 and R2 are interpreted as "prevent encroachment", and if R1 and R2 are interpreted as "manage" then it is not a performance based standard as advertised. Vero Beach suggests one of two approaches: 1. Performance based focused on preventing vegetation related outages. For instance: "Each Transmission Owner shall prevent vegetation related outages (except as noted in Footnote 2) of any of its applicable line(s) ..." Evidence of outages is practical to gather and provide, evidence of encroachment is not. 2. Modify the standard to be similar to the currently mandatory non-results based standard and focus on the word "manage". This would essentially mean eliminating R1

Voter	Entity	Segment	Vote	Comment
				and R2 since the rest of the standard focuses on having a plan and managing to that plan.
Response: The SDT thanks you for your comments. In Order 693, FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation**" (emphasis added). The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct inspections in which clearances are evaluated.				
Danny McDaniel	Cleco Power LLC	1	Negative	Cleco disagrees with the SDT revising the definition for Right-of-Way (ROW). Right-of-Way is a term that has had a consistent meaning throughout history. If NERC tries to redefine the term, it will only add confusion because most entities will not reference the NERC glossary for a term which is widely used in the industry. In lieu of "Active Transmission Line ROW", please use another term such as Transmission Corridor. No assumptions would be made when reading in the Standard the the Entity is to maintain vegetation located within the Transmission Corridor. Since the term is not commonly used, the NERC glossary would be referenced. Also, Cleco disagrees that an encroachment into the MCVD that does not cause an outage should be considered non-compliant as stated in R1 and R2. The encroachment should only be reportable similar to misoperations as is in the PRC-004 standard.
Response: Thank you for your comments. The existing ROW definition in the glossary was created by and for the FAC-003-1 and was moved there when that standard was adopted. The definition includes a series of options that give the Transmission Owner latitude in establishing ROW width. It does not require selecting a single method for its system. The term "blowout standard" is not capitalized and is not a defined				

Voter	Entity	Segment	Vote	Comment
term. This phrase in the definition allows a Transmission Owner to use its internal engineering standards or the general engineering standards that were in effect when the line was constructed to determine the ROW width. The SDT has limited the definition of Right-of-Way to a corridor of land with a defined width to operate a transmission line. This does not include danger tree rights. The definition of the MVCD is now added to this Standard. While use of the pre-2007 records is a compliance issue and is not in the purview of the SDT, it is the intent of the language in the definition that you could use this information. Regarding your second comment, R3 does not suggest the MVCD be used as a distance to manage vegetation. The MVCD was established as a beginning of a series of “building blocks” for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner’s overall vegetation management approach. The net result of this “building block” approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD Other related requirements of this “Defense in Depth” Standard serve to address any number of scenarios which may arise or hinder the TO’s ability to always strictly adhere to the management approach(s) established within R3. Thus the other requirements of this Standard provide the latitude for appropriate actions to remedy the condition without penalty. Further, trees which have encroached inside the MVCD are evidence of a deficiency in vegetation maintenance.				
Christopher L de Graffenried	Consolidated Edison Co. of New York	1	Affirmative	Reply to Question 5 on Comment Form: The added language for the annual work plan percentage complete calculation is shown in R7 not M7 as stated in the question. In the Guideline and Technical Basis Section for Requirement R6, there is a sample calculation shown for the amount of lines the TO failed to inspect. An example should also be included for Requirement R7 since there is some confusion regarding how modifications to the work plan affect the calculation. In the Lower VSL column for R7, it states that the TO failed to complete up to 5% of its annual vegetation work plan (including modifications if any). If a TO operates 100 lines and submits a justified modification that affects 10 miles of

Voter	Entity	Segment	Vote	Comment
				lines, the total number of units in the final amended plan is 90 miles. When you read the VSL, it is somewhat confusing since the information in parenthesis says that the calculation 'includes' the modifications. Should it state 'excludes modifications if any' or the VSLs can simply be re-written to state that ..The TO failed to complete up to x% of the final amended plan.' Also, the VSLs in R6 and R7 should be consistent with each other: R6 says '...TO failed to inspect 5% or less.....' and R7 says '...TO failed to complete up to 5%....' They both should use the same verbiage in each VSL whether it is 'x% or less' or 'up to and including x%.'
Response: The SDT thanks you for your comments. The percentage should be based on the plan as modified. The SDT has changed the language in the standard to reflect this more clearly, and has modified the VSLs to be consistent as you have suggested.				
Robert Martinko	FirstEnergy Energy Delivery	1	Affirmative	FirstEnergy supports standard FAC-003-2 and would appreciate consideration of our comments submitted through the formal comment period.
Response: The SDT thanks you for your comments. Please see our consideration of your comments within the responses to the formal comments.				
Luther E. Fair	Gainesville Regional Utilities	1	Negative	1. It would seem that the impetus for FAC003 is to eliminate vegetation related outages within the rights-of-way as defined and subject to the exclusions as stated in footnote 2. Thus the requirement is to manage the ROW to prevent vegetation related sustained outages with the measure being no outages. With grow-ins and fall-ins from within the defined ROW being controllable factors.

Voter	Entity	Segment	Vote	Comment
				2. Including encroachments leaves the door open for fines to be imposed with no actual outage(s) having occurred. This may be like being found guilty of a crime that has not yet taken place. 3. Combine vegetation related sustained outages by "grow-ins" and "blowing together of lines and vegetation located inside the ROW" as one item as they are both consequences of the growth of vegetation either vertically and horizontally. 4. Leave vegetation related sustained outages by "fall-in" as a standalone as this will be related to structural problems occurring from a variety of sources. 5. Combine R3 and R7 to R1 (development and implementation of a Transmission Vegetation Management Plan which shall include documented maintenance strategies or procedures or processes or specifications, delineation of an annual work plan and completion of same). Thus this would be the competency based requirements as a program without execution is meaningless. 6. R1 and R2 become R2 and R3.
Response: The SDT thanks you for your comments. In Order 693, FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation**" (emphasis added). The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct				

Voter	Entity	Segment	Vote	Comment
inspections in which clearances are evaluated.				
Ted E Hobson	JEA	1	Negative	Need to align the "measures" with the standard requirement language and the performance-based philosophy.
Response: The SDT thanks you for your comments. We are not quite clear as to what misalignment you refer to between the standard language and the measures. The SDT went to great lengths to ensure continuity between the requirements and the measures. While this standard was a first attempt at a "Results Based" approach, the SDT did have limitation in deciding what could be excluded from the standard. This standard has a mixture of the three types of requirements that comprise a results based approach: 1) Performance Based 2) Risk Based and 3) Competency Based. Having only performance-based requirements would not have resulted in a comprehensive, proactive standard.				
Michael Gammon	Kansas City Power & Light Co.	1	Negative	The Standard lacks clarity regarding the facilities that are subject to Requirement 7. It is important that a Standard be clear and not introduce ambiguity or confusion. There are several references throughout the Standard to "for all applicable lines" and it should be made clear the work plan is specific to "all applicable lines".
Response: The SDT thanks you for your comments. The team has made the appropriate modifications where necessary.				
Stan T. Rzad	Keys Energy Services	1	Negative	Concern is that entities may not be able prove compliance with the standard. R1 and R2 say that: "Each Transmission Owner shall manage vegetation to prevent encroachments ...". If the requirements were interpreted such that "manage" is the operative word, then, we are OK because we can provide evidence of managing a program, such as a vegetation management plan and evidence of executing that plan (which does not align with the Measures). However, that 1) would cause the standard to not be performance based, and 2) it would be duplicative of the

Voter	Entity	Segment	Vote	Comment
				other requirements of the standard. If the requirements were interpreted with "prevent encroachment" as the operative phrase (which would be an incorrect interpretation from the construct of the sentence) there is no way to provide sufficient evidence that encroachment was prevented during the audit-period. The suggested Measures are not sufficient evidence to prove compliance with that interpretation of the requirement. For instance, most encroachments do not result in outages; hence, lack of outages cannot prove that there were no encroachments, and real time observations are insufficient because it is a spot-check that does not cover the audit period. There are other weaknesses in the standard, such as R4 being un-measurable therefore unenforceable. However, in the guilty until proven innocent paradigm we live in, FMPA's primary concern is that industry could be put into a no-win situation of not being able to prove compliance with the standard if R1 and R2 are interpreted as "prevent encroachment", and if R1 and R2 are interpreted as "manage" then it is not a performance based standard as advertised. One of two approaches are suggested: Performance based focused on preventing vegetation related outages. For instance: "Each Transmission Owner shall prevent vegetation related outages (except as noted in Footnote 2) of any of its applicable line(s) ..." Evidence of outages is practical to gather and provide, evidence of encroachment is not. Modify the standard to be similar to the currently mandatory

Voter	Entity	Segment	Vote	Comment
				non-results based standard and focus on the word "manage". This would essentially mean eliminating R1 and R2 since the rest of the standard focuses on having a plan and managing to that plan.
Response: The SDT thanks you for your comments. In Order 693, FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation**" (emphasis added). The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct inspections in which clearances are evaluated.				
Walt Gill	Lake Worth Utilities	1	Negative	CLWU's concern is that entities may not be able prove compliance with the standard. R1 and R2 say that: "Each Transmission Owner shall manage vegetation to prevent encroachments ...". If the requirements were interpreted such that "manage" is the operative word, then, we are OK because we can provide evidence of managing a program, such as a vegetation management plan and evidence of executing that plan (which does not align with the Measures). However, that 1) would cause the standard to not be performance based, and 2) it would be duplicative of the other requirements of the standard. Voter	Entity	Segment	Vote	Comment
Saurabh Saksena	National Grid	1	Affirmative	The revised ROW definition emphasizes the ROW width needed to operate the transmission line(s). It is National Grid's interpretation that the width established when the line was constructed is the width to be maintained. This width is documented in engineering drawings, per-2007 vegetation records or blow-out standards. This definition does not imply that danger tree rights beyond the constructed and maintained width are incorporated in the definition; therefore fallins - from outside the ROW but within an area with danger tree rights would not be considered fallin-ins from within the ROW. National Grid would like the SDT to comment on this interpretation in its response to these comments.
Response: Your interpretation is consistent with the intent of the definition that the SDT provided. However the definition includes a series of options that give the Transmission Owner latitude in establishing ROW width. It does not require selecting a single method for its system. This phrase in the definition allows a TO to use its internal engineering standards or the general engineering standards that were in effect when the line was constructed to determine the ROW width. The SDT has limited the definition of Right-of-Way to a corridor of land with a defined width to operate a transmission line. This does not include danger tree rights.				
Michael T. Quinn	Oncor Electric Delivery	1	Affirmative	In footnote 2 (pg. 8) and 4 (page 10), the wording "arboricultural activities or horticultural or agricultural activities" should be deleted and replaced with "or removal of, installation of, or digging around vegetation."
Response: The SDT thanks you for your comments. The footnotes have been changed.				
John C. Collins	Platte River Power Authority	1	Negative	Vegetation Inspection: Is the intent of "... and those vegetation conditions under the TO's control" to clarify that an entity must have ownership of the transmission line and right-of-way in addition to maintenance or operational responsibility (control), or something different? In situations

Voter	Entity	Segment	Vote	Comment
				where a TO owns one circuit on a double circuit, but the other circuit, facilities and ROW belong to another TO who has maintenance, and vegetation management responsibility, who would be responsible for violations? If the definition was modified to allow both maintenance and vegetation inspections to be performed concurrently, the intent might be clearer if it read: “This may be combined with other line inspections”, or “This may be combined with a maintenance inspection” opposed to a general line inspection. R1 and R2: Does R1 correlate to facilities in 4.2.2. and 4.2.3. (overhead transmission lines operated below 200 kV) and R2 correlate to facilities in 4.2.1. (overhead transmission lines operated at 200kV or higher)? It isn’t clear why the two requirements are split. Could it be one requirement which reads “...identified as a facility in Section 4.2”? R4: Our current imminent threat procedure requires a call to the Manager who confirms the existence of a vegetation condition that is likely to cause a Fault at any moment prior to notifying the control center. We assume notification, without any intentional time delay, would take place after managerial confirmation but feel like the enforcement authorities could interpret this differently based on how it is written in R4. If the intent of the requirement is how we interpret it, the requirement might be clearer if it read: After a Transmission Owner has confirmed a vegetation condition likely to cause a Fault at any moment, they shall notify the control center holding switching authority for the associated applicable transmission line, without any

Voter	Entity	Segment	Vote	Comment
				intentional delay.
Response: The SDT thanks you for your comment. With regard to responsibility for a violation, the TO is the accountable party even if it has an agreement with another TO to inspect and manage vegetation. With regard to your suggestion in changing the definition of Vegetation Inspection, the SDT does not believe the proposed changes are necessary for the definition to be clear. With regard to R1 and R2, they applicability applies to 4.2.1 thru 4.2.3. The distinction between the requirement is R1 applies to all lines designated as having an Interconnection Reliability Operating Limit (IROL) in the planning horizon by the Planning Coordinator; or lines designated as Major Western Electricity Coordinating Council (WECC) transfer path(s). With regard to your imminent threat procedure, the standard is not prescriptive to define a TO's imminent threat procedure. So, if your procedure includes managerial confirmation, then this would not be considered intentional delay.				
Sammy Roberts	Progress Energy Carolinas	1	Affirmative	There needs to be a change in the footnote 2 and footnote 4 to remove the exemption for "arboricultural activities or horticultural or agricultural activities" and replace it with the term "or installation of."
Response: The SDT thanks you for your comments. The footnotes have been changed.				
Laurie Williams	Public Service Company of New Mexico	1	Negative	PNM is voting negative but offers the following comments to improve the standard. 1. The last sentence of the Background on page 7 states: Thus, this Standard's emphasis is on vegetation grow-ins. However, R1 says that we shall manage encroachments as follows: R1. Each Transmission Owner shall manage vegetation to prevent encroachment that could result in a Sustained Outage encroachments of the types shown

Voter	Entity	Segment	Vote	Comment
				below, into the Minimum Vegetation Clearance Distance (MVCD) of....... 2. An encroachment due to a fall-in from inside the active transmission line Right-of-Way (ROW) that caused a vegetation-related Sustained Outage, This seems contradictory. 2. Fac-003-2 makes reference to FAC-014 and a “Planning Coordinator” in section 4.2.2 of Applicability: pg 5 see below: 4.2.2. Overhead transmission lines operated below 200kV having been identified as included in the definition of an Interconnection Reliability Operating Limit (IROL) under NERC Standard FAC-014 by the Planning Coordinator. In addition, on pg 8, R1 of FAC-003-2 makes reference to the “planning coordinator” However, FAC-014 makes no reference, or at least it is inconsistent, to a “Planning Coordinator” See below: Taken from FAC-014 4. Applicability 4.1. Reliability Coordinator 4.2. Planning Authority 4.3. Transmission Planner 4.4. Transmission Operator The terminology and definitions seem to be inconsistent.

Voter	Entity	Segment	Vote	Comment
				3. R1 and R2 are the same requirements with different applicabilities. R1 applies to lines that are connected to WECC, IROL, etc. R2 applies to all other applicable lines that are NOT an element of WECC or IROL. My Question is: If the line is not part of WECC or IROL or any other connection then, how is it applicable to the Standard? 4. R7 says the TO shall complete a %100 of annual plan but allows for modifications that include: Change in expected growth rate/ environmental factors Major storms Circumstances that are beyond the control of a Transmission Owner5 Rescheduling work between growing seasons Crew or contractor availability/ Mutual assistance agreements Identified unanticipated high priority work Weather conditions/Accessibility Permitting delays Land ownership changes/Change in land use by the landowner Funding adjustments (increase or decrease) Emerging technologies [VRF - Medium] [Time Horizon - Operations Planning] The requirement says we shall complete a %100 of the annual plan however, some of the modifications have historically taken over a year to mitigate. SHALL should be

Voter	Entity	Segment	Vote	Comment
				replaced with SHOULD with acceptable modifications and without compromising integrity of system.
Response: The SDT thanks you for your comments. Item 1: It is intended that the Standard will cover any situation within the ROW that causes an encroachment into the MVCD including fall-ins, grow-ins or blowing-together. The arrangement of the Violation Severity Levels for R1. and R2. emphasize that a grow-in results in the greatest risk to a power system, and also is the most egregious and severe failure to meet the intent of these requirements. Item 2: The term Planning Authority (PA) included in FAC-014 was replaced by NERC in the functional model Version 5 with Planning Coordinator. Where references to PA are included in legacy Standards, Planning Coordinator is now used as follows Planning Coordinator (Planning Authority). Obviously, proposed new Standards or versions must use the currently accepted terms. Item 3: R1 and R2 are dealing with the differentiation between lines that fall into IROL/WECC Transfer Path definition and those lines that do not. Keep in mind that this standard refers to all transmission lines over 200-kV. Item 4: The SDT believes replacing the word "shall" with the word "should" in Requirement 7 changes the requirement to a recommendation.				
Pawel Krupa	Seattle City Light	1	Affirmative	The revisions to the proposed FAC-003-2 Standards produced a better version through greater clarity, appropriate pragmatism, and technical foundation; A few good points that highlight this follow: 1. Definition of Terms Used in Standard: The revised definition of Right-of-Way (ROW) establishes the width of the corridor from a technical basis with the following statement "The width of the corridor is established by engineering or construction standards..." 2. Introduction, Applicability, Section 4.2 Facilities: Section 4.2.4 which pertains to substations clarifies that this standard does not apply to applicable transmission lines, inside the substation, just to "any portion of the span of the

Voter	Entity	Segment	Vote	Comment
				transmission line that is crossing the substation fence". 3. Requirements and Measures: Requirement 1 underscores sensible purpose by replacing the wording of "preventing outages from vegetation" to "manage vegetation to prevent encroachments..." 4. Guideline and Technical Basis Section: Requirement 7 contains a great practicle reference explanation as it pertains to the annual work plan. Requirement 7 explains: ..." the vegetation management approach should use the full extent of the Transmission Owner's easement, fee simple and other legal rights allowed. A comprehensive approach that exercises the full extent of legal rights on the ROW is superior to incremental management in the long term because it reduces the overall potential for encroachment, and it ensures that future planned work and future planned inspection cycles are sufficient".
Response: The SDT thanks you for your comments.				
William G. Hutchison	Southern Illinois Power Coop.	1	Negative	I beleive that the reliability region should have the right to exclude lines below 200KV. Not all lines above 100KV negative impact the BES.
Response: The SDT thanks you for your comment. This issue is presently before FERC and NERC and is outside the scope of the SDT.				
Keith V Carman	Tri-State G & T Association, Inc.	1	Affirmative	There needs to be a change in the footnote 2 and footnote 4 to remove the exemption for “arboricultural activities or horticultural or agricultural activities” and replace it with the term “ installation of”.

Voter	Entity	Segment	Vote	Comment
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
Brandy A Dunn	Western Area Power Administration	1	Affirmative	There needs to be a change in the footnote 2 and footnote 4 to remove the exemption for "arboricultural activities or horticultural or agricultural activities" and replace it with the term " installation of"
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
Gregory L Pieper	Xcel Energy, Inc.	1	Affirmative	Xcel Energy still believes the requirement in R6 that mandates an annual inspection is an ineffective approach and may actually go against the Commission's determination in FERC Order No. 693. The drafting team's response to our last round of comments on this issue was that "...the SDT was directed by Order 693 to set a minimum inspection criteria". It is clear in Order 693 that the Commission is not satisfied with allowing entities to choose their own inspection cycles, as the standard currently allows. However, we fail to see where the Commission mandated a minimum inspection cycle to be uniformly applied continent-wide. We urge the drafting team to revisit paragraphs 719 through 721 of Order 693. According to paragraph 721, the Commission recognizes that unique intervals by region, "based on local factors", are reasonable and appropriate. By use of the plural term "cycles", FERC anticipates the resolution may include multiple inspection cycles. Furthermore, in paragraph 719, FERC acknowledges that a minimum inspection cycle may not be the only way to address their concern. In fact, mandating an annual inspection cycle may actually go against the Commission's guidance in paragraph 720. Here is an excerpt: "...the

Voter	Entity	Segment	Vote	Comment
				Commission is dissuaded from requiring the ERO to create a backstop inspection cycle at this time. Instead, the Commission agrees that an entity's vegetation management program should be tailored to anticipated growth in the region and take into account other environmental factors. The goal is to assure that transmission owners conduct inspections at reasonable intervals." As an alternative, we propose a mid-cycle inspection. A mid-cycle inspection is based on an interval that is justified with data and technical expertise. A mid-cycle inspection would still require entities to conduct inspections at a specified interval, while allowing for differences based upon "physical and geographic factors". Not only would this approach fully address the Commissions concerns, but it would take into account the interests of stakeholders, landowners and rate-payers. We recognize that a mid-cycle inspection interval is not as easy to audit as an annual requirement, but it is a far more practical and cost-effective approach that, when applied based on an entity's expertise with its own facilities, ensures reliability.
Response: The SDT thanks you for your comments. The SDT recognizes that a number of Transmission Owners in North America may prefer to set their own inspection intervals. The SDT can also see attractiveness for a mid-cycle inspection concept; however, this introduces new complexities in planning, documentation and auditing. Because there is substantial industry support for an annual inspection interval the SDT believes that the industry is best served with this approach.				
Mark B Thompson	Alberta Electric System Operator	2	Abstain	Due to slow vegetation growth rates in many parts of Alberta, not all transmission right-of-ways require annual inspection as required in R6. TOs should be able to include planned inspection cycles in their Transmission Vegetation Management Plan.

Voter	Entity	Segment	Vote	Comment
Response: The SDT thanks you for your comments. In FERC Order 693, para. 721, FERC stated, “The Commission continues to be concerned with leaving complete discretion to the transmission owners in determining inspection cycles, which limits the effectiveness of the Reliability Standard.” The SDT established an inspection cycle at least once per calendar year and with no more than 18 calendar months between inspections on the same ROW. There was a survey of the industry in a previous request for comments to this standard. The response to that survey is the basis for the use of the 1-year period. While there was a range of growth rates across the continent, the SDT had sufficient feedback to recommend the 1-year cycle. The inspection also would cover inspecting for fall-in threats. Please note that vegetation inspections can also be combined with other line inspections.				
Alden Briggs	New Brunswick System Operator	2	Affirmative	The term “encroachment” has to be defined, and the use of that term and the clearances required clarification. The Table listing the clearances also needed clarification.
Response: The SDT thanks you for your comment. The SDT endorses the standard dictionary definition of the term “encroachment” and as such it does not require a NERC-specific definition. The use of encroachment regarding the clearance table is explained in detail in the Technical Reference Document.”				
Richard J. Mandes	Alabama Power Company	3	Affirmative	There needs to be a change in the footnote 2 and footnote 4 to remove the exemption for “arboricultural activities or horticultural or agricultural activities” and replace it with the term “ installation of”.
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
Steven Norris	APS	3	Negative	The objective, as written, is about outages that can lead to cascading and not about reliability. Recommended change to Standard Objective: To maintain a reliable electric transmission system, implement a defense-in-depth strategy to manage vegetation located on transmission rights of way (ROW) and minimize encroachments from vegetation located adjacent to the ROW.

Voter	Entity	Segment	Vote	Comment
Response: The SDT thanks you for your comment. With respect to the Purpose as written in the proposed standard, the language clearly states "To improve the reliability of the electric Transmission system…". The SDT made it a point to keep the Purpose as concise as possible without getting into issues that are covered further in the body of the standard.				
Rebecca Berdahl	Bonneville Power Administration	3	Affirmative	In R1 and R2 and their associated VSLs, the SDT added the phrase "in order of increasing severity" and added the sentence, "The types of encroachments are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a TO's vegetation maintenance program." to the Rationale boxes for R1/R2. Do you agree? If answer is no, please explain. BPA prefers the stratified levels of violation severity presented in the table for R1 and R2. Foot note # 2 on page 8 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. Foot note # 4 on page 12 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. In response to comments received that requirement R3 is unclear with respect to intent, the SDT added "maintenance strategies." Do you agree this clarifies the intent? If answer is no, please offer alternative language. The TO procedures / policies and specifications shall demonstrate the TO's ability to manage the system at all rated conditions to maintain reliability. BPA believes that the intent is clear, but the fundamental approach of using the MVCD (table 2) to manage a vegetation program is still

Voter	Entity	Segment	Vote	Comment
				problematic. These values are flashover distances and are way too close. This is acknowledged in a footnote to table 2 but no identification of allowable buffers/distances between energized phase conductors at rated temperatures and vegetation is discussed (this is left up the transmission owners). Clarity is needed on this topic. Setting a finite distance limit based on recognized standards, good science and risk avoidance should be done for the industry. BPA has previously made this comment during the drafting of the standard. It was not addressed then, nor has it been addressed now.
Response: The SDT thanks you for your comments. Footnotes #2 and #4 have been changed to reflect your suggestion to clarify arboricultural or horticultural or agricultural activities. With respect to comments about the MVCD, R3 does not suggest the MVCD be used as a distance to manage vegetation. The MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD In a performance based standard, requirements are focused on "what" needs to be accomplished to achieve desired results and avoids prescriptive requirements of "how" to achieve that result. TO's are in the best position to determine the appropriate management approach suited for their system, rather than a "one size fits all" or "fill in the blank" requirement that could suppress best practices for vegetation management.				
Matt Culverhouse	City of Bartow, Florida	3	Negative	The suggested Measures are not sufficient evidence to prove compliance with that interpretation of the requirement. For instance, most encroachments do not result in outages; hence, lack of outages cannot prove that there were no encroachments, and real time observations

Voter	Entity	Segment	Vote	Comment
				are insufficient because it is a spot-check that does not cover the audit period. There are other weaknesses in the standard, such as R4 being un-measurable therefore unenforceable. However, in the guilty until proven innocent paradigm we live in, FMPA's primary concern is that industry could be put into a no-win situation of not being able to prove compliance with the standard if R1 and R2 are interpreted as "prevent encroachment", and if R1 and R2 are interpreted as "manage" then it is not a performance based standard as advertised.
Response: The SDT thanks you for your comments. In Order 693, FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation**" (emphasis added). The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct inspections in which clearances are evaluated. Also please reference footnote 3.				
Bryan Y Harper	Cleco Utility Group	3	Negative	Cleco disagrees with the SDT revising the definition for Right-of-Way (ROW). Right-of-Way is a term that has had a consistent meaning throughout history. If NERC tries to redefine the term, it will only add confusion because most entities will not reference the NERC glossary for a term which is widely used in the industry. In lieu of "Active Transmission Line ROW", please use another term such as Transmission Corridor. No assumptions would be made when reading in the Standard the the Entity is to maintain vegetation located within the Transmission Corridor. Since the term is not commonly used, the NERC glossary would be referenced. Also, Cleco disagrees that an encroachment into the MCVD

Voter	Entity	Segment	Vote	Comment
				that does not cause an outage should be considered non-compliant as stated in R1 and R2. The encroachment should only be reportable similar to misoperations as is in the PRC-004 standard.

Response: Thanks for your comments. The existing ROW definition in the glossary was created by and for the FAC-003-1 and was moved there when that standard was adopted. The definition includes a series of options that give the Transmission Owner latitude in establishing ROW width. It does not require selecting a single method for its system. The term blowout standard is not capitalized and is not a defined term. This phrase in the definition allows a Transmission Owner to use its internal engineering standards or the general engineering standards that were in effect when the line was constructed to determine the ROW width. The SDT has limited the definition of Right-of-Way to a corridor of land with a defined width to operate a transmission line. This does not include danger tree rights. The definition of the MVCD is now added to this Standard. While use of the pre-2007 records is a compliance issue and is not in the purview of the SDT, it is the intent of the language in the definition that you could use this information.

Regarding your second comment, the MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions.

R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD.

Other related requirements of this "Defense in Depth" Standard serve to address any number of scenarios which may arise or hinder the TO's ability to always strictly adhere to the management approach(s) established within R3. Thus the other requirements of this Standard provide the latitude for appropriate actions to remedy the condition without penalty. Further, trees which have encroached inside the MVCD are evidence of a deficiency in vegetation maintenance.

Voter	Entity	Segment	Vote	Comment
Peter T Yost	Consolidated Edison Co. of New York	3	Affirmative	Reply to Question 5 on Comment Form: The added language for the annual work plan percentage complete calculation is shown in R7 not M7 as stated in the question. In the Guideline and Technical Basis Section for Requirement R6, there is a sample calculation shown for the amount of lines the TO failed to inspect. An example should

Voter	Entity	Segment	Vote	Comment
				also be included for Requirement R7 since there is some confusion regarding how modifications to the work plan affect the calculation. In the Lower VSL column for R7, it states that the TO failed to complete up to 5% of its annual vegetation work plan (including modifications if any). If a TO operates 100 lines and submits a justified modification that affects 10 miles of lines, the total number of units in the final amended plan is 90 miles. When you read the VSL, it is somewhat confusing since the information in parenthesis says that the calculation 'includes' the modifications. Should it state 'excludes modifications if any' or the VSLs can simply be re-written to state that ..The TO failed to complete up to x% of the final amended plan.' Also, the VSLs in R6 and R7 should be consistent with each other: R6 says '...TO failed to inspect 5% or less.....' and R7 says '...TO failed to complete up to 5%....' They both should use the same verbiage in each VSL whether it is 'x% or less' or 'up to and including x%.'
Response: The SDT thanks you for your comments. Your correction is accurate. The percentage should be based on the plan as modified. The SDT has changed the language in the standard to reflect this more clearly. The VSLs have been modified to be consistent as suggested.				
David A. Lapinski	Consumers Energy	3	Negative	Comments on FAC-003-2 February 25, 2011 Consumers Energy submits the following comments on FAC-003-2: In general we are please with FAC-003-2 and the many clarifications that the STD has made in this version of the standard. However, we do have one major disagreement with the STD and cannot support this standard as drafted.

Voter	Entity	Segment	Vote	Comment
				We disagree with the use of the Minimum Vegetation Clearance Distance (MVCD) developed by the drafting team for Requirements R1 and R2. These distances are not the design distances used for designing and constructing transmission facilities as stated in the document for minimum distances between conductors and grounded objects. The proposed Table 2 provides a distance of 3.12 feet as the acceptable distance for an alternate current 345kV line at sea level. This distance is considerably less than the distance used for line design to separate the grounded tower structure from the energized conductor. If the distance in Table 2 is acceptable to prevent energized portions of a transmission line from grounding to a tree why then is this distance not the design criteria used for tower design to prevent flashover from conductor to tower? The STD needs to explain why a ground tree should have a different standard that a grounded steel tower or wood pole structure. The STD erroneously viewed the possibility of transient over voltage as only occurring during re-energizing and not from natural events such as a lightning strike that can occur and does occur to energized operating lines. Secondly, the proposed distances in Table 2 are considerably less than the distances specified in OSHA requirements for air gap clearance required by tree workers to safely remove trees or limbs from conductors energized at the voltages specified. A transmission owner/operator could let a tree grow to within 3.5 feet of a 345 kV line and not be in violation of this proposed standard. To remove the tree, the

Voter	Entity	Segment	Vote	Comment
				line would have to be de-energized, tagged, tested de-energized, and grounded. Working clearance would have to be established by the operating entity and then the tree crew could remove the tree. The net result is the loss of the capacity of the line because an outage was forced on the line in order to remove the tree that did not trigger a violation of FAC-003-2. This situation, in our opinion, is a violation of the intent of the standard, which is to ensure the continued operation of the line. Therefore, the minimum distance any tree should be able to approach a conductor is more than the minimum requirement for air gap distance between the tree and conductor as required by OSHA worker standards. The STD did not like referring to another standard to provide the distance requirements for R1 and R2. This can be alleviated by putting in a table with the IEEE 516 distances but not reference it as the IEEE 516 standard. The distances provided in the current draft do not adequately provide or ensure the continued safe operation of the transmission facilities in the United States and the reasoning for the distances provided is unfounded and not based on current design practices.

Response: The SDT thanks you for your comments. You are correct that these distances do not represent complete design specifications for towers, nor define and describe safe worker approach distances. These practices are correctly specified in the other standards you referenced. The SDT feels the standard is clear in that regard. The footnote associated with the Table 2 distances clearly states that these are only distances to prevent flashover under appropriate conditions. The SDT would also like to point out that the transient overvoltage factors used to derive these distances are the maximums normally seen with a transmission line in steady state service. Thus, a tower design would have to account for the larger overvoltage factors that are possible while taking lines out of service.

As has been stated before, these distances were derived using a known set of line design equations and only represent distances that will prevent spark-over from the transmission line to a grounded object. These are not distances to be managed to – they have been established as a beginning of a series of "building blocks" for a program to ensure reliability of a

Voter	Entity	Segment	Vote	Comment
Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner' consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD. These distances are smaller than safety standard distances that have many other factors involved in the determination, such as inadvertent human movement and larger safety factors. In regard to the over-voltages caused by lightning, even the maximum overvoltage factors contained in the IEEE-516 tables do not account for these.				
Russell A Noble	Cowlitz County PUD	3	Negative	Referring back to Cowlitz' negative vote made on the 7/9-19/2010 ballot, Cowlitz tried to convey the problem that the statement in R4 "without intentional time delay" will require subjective judgment on the part of the auditor. In other words, maintaining equal auditing standard throughout the interconnection will be impossible with this verbiage in a requirement. Cowlitz agrees with the SDT that establishing an equitable time frame is very difficult (it may be impossible!); however leaving it to the judgment of the auditor to determine whether an intentional delay was made is most disagreeable. Cowlitz respectfully points out that the SDT did not adequately address the subjective nature the auditor is forced into with this requirement. If establishing "[t]he time required by the to report an issue is subject to many variables..." and "[f]or this reason it is difficult to establish a time period which would fairly apply to all TO's," how does leaving this to the auditor to decide going to make it any better?
Response: The SDT believes that it was not prudent to suggest a quantitative time element for notification in R4. The technical reference offers examples of acceptable unintentional delays for your review. The SDT notes that this language is already embodied in at least one other FERC-approved, in-force Standard.				

Voter	Entity	Segment	Vote	Comment
Kevin Querry	FirstEnergy Solutions	3	Affirmative	FirstEnergy supports standard FAC-003-2 and would appreciate consideration of our comments submitted through the formal comment period.
Response: The SDT thanks you for your comments. Please see our consideration of your comments within the responses to the formal comments.				
Lee Schuster	Florida Power Corporation	3	Affirmative	There needs to be a change in the footnote 2 and footnote 4 to remove the exemption for “arboricultural activities or horticultural or agricultural activities” and replace it with the term “installation of."
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
Anthony L Wilson	Georgia Power Company	3	Affirmative	There needs to be a change in the footnote 2 and footnote 4 to remove the exemption for “arboricultural activities or horticultural or agricultural activities” and replace it with the term “ installation of”.
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
Charles Locke	Kansas City Power & Light Co.	3	Negative	The Standard lacks clarity regarding the facilities that are subject to Requirement 7. It is important that a Standard be clear and not introduce ambiguity or confusion. There are several references throughout the Standard to "for all applicable lines" and it should be made clear the work plan is specific to "all applicable lines".
Response: The SDT thanks you for your comments. The team has made the appropriate modifications where necessary.				
Mace Hunter	Lakeland Electric	3	Affirmative	R1. Each Transmission Owner shall manage vegetation to prevent encroachments of the types shown below, ------------

Voter	Entity	Segment	Vote	Comment
				---- and all Rated Electrical Operating Conditions.2 1. An encroachment into the MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage, that is not corrected within 5 working days of discovery, Make the same change to R2 Type 1 encroachment and reflect the changes in Table 1. Rational: This condition would enable a entity to discover an encroachment and clear it without having to self report a possible violation as long as the conditions was corrected within 5 working days. The change should encourage extra inspections for problem areas more often than annually as required in R6. There should be no negative consequences for diligent inspection of lines as long as the problem is clear with a defined time such as 5 or 10 working days.
Response: The SDT thanks you for your comment. As a general rule, a revised standard should not be less stringent than the existing standard it replaces. In the existing standard, a violation occurs when the encroachment occurs. A 'find and fix' of five days would be viewed as a lowering of the level of required performance established by the current standard.				
Bruce Merrill	Lincoln Electric System	3	Affirmative	While supportive of the drafting team's efforts, LES believes a change is warranted in Footnote 2 and Footnote 4 to remove the exemption for "arboricultural activities or horticultural or agricultural activities" and replace with the term "installation of". As currently drafted, the wording could potentially be construed to mean that the TO would or could be constrained or refused permission to prune and remove any and all vegetation in the ROW in accordance with the full legal rights of the ROW agreement(s).
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
Don Horsley	Mississippi Power	3	Affirmative	There needs to be a change in the footnote 2 and footnote 4 to remove the exemption for "arboricultural activities or

Voter	Entity	Segment	Vote	Comment
				horticultural or agricultural activities" and replace it with the term " installation of".
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
Terry L Baker	Platte River Power Authority	3	Negative	FAC-003-2 Comments Vegetation Inspection: Is the intent of "... and those vegetation conditions under the TO's control" to clarify that an entity must have ownership of the transmission line and right-of-way in addition to maintenance or operational responsibility (control), or something different? In situations where a TO owns one circuit on a double circuit, but the other circuit, facilities and ROW belong to another TO who has maintenance, and vegetation management responsibility, who would be responsible for violations? If the definition was modified to allow both maintenance and vegetation inspections to be performed concurrently, the intent might be clearer if it read: "This may be combined with other line inspections", or "This may be combined with a maintenance inspection" opposed to a general line inspection. R1 and R2: Does R1 correlate to facilities in 4.2.2. and 4.2.3. (overhead transmission lines operated below 200 kV) and R2 correlate to facilities in 4.2.1. (overhead transmission lines operated at 200kV or higher)? It isn't clear why the two requirements are split. Could it be one requirement which reads "...identified as a facility in Section 4.2"? R4: Our current imminent threat procedure requires a call

Voter	Entity	Segment	Vote	Comment
				to the Manager who confirms the existence of a vegetation condition that is likely to cause a Fault at any moment prior to notifying the control center. We assume notification, without any intentional time delay, would take place after managerial confirmation but feel like the enforcement authorities could interpret this differently based on how it is written in R4. If the intent of the requirement is how we interpret it, the requirement might be clearer if it read: After a Transmission Owner has confirmed a vegetation condition likely to cause a Fault at any moment, they shall notify the control center holding switching authority for the associated applicable transmission line, without any intentional delay.
Response: The SDT thanks you for your comment. With regard to responsibility for a violation, the TO is the accountable party even if it has an agreement with another TO to inspect and manage vegetation. With regard to your suggestion in changing the definition of Vegetation Inspection, the SDT does not believe the proposed changes are necessary for the definition to be clear. With regard to R1 and R2, they applicability applies to 4.2.1 thru 4.2.3. The distinction between the requirement is R1 applies to all lines designated as having an Interconnection Reliability Operating Limit (IROL) in the planning horizon by the Planning Coordinator; or lines designated as Major Western Electricity Coordinating Council (WECC) transfer path(s). With regard to your imminent threat procedure, the standard is not prescriptive to define a TO's imminent threat procedure. So, if your procedure includes managerial confirmation, then this would not be considered intentional delay.				
Dana Wheelock	Seattle City Light	3	Affirmative	The revisions to the proposed FAC-003-2 Standards produced a better version through greater clarity, appropriate pragmatism, and technical foundation; A few good points that highlight this follow: 1. Definition of Terms Used in Standard: The revised definition of Right-of-Way (ROW) establishes the width of the corridor from a technical basis with the following

Voter	Entity	Segment	Vote	Comment
				statement "The width of the corridor is established by engineering or construction standards..." 2. Introduction, Applicability, Section 4.2 Facilities: Section 4.2.4 which pertains to substations clarifies that this standard does not apply to applicable transmission lines, inside the substation, just to "any portion of the span of the transmission line that is crossing the substation fence". 3. Requirements and Measures: Requirement 1 underscores sensible purpose by replacing the wording of "preventing outages from vegetation" to "manage vegetation to prevent encroachments..." 4. Guideline and Technical Basis Section: Requirement 7 contains a great practicle reference explanation as it pertains to the annual work plan. Requirement 7 explains: ..." the vegetation management approach should use the full extent of the Transmission Owner's easement, fee simple and other legal rights allowed. A comprehensive approach that exercises the full extent of legal rights on the ROW is superior to incremental management in the long term because it reduces the overall potential for encroachment, and it ensures that future planned work and future planned inspection cycles are sufficient".
Response: The SDT thanks you for your comments.				
Michael Ibold	Xcel Energy, Inc.	3	Affirmative	Xcel Energy still believes the requirement in R6 that mandates an annual inspection is an ineffective approach and may actually go against the Commission’s

Voter	Entity	Segment	Vote	Comment
				determination in FERC Order No. 693. The drafting team's response to our last round of comments on this issue was that "...the SDT was directed by Order 693 to set a minimum inspection criteria". It is clear in Order 693 that the Commission is not satisfied with allowing entities to choose their own inspection cycles, as the standard currently allows. However, we fail to see where the Commission mandated a minimum inspection cycle to be uniformly applied continent-wide. We urge the drafting team to revisit paragraphs 719 through 721 of Order 693. According to paragraph 721, the Commission recognizes that unique intervals by region, "based on local factors", are reasonable and appropriate. By use of the plural term "cycles", FERC anticipates the resolution may include multiple inspection cycles. Furthermore, in paragraph 719, FERC acknowledges that a minimum inspection cycle may not be the only way to address their concern. In fact, mandating an annual inspection cycle may actually go against the Commission's guidance in paragraph 720. Here is an excerpt: "...the Commission is dissuaded from requiring the ERO to create a backstop inspection cycle at this time. Instead, the Commission agrees that an entity's vegetation management program should be tailored to anticipated growth in the region and take into account other environmental factors. The goal is to assure that transmission owners conduct inspections at reasonable intervals." As an alternative, we propose a mid-cycle inspection. A mid-cycle inspection is based on an interval that is justified with data and technical expertise. A mid-cycle inspection would still require entities to conduct inspections at a specified interval, while allowing for differences based upon "physical

Voter	Entity	Segment	Vote	Comment
				and geographic factors". Not only would this approach fully address the Commissions concerns, but it would take into account the interests of stakeholders, landowners and rate-payers. We recognize that a mid-cycle inspection interval is not as easy to audit as an annual requirement, but it is a far more practical and cost-effective approach that, when applied based on an entity's expertise with its own facilities, ensures reliability.
Response: The SDT thanks you for your comments. The SDT recognizes that a number of Transmission Owners in North America may prefer to set their own inspection intervals. The SDT can also see attractiveness for a mid-cycle inspection concept; however, this introduces new complexities in planning, documentation and auditing. Because there is substantial industry support for an annual inspection interval the SDT believes that the industry is best served with this approach.				
Rick Syring	Cowlitz County PUD	4	Negative	Referring back to Cowlitz' negative vote made on the 7/9-19/2010 ballot, Cowlitz tried to convey the problem that the statement in R4 "without intentional time delay" will require subjective judgment on the part of the auditor. In other words, maintaining equal auditing standard throughout the interconnection will be impossible with this verbiage in a requirement. Cowlitz agrees with the SDT that establishing an equitable time frame is very difficult (it may be impossible!); however leaving it to the judgment of the auditor to determine whether an intentional delay was made is most disagreeable. Cowlitz respectfully points out that the SDT did not adequately address the subjective nature the auditor is forced into with this requirement. If "[t]he time required by the entity to report an issue is subject to many variables..." and "[f]or this reason it is difficult to establish a time period which would fairly apply to all TO's," how does leaving this to the auditor to decide going to make it any better? You will be forcing the audited entity to "prove the negative."

Voter	Entity	Segment	Vote	Comment
Response: The SDT believes that it was not prudent to suggest a quantitative time element for notification in R4. The technical reference offers examples of acceptable unintentional delays for your review. The SDT notes that this language is already embodied in at least one other FERC-approved, in-force Standard.				
Frank Gaffney	Florida Municipal Power Agency	4	Negative	R1 and R2 requirement reads: "Each Transmission Owner shall manage to prevent encroachment ....". The results of manage would be invoices of tree trimming actually performed, documentation of a vegetation management program that would be managed to, etc. However, the Measures proposed are all actual outages which are neither evidence of management nor evidence of encroachment since there can be encroachment without an outage, and in fact, many if not most encroachments do not result in outages. Hence, the Measures are inconsistent with the requirements. Further, there is ambiguity of the action required in requirements R1 and R2 - e.g., do entities need evidence that they: 1) "manage", or 2) "prevent encroachment"; or 3) as implied by the Measures, prevent vegetation related outages?. In other words, what needs to be proven through evidence? Certainly the third, prevent vegetation related outages, is not in the Requirement; yet, that us what is proposed for the Measures, highlighting the inconsistency between Requirements and Measures. But, how would the ambiguity between "manage" and "prevent encroachment" be resolved? One auditor could interpret that the requirement is to "manage" and accept a vegetation management program and plan and proof that the plan was executed as appropriate evidence. Another auditor could interpret that "prevent" is the key word and look for evidence proving that there was never a vegetation

Voter	Entity	Segment	Vote	Comment
				encroachment. How would evidence be produced to provide the auditor that vegetation never encroached? Would video cameras and other surveillance measures need to operate 24 hours a day? Would we cause an entity to survey the lines periodically? One can easily see that "prevent encroachment" is inappropriate here since it is infeasible to create evidence of compliance. FMPA suggests one of two approaches: Eliminate the word manage, but do not focus on encroachment and instead focus on outages. For instance: "Each Transmission Owner shall prevent vegetation related outages (except as noted in Footnote 2) of any of its applicable line(s) ..." Evidence of outages is practical to gather and provide, evidence of encroachment is not. Focus on the word "manage", similar to the existing FAC-003 standard, and move R3 to a new R1 to develop a management plan, and then the existing R1 and R2 become R2 an R3 and require execution of that plan in the words of R7, which would in turn enables elimination of R7.
Response: The SDT thanks you for your comments. In Order 693, FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation**" (emphasis added). The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct inspections in which clearances are evaluated.				
Thomas W. Richards	Fort Pierce Utilities	4	Negative	R1 and R2 requirement reads: "Each Transmission Owner shall manage to prevent encroachment ....". The results of

				with the full legal rights of the ROW agreement(s).”
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
Douglas Hohlbaugh	Ohio Edison Company	4	Affirmative	FirstEnergy supports standard FAC-003-2 and would appreciate consideration of our comments submitted through the formal comment period.
Response: The SDT thanks you for your comments. Please see our consideration of your comments within the responses to the formal comments.				
Hao Li	Seattle City Light	4	Affirmative	The revisions to the proposed FAC-003-2 Standards produced a better version through greater clarity, appropriate pragmatism, and technical foundation; A few good points that highlight this follow: 1. Definition of Terms Used in Standard: The revised definition of Right-of-Way (ROW) establishes the width of the corridor from a technical basis with the following statement "The width of the corridor is established by engineering or construction standards..." 2. Introduction, Applicability, Section 4.2 Facilities: Section 4.2.4 which pertains to substations clarifies that this standard does not apply to applicable transmission lines, inside the substation, just to "any portion of the span of the transmission line that is crossing the substation fence". 3. Requirements and Measures: Requirement 1 underscores sensible purpose by replacing the wording of "preventing outages from vegetation" to "manage vegetation to prevent encroachments..."

Voter	Entity	Segment	Vote	Comment
				4. Guideline and Technical Basis Section: Requirement 7 contains a great practicle reference explanation as it pertains to the annual work plan. Requirement 7 explains: ..." the vegetation management approach should use the full extent of the Transmission Owner's easement, fee simple and other legal rights allowed. A comprehensive approach that exercises the full extent of legal rights on the ROW is superior to incremental management in the long term because it reduces the overall potential for encroachment, and it ensures that future planned work and future planned inspection cycles are sufficient".
Response: The SDT thanks you for your comments.				
Brock Ondayko	AEP Service Corp.	5	Affirmative	American Electric Power believes that the phrase "arboricultural activities or horticultural or agricultural activities" was mistakenly introduced into Footnotes 2 and 4, and should be deleted from both footnotes. If the phrase remains in the Standard, it may empower orchard growers, landowners and others to plant trees on the right of way and challenge Transmission Owners' rights to perform maintenance on the presumption that the standard will exempt the TO from violating the outage or encroachment requirements. For increased clarity, AEP offers the following change to the second paragraph of M1, as well as the second paragraph of M2. The original text “If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the

Voter	Entity	Segment	Vote	Comment
				equivalent of a Real-time observation" should be replaced with "If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation growing into or blowing together with the conductor within the ROW, this shall be considered the equivalent of a Real-time observation. A brief encroachment caused by falling vegetation passing through the MVCD is not considered an encroachment in this requirement".
Response: Thanks you for your comments. The SDT made suggested changes. Regarding the issue of fall-ins, the SDT is sympathetic to your concern. In fact, the SDT had originally crafted language similar to that which you suggested. However, due to concerns expressed by regulators and others, the exemption for encroachment violations due to falling vegetation from inside the right of way was removed.				
Francis J. Halpin	Bonneville Power Administration	5	Affirmative	In R1 and R2 and their associated VSLs, the SDT added the phrase "in order of increasing severity" and added the sentence, "The types of encroachments are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a TO's vegetation maintenance program." to the Rationale boxes for R1/R2. Do you agree? If answer is no, please explain. BPA prefers the stratified levels of violation severity presented in the table for R1 and R2. Foot note # 2 on page 8 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. Foot note # 4 on page 12 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities.

Voter	Entity	Segment	Vote	Comment
				In response to comments received that requirement R3 is unclear with respect to intent, the SDT added “maintenance strategies.” Do you agree this clarifies the intent? If answer is no, please offer alternative language. The TO procedures / policies and specifications shall demonstrate the TO’s ability to manage the system at all rated conditions to maintain reliability. BPA believes that the intent is clear, but the fundamental approach of using the MVCD (table 2) to manage a vegetation program is still problematic. These values are flashover distances and are way too close. This is acknowledged in a footnote to table 2 but no identification of allowable buffers/distances between energized phase conductors at rated temperatures and vegetation is discussed (this is left up the transmission owners). Clarity is needed on this topic. Setting a finite distance limit based on recognized standards, good science and risk avoidance should be done for the industry. BPA has previously made this comment during the drafting of the standard. It was not addressed then, nor has it been addressed now.

Response: The SDT thanks you for your comments. The footnotes were changed to conform with your suggestions.

With respect to comments about the MVCD, R3 does not suggest the MVCD be used as a distance to manage vegetation. The MVCD was established as a beginning of a series of “building blocks” for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions.

R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner’s overall vegetation management approach. The net result of this “building block” approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD distances.

Voter	Entity	Segment	Vote	Comment
In a performance based standard, requirements are focused on “what” needs to be accomplished to achieve desired results and avoids prescriptive requirements of “how” to achieve that result. TO’s are in the best position to determine the appropriate management approach suited for their system rather than a “one size fits all” or “fill in the blanks” requirements that could suppress best practices for vegetation management.				
Wilket (Jack) Ng	Consolidated Edison Co. of New York	5	Affirmative	Reply to Question 5 on Comment Form: The added language for the annual work plan percentage complete calculation is shown in R7 not M7 as stated in the question. In the Guideline and Technical Basis Section for Requirement R6, there is a sample calculation shown for the amount of lines the TO failed to inspect. An example should also be included for Requirement R7 since there is some confusion regarding how modifications to the work plan affect the calculation. In the Lower VSL column for R7, it states that the TO failed to complete up to 5% of its annual vegetation work plan (including modifications if any). If a TO operates 100 lines and submits a justified modification that affects 10 miles of lines, the total number of units in the final amended plan is 90 miles. When you read the VSL, it is somewhat confusing since the information in parenthesis says that the calculation 'includes' the modifications. Should it state 'excludes modifications if any' or the VSLs can simply be re-written to state that ..The TO failed to complete up to x% of the final amended plan.' Also, the VSLs in R6 and R7 should be consistent with each other: R6 says '...TO failed to inspect 5% or less.....' and R7 says '...TO failed to complete up to 5%....' They both should use the same verbiage in each VSL whether it is 'x% or less' or 'up to and including x%.'

Voter	Entity	Segment	Vote	Comment
Response: The SDT thanks you for your comments. The percentage should be based on the plan as modified. The SDT has changed the language in the standard to reflect this more clearly, and has modified the VSLs to be consistent as you have suggested.				
James B Lewis	Consumers Energy	5	Negative	Consumers Energy submits the following comments on FAC-003-2: In general we are please with FAC-003-2 and the many clarifications that the STD has made in this version of the standard. However, we do have one major disagreement with the STD and cannot support this standard as drafted. We disagree with the use of the Minimum Vegetation Clearance Distance (MVCD) developed by the drafting team for Requirements R1 and R2. These distances are not the design distances used for designing and constructing transmission facilities as stated in the document for minimum distances between conductors and grounded objects. The proposed Table 2 provides a distance of 3.12 feet as the acceptable distance for an alternate current 345kV line at sea level. This distance is considerably less than the distance used for line design to separate the grounded tower structure from the energized conductor. If the distance in Table 2 is acceptable to prevent energized portions of a transmission line from grounding to a tree why then is this distance not the design criteria used for tower design to prevent flashover from conductor to tower? The STD needs to explain why a ground tree should have a different standard that a grounded steel tower or wood pole structure. The STD erroneously viewed the possibility of transient over

Voter	Entity	Segment	Vote	Comment
				voltage as only occurring during re-energizing and not from natural events such as a lightning strike that can occur and does occur to energized operating lines. Secondly, the proposed distances in Table 2 are considerably less than the distances specified in OSHA requirements for air gap clearance required by tree workers to safely remove trees or limbs from conductors energized at the voltages specified. A transmission owner/operator could let a tree grow to within 3.5 feet of a 345 kV line and not be in violation of this proposed standard. To remove the tree, the line would have to be de-energized, tagged, tested de-energized, and grounded. Working clearance would have to be established by the operating entity and then the tree crew could remove the tree. The net result is the loss of the capacity of the line because an outage was forced on the line in order to remove the tree that did not trigger a violation of FAC-003-2. This situation, in our opinion, is a violation of the intent of the standard, which is to ensure the continued operation of the line. Therefore, the minimum distance any tree should be able to approach a conductor is more than the minimum requirement for air gap distance between the tree and conductor as required by OSHA worker standards. The STD did not like referring to another standard to provide the distance requirements for R1 and R2. This can be alleviated by putting in a table with the IEEE 516 distances but not reference it as the IEEE 516 standard. The distances provided in the current draft do not adequately provide or ensure the continued safe operation of the transmission facilities in the United States and the reasoning for the distances provided is unfounded and not based on current design practices.

Voter	Entity	Segment	Vote	Comment
Response: The SDT thanks you for your comments. You are correct that these distances do not represent complete design specifications for towers, nor define and describe safe worker approach distances. These practices are correctly specified in the other standards you referenced. The SDT feels the standard is clear in that regard. The footnote associated with the Table 2 distances clearly states that these are only distances to prevent flashover under appropriate conditions. The SDT would also like to point out that the transient overvoltage factors used to derive these distances are the maximums normally seen with a transmission line in steady state service. Thus, a tower design would have to account for the larger overvoltage factors that are possible while taking lines out of service. As has been stated before, these distances were derived using a known set of line design equations and only represent distances that will prevent spark-over from the transmission line to a grounded object. These are not distances to be managed to – they have been established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD. These distances are smaller than safety standard distances that have many other factors involved in the determination, such as inadvertent human movement and larger safety factors. In regard to the over-voltages caused by lightning, even the maximum overvoltage factors contained in the IEEE-516 tables do not account for these.				
Bob Essex	Cowlitz County PUD	5	Negative	Referring back to Cowlitz' negative vote made on the 7/9-19/2010 ballot, Cowlitz tried to convey the problem that the statement in R4 "without intentional time delay" will require subjective judgment on the part of the auditor. In other words, maintaining equal auditing standard throughout the interconnection will be impossible with this verbiage in a requirement. Cowlitz agrees with the SDT that establishing an equitable time frame is very difficult (it may be impossible!); however leaving it to the judgment of the auditor to determine whether an intentional delay was made is most disagreeable. Cowlitz respectfully points out that the SDT did not adequately address the subjective nature the auditor is forced into with this requirement. If

Voter	Entity	Segment	Vote	Comment
				establishing "[t]he time required by the to report an issue is subject to many variables..." and "[f]or this reason it is difficult to establish a time period which would fairly apply to all TO's," how does leaving this to the auditor to decide going to make it any better?
Response: The SDT believes that it was not prudent to suggest a quantitative time element for notification in R4. The technical reference offers examples of acceptable unintentional delays for your review. The SDT notes that this language is already embodied in at least one other FERC-approved, in-force Standard.				
Kenneth Dresner	FirstEnergy Solutions	5	Affirmative	FirstEnergy supports standard FAC-003-2 and would appreciate consideration of our comments submitted through the formal comment period.
Response: The SDT thanks you for your comments. Please see our consideration of your comments within the responses to the formal comments.				
David Schumann	Florida Municipal Power Agency	5	Negative	R1 and R2 requirement reads: "Each Transmission Owner shall manage to prevent encroachment ....". The results of manage would be invoices of tree trimming actually performed, documentation of a vegetation management program that would be managed to, etc. However, the Measures proposed are all actual outages which are neither evidence of management nor evidence of encroachment since there can be encroachment without an outage, and in fact, many if not most encroachments do not result in outages. Hence, the Measures are inconsistent with the requirements. Further, there is ambiguity of the action required in requirements R1 and R2 - e.g., do entities need evidence that they: 1) "manage", or 2) "prevent encroachment"; or 3) as implied by the Measures, prevent vegetation related outages?. In other words, what needs to be proven through evidence? Certainly the third, prevent vegetation related

Voter	Entity	Segment	Vote	Comment
				outages, is not in the Requirement; yet, that us what is proposed for the Measures, highlighting the inconsistency between Requirements and Measures. But, how would the ambiguity between "manage" and "prevent encroachment" be resolved? One auditor could interpret that the requirement is to "manage" and accept a vegetation management program and plan and proof that the plan was executed as appropriate evidence. Another auditor could interpret that "prevent" is the key word and look for evidence proving that there was never a vegetation encroachment. How would evidence be produced to provide the auditor that vegetation never encroached? Would video cameras and other surveillance measures need to operate 24 hours a day? Would we cause an entity to survey the lines periodically? One can easily see that "prevent encroachment" is inappropriate here since it is infeasible to create evidence of compliance. FMPA suggests one of two approaches: Eliminate the word manage, but do not focus on encroachment and instead focus on outages. For instance: "Each Transmission Owner shall prevent vegetation related outages (except as noted in Footnote 2) of any of its applicable line(s) ..." Evidence of outages is practical to gather and provide, evidence of encroachment is not. Focus on the word "manage", similar to the existing FAC-003 standard, and move R3 to a new R1 to develop a management plan, and then the existing R1 and R2 become R2 an R3 and require execution of that plan in the words of R7, which would in turn enables elimination of R7.

Response: The SDT thanks you for your comments. In Order 693, FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation**" (emphasis added). The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines

Voter	Entity	Segment	Vote	Comment
how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct inspections in which clearances are evaluated.				
Richard J. Padilla	Pacific Gas and Electric Company	5	Affirmative	There needs to be a change in the footnotes 2 and 4 to remove the exemption for “arboricultural activities or horticultural or agricultural activities” and replace it with the term “ installation of"
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
Wayne Lewis	Progress Energy Carolinas	5	Affirmative	There needs to be a change in the footnote 2 and footnote 4 to remove the exemption for “arboricultural activities or horticultural or agricultural activities” and replace it with the term “installation of.
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
Liam Noailles	Xcel Energy, Inc.	5	Affirmative	Xcel Energy still believes the requirement in R6 that mandates an annual inspection is an ineffective approach and may actually go against the Commission’s determination in FERC Order No. 693. The drafting team’s response to our last round of comments on this issue was that “...the SDT was directed by Order 693 to set a minimum inspection criteria”. It is clear in Order 693 that the Commission is not satisfied with allowing entities to choose their own inspection cycles, as the standard currently allows. However, we fail to see where the Commission mandated a minimum inspection cycle to be uniformly applied continent-wide. We urge the drafting team to revisit paragraphs 719 through 721 of Order 693. According to paragraph 721, the Commission recognizes that unique intervals by region, “based on local factors”, are reasonable and appropriate. By use of the plural term “cycles”, FERC anticipates the resolution may include multiple inspection

Voter	Entity	Segment	Vote	Comment
				cycles. Furthermore, in paragraph 719, FERC acknowledges that a minimum inspection cycle may not be the only way to address their concern. In fact, mandating an annual inspection cycle may actually go against the Commission's guidance in paragraph 720. Here is an excerpt: "...the Commission is dissuaded from requiring the ERO to create a backstop inspection cycle at this time. Instead, the Commission agrees that an entity's vegetation management program should be tailored to anticipated growth in the region and take into account other environmental factors. The goal is to assure that transmission owners conduct inspections at reasonable intervals." As an alternative, we propose a mid-cycle inspection. A mid-cycle inspection is based on an interval that is justified with data and technical expertise. A mid-cycle inspection would still require entities to conduct inspections at a specified interval, while allowing for differences based upon "physical and geographic factors". Not only would this approach fully address the Commissions concerns, but it would take into account the interests of stakeholders, landowners and rate-payers. We recognize that a mid-cycle inspection interval is not as easy to audit as an annual requirement, but it is a far more practical and cost-effective approach that, when applied based on an entity's expertise with its own facilities, ensures reliability.
Response: The SDT thanks you for your comments. The SDT recognizes that a number of Transmission Owners in North America may prefer to set their own inspection intervals. The SDT can also see attractiveness for a mid-cycle inspection concept; however, this introduces new complexities in planning, documentation and auditing. Because there is substantial industry support for an annual inspection interval , the SDT believes that the industry is best served with this approach.

Brenda S. Anderson	Bonneville Power Administration	6	Affirmative	BPA Comments with Yes Vote: In R1 and R2 and their associated VSLs, the SDT added the phrase “in order of increasing severity” and added the sentence, “The types of encroachments are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a TO’s vegetation maintenance program.” to the Rationale boxes for R1/R2. Do you agree? If answer is no, please explain. BPA prefers the stratified levels of violation severity presented in the table for R1 and R2. Foot note # 2 on page 8 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. Foot note # 4 on page 12 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. In response to comments received that requirement R3 is unclear with respect to intent, the SDT added “maintenance strategies.” Do you agree this clarifies the intent? If answer is no, please offer alternative language. The TO procedures / policies and specifications shall demonstrate the TO’s ability to manage the system at all rated conditions to maintain reliability. BPA believes that the intent is clear, but the fundamental approach of using the MVCD (table 2) to manage a vegetation program is still problematic. These values are

Voter	Entity	Segment	Vote	Comment
				flashover distances and are way too close. This is acknowledged in a footnote to table 2 but no identification of allowable buffers/distances between energized phase conductors at rated temperatures and vegetation is discussed (this is left up the transmission owners). Clarity is needed on this topic. Setting a finite distance limit based on recognized standards, good science and risk avoidance should be done for the industry. BPA has previously made this comment during the drafting of the standard. It was not addressed then, nor has it been addressed now.
Response: The SDT thanks you for your comments. The footnotes were changed to conform with your suggestions. With respect to comments about the MVCD, R3 does not suggest the MVCD be used as a distance to manage vegetation. The MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD distances. In a performance based standard, requirements are focused on "what" needs to be accomplished to achieve desired results and avoids prescriptive requirements of "how" to achieve that result. TO's are in the best position to determine the appropriate management approach suited for their system rather than a "one size fits all" or "fill in the blanks" requirements that could suppress best practices for vegetation management.				
Matthew D Cripps	Cleco Power LLC	6	Negative	Cleco disagrees with the SDT revising the definition for Right-of-Way (ROW). Right-of-Way is a term that has had a consistent meaning throughout history. If NERC tries to redefine the term, it will only add confusion because most entities will not reference the NERC glossary for a term which is widely used in the industry. In lieu of "Active Transmission Line ROW", please use another term such as Transmission Corridor. No assumptions would be made when reading in the Standard the the Entity is to maintain

Voter	Entity	Segment	Vote	Comment
				vegetation located within the Transmission Corridor. Since the term is not commonly used, the NERC glossary would be referenced. Also, Cleco disagrees that an encroachment into the MCVD that does not cause an outage should be considered non-compliant as stated in R1 and R2. The encroachment should only be reportable similar to misoperations as is in the PRC-004 standard.
Response: Thanks for your comments. The existing ROW definition in the glossary was created by and for the FAC-003-1 and was moved there when that standard was adopted. The definition includes a series of options that give the Transmission Owner latitude in establishing ROW width. It does not require selecting a single method for its system. The term blowout standard is not capitalized and is not a defined term. This phrase in the definition allows a Transmission Owner to use its internal engineering standards or the general engineering standards that were in effect when the line was constructed to determine the ROW width. The SDT has limited the definition of Right-of-Way to a corridor of land with a defined width to operate a transmission line. This does not include danger tree rights. The definition of the MVCD is now added to this Standard. While use of the pre-2007 records is a compliance issue and is not in the purview of the SDT, it is the intent of the language in the definition that you could use this information. Regarding your second comment (begins with Also,): the MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD. Other related requirements of this "Defense in Depth" Standard serve to address any number of scenarios which may arise or hinder the TO's ability to always strictly adhere to the management approach(s) established within R3. Thus the other requirements of this Standard provide the latitude for appropriate actions to remedy the condition without penalty. Further, trees which have encroached inside the MVCD are evidence of a deficiency in vegetation maintenance.				
Nickesha P Carrol	Consolidated Edison Co. of	6	Affirmative	Reply to Question 5 on Comment Form: The added language for the annual work plan percentage complete calculation is

Voter	Entity	Segment	Vote	Comment
	New York			shown in R7 not M7 as stated in the question. In the Guideline and Technical Basis Section for Requirement R6, there is a sample calculation shown for the amount of lines the TO failed to inspect. An example should also be included for Requirement R7 since there is some confusion regarding how modifications to the work plan affect the calculation. In the Lower VSL column for R7, it states that the TO failed to complete up to 5% of its annual vegetation work plan (including modifications if any). If a TO operates 100 lines and submits a justified modification that affects 10 miles of lines, the total number of units in the final amended plan is 90 miles. When you read the VSL, it is somewhat confusing since the information in parenthesis says that the calculation 'includes' the modifications. Should it state 'excludes modifications if any' or the VSLs can simply be re-written to state that ..The TO failed to complete up to x% of the final amended plan.'
Response: The SDT thanks you for your comments. The percentage should be based on the plan as modified. The SDT has changed the language in the standard to reflect this more clearly.				
Mark S Travaglianti	FirstEnergy Solutions	6	Affirmative	FirstEnergy supports standard FAC-003-2 and would appreciate consideration of our comments submitted through the formal comment period.
Response: The SDT thanks you for your comments. Please see our consideration of your comments within the responses to the formal comments.				
Thomas E Washburn	Florida Municipal Power Pool	6	Negative	The concern is that entities may not be able prove compliance with the standard. R1 and R2 say that: "Each Transmission Owner shall manage vegetation to prevent encroachments ...". If the requirements were interpreted such that "manage" is the operative word, then, we are OK because we can provide evidence of managing a program,

Voter	Entity	Segment	Vote	Comment
				such as a vegetation management plan and evidence of executing that plan (which does not align with the Measures). However, that 1) would cause the standard to not be performance based, and 2) it would be duplicative of the other requirements of the standard. If the requirements were interpreted with "prevent encroachment" as the operative phrase (which would be an incorrect interpretation from the construct of the sentence) there is no way to provide sufficient evidence that encroachment was prevented during the audit-period. The suggested Measures are not sufficient evidence to prove compliance with that interpretation of the requirement. For instance, most encroachments do not result in outages; hence, lack of outages cannot prove that there were no encroachments, and real time observations are insufficient because it is a spot-check that does not cover the audit period. There are other weaknesses in the standard, such as R4 being un-measurable therefore unenforceable. However, in the guilty until proven innocent paradigm we live in, FMPA's primary concern is that industry could be put into a no-win situation of not being able to prove compliance with the standard if R1 and R2 are interpreted as "prevent encroachment", and if R1 and R2 are interpreted as "manage" then it is not a performance based standard as advertised. Performance based focused on preventing vegetation related outages. For instance: "Each Transmission Owner

Voter	Entity	Segment	Vote	Comment
				shall prevent vegetation related outages (except as noted in Footnote 2) of any of its applicable line(s) ..." Evidence of outages is practical to gather and provide, evidence of encroachment is not. Modify the standard to be similar to the currently mandatory non-results based standard and focus on the word "manage". This would essentially mean eliminating R1 and R2 since the rest of the standard focuses on having a plan and managing to that plan..
Response: The SDT thanks you for your comments. In Order 693, FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation**" (emphasis added). The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct inspections in which clearances are evaluated.				
Silvia P. Mitchell	Florida Power & Light Co.	6	Affirmative	1. The SDT proposes a revised NERC Glossary definition for Right-of-Way (ROW). This revised definition will be used in lieu of the Active Transmission Line ROW. Do you agree? If answer is no, please explain. Yes 2. In R1 and R2 and their associated VSLs, the SDT added the phrase "in order of increasing severity" and added the sentence "The types of encroachments are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a TO's vegetation maintenance program." to the Rationale boxes for R1/R2. Do you agree? If answer is no, please explain. Yes Although NextEra Energy Inc. (NextEra), including Florida Power & Light Company, agrees with the changes referenced for R1

Voter	Entity	Segment	Vote	Comment
				and R2, NextEra is concerned that the exemptions identified in footnote 2 for "...arboricultural activities or horticultural or agricultural activities...," and similar language in footnote 4, are too broad. For example, this language appears to include an exemption for a landowner, who, during arboricultural activities or horticultural or agricultural activities, causes a vegetation contact with a transmission line (e.g., cutting or lifting a tree into a transmission line). This places the Transmission Owner in the difficult position of a landowner arguing it is exempt from a controllable risk. Thus, the "...arboricultural activities or horticultural or agricultural activities..." references should be removed from footnote 2, and the similar language in footnote 4 3. In response to comments received regarding the term "investigation" in M1/M2, the SDT substituted "confirmation...by the Transmission Owner.." in its place, among other minor edits to these measures. Do you agree? If answer is no, please explain. Yes 4. In response to comments received that requirement R3 is unclear with respect to intent, the SDT added "maintenance strategies". Do you agree this clarifies the intent? If answer is no, please offer alternative language. Yes 5. The SDT added clarifying language in M7 to explain how the annual work plan percentage complete calculation is to be performed. Is this adequate? If no, please provide improved examples. Yes

Voter	Entity	Segment	Vote	Comment
Response: The SDT thanks you for your comments. The team has made the appropriate modifications to the footnotes as you suggested.				
Thomas Saitta	Kansas City Power & Light Co.	6	Negative	The Standard lacks clarity regarding the facilities that are subject to Requirement 7. It is important that a Standard be clear and not introduce ambiguity or confusion. There are several references throughout the Standard to "for all applicable lines" and it should be made clear the work plan is specific to "all applicable lines".
Response: The SDT thanks you for your comments. The phrase, "applicable lines" was added to R7 in support of your suggestion.				
Eric Ruskamp	Lincoln Electric System	6	Affirmative	While supportive of the drafting team's efforts, LES believes a change is warranted in Footnote 2 and Footnote 4 to remove the exemption for "arboricultural activities or horticultural or agricultural activities" and replace with the term "installation of". As currently drafted, the wording could potentially be construed to mean that the TO would or could be constrained or refused permission to prune and remove any and all vegetation in the ROW in accordance with the full legal rights of the ROW agreement(s).
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
John T Sturgeon	Progress Energy	6	Affirmative	There needs to be a change in the footnote 2 and footnote 4 to remove the exemption for "arboricultural activities or horticultural or agricultural activities" and replace it with the term "installation of.
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
David F. Lemmons	Xcel Energy, Inc.	6	Affirmative	Xcel Energy still believes the requirement in R6 that mandates an annual inspection is an ineffective approach and may actually go against the Commission's

Voter	Entity	Segment	Vote	Comment
				determination in FERC Order No. 693. The drafting team's response to our last round of comments on this issue was that "...the SDT was directed by Order 693 to set a minimum inspection criteria". It is clear in Order 693 that the Commission is not satisfied with allowing entities to choose their own inspection cycles, as the standard currently allows. However, we fail to see where the Commission mandated a minimum inspection cycle to be uniformly applied continent-wide. We urge the drafting team to revisit paragraphs 719 through 721 of Order 693. According to paragraph 721, the Commission recognizes that unique intervals by region, "based on local factors", are reasonable and appropriate. By use of the plural term "cycles", FERC anticipates the resolution may include multiple inspection cycles. Furthermore, in paragraph 719, FERC acknowledges that a minimum inspection cycle may not be the only way to address their concern. In fact, mandating an annual inspection cycle may actually go against the Commission's guidance in paragraph 720. Here is an excerpt: "...the Commission is dissuaded from requiring the ERO to create a backstop inspection cycle at this time. Instead, the Commission agrees that an entity's vegetation management program should be tailored to anticipated growth in the region and take into account other environmental factors. The goal is to assure that transmission owners conduct inspections at reasonable intervals." As an alternative, we propose a mid-cycle inspection. A mid-cycle inspection is based on an interval that is justified with data and technical expertise. A mid-cycle inspection would still require entities to conduct inspections at a specified interval, while allowing for differences based upon "physical

Voter	Entity	Segment	Vote	Comment
				and geographic factors". Not only would this approach fully address the Commissions concerns, but it would take into account the interests of stakeholders, landowners and rate-payers. We recognize that a mid-cycle inspection interval is not as easy to audit as an annual requirement, but it is a far more practical and cost-effective approach that, when applied based on an entity's expertise with its own facilities, ensures reliability.
Response The SDT thanks you for your comments. The SDT recognizes that a number of Transmission Owners in North America may prefer to set their own inspection intervals. The SDT can also see attractiveness for a mid-cycle inspection concept; however, this introduces new complexities in planning, documentation and auditing. Because there is substantial industry support for an annual inspection interval and due to the vastly simpler auditing associated with an annual interval, the SDT believes that the industry is best served with this approach.				
Jacquie Smith	ReliabilityFirst Corporation	10	Negative	ReliabilityFirst votes "No" on the proposed FAC-003-2 because ReliabilityFirst believes that the currently effective FAC-003-1, despite any weaknesses it may have, better ensures the reliability of the bulk electric system. First, under the proposed FAC-003-2, Requirements 1 and 2, the minimum clearances are reduced. Second, under the proposed structure of FAC-003-2, Requirements 1 and 2, violations would only occur where an encroachment of the Minimum Vegetation Clearance Distance ("MVCD") is observed in real time or after vegetation contact, i.e., after actual harm has occurred. Consequently, the proposed structure appears to convert a preventative maintenance standard into a standard that is essentially only violated after it is too late. The current structure from Version 1 of the standard (i.e., the Clearance

Voter	Entity	Segment	Vote	Comment
				1 and 2 requirements) better ensures reliability because they seek to ensure that registered entities discover problematic vegetation conditions prior to encroachments leading to flashover or vegetation contacts. For example, the current Clearance 1 is the "clearance distances to be achieved at the time of transmission vegetation management work." And the current Clearance 2 is the "specific radial clearances to be maintained under all rated electrical operating conditions." See FAC-003-1, R1.2.1 and R1.2.2 (emphasis added). Third, the draft standard appears to inappropriately and unnecessarily reduce the risk factor assigned to some failures to manage vegetation. It draws a distinction between those transmission lines that are elements of IROLs or Major Western Electricity Coordinating Council ("WECC") transfer paths and those that are not. This distinction is apparently based on the assumption that vegetation management violations on transmission lines that are not elements of IROLS or Major WECC transfer paths are less important. ReliabilityFirst disagrees with this assumption. Simply put, both are serious issues and the distinction is inappropriate and unnecessary. The Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations, highlights the importance of all vegetation management work by identifying inadequate vegetation management as one of the causes of the 2003 Blackout. See Blackout Report, at p. 20. Finally, ReliabilityFirst disagrees with the proposed Violation Risk Factors ("VRFs") and Violation Severity Levels ("VSLs")

Voter	Entity	Segment	Vote	Comment
				because they are premised on the same inappropriate and unnecessary distinction that vegetation management violations on transmission lines that are not elements of IROLS or Major WECC transfer paths are less important. For the foregoing reasons, ReliabilityFirst votes "No" on the proposed FAC-003-2.

Response: As with a Transmission Owner's determination of its Clearance 1 distances under version 1 of the Standard, Requirement 3 of the revised Standard begins with the MVCD distances (just as Clearance 1 began with IEEE-516 distances) and then requires additional consideration for conductor movement, vegetation growth variables, and the utility's maintenance approach. These are essentially the same considerations required by version 1 of the existing Standard when developing Clearance 1 distances. Therefore, nothing has been lost in the revised Standard.

The MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions.

R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD distances.

The defense-in-depth strategy for reliability standards development recognizes that each requirement in a NERC reliability standard has a role in preventing system failures, and that these roles are complementary and reinforcing. Reliability standards should not be viewed as a body of unrelated requirements, but rather should be viewed as part of a portfolio of requirements designed to achieve an overall defense-in-depth strategy and comport with the quality objectives of a reliability standard. The draft, when taken in whole, does present a "preventative" maintenance standard.

The Standard has been designed utilizing a "Defense in Depth" strategy which provides for multiple layers of defense against a MVCD encroachment or an outage. These other layers of defense are identified in requirements R3 through R7. R3 through R7 are the same preventative maintenance requirements as contained in Version 1 of the Standards. Additionally, Measure 3 for R3 now tests the reasonableness and practicality of a TO's vegetation management approach long before field work is implemented; other requirements such as R7 require preventative maintenance work to be completed before encroachments occur.

The SDT asserts that different VRF's for IROL and non-IROL lines strengthens the reliability of the standard. Vegetation

Voter	Entity	Segment	Vote	Comment
managers that do not know which lines have IROLs or are designated as WECC Transfer Paths may be inappropriately limiting resources allocated to vegetation management for a line with an IROL or a line designated as a WECC Transfer Path. A vegetation manager must ensure that the lines with IROLs and lines designated as WECC transfer paths are absolutely clear. By correctly identifying the risk associated with lines with IROLs line and/or lines designated as WECC Transfer Paths, the standard helps to assure that appropriate resources are applied.

Analysis of how VRFs and VSLs Were Determined Using FERC Guidelines

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Violation Risk Factor and Violation Severity Level Assignments

Project 2007-07 Vegetation Management

This document provides the drafting team's justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in FAC-003-2 Vegetation Management.

Each primary requirement is assigned a VRF and a set of one or more VSLs. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the ERO Sanction Guidelines.

Justification for Assignment of Violation Risk Factors

The SDT applied the following NERC criteria when developing these VRFs:

High Risk Requirement
A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement
A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement
A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

The SDT also considered consistency with the FERC Violation Risk Factor Guidelines for setting VRFs:[1]

Guideline (1) — Consistency with the Conclusions of the Final Blackout Report
The Commission seeks to ensure that Violation Risk Factors assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System.

In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:[2]

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief.

Guideline (2) — Consistency within a Reliability Standard

The Commission expects a rational connection between the sub-Requirement Violation Risk Factor assignments and the main Requirement Violation Risk Factor assignment.

[1] North American Electric Reliability Corp., 119 FERC ¶ 61,145, order on reh'g and compliance filing, 120 FERC ¶ 61,145 (2007) ("VRF Rehearing Order").
[2] Id. at footnote 15.

Guideline (3) — Consistency among Reliability Standards

The Commission expects the assignment of Violation Risk Factors corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) — Consistency with NERC's Definition of the Violation Risk Factor Level

Guideline (4) was developed to evaluate whether the assignment of a particular Violation Risk Factor level conforms to NERC's definition of that risk level.

Guideline (5) — Treatment of Requirements that Co-mingle More Than One Obligation

Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

The following discussion addresses how the SDT considered FERC's VRF Guidelines 2 through 5. The team did not address Guideline 1 directly because of an apparent conflict between Guidelines 1 and 4. Whereas Guideline 1 identifies a list of topics that encompass nearly all topics within NERC's Reliability Standards and implies that these requirements should be assigned a "High" VRF, Guideline 4 directs assignment of VRFs based on the impact of a specific requirement to the reliability of the system. The SDT believes that Guideline 4 is reflective of the intent of VRFs in the first instance and therefore concentrated its approach on the reliability impact of the requirements.

VRF Justification

VRF for FAC-003-2, Requirements R1:

The SDT assigned this requirement a VRF of High.

- FERC's Guideline 2 — Consistency within a Reliability Standard. The Requirement states transmission owners must manage vegetation for lines that represent a significant risk of cascading, instability, or separation. The VRF is only applied at the Requirement level and each Requirement Part is treated equally.
- FERC's Guideline 3 — Consistency among Reliability Standards. The requirement mandates measurable performance with regard to vegetation management to ensure that the risk of cascading, separation, and instability is minimized. Other requirements with similar performance based outcomes that could lead to cascading, instability, or separation carry a High VRF.

- FERC's Guideline 4 — Consistency with NERC's Definition of a VRF. IROLs and Major WECC Transfer Paths by definition have an increased potential for leading to cascading, separation, or instability. Therefore this requirement was assigned a High VRF.
- FERC's Guideline 5 — Treatment of Requirements that Co-mingle More Than One Objective. The requirement contains only one objective (to manage vegetation of lines that carry increased risk of instability, cascading, or separation) and only one VRF was assigned.

VRF for FAC-003-2, Requirements R2:

The SDT assigned this requirement a VRF of Medium.

- FERC's Guideline 2 — Consistency within a Reliability Standard. The Requirement states transmission owners must manage vegetation for lines that do not represent a significant risk of cascading, instability, or separation. The VRF is only applied at the Requirement level and each Requirement Part is treated equally.
- FERC's Guideline 3 — Consistency among Reliability Standards. The requirement mandates measurable performance with regard to vegetation management to ensure that the risk of equipment damage is minimized. Other requirements similar performance based outcomes that could lead to equipment damage carry a Medium VRF.
- FERC's Guideline 4 — Consistency with NERC's Definition of a VRF. Lines that are not IROLs and Major WECC Transfer Paths by definition have less potential for leading to cascading, separation, or instability. Therefore this requirement was assigned a Medium VRF.
- FERC's Guideline 5 — Treatment of Requirements that Co-mingle More Than One Objective. The requirement contains only one objective (to manage vegetation of lines that carry minimal risk instability, cascading, or separation) and only one VRF was assigned.

VRF for FAC-003-2, Requirements R3:

The SDT assigned this requirement a VRF of Lower.

- FERC's Guideline 2 — Consistency within a Reliability Standard. The Requirement mandates the Transmission Owner to have documented strategies, procedures, processes, or specifications. The VRF is only applied at the Requirement level and each Requirement Part is treated equally.
- FERC's Guideline 3 — Consistency among Reliability Standards. This requirement calls for an entity to have documented strategies, procedures, processes, or specifications. This requirement is administrative in nature, and is consistent with other standards requiring documentation.
- FERC's Guideline 4 — Consistency with NERC's Definition of a VRF. Failure to have a document is not likely to directly affect the electrical state or the capability of the bulk electric system, or the

ability to effectively monitor and control the bulk electric system. Development of the documents is a requirement that is administrative in nature and is in a planning time frame that, if violated, would not, under emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system.. Therefore this requirement was assigned a Lower VRF.

- FERC's Guideline 5 — Treatment of Requirements that Co-mingle More Than One Objective. R2 contains only one objective which is to have documents(s). Since the requirement is to have a documents, only one VRF was assigned.

VRF for FAC-003-2, Requirements R4:

The SDT assigned this requirement a VRF of Medium.

- FERC's Guideline 2 — Consistency within a Reliability Standard. The Requirement specifies that transmission owners must report vegetation conditions that are likely to cause a Fault to the control center holding switching authority for the associated line. The VRFs are only applied at the Requirement level and there are no Requirement Parts for separate consideration.
- FERC's Guideline 3 — Consistency among Reliability Standards. The requirement mandates notifications that could hinder the ability to effectively monitor and control the bulk electric system. Other requirements that address with similar outcomes are also assigned Medium VRFs.
- FERC's Guideline 4 — Consistency with NERC's Definition of a VRF. Failure to report vegetation conditions may affect the ability to effectively monitor and control the bulk electric system Therefore this requirement was assigned a Medium VRF.
- FERC's Guideline 5 — Treatment of Requirements that Co-mingle More Than One Objective. The requirement contains only one objective (to report) , and only one VRF was assigned.

VRF for FAC-003-2, Requirements R5:

The SDT assigned this requirement a VRF of Medium.

- FERC's Guideline 2 — Consistency within a Reliability Standard. The Requirement mandates that a Transmission Owner, when constrained from performing vegetation work that may lead to a vegetation risk encroachment into the MVCD prior to the implementation of the next annual work plan, must take corrective action to ensure continued vegetation management to prevent encroachments. The VRF is only applied at the Requirement level and there are no Requirement Parts for separate consideration.
- FERC's Guideline 3 — Consistency among Reliability Standards. The requirement mandates corrective action that, if not taken, could directly affect the electrical state or the capability of the bulk electric system. Other requirements with similar outcomes are also assigned Medium VRFs.

- FERC's Guideline 4 — Consistency with NERC's Definition of a VRF. Failure to take corrective action could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. Therefore this requirement was assigned a Medium VRF.
- FERC's Guideline 5 — Treatment of Requirements that Co-mingle More Than One Objective. The requirement contains only one objective (to take corrective action), and only one VRF was assigned.

VRF for FAC-003-2, Requirements R6:

The SDT assigned this requirement a VRF of Medium.

- FERC's Guideline 2 — Consistency within a Reliability Standard. The Requirement specifies that the transmission owner must perform a Vegetation Inspection of 100% of its lines at least once per calendar year. The VRFs are only applied at the Requirement level and there are no Requirement Parts for separate consideration.
- FERC's Guideline 3 — Consistency among Reliability Standards. The requirement mandates inspections that, if not performed, could affect the ability to effectively monitor and control the bulk electric system. Other requirements with similar outcomes are also assigned Medium VRFs.
- FERC's Guideline 4 — Consistency with NERC's Definition of a VRF. Failure to perform an inspection could affect the ability to effectively monitor and control the bulk electric system. Therefore this requirement was assigned a lower VRF.
- FERC's Guideline 5 — Treatment of Requirements that Co-mingle More Than One Objective. The requirement contains only one objective (to perform a Vegetation inspection), and only one VRF was assigned.

VRF for FAC-003-2, Requirements R7:

The SDT assigned this requirement a VRF of Medium.

- FERC's Guideline 2 — Consistency within a Reliability Standard. The Requirement specifies that the Transmission Owner must complete 100% of its annual vegetation work plan. The VRFs are only applied at the Requirement level and there are no Requirement Parts for separate consideration.
- FERC's Guideline 3 — Consistency among Reliability Standards. The requirement mandates completion of work that, if not completed, could affect the electrical state or the capability of the bulk electric system. Other requirements with similar outcomes are also assigned Medium VRFs.
- FERC's Guideline 4 — Consistency with NERC's Definition of a VRF. Failure to complete the annual vegetation work plan could affect the electrical state or the capability of the bulk electric system. Therefore this requirement was assigned a lower VRF.

- FERC's Guideline 5 — Treatment of Requirements that Co-mingle More Than One Objective. The Requirement contains only one objective (to complete 100% of the annual vegetation work plan), and only one VRF was assigned.

Justification for Assignment of Violation Severity Levels

In developing the VSLs, the SDT anticipated the evidence that would be reviewed during an audit, and developed its VSLs based on the noncompliance an auditor may find during a typical audit. The SDT based its assignment of VSLs on the following NERC criteria:

Lower	Moderate	High	Severe
Missing a minor element (or a small percentage) of the required performance The performance or product measured has significant value as it almost meets the full intent of the requirement.	Missing at least one significant element (or a moderate percentage) of the required performance. The performance or product measured still has significant value in meeting the intent of the requirement.	Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital component. The performance or product has limited value in meeting the intent of the requirement.	Missing most or all of the significant elements (or a significant percentage) of the required performance. The performance measured does not meet the intent of the requirement or the product delivered cannot be used in meeting the intent of the requirement.

FERC's VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement meet the FERC Guidelines for assessing VSLs:

Guideline 1: Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

> Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of non-compliance were used.

Guideline 2: Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a “binary” type requirement must be a “Severe” VSL.

Do not use ambiguous terms such as “minor” and “significant” to describe noncompliant performance.

Guideline 3: Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

Guideline 4: Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations

. . . unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the “default” for penalty calculations.

VSLs for FAC-003-2 Requirement R1:

R#	Compliance with NERC's VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R1	Meets NERC's VSL guidelines. There is an incremental aspect to the violation and the VSLs follow the guidelines for incremental violations..	This is a new requirement, and accordingly cannot lower the current level of compliance.	The proposed VSL does not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.	The proposed VSL uses the same terminology as used in the associated requirement, and is, therefore, consistent with the requirement.	The VSL is based on a single violation and not cumulative violations.

VSLs for FAC-003-2 Requirement R2:

R#	Compliance with NERC's VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R2.	Meets NERC's VSL guidelines. There is an incremental aspect to the violation and the VSLs follow the guidelines for incremental violations.	This is a new requirement, and accordingly cannot lower the current level of compliance.	The proposed VSL does not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.	The proposed VSL uses the same terminology as used in the associated requirement, and is, therefore, consistent with the requirement.	The VSL is based on a single violation and not cumulative violations.

VSLs for FAC-003-3 Requirement R3

R#	Compliance with NERC's Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R3.	Meets NERC's VSL guidelines. There is an incremental aspect to the violation and the VSLs follow the guidelines for incremental violations.	The previous standard graded the VSLs based on the completeness of the TVMP. The new VSL is structured similarly, but has omitted the "Low" level, effectively raising the minimum level of compliance.	The proposed VSLs do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.	The proposed VSLs use the same terminology as used in the associated requirement, and are, therefore, consistent with the requirement.	The VSLs are based on a single violation and not cumulative violations.

VSLs for FAC-003-3 Requirement R4:

R#	Compliance with NERC's Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R4.	Meets NERC's VSL guidelines. There is an incremental aspect to the violation and the VSLs follow the guidelines for incremental violations.	The previous standard does not require actual communication, while the new standard does. Accordingly, this should be treated as a new requirement, and therefore cannot lower the current level of compliance.	The proposed VSLs do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.	The proposed VSLs use the same terminology as used in the associated requirement, and are, therefore, consistent with the requirement.	The VSLs are based on a single violation and not cumulative violations.

VSLs for FAC-003-3 Requirement R5:

R#	Compliance with NERC's Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R5.	Meets NERC's VSL guidelines - Severe: The performance or product measured does not substantively meet the intent of the requirement.	The only VSL is Severe, and therefore, the VSL cannot result in a lower level of compliance.	The proposed VSLs do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.	The proposed VSLs use the same terminology as used in the associated requirement, and are, therefore, consistent with the requirement.	The VSLs are based on a single violation and not cumulative violations.

VSLs for FAC-003-3 Requirement R6:

R#	Compliance with NERC's Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R6.	Meets NERC's VSL guidelines. There is an incremental aspect to the violation and the VSLs follow the guidelines for incremental violations.	The previous standard does not require actual inspections, while the new standard does. Accordingly, this should be treated as a new requirement, and therefore cannot lower the current level of compliance.	The proposed VSLs do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.	The proposed VSLs use the same terminology as used in the associated requirement, and are, therefore, consistent with the requirement.	The VSLs are based on a single violation and not cumulative violations.

VSLs for FAC-003-3 Requirement R7:

R#	Compliance with NERC's Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R7.	Meets NERC's VSL guidelines. There is an incremental aspect to the violation and the VSLs follow the guidelines for incremental violations.	The VSLs in the previous standard were focused on completeness of the document, with the "Severe" VSL only reserved for entities that did not have or implement their plan. The proposed VSLs are graded based on the amount of the plan completed, giving a clear indication that partial completion is still a violation, establishing a level of compliance in excess of what was established previously.	The proposed VSLs do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.	The proposed VSLs use the same terminology as used in the associated requirement, and are, therefore, consistent with the requirement.	The VSLs are based on a single violation and not cumulative violations.

Record of Development of Proposed FAC-003-2 — Transmission Vegetation Management Reliability Standard

Project 2007-07
Transmission Vegetation Management

Related Files

Status:
Adopted by the Board of Trustees on November 3, 2011.

Purpose / Industry Need:
FAC-003-1 was approved in 2006. It has some 'fill-in-the-blank' components to eliminate. In addition, the following comments submitted by FERC and stakeholders need to be addressed in the refinement of the standard:

FERC Order 693 items
Address the issue regarding applicability:

- Work with the reliability entities and the ERO to collect and make available to the FERC, a list of critical lower voltage transmission lines. (Refer to Applicability 4.3 section of the standard.)
- Consider other criteria in determining applicability of the standard to sub 200kV lines.
- Address the issue of clearances for lines on both federal and non-federal lands:
- Review and analyze outage data (collected by the ERO) then consider defining clearances needed to avoid sustained vegetation-related outages that would apply to transmission lines crossing both federal and non-federal land.
- Consider revising the definition of right of way to encompass required clearance areas.
- Review the suitability of IEEE 516-2003 standard for minimum vegetation clearance.
- Review and analyze outage data (collected by the ERO) then consider defining clearances needed to avoid sustained vegetation-related outages that would apply to transmission lines crossing both federal and non-federal land.
- Consider revising the definition of right of way to encompass required clearance areas.
- Review the suitability of IEEE 516-2003 standard for minimum vegetation clearance.

Procedural items

- Re-format standard to bring it into conformance with the latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines.
- Remove references to RRO in the standard and substitute a responsible entity.
- Add newly developed compliance elements such as time horizons, violation risk factors, violation severity levels, etc.

Stakeholder items

- Prepare technical reference material such as a "white paper" to aid in understanding the technical basis for the standard.
- Review reporting criteria for Category 3 outages in the proposed technical reference material and may remove the reporting requirement of Category 3 outages in R.3 and R.4.
- Consider deleting requirement R.4.
- Review the reporting exemptions to include all category outages under major disasters in Requirement R3.2.

The development may include other improvements to the standards deemed appropriate by the drafting team, with the consensus of stakeholders, consistent with establishing high quality, enforceable and technically sufficient bulk power system reliability standards.

Standard Authorization Request Form

Title of Proposed Standard Project 2007-07	Revisions to FAC-003-1 Vegetation Management Program
Request Date	January 9, 2007

SAR Requestor Information	**SAR Type** (*Check a box for each one that applies.*)	
Name Richard Schneider (To be replaced by SAR DT Chair when the SAR DT is appointed.)	☐	New Standard
Primary Contact Richard Schneider	☒	Revision to existing Standard
Telephone 609-452-8060 Fax	☐	Withdrawal of existing Standard
E-mail Richard.schneider@nerc.net	☐	Urgent Action

Purpose / Industry Need (Describe the purpose of the standard — what the standard will achieve in support of reliability.)

The purpose of revising this standard is to:

1. Provide an adequate level of reliability for the North American bulk power systems - the standard is complete and the requirements are set at an appropriate level to ensure reliability.
2. Ensure it is enforceable as a mandatory reliability standard with financial penalties - the applicability to bulk power system owners, operators, and users, and as appropriate particular classes of facilities, is clearly defined; the purpose, requirements, and measures are results-focused and unambiguous; the consequences of violating the requirements are clear.
3. Incorporate other general improvements described in the attached Standard Review Guidelines
4. Consider comments received from ERO regulatory authorities and stakeholders, as noted in the attached review sheets.
5. Satisfy the standards procedure requirement for five-year review of the standards.

Brief Description

This is a new standard that was approved in 2006. It has some 'fill-in-the-blank' components to eliminate. In addition, the following comments submitted by FERC and stakeholders need to be addressed in the refinement of the standard:

FERC NOPR

- Develop a minimum vegetation inspection cycle that allows variation for physical differences, as discussed above; and
- Remove the applicability to transmission lines operated at 200 kV and above so that the Reliability Standard applies to Bulk-Power System transmission lines that have an impact of reliability as determined by the ERO.

FERC staff report

- Objections to use of IEEE standard

Stakeholder Comments

- RA vs. RRO
- Too weak on compliance
- Format inconsistencies

The development may include other improvements to the standards deemed appropriate by the drafting team, with the consensus of stakeholders, consistent with establishing high quality, enforceable and technically sufficient bulk power system reliability standards.

Reliability Functions

The Standard will Apply to the Following Functions *(Check box for each one that applies.)*		
☐	Reliability Coordinator	Ensures the reliability of the bulk transmission system within its Reliability Coordinator area. This is the highest reliability authority.
☐	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within its metered boundary and supports system frequency in real time.
☐	Interchange Authority	Authorizes valid and balanced Interchange Schedules.
☐	Planning Authority	Plans the Bulk Electric System.
☐	Resource Planner	Develops a long-term (>one year) plan for the resource adequacy of specific loads within a Planning Authority area.
☐	Transmission Planner	Develops a long-term (>one year) plan for the reliability of transmission systems within its portion of the Planning Authority area.
☐	Transmission Service Provider	Provides transmission services to qualified market participants under applicable transmission service agreements
☒	Transmission Owner	Owns transmission facilities.
☐	Transmission Operator	Operates and maintains the transmission facilities, and executes switching orders.
☐	Distribution Provider	Provides and operates the “wires” between the transmission system and the customer.
☐	Generator Owner	Owns and maintains generation unit(s).
☐	Generator Operator	Operates generation unit(s) and performs the functions of supplying energy and Interconnected Operations Services.
☐	Purchasing-Selling Entity	The function of purchasing or selling energy, capacity, and all necessary Interconnected Operations Services as required.
☐	Market Operator	Integrates energy, capacity, balancing, and transmission resources to achieve an economic, reliability-constrained dispatch.
☐	Load-Serving Entity	Secures energy and transmission (and related generation services) to serve the end user.

Reliability and Market Interface Principles

Applicable Reliability Principles *(Check box for all that apply.)*	
☐	1. Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☐	2. The frequency and voltage of interconnected bulk electric systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☐	3. Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably.
☐	4. Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.
☒	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk electric systems.
☐	6. Personnel responsible for planning and operating interconnected bulk electric systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☐	7. The security of the interconnected bulk electric systems shall be assessed, monitored and maintained on a wide area basis.

Does the proposed Standard comply with all the following Market Interface Principles? *(Select "yes" or "no" from the drop-down box.)*
1. The planning and operation of bulk electric systems shall recognize that reliability is an essential requirement of a robust North American economy. Yes
2. An Organization Standard shall not give any market participant an unfair competitive advantage.Yes
3. An Organization Standard shall neither mandate nor prohibit any specific market structure. Yes
4. An Organization Standard shall not preclude market solutions to achieving compliance with that Standard. Yes
5. An Organization Standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes

Standard Review Guidelines

Applicability

Does this reliability standard clearly identify the functional classes of entities responsible for complying with the reliability standard, with any specific additions or exceptions noted? Where multiple functional classes are identified is there a clear line of responsibility for each requirement identifying the functional class and entity to be held accountable for compliance? Does the requirement allow overlapping responsibilities between Registered Entities possibly creating confusion for who is ultimately accountable for compliance?

Does this reliability standard identify the geographic applicability of the standard, such as the entire North American bulk power system, an interconnection, or within a regional entity area? If no geographic limitations are identified, the default is that the standard applies throughout North America.

Does this reliability standard identify any limitations on the applicability of the standard based on electric facility characteristics, such as generators with a nameplate rating of 20 MW or greater, or transmission facilities energized at 200 kV or greater or some other criteria? If no functional entity limitations are identified, the default is that the standard applies to all identified functional entities.

Purpose

Does this reliability standard have a clear statement of purpose that describes how the standard contributes to the reliability of the bulk power system? Each purpose statement should include a value statement.

Performance Requirements

Does this reliability standard state one or more performance requirements, which if achieved by the applicable entities, will provide for a reliable bulk power system, consistent with good utility practices and the public interest?

Does each requirement identify who shall do what under what conditions and to what outcome?

Measurability

Is each performance requirement stated so as to be objectively measurable by a third party with knowledge or expertise in the area addressed by that requirement?

Does each performance requirement have one or more associated measures used to objectively evaluate compliance with the requirement?

If performance results can be practically measured quantitatively, are metrics provided within the requirement to indicate satisfactory performance?

Technical Basis in Engineering and Operations

Is this reliability standard based upon sound engineering and operating judgment, analysis, or experience, as determined by expert practitioners in that particular field?

Completeness

Is this reliability standard complete and self contained? Does the standard depend on external information to determine the required level of performance?

Consequences for Noncompliance
In combination with guidelines for penalties and sanctions, as well as other ERO and regional entity compliance documents, are the consequences of violating a standard clearly known to the responsible entities?

Clear Language
Is the reliability standard stated using clear and unambiguous language? Can responsible entities, using reasonable judgment and in keeping with good utility practices, arrive at a consistent interpretation of the required performance?

Practicality
Does this reliability standard establish requirements that can be practically implemented by the assigned responsible entities within the specified effective date and thereafter?

Capability Requirements versus Performance Requirements
In general, requirements for entities to have "capabilities" (this would include facilities for communication, agreements with other entities, etc.) should be located in the standards for certification. The certification requirements should indicate that entities have a responsibility to "maintain" their capabilities.

Consistent Terminology
To the extent possible, does this reliability standard use a set of standard terms and definitions that are approved through the NERC reliability standards development process?

If the standard uses terms that are included in the NERC Glossary of Terms Used in Reliability Standards, then the term must be capitalized when it is used in the standard. New terms should not be added unless they have a "unique" definition when used in a NERC reliability standard. Common terms that could be found in a college dictionary should not be defined and added to the NERC Glossary.

Are the verbs on the "verb list" from the Drafting Team Guidelines? If not, do new verbs need to be added to the guidelines or could you use one of the verbs from the verb list?

Violation Risk Factors (Risk Factor)

High Risk Requirement
A requirement that, if violated, could directly cause or contribute to bulk power system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk power system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement
A requirement that, if violated, could directly affect the electrical state or the capability of the bulk power system, or the ability to effectively monitor and control the bulk power system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement
A requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk power system, or the ability to effectively monitor and control the bulk power system. A requirement that is administrative in nature;

or a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

Mitigation Time Horizon
The drafting team should also indicate the time horizon available for mitigating a violation to the requirement using the following definitions:

- **Long-term Planning** — a planning horizon of one year or longer.
- **Operations Planning** — operating and resource plans from day ahead up to and including seasonal.
- **Same-day Operations** — routine actions required within the time frame of a day, but not real time.
- **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk power system.
- **Operations Assessment** — follow-up evaluations and reporting of real-time operations.

Violation Severity Levels
The drafting team should indicate a set of violation severity levels that can be applied for the requirements within a standard. (“Violation severity levels” replace existing “levels of non-compliance.”) The violation severity levels may be applied for each requirement or combined to cover multiple requirements, as long as it is clear which requirements are included.

The violation severity levels should be based on the following definitions:

- **Lower: mostly compliant with minor exceptions** — The responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more minor details. Equivalent score: 95% to 99% compliant.
- **Moderate: mostly compliant with significant exceptions** — The responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more significant elements. Equivalent score: 85% to 94% compliant.

- **High: marginal performance or results** — The responsible entity has only partially achieved the reliability objective of the requirement and is missing one or more significant elements. Equivalent score: 70% to 84% compliant.
- **Severe: poor performance or results** — The responsible entity has failed to meet the reliability objective of the requirement. Equivalent score: less than 70% compliant.

Compliance Monitor
Replace "Regional Reliability Organization" with "Electric Reliability Organization"

Fill-in-the-blank Requirements
Do not include any "fill-in-the-blank" requirements. These are requirements that assign one entity responsibility for developing some performance measures without requiring that the performance measures be included in the body of a standard — then require another entity to comply with those requirements.

Every reliability objective can be met, at least at a threshold level, by a North American standard. If we need regions to develop regional standards, such as in underfrequency load shedding, we can always write a uniform North American standard for the applicable functional entities as a means of encouraging development of the regional standards.

Requirements for Regional Reliability Organization
Do not write any requirements for the Regional Reliability Organization. Any requirements currently assigned to the RRO should be re-assigned to the applicable functional entity.

Effective Dates
Must be 1st day of 1st quarter after entities are expected to be compliant — must include time to file with regulatory authorities and provide notice to responsible entities of the obligation to comply. If the standard is to be actively monitored, time for the Compliance Monitoring and Enforcement Program to develop reporting instructions and modify the Compliance Data Management System(s) both at NERC, and Regional Entities must be provided in the implementation plan.

Associated Documents
If there are standards that are referenced within a standard, list the full name and number of the standard under the section called, "Associated Documents."

Functional Model Version 3
Review the requirements against the latest descriptions of the responsibilities and tasks assigned to functional entities as provided in pages 13 through 53 of the draft Functional Model Version 3.

Maureen E. Long
Standards Process Manager

January 15, 2007

TO: REGISTERED BALLOT BODY

Ladies and Gentlemen:

Announcement: Comment Periods Open for SAR to Modify Vegetation Management, SAR for Reliability Coordination and SAR and Standard to Modify Facility Ratings Standards

The Standards Committee (SC) announces the following standards actions:

SAR to Modify the Vegetation Management Standard FAC-003-1 Posted for 30-day Comment Period January 15–February 14, 2007

The SAR for Project 2007-07 proposes modifying the Vegetation Management standard FAC-003-1 to address concerns raised by FERC and stakeholders and to bring the standard into conformance with the ERO Rules of Procedure and the latest version of the *Reliability Standards Development Procedure.* Please use the comment form to provide comments on this SAR.

SAR to Modify the Reliability Coordinator Standards Posted for 30-day Comment Period January 15–February 14, 2007

The SAR for Project 2006-06 proposes retiring, modifying, or adding to existing requirements for the reliability coordinator to ensure that the complete set of requirements addresses all the processes, procedures, plans, tools, and authorities the reliability coordinator needs to support the reliable operation of the interconnected bulk power systems. This project involves addressing concerns raised by FERC and stakeholders and also involves bringing the set of standards into conformance with the ERO Rules of Procedure and the latest version of the *Reliability Standards Development Procedure.* Please use the comment form to provide comments on this SAR.

SAR and Standard to Modify the Facility Ratings Standards Posted for 45-day Comment Period January 15–February 28, 2007

The SAR for Project 2006-09 proposes modifying two Facility Ratings standards, FAC-008-1 and FAC-009-1, to address concerns raised by FERC and stakeholders and to bring the standard into conformance with the ERO Rules of Procedure and the latest version of the *Reliability Standards Development Procedure.* Because there were relatively few technical changes recommended for this set of standards, the revised standard, which combines FAC-008-1 and FAC-009-1, is posted for comment along with an implementation plan. Please use the comment form to provide comments on this SAR, standard and implementation plan.

Standards Development Process

The *Reliability Standards Development Procedure* contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate. If you have any questions, please contact me at 813-468-5998 or maureen.long@nerc.net.

Sincerely,

Maureen E. Long

Background Information:

FAC-003-1 is a relatively new standard that was approved in 2006. FAC-003 has some "fill-in-the-blank" components to eliminate. In addition, the following comments submitted by FERC and stakeholders need to be addressed in the refinement of the standard:

FERC NOPR

- Develop a minimum vegetation inspection cycle that allows variation for physical differences, as discussed above; and
- Remove the applicability to transmission lines operated at 200 kV and above so that the Reliability Standard applies to bulk power system transmission lines that have an impact of reliability as determined by the ERO.

FERC staff report

- Objections to use of IEEE standard

Stakeholder Comments

- Reliability Coordinator vs. Regional Reliability Organization
- Too weak on compliance
- Format inconsistencies

The improvements to the standard should bring the standard's format and elements into conformance with the latest version of the *Reliability Standards Development Procedure* and the ERO Rules of Procedure.

The development may include other improvements to the standards deemed appropriate by the drafting team, with the consensus of stakeholders, consistent with establishing high quality, enforceable and technically sufficient bulk power system reliability standards.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

The improvements to the standard should bring the standard's format and elements into conformance with the latest version of the *Reliability Standards Development Procedure* and the ERO Rules of Procedure.

The development may include other improvements to the standards deemed appropriate by the drafting team, with the consensus of stakeholders, consistent with establishing high quality, enforceable and technically sufficient bulk power system reliability standards.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that there is a reliability-related need to address the proposed revisions to FAC-003-1 — Transmission Vegetation Management? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: Ok, Yes and No. The first FERC NOPR bullet needs to be addressed. The second bullet is clearly discribed in the standard. A. 4.4.3. The reader must read the statement in context. It meets the Standard Review Guidelines.

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

   ☒ Yes

   ☐ No

   Comments: Since this posting is for comment it would have been nice to provide more information as to why the FERC staff objects to the IEEE standard (since it meet the guidelines for as a North America standard. Also, why are stakeholder concerned with Reliability Coordinators vs. RRO?

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

   ☒ Yes

   ☐ No

   Comments: It is not clear if categroy 1 and 2 refer only to occupied ROW, or also to unoccupied area reserved by the Transmission Owner for future expansion.

Please use this form to submit comments on the Vegetation Management SAR. Comments must be submitted by **February 14, 2007.** You may submit the completed form by e-mail to sarcomm@nerc.com with the words "Vegetation Management" in the subject line. If you have questions, please contact Richard Schneider at richard.schneider@nerc.net or by telephone at 609-452-8060.

Background Information:

FAC-003-1 is a relatively new standard that was approved in 2006. FAC-003 has some "fill-in-the-blank" components to eliminate. In addition, the following comments submitted by FERC and stakeholders need to be addressed in the refinement of the standard:

FERC NOPR

- Develop a minimum vegetation inspection cycle that allows variation for physical differences, as discussed above; and
- Remove the applicability to transmission lines operated at 200 kV and above so that the Reliability Standard applies to bulk power system transmission lines that have an impact of reliability as determined by the ERO.

FERC staff report

- Objections to use of IEEE standard

Stakeholder Comments

- Reliability Coordinator vs. Regional Reliability Organization
- Too weak on compliance
- Format inconsistencies

The improvements to the standard should bring the standard's format and elements into conformance with the latest version of the *Reliability Standards Development Procedure* and the ERO Rules of Procedure.

The development may include other improvements to the standards deemed appropriate by the drafting team, with the consensus of stakeholders, consistent with establishing high quality, enforceable and technically sufficient bulk power system reliability standards.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a “check” mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that there is a reliability-related need to address the proposed revisions to FAC-003-1 — Transmission Vegetation Management? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: The revisions listed in the NOPR and FERC Staff Report do not provide the necessary justification to alter the requirements in the current FAC-003-1 document. The existing requirements already allow for each utility to specify the inspection requirements. There is no need to more prescriptive. The existing requirements already allow for the ERO to designate critical lines less than 200 kV so removal of the 200 kV benchmark is unecessary. The IEEE Standard is worthwhile to keep as a benchmark without which there would be no solid guidance for minimum clearances.

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: As noted above.

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

   ☐ Yes

   ☒ No

1. Do you agree that there is a reliability-related need to address the proposed revisions to FAC-003-1 — Transmission Vegetation Management? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: The items listed as potential revisions are vague and do not provide sufficient justification to alter the current requirements of this standard which has been in effect less than 1 year. The current standard allows for the region to determine which transmission lines are critical to reliability and should be included in a Transmission Owner's Transmission Vegetation Management Plan regardless of voltage classification. The current standard also allows each TO the flexibility to develop its plan in accordance with its specific geography and operating environment. There is no need to be more prescriptive.

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

   ☒ Yes

   ☒ No

   Comments: As submitted, the SAR appears to completely re-open this standard negating many months of work and industry comment to reach the consensus reflected in the current FAC-003.

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

   ☐ Yes

   ☒ No

   Comments: See Comment #2

1. Do you agree that there is a reliability-related need to address the proposed revisions to FAC-003-1 — Transmission Vegetation Management? If not, please explain in the comment area.

☐ Yes

☒ No

Comments: We believe that at this time it is premature to move forward with changes to the standard that are based on voltage class issues. The Standard, as developed, applies to the BES which have been determined by a performance based methodology. NERC should wait until the BES vs. BPS issue is resolved.

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

☐ Yes

☒ No

Comments: To address FERC's objection to use the IEEE standard, it is necessary to clarify the objective of the Vegetation Management Standard. As we understand it, the focus of the FAC-003-1 standard is system reliability and as such, the responsibility and authority on defining and applying the safety margins is rightly assigned to the transmission owner. We request clarification on how employing safety factors will address reliability and how prescribing minimum clearances within the standard will improve reliability.

Please note that the Canadian Standards Association is revising standard C22.3 No. 1 - Overhead Systems. The new version will include clearances to vegetation and the proposed minimum clearances are in alignment with FAC-003-1.

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

☐ Yes

☒ No

1. Do you agree that there is a reliability-related need to address the proposed revisions to FAC-003-1 — Transmission Vegetation Management? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: The SERC VMS is unsure how to answer the question as it is worded, but has the following comments on the SAR:

   The current standard contains appropriate requirements and measures to ensure the owners vegetation management program is implemented and managed to ensure the reliability of the transmission system. Mandating inspection cycle frequencies will not enhance nor ensure reliability by inspecting more or less frequently. The minimum vegetation clearances at maximum operating conditions that are established within the owner's program, which is auditable by the ERO, will ensure reliability. Extending the requirements to lines other than those >200KV may reduce the focus on those lines and may cause the allocation of resources away from lines >200KV. Generally easements are narrower on lower voltage lines, requiring more resources and emphasis on these lines. This may have an effect on the ability to focus clearing efforts on those lines that will have a much greater impact on the bulk power system. The IEEE standard when used as the minimum clearance distance at maximum operating condition will ensure reliability when these clearances are maintained by vegetation management activities. In addition, we do not agree that a standard of zero tolerance for vegetaion-related outages in the ROW is weak on compliance.

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

   ☐ Yes

   ☐ No

   Comments: Minimum Inspection Intervals:
   The SERC VMS believes that FAC 003-1 provides the proper amount of flexibility regarding vegetation inspection cycles and that the Standards Drafting Team should not impose minimum inspection intervals on a continent with such regional diversity in climate and plant life.

   The purpose of Requirement 1.1 of standard FAC-003-1 is to put the responsibility for proper inspection cycles on the entity that knows the local conditions and can best define what that inspection frequency should be, the Transmission Owner. Both NERC and the FERC staff have recognized that various local conditions can have an affect on the determination of adequate inspection frequencies. Establishing a mandatory minimum inspection frequency could have two detrimental effects on the industry.

   First, where a particular region is heavily forested and has heavy rainfall along with extended or year round growing seasons, a "back stop" minimum inspection frequency could lead transmission owners to conduct inspections less frequently than required by the local conditions. This could result in a Transmission Owner complying with the standard while not adequately protecting the reliability of that region's transmission system. This is a "lowest common denominator" approach which FERC has repeatedly stated is inappropriate for the reliability standards.

Second, where a particular region is arid, sparsely forested or has a minimum growing season, a "back stop" minimum could require a more frequent interval than is realistically needed. This would result in increased and unnecessary costs for electric utility customers without providing an increase in system reliability.

In its discussion of inspection intervals, FERC indicates that a "one-year vegetation inspection cycle is reasonable." FERC NOPR, 10/20/2002 paragraph 383. The Commission continues by stating "a one-year inspection cycle is the 'norm' for the industry, but not the lowest common denominator…" It follows from this observation that the industry as a whole recognizes and follows appropriate inspection intervals without a need to change the standard. Further, FERC also states "some variation to a continent-wide, one-year minimum inspection cycle should be allowed due to physical differences such as climate and species of vegetation." FERC NOPR 10/20/2006, paragraph 382. FERC's express recognition that a "one size fits all" approach is not appropriate further supports the SERC VMS's contention that the existing inspection requirements in standard FAC-003-1 should remain unchanged.

Finally, the performance metrics of FAC-003 require the reporting of applicable transmission interruptions that are caused by vegetation. This process should appropriately identify Transmission Owners' inspection cycles that are not adequate. In this event, the ERO has the authority to engage the Transmission Owner in enforcement compliance actions and, therefore, can remedy any vegetation-related outage that is attributed to the Transmission Owner's inspection frequency.

Standard Applicability:
The SERC VMS disagrees with the proposal to revise the 200 kV threshold for determining facilities subject to this standard.

The majority of transmission facilities below 200 kV have significantly different design/construction/operating characteristics and have not been cited as impacting bulk power system reliability. For example, the Final Report on the August 14, 2003 Blackout in the United states and Canada: Causes and Recommendations April 2004 by the U.S.-Canada Power System Outage Task Force and all referenced major blackouts(pages 103-115) in that report, cited only outages which involved vegetation at line voltages above 200 kV. Generally applying requirements appropriate for 200 kV lines to lines less than 200 kV will result in significant documentation and reporting of items such as restrictions, mitigation plans, off right-of-way vegetation-related outage investigation/information and other issues, all of which dilutes the focus on lines that directly impact bulk power system reliability.

Revising the standard to use general criteria or broad language for defining "Bulk Power System" transmission lines covered by the standard could become a "one size fits all" approach. If that approach were taken, the standard would cover a significant number of transmission lines that have no direct impact on bulk power system reliability under standard planning/operating conditions, resulting in a significant increase in costs for electric customers without improving "Bulk Power System" system reliability. The SERC VMS believes that the applicability provision of the standard should instead focus attention of the standard only on the transmission lines below 200 kV that directly impact "Bulk Power System" reliability, as the current version requires.

In sum, while the SERC VMS recognizes some validity in the Commission's concern, the SERC VMS recommends that the applicability provision of this standard should be revised only if existing system design, planning or operating reliability criteria and parameters are considered as a basis for defining the applicability of the standard. To that end, the SERC VMS recommends each Regional Entity (RE) determine applicability of FAC-003 to those lines within the region that are between 100 kV and 200 KV if and only if they are identified as operationally significant elements of Interconnection Reliability Operating Limits ("IROLs").

IEEE Standard for Minimum Clearances:
The SERC VMS disagrees with objections in the FERC staff report to the use of the IEEE 516-2003 clearance as the minimum acceptable distances for "Clearance 2". The IEEE 516-2003 tables are appropriate for defining the minimum acceptable clearances to prevent flashover between conductors and vegetation under all rated electrical operating conditions. Closer minimum clearances such as the minimum length of a support insulator could have been adopted as a "lowest common denominator" clearance. However the clearance in IEEE 516-2003 was adopted to ensure an additional margin of reliability. FERC staff references ANSI Z-133 which is a safety standard that addresses worker safety as well as the safety of the general public. As such, the purpose of ANSI Z-133 is to address worker safety and is not focused on transmission line reliability, which is the purpose of FAC-003-1. OSHA, NESC and other related safety standards have clearances in excess of IEEE 516-2003. Those clearances are clearly focused on safety issues and will still apply to other aspects of design and operation of electric facilities (such as public and worker safety) but do not need to be referenced in a vegetation management reliability standard.

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

☒ Yes

☐ No

Comments: Standard Applicability:
The outage reporting requirement for the RRO should be deleted. Making FAC-003 applicable to the RRO is in violation of the legislation that established the ERO. This legislation states that enforceable standards can apply only to owners, users and operators of the bulk power system. Futher, in the NOPR on NERC standards, FERC declined to approve those standards that applied to the RROs, in part because the RROs are not owners, users or operators.

Compliance:
The SERC VMS recommends deleting reporting requirements for Category 3 outages. These outages are not controllable, not relevant to compliance, not related to grid reliability, not related to cascading blackouts, and such reporting leads to unnecessarily biasing reliability related information.

Please use this form to submit comments on the Vegetation Management SAR. Comments must be submitted by **February 14, 2007.** You may submit the completed form by e-mail to sarcomm@nerc.com with the words "Vegetation Management" in the subject line. Background Information:

FAC-003-1 is a relatively new standard that was approved in 2006. FAC-003 has some "fill-in-the-blank" components to eliminate. In addition, the following comments submitted by FERC and stakeholders need to be addressed in the refinement of the standard:

FERC NOPR

- Develop a minimum vegetation inspection cycle that allows variation for physical differences, as discussed above; and
- Remove the applicability to transmission lines operated at 200 kV and above so that the Reliability Standard applies to bulk power system transmission lines that have an impact of reliability as determined by the ERO.

FERC staff report

- Objections to use of IEEE standard

Stakeholder Comments

- Reliability Coordinator vs. Regional Reliability Organization
- Too weak on compliance
- Format inconsistencies

The improvements to the standard should bring the standard's format and elements into conformance with the latest version of the *Reliability Standards Development Procedure* and the ERO Rules of Procedure.

The development may include other improvements to the standards deemed appropriate by the drafting team, with the consensus of stakeholders, consistent with establishing high quality, enforceable and technically sufficient bulk power system reliability standards.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that there is a reliability-related need to address the proposed revisions to FAC-003-1 — Transmission Vegetation Management? If not, please explain in the comment area.

   ☒ Yes

   ☐ No

   Comments:

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: We disagree with the proposal from FERC NOPR regarding removing applicability to transmission lines >200kv. The proposal to apply the Standard to lines the ERO deems to have an impact on reliability can create inconsistency between regions and is a "fill in the blank" requirement. It is not clear whether the proposed change would increase or decrease the number of transmission lines which are subject to reportable outages. In addition, we support the Standard's existing language that limits reporting to locked out lines only.

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

   ☐ Yes

   ☒ No

1. Do you agree that there is a reliability-related need to address the proposed revisions to FAC-003-1 — Transmission Vegetation Management? If not, please explain in the comment area.

   ☒ Yes

   ☐ No

   Comments:

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

   ☒ Yes

   ☒ No

   Comments: The scope of this SAR would have been better defined if the complete Standard Review Form for the Vegetation Management Standard had been included as an attachment to the SAR. Several issues in the Standard Review Form for this SAR were excluded with this posted SAR. For example, issues related to R3.1 and R3.2.

   The MRO is also not clear on the scope of the instruction to the SDT to "Expand the applicability to include transmission lines operated at 200 kV and above and other facilities as determined by the ERO so that the Reliability Standard applies to Bulk-Power System transmission lines that have an impact on reliability" It is not clear to the MRO what is meant by "as determined by the ERO". What process will the ERO use? The ERO should use stakeholder input to make this determination. The current standard is applicable to all transmission lines 200 kV and above and to any lower voltage lines designated by the RRO as critical to the electric system in the region. Will the ERO be in a position to assume the assessment of the criticality of lines less than 200 kV without input from the entities that have historically operated in each region?

   Also, the MRO is not clear on what is included in the term Bulk-Power System. What guidance will the SDT have in determining what is meant by the Bulk-Power System? Since this relates to the large issue of the Bulk Electric System versus Bulk-Power System is this SAR the appropriate vehicle to address this issue? There should be a wider discussion and resolution to this issue for consistent application to all standards by all SDTs.

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

   ☒ Yes

   ☐ No

   Comments: Since the IEEE standard does not appear to be a favorable clearance requirement, minimum clearance requirements should be tied to legal documents such as easments, state statute, or permits. This will help Transmission Owners to maintain their ROWs based on their agreements with the land owners and not rely on historical ROW management practices. It would also provide flexibility in clearance requirements based on geopraphical and climatological factors that influence different regions because landowner agreements will be different depending on local influences.

1. Do you agree that there is a reliability-related need to address the proposed revisions to FAC-003-1 — Transmission Vegetation Management? If not, please explain in the comment area.

   ☒ Yes

   ☐ No

   Comments: FPL recognizes the need to address the concerns outlined in the NOPR and by the FERC Staff.

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: Establishing minimum inspection cycles is a very problematic given the large variety of vegetative conditions throughout North America. In reality most lines are inspected annually for all failure modes including vegetation. The trees that played a part of the North East Blackout were known and on the radar screen. The utility failed to take action. The inspection did not prevent the outage from occurring. The failure to take action on the known site condition was the contributing factor to the Blackout.

   We do not understand the need to establish separate criteria other than the RRO’s critical designation. A transmission line is either necessary to the system to prevent an overload situation or it is not. To add lines that might not be critical to the system would dilute the effort needed to insure that the critical lines are properly maintained. Since system stability is the focus of the standard, what criteria would be used to bring additional lower voltage lines under the standard.

   When developing Clearance 2, the committee needed to determine a distance at which a Transmission Owner could be out of compliance even though no interruption has occurred. In a sense this is the maximum ‘speed limit’ at which the utility would be in violation. Their criteria was “How close can a tree be and not cause an outage?” The engineers on the team reviewed scientific data and current standards. The IEEE MAID standard was the consensus selection of the sub committee. All parties need to understand that this is one of the building blocks that would be used in determining the width of an easement or ROW. Picking the ANSI Z133.1 Table 1 or 2 as the NOPR suggests could immediately place thousands of miles of transmission lines out of compliance that have performed satisfactorily for years. The ANSI tables are phase to phase safety calculations when grow-in tree interruptions are phase to ground situations.

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

☒ Yes

☐ No

Comments: Requirement 3.2 exempts reporting of outages from outside the ROW when natural disasters such as tornados or hurricanes occur. Our experience with numerous hurricanes indicates that all outages during these types of events should be exempt. The focus in these situations is to get the lines back in service and restore customers. There is insufficient manpower to adequately complete the forensics necessary to determine an accurate root cause. It is not uncommon to find vegetation debris in the lines or downed trees on the ROW in this situation. In most cases it is not possible to determine the original location of these trees.

In the compliance section of the document a transmission owner becomes non compliant with a single category 1 or 2 outage. This occurs regardless of the circumstances. A non compliant penalty for a single outage in a situation where no customers were affected and the system could not have been compromised is not reasonable. It is also not an indicator of a poorly maintained system. We agree that several Category 1 or 2 interruptions could be an indicator of neglect but one is not. We recommend that The compliance section be reviewed with this in mind.

The improvements to the standard should bring the standard's format and elements into conformance with the latest version of the *Reliability Standards Development Procedure* and the ERO Rules of Procedure.

The development may include other improvements to the standards deemed appropriate by the drafting team, with the consensus of stakeholders, consistent with establishing high quality, enforceable and technically sufficient bulk power system reliability standards.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a “check” mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that there is a reliability-related need to address the proposed revisions to FAC-003-1 — Transmission Vegetation Management? If not, please explain in the comment area.

   ☒ Yes

   ☐ No

   Comments:
   NERC as the ERO along with its regulated stakeholders need to use the Standards Process to continue refining the industry's suite of standards, especially to address inconsistencies within the standards. The process also serves to address real or perceived reliability concerns in a balanced and open forum.

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: As stated in this SAR comment form, the improvements should be made to bring the standard into conformance with the Reliability Standards Development Procedure which at this time is version 6.0, adopted by NERC BOT, 11/1/2006. The SAR scope via the attached Standard Review Guidelines includes two areas not defined within the procedure. The Mitigation Time Horizons and definitions for the violation severity levels (VSLs), Lower, Moderate, High and Severe.

   We understand the description of Mitigation Time Horizons and definitions for VSLs are included in the SAR (the concept of Violation Time Horizons is included in the Sanctions Guidelines, appendix 4B, NERC Compliance Filing to FERC dated October 18th, 2006), but these discrepancies are part of a broader policy issue and since their use is not clearly stipulated in the NERC Reliability Standards Development Procedure, including them in the scope of the SAR is premature and will cause unnecessary confusion to stakeholders and regulators.

   The process is requesting the industry to comment on a scope that is defined outside the reliability standards process and as such is subject to revisions and interpretations outside the process as well. This appears inappropriate and at the extreme will lead to inconsistent understanding, measurement and enforcement of compliance actions.

   The Mitigation Time Horizons and VSL levels should be defined in the Reliability Standards Development Procedure prior to inclusion in the scope of a SAR.

   Specific Items Within Current SAR Scope:

   The establishment of minimum inspection cycles has been addressed previously, in the development of the current standard and was found very problematic given the large variety of vegetative conditions throughout North America. The vegetation that was identified as a contributing cause to the 2003 Northeast Blackout had already been identified by previous inspection activities. It was the failure to take action on the known site conditions that contributed to the event. Therefore, a minimum inspection cycle would still NOT have prevented or mitigated the scope of the Blackout.

The current 200 kV threshold ensures that vegetation management efforts are focused on the critical bulk power transfer lines and that TVM efforts are not diluted by including additional lower voltage lines. In practicality, the RRO designation process provides the necessary flexibility to the Regions to address localized areas where bulk power system reliability may be compromised by lower voltage vegetation outages. To note as well, Northeast Blackout related vegetation outages which initiated the cascade occurred on lines that operate at 345 kV, well above the current threshold.

The FRCC supported the development of Clearance 2, as established in the current standard, as this was a consensus selection by not only the subject matter experts, but many industry participants. Picking the ANSI Z133.1 Table 1 or 2 as the NOPR suggests, could immediately place thousands of miles of transmission lines out of compliance even though operating data indicates that the lines have performed satisfactorily for years. The concern would be, the resulting dilution of valuable industry and regulator resources.

The SAR includes the following stakeholder comment: "Too weak on compliance" .
We caution that we feel the compliance section does need refining, but that in a world of limited resources should focus on trends in vegetation outages and not necessarily on single outages. For transmission owners, two outages on a radial 230 kV circuit should not carry the same penalty as eight outages on multiple 230 kV circuits within a network. We would recommend that compliance be refined to identify trends, relevance and risk probability to help the industry focus their resources appropriately.

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

☒ Yes

☐ No

Comments:
Requirement 3.2, item (1), the reporting exemption for outages occuring due to natural disaters should be expanded to include all vegetation outages that occur as a result of the disaster. Currently the exemption applies to vegetation from outside the ROW.

As a result of significant experience with hurricanes, our operators have found that this distinction results in a waste of post-disaster resources. The standard currently requires the owner to investigate and determine the original location of the vegetation that may have caused an outage. Restoration of circuits may be delayed and often times, determination of the original location of the vegetation is not possible .

1. Do you agree that there is a reliability-related need to address the proposed revisions to FAC-003-1 — Transmission Vegetation Management? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: The proposed revisions listed under the FERC NOPR do not provide proper justification to alter the requirements in the current FAC-003-1 document that was adopted one year ago.

   First, "a minimum vegatation inspection cycle that allows variation in physical difference" is already called for under the current standard. As stated in Section R1.1. of FAC-003-1, a schedule already should be defined under the transmission vegetation management program (TVMP). This schedule already allows for "variation in physical difference" since the current standard states that "this schedule should be flexible enough to adjust for changing conditions."

   Secondly, under Applicability Section 4.3., the current standard already allows for lines with lower voltage than 200kV to be "designated by the RRO as critical" and therefore applicable to the standard. Removal of the 200kV benchmark is not needed.

   And lastly, under the FERC staff report, the IEEE standard provides guidance in clearances and has been the industry standard for many years. If FERC objects to using this standard then they should provide clearances that can be discussed and agreed upon by the transmission owners.

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: See comments above.

1. Do you agree that there is a reliability-related need to address the proposed revisions to FAC-003-1 — Transmission Vegetation Management? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: There was no empirical or anecdotal evidence presented by FERC staff to support the Commission's view that the reliability of the Bulk Power System will be enhanced with further revisions to FAC-003-1. This standard was the subject of vigorous industry debate in a previous SAR. Although it is far from perfect, the proposed revisions will not improve reliability and may very well damage existing VM programs.

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: The Commission's reccomendation to develop a "minimum" vegetation inspection cycle is untimely and their proposal to revise the scope ignores plain language contained in the standard.

   In SCE’s view, the Commission's incessant need to bolt on a "widget count" requirement (for minimum inspection cylcles) will likely lead to an increased number of tree-to-line contacts. Unlike the static equipment located in power plants and substations, trees and foliage in and around Transmission ROWs are subject to uncontrolable and fairly unpredictable natural forces. Industry debate during the previous SAR and comments submitted in the recently concluded NOPR demonstrate this approach is unsound. Transmission Owners in neighboring states commented that their cycles and trimming protocols vary from year to year and sometimes circuit to circuit. Instituting a minimum inspection cycle of 3 years (for example) might appeal to certain TOs because doing so will support a case for increased rate recovery. But for others, a mandatory 3 year inspection cycle will offer a potential cost reduction opportunity because they are already following a voluntary 2 year inspection cycle.

   The Commission's other reccomendedation should be rejected because subsection 4.3 clearly covers transmission lines operating below 200 kV. ["….any lower voltage lines designated by the RRO as critical to the reliabilty of the electric system in the region.”]

   FAC-003-1 requires Transmission Owners to - “define a schedule for and the type (aerial, ground) of ROW vegetation inspections”. Although the Commission staff would prefer a specific time duration because it suits their "check list" style of enforcement, the prudent thing to do is allow TOs the latitude to manage their part of the bulk system and hold each accountable to the existing compliance measures in FAC-003-1. Similarly, revising subsection 4.3 in deferrence to the Commission's or staff's misinterpretation of plain text is unwarranted.

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

   ☐ Yes

   ☒ No

   Comments: Although SCE is wholly dissatisfied with the integration of IEEE 516-2003 into FAC-003-1 and looks forward to the day when qualified industry professionals and utility arborists are provided an opportunity to develop a reasonable and scientifically sound method for determining “minimum” tree-to-line clearances, we believe this standard should be allowed to “soak” a bit before subjecting it to further revision.

Background Information:

FAC-003-1 is a relatively new standard that was approved in 2006. FAC-003 has some "fill-in-the-blank" components to eliminate. In addition, the following comments submitted by FERC and stakeholders need to be addressed in the refinement of the standard:

FERC NOPR
- Develop a minimum vegetation inspection cycle that allows variation for physical differences, as discussed above; and
- Remove the applicability to transmission lines operated at 200 kV and above so that the Reliability Standard applies to bulk power system transmission lines that have an impact of reliability as determined by the ERO.

FERC staff report
- Objections to use of IEEE standard

Stakeholder Comments
- Reliability Coordinator vs. Regional Reliability Organization
- Too weak on compliance
- Format inconsistencies

The improvements to the standard should bring the standard's format and elements into conformance with the latest version of the *Reliability Standards Development Procedure* and the ERO Rules of Procedure.

The development may include other improvements to the standards deemed appropriate by the drafting team, with the consensus of stakeholders, consistent with establishing high quality, enforceable and technically sufficient bulk power system reliability standards.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that there is a reliability-related need to address the proposed revisions to FAC-003-1 — Transmission Vegetation Management? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: The current standard contains appropriate levels of guidelines and penalties to ensure the owners vegetation management program is implemented and managed to ensure the reliability of the transmission system. Mandating inspection cycle frequencies will not enhance nor ensure reliability by inspecting more or less frequently. The minimum vegetation clearances at maximum operating conditions that are established within the owner's program that are auditable by the ERO will ensure reliability. By adding lines other than those >200KV may reduce the focus on those lines and impact the budget dollars allocated to focus on the lines >200KV. Generally easements are much more narrow on lower voltage lines, the impact on budget dollars would often require more emphasis on these lines. This may have an effect on the ability to focus clearing efforts on those lines that will have a much greater impact on the bulk power system. The IEEE standard when used as the minimum clearance distance at maximum operating condition will ensure reliability when these clearances are maintained by vegetation management activities.

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments:
   Minimum Inspection Intervals:
   Progress Energy believes that this standard provides the proper amount of flexibility regarding vegetation inspection cycles and that the FAC-003 standard revision should not develop minimum inspection intervals on a continent with such regional diversity in climate and plant life.

   The purpose of Requirement 1.1 of standard FAC-003-1 is to put the responsibility for proper inspection cycles on the entity that knows the local conditions and can best define what that inspection frequency should be, the Transmission Owner. Both NERC and the FERC staff have recognized that various local conditions can have an affect on the determination of adequate inspection frequencies. Establishing a mandatory minimum inspection frequency could have two detrimental effects on the industry.

   First, where a particular region is heavily forested and has heavy rainfall along with extended or year round growing seasons, a "back stop" minimum inspection frequency could lead transmission owners to conduct inspections less frequently than what the local conditions require. This could result in a Transmission Owner complying with the standard while not adequately protecting the reliability of that region's transmission system. This is a "lowest common denominator" approach which FERC has repeatedly stated is inappropriate for the reliability standards.

Second, where a particular region is arid, sparsely forested or has a minimum growing season, a “back stop” minimum could require a more frequent interval than is realistically needed. This would result in increased and unnecessary costs for electric utility customers without providing an increase in system reliability.

In its discussion of inspection intervals, FERC indicates that a “one-year vegetation inspection cycle is reasonable.” NOPR, P 383. The Commission continues by stating “a one-year inspection cycle is the ‘norm’ for the industry, but not the lowest common denominator…” It follows from this observation that the industry as a whole recognizes and follows appropriate inspection intervals without a need to change the standard. Further, FERC also states “some variation to a continent-wide, one-year minimum inspection cycle should be allowed due to physical differences such as climate and species of vegetation.” NOPR, P 382. FERC’s express recognition that a “one size fits all” approach is not appropriate further supports Progress Energy’s contention that the existing inspection requirements in standard FAC-003 should remain unchanged.

Finally, the performance metrics of proposed standard FAC-003 require the reporting of applicable transmission interruptions that are caused by vegetation. This process should appropriately identify Transmission Owners’ inspection cycles that are not adequate. In this event, the ERO has the authority to engage the Transmission Owner in enforcement compliance actions and, therefore, can remedy any vegetation-related outage that is attributed to the Transmission Owner’s inspection frequency.

Standard Applicability:
Progress Energy disagrees with the proposal to revise the 200 kV guidepost for determining facilities subject to this standard.

The majority of transmission facilities below 200 kV have significantly different design/construction/operating characteristics and have not been cited as impacting bulk power system reliability. For example, the 2003 DOE “Blackout Report,” and all referenced major blackouts in the Report, cited only outages which involved vegetation at line voltages above 200 kV. The characteristics of lines below 200 kV will result in significant documentation and reporting of items such as restrictions, mitigation plans, off right-of-way vegetation-related outage investigation/information and other issues, all of which dilutes the focus on lines that directly impact bulk power system reliability.

Revising the standard to use general criteria or broad language for defining "Bulk Power System" transmission lines covered by the standard could become a “one size fits all” approach. If that approach were taken, the standard would cover a significant number of transmission lines that have no direct impact on bulk power system reliability under standard planning/operating conditions, resulting in a significant increase in costs for electric customers without improving “Bulk Power System” system reliability. Progress Energy believes that the applicability provision of the standard should instead focus attention of the standard only on the transmission lines below 200 kV that directly impact “Bulk Power System” reliability, as the current version requires.

In sum, while Progress Energy recognizes some validity in the Commission’s concern, Progress Energy recommends that the applicability provision of this standard should be revised only if existing system design, planning or operating reliability criteria and parameters are considered as a basis for defining the applicability of the standard. For example, it may be appropriate to limit the applicability of the standard to all lines that are operated at 200 kV and above and to operationally significant circuits between 100 kV and 200 KV that are elements of Interconnection Reliability Operating Limits (“IROLs”).

IEEE Standard for Minimum Clearances:
Progress Energy disagrees with objections in the FERC staff report to the use of the IEEE 516-2003 clearance as the minimum acceptable distances for “Clearance 2”. The IEEE

516-2003 tables are appropriate for defining the minimum acceptable clearances to prevent flashover between conductors and vegetation under all rated electrical operating conditions. Closer minimum clearances such as the minimum length of a support insulator could have been adopted as a "lowest common denominator" clearance. However the clearance in IEEE 516-2003 was adopted to ensure an additional margin of reliability. FERC staff references ANSI Z-133 which is a safety standard that addresses worker safety as well as the safety of the general public. As such, the purpose of ANSI Z-133 is to address safety and is not focused on transmission line reliability, which is the purpose of FAC-003-1. OSHA, NESC and other related safety standards have clearances in excess of IEEE 516-2003. Those clearances are clearly focused on safety issues and will still apply to other aspects of design and operation of electric facilities (such as public and worker safety) but do not need to be referenced in a vegetation management reliability standard. Reliability standards are not the appropriate forum for addressing safety standards or issues, such as worker safety. The reliability standards should focus on reliability issues.

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

☒ Yes

☐ No

Comments: Standard Applicability:
The outage reporting requirement for the RRO should be deleted. Making FAC-003 applicable to the RRO is in violation of the legislation that established the ERO. This legislation states that enforceable standards can apply only to owners, users and opeartors of the bulk power system. Futher, in the NOPR on NERC standards, FERC declined to approve those standards that applied to the RROs, in part because the RROs are not owners, users or operators.

Compliance:
Progress Energy believes that FAC-003 should focus compliance on the issues that improve system/grid reliability. The VM standard outage reporting requirements do not focus on ensuring grid/network reliability.
Category 2 outages ("Fall-ins" from vegetation within the R/W) result in a level of non-compliance (Level 2 or 3). However, "Fall-ins", either off-R/W or within the R/W, are random events. They would not occur sequentially (i.e., a fall-in causing another line section to overload resulting in another "fall-in") and would not have the potential to cascade into a widespread blackout. This is a customer reliability issue for that line, not a grid reliability issue. While it may be worthwhile to report for tracking and trending, it is not an outage that should result in non-compliance.
Category 1 "Grow-ins" include outages that result from conductor side-wing would be reported as Category 1 outages, resulting in non-compliance (Level 3 or 4). However, conductor side-swing outages are random occurrences. They are not the sequential outages that would have the potential to cascade into a widespread blackout. This is a customer reliability issue for that line, not a grid reliability issue.
These types of outages should be not be considered any different than numerous other random events that result in transmission line outages.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that there is a reliability-related need to address the proposed revisions to FAC-003-1 — Transmission Vegetation Management? If not, please explain in the comment area.

   ☐ Yes
   ☒ No

   Comments: The current draft FAC 003 1 will provide a high level of reliability for the transmission bulk delivery system which the public now expects. After a comprehensive industry rewiew which included industry balloting, the current Vegetaion Management Standard 003 1 was approved in Feburary 2006 and several sections did not go in to effect for one year (2007). Sufficient time should be allowed so that impact of the current standard can be monitored.
   FAC 003 1 was designed to prevent cascading type outages and by establishing a standard for 200KV lines and above catastrophic type power outages will be eliminated. Lower volatge lines can be placed under this standard when the impact on the bulk delivery system requires tighter management as determined by local reliability organizations. Inspection cycles must be designed to meet regional needs based on local conditons, and the current standard provides this flexiblity.

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

   ☐ Yes
   ☒ No

   Comments: The current standard FAC 003 1 should be monitored for one to two full years after all segments have been implemented. February 14, 2007 is too soon to determine if a revision is required.
   The standard should apply to 200 KV lines and higher voltages to prevent cascading type power outages.
   The IEEE table 516 is referenced as a minimum guide for table 2 clearances. This table provides clear and measurable distances that can used for audits and potential compliance issues. The current standard allows enough flexibility so that the clearance 2 distance can be expanded if a utility feels that is the correct approach in a specfic region.
   The physical differences between electric systems, tree growth rates, local regulations, climate, and geography make it important to provide a flexible standard, a "one size fits all" approach will not be effective in the long run.

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

   ☐ Yes
   ☒ No

Comments: The Vegetation Management Standard FAC 003 1 is comprehensive, and utilities following the established guidelines will be able to meet FERC's expecation of preventing bulk power delivery outages by using crisp measurable guidleines that offer limited flexiblity for varying conditions.

The improvements to the standard should bring the standard's format and elements into conformance with the latest version of the *Reliability Standards Development Procedure* and the ERO Rules of Procedure.

The development may include other improvements to the standards deemed appropriate by the drafting team, with the consensus of stakeholders, consistent with establishing high quality, enforceable and technically sufficient bulk power system reliability standards.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that there is a reliability-related need to address the proposed revisions to FAC-003-1 — Transmission Vegetation Management? If not, please explain in the comment area.

   ☒ Yes

   ☒ No

   Comments: We are not sure what you are asking? If you are asking whether we support the standard as it exists today-Southern does! If you are asking whether Southern Co. supports the changes being recommended in this Standard-we DON"T.

   The present standard appears to be serving its intended purpose and the industry as currently written. The standard should not be revised until it has demonstrated it is ineffective or inadequate for ensuring the reliability of the nation's transmssion grid.

   Any changes to the standard should be based on empirical data rather than the assumption that the Standard is not serving its intended purpose. The standard has not been in effect long enough to determine if it is ineffective.

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: The scope of the SAR should be limited to formatting and changes of wording that recognize the formation of the ERO and its procedures.

   The drafting team should not attempt to re-write the present clearance requirements, which are based on IEEE flashover distances. The clearance requirements in the orignal standard were written through extensive evaluation and input from the industry. There was strong industry consensus on the present language and the standard is serving its intended purpose very well. The clearance standard should not be revised until it is found to be ineffective or inadequate.

   The drafting team should not attempt to change the applicability of the present standard. The present standard applies to all 200 KV and higher lines, plus any other line the Regional Entity deems critical. A change in wording to make the standard apply to any bulk power system transmission line deemed critical by the ERO does not provide any additional safeguard that is not already contained in the standard as presently written.

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

   ☐ Yes

☒ No

   ☒ No

   Comments:
   With respect to the item in the Brief Description section under FERC NOPR:
   "Remove the applicability to transmission lines operated at 200 kV and above so that the Reliability Standard applies to Bulk Power System transmission lines that have an impact on reliability as determined by the ERO." It is the IESO's view that requiring the ERO to make these determinations, is inappropriate. We believe the standard should remain applicable to lines 200 kV and above and lines below 200 kV as determined by the Reliability Coordinator, similar to the PRC-023 standard.

   The IESO also suggests that it be made clear in the SAR that it will be a complete review of the subject requirements: to include the addition, deletion and modification of requirements, as agreed to by public consensus.

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

   ☐ Yes

Background Information:

FAC-003-1 is a relatively new standard that was approved in 2006. FAC-003 has some "fill-in-the-blank" components to eliminate. In addition, the following comments submitted by FERC and stakeholders need to be addressed in the refinement of the standard:

FERC NOPR

- Develop a minimum vegetation inspection cycle that allows variation for physical differences, as discussed above; and
- Remove the applicability to transmission lines operated at 200 kV and above so that the Reliability Standard applies to bulk power system transmission lines that have an impact of reliability as determined by the ERO.

FERC staff report

- Objections to use of IEEE standard

Stakeholder Comments

- Reliability Coordinator vs. Regional Reliability Organization
- Too weak on compliance
- Format inconsistencies

The improvements to the standard should bring the standard's format and elements into conformance with the latest version of the *Reliability Standards Development Procedure* and the ERO Rules of Procedure.

The development may include other improvements to the standards deemed appropriate by the drafting team, with the consensus of stakeholders, consistent with establishing high quality, enforceable and technically sufficient bulk power system reliability standards.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that there is a reliability-related need to address the proposed revisions to FAC-003-1 — Transmission Vegetation Management? If not, please explain in the comment area.

   ☒ Yes

   ☒ No

   Comments: As worded this question is confusing however the following comments are presented on the SAR:

   The current standard contains appropriate requirements and measures to ensure that vegetation related outages will not cause cascading transmission blackouts. Mandating new expiicit inspection cycle frequencies will not enhance nor ensure reliability by inspecting more or less frequently. The current minimum vegetation clearances at maximum operating conditions that are established within the owner's program, which is auditable by the ERO, is sufficient to prevent vegetation related cascading transmission blackouts. Extending the requirements to a much a larger population of lines would reduce the current focus on the most important lines (those >200 kV). The IEEE standard when used as the minimum vegetation clearance distance at maximum operating condition will ensure desired performance of the lines. A standard of zero tolerance for vegetaion related outages in the ROW is not a weak standard on compliance.

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: Minimum Inspection Intervals:

   FAC 003-1 provides the proper amount of flexibility regarding vegetation inspection cycles and that the Standards Drafting Team should not impose minimum inspection intervals on a continent with such regional diversity in climate and plant life.

   Requirement 1.1 of standard FAC-003-1 places the responsibility for proper inspection cycles on the entity that knows the local conditions and can best define what that inspection frequency should be, the Transmission Owner. Both NERC and the FERC staff have recognized that various local conditions can have an affect on the determination of adequate inspection frequencies. Establishing a mandatory minimum inspection frequency could have two detrimental effects on the industry.

   First, where a particular region is heavily forested and has heavy rainfall along with extended or year round growing seasons, a "back stop" minimum inspection frequency could lead transmission owners to conduct inspections less frequently than required by the local conditions. This could result in a Transmission Owner complying with the standard while not adequately protecting the reliability of that region's transmission system. This is a "lowest common denominator" approach which FERC has repeatedly stated is inappropriate for the reliability standards.

Second, where a particular region is arid, sparsely forested or has a minimum growing season, a "back stop" minimum could require a more frequent interval than is realistically needed. This would result in increased and unnecessary costs for electric utility customers without providing an increase in system reliability.

In its discussion of inspection intervals, FERC indicates that a "one-year vegetation inspection cycle is reasonable." FERC NOPR, 10/20/2002 paragraph 383. The Commission continues by stating "a one-year inspection cycle is the 'norm' for the industry, but not the lowest common denominator…" It follows from this observation that the industry as a whole recognizes and follows appropriate inspection intervals without a need to change the standard. Further, FERC also states "some variation to a continent-wide, one-year minimum inspection cycle should be allowed due to physical differences such as climate and species of vegetation." FERC NOPR 10/20/2006, paragraph 382. FERC's recognition that a "one size fits all" approach is not appropriate supports maintaining the existing inspection requirements in standard FAC-003-1.

Finally, the performance metrics of FAC-003 require the reporting of applicable transmission interruptions that are caused by vegetation. This process will identify Transmission Owners' inspection cycles that are not adequate. In this event, the ERO has the authority to engage the Transmission Owner in enforcement compliance actions and, therefore, can remedy any vegetation-related outage that is attributed to the Transmission Owner's inspection frequency.

Standard Applicability:
The 200 kV threshold for determining facilities subject to this standard should not be revised.

The transmission facilities below 200 kV have not been cited as impacting bulk power system reliability. The Final Report on the August 14, 2003 Blackout in the United states and Canada: Causes and Recommendations April 2004 by the U.S.- Canada Power System Outage Task Force and all referenced major blackouts(pages 103-115) in that report, cited only outages which involved vegetation at line voltages above 200 kV. Generally applying requirements appropriate for 200 kV lines to lines less than 200 kV will result in significant documentation and reporting of items such as restrictions, mitigation plans, off right-of-way vegetation-related outage investigation/information and other issues, all of which dilutes the focus on lines that directly impact bulk power system reliability.

Revising the standard to use general criteria or broad language for defining "Bulk Power System" transmission lines covered by the standard could become a "one size fits all" approach. If that approach were taken, the standard would cover a significant number of transmission lines that have no direct impact on bulk power system reliability under standard planning/operating conditions, resulting in a significant increase in costs for electric customers without improving "Bulk Power System" system reliability. The SERC VMS believes that the applicability provision of the standard should instead focus attention of the standard only on the transmission lines below 200 kV that directly impact "Bulk Power System" reliability, as the current version requires.

The applicability provision of this standard should be revised only if existing system design, planning or operating reliability criteria and parameters are considered as a basis for defining the applicability of the standard. To that end, each Regional Entity (RE) should determine the applicability of FAC-003 to those lines within the region that are between 100 kV and 200 KV if and only if they are identified as operationally significant elements of Interconnection Reliability Operating Limits ("IROLs").

IEEE Standard for Minimum Clearances:

The IEEE 516-2003 should continue to be used as the minimum acceptable distances for "Clearance 2". The IEEE 516-2003 tables are appropriate for defining the minimum acceptable clearances to prevent flashover between conductors and vegetation under all rated electrical operating conditions. Closer minimum clearances such as the minimum length of a support insulator could have been adopted as a "lowest common denominator" clearance. However the clearance in IEEE 516-2003 was adopted to ensure an additional margin of reliability. FERC staff references ANSI Z-133 which is a safety standard that addresses worker safety as well as the safety of the general public. As such, the purpose of ANSI Z-133 is to address worker safety and is not focused on transmission line reliability, which is the purpose of FAC-003-1. OSHA, NESC and other related safety standards have clearances in excess of IEEE 516-2003. Those clearances are clearly focused on safety issues and will still apply to other aspects of design and operation of electric facilities (such as public and worker safety) but do not need to be referenced in a vegetation management reliability standard.

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

   ☒ Yes

   ☐ No

   Comments: Standard Applicability:
   The outage reporting requirement for the RRO should be deleted. Making FAC-003 applicable to the RRO is in violation of the legislation that established the ERO. This legislation states that enforceable standards can apply only to owners, users and operators of the bulk power system. Futher, in the NOPR on NERC standards, FERC declined to approve those standards that applied to the RROs, in part because the RROs are not owners, users or operators.

   Compliance:
   Reporting requirements for Category 3 outages should be eliminated. These outages are not controllable, not relevant to compliance, not related to grid reliability, not related to cascading blackouts, and such reporting leads to unnecessarily biasing reliability related information.

1. Do you agree that there is a reliability-related need to address the proposed revisions to FAC-003-1 — Transmission Vegetation Management? If not, please explain in the comment area.

   ☒ Yes

   ☒ No

   Comments: The SERC VMS is unsure how to answer the question as it is worded, but has the following comments on the SAR:

   The current standard contains appropriate requirements and measures to ensure the owners vegetation management program is implemented and managed to ensure the reliability of the transmission system. Mandating inspection cycle frequencies will not enhance nor ensure reliability by inspecting more or less frequently. The minimum vegetation clearances at maximum operating conditions that are established within the owner's program, which is auditable by the ERO, will ensure reliability. Extending the requirements to lines other than those >200KV may reduce the focus on those lines and may cause the allocation of resources away from lines >200KV. Generally easements are narrower on lower voltage lines, requiring more resources and emphasis on these lines. This may have an effect on the ability to focus clearing efforts on those lines that will have a much greater impact on the bulk power system. The IEEE standard when used as the minimum clearance distance at maximum operating condition will ensure reliability when these clearances are maintained by vegetation management activities. In addition, we do not agree that a standard of zero tolerance for vegetaion-related outages in the ROW is weak on compliance.

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: Minimum Inspection Intervals:
   The SERC VMS believes that FAC 003-1 provides the proper amount of flexibility regarding vegetation inspection cycles and that the Standards Drafting Team should not impose minimum inspection intervals on a continent with such regional diversity in climate and plant life.

   The purpose of Requirement 1.1 of standard FAC-003-1 is to put the responsibility for proper inspection cycles on the entity that knows the local conditions and can best define what that inspection frequency should be, the Transmission Owner. Both NERC and the FERC staff have recognized that various local conditions can have an affect on the determination of adequate inspection frequencies. Establishing a mandatory minimum inspection frequency could have two detrimental effects on the industry.

   First, where a particular region is heavily forested and has heavy rainfall along with extended or year round growing seasons, a "back stop" minimum inspection frequency could lead transmission owners to conduct inspections less frequently than required by the local conditions. This could result in a Transmission Owner complying with the standard while not adequately protecting the reliability of that region's transmission system. This is a "lowest common denominator" approach which FERC has repeatedly stated is inappropriate for the reliability standards.

Second, where a particular region is arid, sparsely forested or has a minimum growing season, a "back stop" minimum could require a more frequent interval than is realistically needed. This would result in increased and unnecessary costs for electric utility customers without providing an increase in system reliability.

In its discussion of inspection intervals, FERC indicates that a "one-year vegetation inspection cycle is reasonable." FERC NOPR, 10/20/2002 paragraph 383. The Commission continues by stating "a one-year inspection cycle is the 'norm' for the industry, but not the lowest common denominator…" It follows from this observation that the industry as a whole recognizes and follows appropriate inspection intervals without a need to change the standard. Further, FERC also states "some variation to a continent-wide, one-year minimum inspection cycle should be allowed due to physical differences such as climate and species of vegetation." FERC NOPR 10/20/2006, paragraph 382. FERC's express recognition that a "one size fits all" approach is not appropriate further supports the SERC VMS's contention that the existing inspection requirements in standard FAC-003-1 should remain unchanged.

Finally, the performance metrics of FAC-003 require the reporting of applicable transmission interruptions that are caused by vegetation. This process should appropriately identify Transmission Owners' inspection cycles that are not adequate. In this event, the ERO has the authority to engage the Transmission Owner in enforcement compliance actions and, therefore, can remedy any vegetation-related outage that is attributed to the Transmission Owner's inspection frequency.

Standard Applicability:
The SERC VMS disagrees with the proposal to revise the 200 kV threshold for determining facilities subject to this standard.

The majority of transmission facilities below 200 kV have significantly different design/construction/operating characteristics and have not been cited as impacting bulk power system reliability. For example, the Final Report on the August 14, 2003 Blackout in the United states and Canada: Causes and Recommendations April 2004 by the U.S.-Canada Power System Outage Task Force and all referenced major blackouts(pages 103-115) in that report, cited only outages which involved vegetation at line voltages above 200 kV. Generally applying requirements appropriate for 200 kV lines to lines less than 200 kV will result in significant documentation and reporting of items such as restrictions, mitigation plans, off right-of-way vegetation-related outage investigation/information and other issues, all of which dilutes the focus on lines that directly impact bulk power system reliability.

Revising the standard to use general criteria or broad language for defining "Bulk Power System" transmission lines covered by the standard could become a "one size fits all" approach. If that approach were taken, the standard would cover a significant number of transmission lines that have no direct impact on bulk power system reliability under standard planning/operating conditions, resulting in a significant increase in costs for electric customers without improving "Bulk Power System" system reliability. The SERC VMS believes that the applicability provision of the standard should instead focus attention of the standard only on the transmission lines below 200 kV that directly impact "Bulk Power System" reliability, as the current version requires.

In sum, while the SERC VMS recognizes some validity in the Commission's concern, the SERC VMS recommends that the applicability provision of this standard should be revised only if existing system design, planning or operating reliability criteria and parameters are considered as a basis for defining the applicability of the standard. To that end, the SERC VMS recommends each Regional Entity (RE) determine applicability of FAC-003 to those lines within the region that are between 100 kV and 200 KV if and only if they are identified as operationally significant elements of Interconnection Reliability Operating Limits ("IROLs").

IEEE Standard for Minimum Clearances:
The SERC VMS disagrees with objections in the FERC staff report to the use of the IEEE 516-2003 clearance as the minimum acceptable distances for "Clearance 2". The IEEE 516-2003 tables are appropriate for defining the minimum acceptable clearances to prevent flashover between conductors and vegetation under all rated electrical operating conditions. Closer minimum clearances such as the minimum length of a support insulator could have been adopted as a "lowest common denominator" clearance. However the clearance in IEEE 516-2003 was adopted to ensure an additional margin of reliability. FERC staff references ANSI Z-133 which is a safety standard that addresses worker safety as well as the safety of the general public. As such, the purpose of ANSI Z-133 is to address worker safety and is not focused on transmission line reliability, which is the purpose of FAC-003-1. OSHA, NESC and other related safety standards have clearances in excess of IEEE 516-2003. Those clearances are clearly focused on safety issues and will still apply to other aspects of design and operation of electric facilities (such as public and worker safety) but do not need to be referenced in a vegetation management reliability standard.

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

☒ Yes

☐ No

Comments: Standard Applicability:
The outage reporting requirement for the RRO should be deleted. Making FAC-003 applicable to the RRO is in violation of the legislation that established the ERO. This legislation states that enforceable standards can apply only to owners, users and operators of the bulk power system. Futher, in the NOPR on NERC standards, FERC declined to approve those standards that applied to the RROs, in part because the RROs are not owners, users or operators.

Compliance:
The SERC VMS recommends deleting reporting requirements for Category 3 outages. These outages are not controllable, not relevant to compliance, not related to grid reliability, not related to cascading blackouts, and such reporting leads to unnecessarily biasing reliability related information.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that there is a reliability-related need to address the proposed revisions to FAC-003-1 — Transmission Vegetation Management? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: While there may be "statutory" needs to address (e.g., FERC's request to modify particular components of the existing Standard), we do not feel there is a reliability need to do so.

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: The Standard Drafting Team should not be given lattitude to "include other improvements to the standards deemed appropriate by the drafting team." The purpose of the SAR is to identify the changes contemplated by the need for the Standard Revision. If there are changes that the SAR requestor would like to make to the Standard, they should be spelled out in the SAR. If the SAR requestor does not really know the changes that should be made to the standard, then the SAR should be withdrawn until the need for a SAR can be adequately justified.

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

   ☐ Yes

   ☒ No

   Comments: We think the Standard is fine the way it is.

Background Information:

FAC-003-1 is a relatively new standard that was approved in 2006. FAC-003 has some “fill-in-the-blank” components to eliminate. In addition, the following comments submitted by FERC and stakeholders need to be addressed in the refinement of the standard:

FERC NOPR

- Develop a minimum vegetation inspection cycle that allows variation for physical differences, as discussed above; and
- Remove the applicability to transmission lines operated at 200 kV and above so that the Reliability Standard applies to bulk power system transmission lines that have an impact of reliability as determined by the ERO.

FERC staff report

- Objections to use of IEEE standard

Stakeholder Comments

- Reliability Coordinator vs. Regional Reliability Organization
- Too weak on compliance
- Format inconsistencies

The improvements to the standard should bring the standard’s format and elements into conformance with the latest version of the *Reliability Standards Development Procedure* and the ERO Rules of Procedure.

The development may include other improvements to the standards deemed appropriate by the drafting team, with the consensus of stakeholders, consistent with establishing high quality, enforceable and technically sufficient bulk power system reliability standards.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. Do you agree that there is a reliability-related need to address the proposed revisions to FAC-003-1 — Transmission Vegetation Management? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: American Electric Power believes that the current standard (when thoroughly read and understood) is completely adequate to maintain a reliable transmission system with minimum risk of vegetation-related outages.

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: American Electric Power is not aware of any evidence to support a need for revising the vegetation management standard.

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

   ☐ Yes

   ☒ No

   Comments: As stated in responses to questions 1 and 2, AEP believes that the current standard is adequate and that we are not aware of evidence to support a need for revising the current vegetation management standard.

Please use this form to submit comments on the Vegetation Management SAR. Comments must be submitted by **February 14, 2007.** You may submit the completed form by e-mail to sarcomm@nerc.com with the words "Vegetation Management" in the subject line. If you have questions, please contact Richard Schneider at richard.schneider@nerc.net or by telephone at 609-452-8060.

1. Do you agree that there is a reliability-related need to address the proposed revisions to FAC-003-1 — Transmission Vegetation Management? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: CenterPoint Energy disagrees that there is a reliability-related need to address the proposed revisions to FAC-003-1.

   This SAR proposes to establish a minimum vegetation inspection cycle for transmission facilities throughout the United States. Yet, based upon the location of each utility, different vegetation and growth rates will be experienced throughout the country. Placing a time specific vegetation management cycle for all regions does not address the wide divergence of vegetation and growth rates that each utility must face.

   For instance, in certain areas of the country, such as desert areas, vegetation growth rates are exceedingly small; therefore, vegetation management cycles would likely be for extended periods of time. Placing a required frequent cycle will unnecessarily increase the costs to ratepayers. While in other parts of the country, vegetation can grow rapidly, and there should be shorter periods of time for the vegetation management cycle.

   Based upon these facts, CenterPoint Energy does not believe that adopting a standard inspection cycle that is applicable to all regions is prudent. However, CenterPoint Energy understands and supports the concept of standard requirements applicable to all regions where such standardization is practical and reasonable. In the specific case of vegetation management, it may be reasonable and practical to establish a national standard based on maximum number of allowed annual vegetation-caused outages per 100-circuit-miles of transmission. Such a standard would allow utilities flexibility to use inspection cycles and other practices that are prudent based on each utility's circumstances while still holding utilities accountable for the results.

   The SAR also proposes to change the 200 kV threshold and use of the IEEE standard for minimum clearances. These requirements were established by a broad consensus of industry experts. CenterPoint Energy believes the broad industry consensus on these matters should be respected.

   CenterPoint Energy submits the following specific comments:

   Minimum inspection cycle, FERC NOPR Paragraph 382-

   CenterPoint Energy disagrees that "complete discretion left to the transmission owners in determining inspection cycles limits the effectiveness of the Reliability Standard." The standard is effective because it requires the transmission owners to balance several factors to achieve the optimum inspection cycle.

It is not necessary to specify a specific inspection interval in the standard. The inspection cycle interval is one component of several conditions to be considered in FAC-003-1 Requirement R1.2.1 for establishing the required Clearance 1 of the NERC standard. Other conditions that should be considered include operating voltage, appropriate vegetation management techniques, fire risk, reasonably anticipated tree and conductor movement, species types and growth rates, species failure characteristics, local climate and rainfall patterns, line terrain and elevation, location of the vegetation within the span, and worker approach distance requirements. It is the growth rate of the vegetation coupled with the amount of clearance achieved at the time of maintenance that determines the inspection cycle interval. As such, the longer the inspection interval, the larger the clearance that must attained to achieve balance. If the utility does not achieve balance, then it will likely not avoid vegetation-related outages. It would not be necessary for a utility to be faulted based on its inspection interval, rather it would be measured for compliance under FAC-003-1 D2.3.1, D2.3.2, D2.3.3, and D2.4.1 for operational conditions regarding maintaining the minimum clearance (Clearance 2) required under FAC-003-1 Requirement R1.2.2 and any actual vegetation-related outages.

FERC NOPR Paragraph 383-

CenterPoint Energy disagrees that "a one-year vegetation inspection cycle is the "norm" for the industry." The reference to "76 of 161 entities surveyed conduct ground inspections once a year" was taken from Table 3 entitled "Ground Inspection Frequency". The table can also be interpreted to indicate that 78 of 161 entities surveyed conduct ground inspections on cycles other than once a year. At best, the table shows a distribution of the varying practices of companies surveyed. The table by itself does not indicate the level of reliability provided by each of those companies.

The table entries may also be incomplete because the original order under Docket EL04-52-000 under paragraph 12c asked "how often the transmission provider inspects that facility for vegetation management purposes" which did not specify ground or aerial inspection. The EEI template that many respondents used did specify ground inspection and aerial inspection separately, but the template was not used by all of the respondents as noted in the report. Interpolation of the data collected may have affected the accuracy of the results reported, so specific conclusions should consider the disparity between how the data request was worded and how the data was reported. It is important to clearly distinguish between ground inspection, aerial inspection, and pruning cycle when soliciting and interpreting industry data. Additionally, new technologies such as airborne laser surveys are coming to the market which may replace or augment other types of vegetation inspections as they become cost-effective. The industry "norm" may change as a result.

FERC NOPR Paragraph 384-

Although CenterPoint Energy does not agree with establishing a "one year minimum inspection cycle", it should be left to the discretion of the transmission owner as to what type of inspection is employed so that the most cost-effective methods can be utilized, depending on the system's size and terrain. It should also be made clear that "inspection cycle" is not intended to mean "pruning cycle".

Remove 200kV threshold, FERC NOPR Paragraph 385-

CenterPoint Energy believes the applicability of FAC-003-1 should be "to all transmission lines operated at 200kV and above and to any lower voltage lines designated by the regional reliability organization as critical to reliability", because such a standard most closely matches the vegetation management reporting requirements from Docket EL04-52-000. Voltages below this threshold are not likely to impact the reliability of the Bulk Power System. Further, regional reliability organizations have the authority to designate lower voltages critical to reliability as appropriate. The proposed change is unnecessary.

IEEE Standard as basis for minimum clearance to prevent flashover (Clearance 2) -

CenterPoint Energy believes that the IEEE standard is sufficient and appropriate as a basis to determine the specific radial clearances to be maintained between vegetation and conductors under all rated electrical operating conditions (Clearance 2). Clearance 2 also must consider additional clearance for the dynamic movement of the transmission conductors to avoid vegetation related outages. Thus, the minimum clearances that a transmission owner must identify and document depend on a variety of conditions including, but not limited to, transmisison line voltage, temperature, wind velocities, and altitude.

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

☐ Yes

☒ No

Comments: CenterPoint Energy does not agree with the scope of the SAR for the reasons discussed in response to question 1.

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

☐ Yes

☒ No

   ☒ Yes

   ☐ No

   Comments:

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: We are concerned that lowering the applicability threshold to all lines below 200KV will divert attention and resources from the higher voltage lines which have a higher probability of causing grid problems. The RRO and transmission owners best know which lower voltage lines should be included under the requirements of the standard.

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

   ☐ Yes

   ☒ No

1. Do you agree that there is a reliability-related need to address the proposed revisions to FAC-003-1 — Transmission Vegetation Management? If not, please explain in the comment area.

   ☒ Yes

   ☐ No

   Comments:

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: The scope of the SAR is too vague on several important points. (1) There is no definition for the phrase bulk-power system - it would be therefore unclear as to what facilities would be covered by the standard. What guidance will the SDT have in determining what is meant by the bulk-power system? Since this relates to the large issue of the Bulk Electric System versus Bulk-Power System is this SAR the appropriate vehicle to address this issue? There should be a wider discussion and resolution to this issue for consistent application to all standards by all SDTs. (2)The concept of Mitigation Time Horizons has not been defined and the use of Mitigation Time Horizons has not been detailed. (3)The ERO is not the appropriate entity to determine which lines have an impact on reliability. This should be Transmission Operators in coordination with Reliability Coordinators. If this standard is to include the methodology to determine which lines have a reliability impact on the bulk-power system, the the applicability of the standard will have to include other entities besides the Transmission Owners. (4) The SAR refers to RA, i.e., Reliability Authority. This entity no longer exists in the Functional Model but has been replaced by Reliability Coordinator. (5) What is meant by "Too weak on compliance"? (5) FERC objects to IEEE Standard but there is no other guidance to the standard drafting team.

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

   ☐ Yes

   ☐ No

   Comments: None identified.

1. Do you agree that there is a reliability-related need to address the proposed revisions to FAC-003-1 — Transmission Vegetation Management? If not, please explain in the comment area.

   ☒ Yes

   ☒ No

   Comments: SCE&G is unsure how to interpret the question but would like to offer the following comments:

   The current standard contains appropriate requirements and measures to ensure the owners vegetation management program is implemented and managed to ensure the reliability of the transmission system. Mandating inspection cycle frequencies will not enhance nor ensure reliability by inspecting more or less frequently. The minimum vegetation clearances at maximum operating conditions that are established within the owner's program, which is auditable by the ERO, will ensure reliability. Extending the requirements to lines other than those >200KV may reduce the focus on those lines and may cause the allocation of resources away from lines >200KV. Generally easements are narrower on lower voltage lines, requiring more resources and emphasis on these lines. This may have an effect on the ability to focus clearing efforts on those lines that will have a much greater impact on the bulk power system. The IEEE standard when used as the minimum clearance distance at maximum operating condition will ensure reliability when these clearances are maintained by vegetation management activities. In addition, we do not agree that a standard of zero tolerance for vegetaion-related outages in the ROW is weak on compliance.

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

   ☐ Yes

   ☒ No

   Comments: Minimum Inspection Intervals:
   SCE&G believes that FAC 003-1 provides the proper amount of flexibility regarding vegetation inspection cycles and that the Standards Drafting Team should not impose minimum inspection intervals on a continent with such regional diversity in climate and plant life.

   The purpose of Requirement 1.1 of standard FAC-003-1 is to put the responsibility for proper inspection cycles on the entity that knows the local conditions and can best define what that inspection frequency should be, the Transmission Owner. Both NERC and the FERC staff have recognized that various local conditions can have an affect on the determination of adequate inspection frequencies. Establishing a mandatory minimum inspection frequency could have two detrimental effects on the industry.

   First, where a particular region is heavily forested and has heavy rainfall along with extended or year round growing seasons, a “back stop” minimum inspection frequency could lead transmission owners to conduct inspections less frequently than required by the local conditions. This could result in a Transmission Owner complying with the standard while not adequately protecting the reliability of that region's transmission system. This is a "lowest common denominator" approach which FERC has repeatedly stated is inappropriate for the reliability standards.

Second, where a particular region is arid, sparsely forested or has a minimum growing season, a "back stop" minimum could require a more frequent interval than is realistically needed. This would result in increased and unnecessary costs for electric utility customers without providing an increase in system reliability.

In its discussion of inspection intervals, FERC indicates that a "one-year vegetation inspection cycle is reasonable." FERC NOPR, 10/20/2002 paragraph 383. The Commission continues by stating "a one-year inspection cycle is the 'norm' for the industry, but not the lowest common denominator…" It follows from this observation that the industry as a whole recognizes and follows appropriate inspection intervals without a need to change the standard. Further, FERC also states "some variation to a continent-wide, one-year minimum inspection cycle should be allowed due to physical differences such as climate and species of vegetation." FERC NOPR 10/20/2006, paragraph 382. FERC's express recognition that a "one size fits all" approach is not appropriate further supports the SERC VMS's contention that the existing inspection requirements in standard FAC-003-1 should remain unchanged.

Finally, the performance metrics of FAC-003 require the reporting of applicable transmission interruptions that are caused by vegetation. This process should appropriately identify Transmission Owners' inspection cycles that are not adequate. In this event, the ERO has the authority to engage the Transmission Owner in enforcement compliance actions and, therefore, can remedy any vegetation-related outage that is attributed to the Transmission Owner's inspection frequency.

Standard Applicability:
SCE&G disagrees with the proposal to revise the 200 kV threshold for determining facilities subject to this standard.

The majority of transmission facilities below 200 kV have significantly different design/construction/operating characteristics and have not been cited as impacting bulk power system reliability. For example, the Final Report on the August 14, 2003 Blackout in the United states and Canada: Causes and Recommendations April 2004 by the U.S.-Canada Power System Outage Task Force and all referenced major blackouts(pages 103-115) in that report, cited only outages which involved vegetation at line voltages above 200 kV. Generally applying requirements appropriate for 200 kV lines to lines less than 200 kV will result in significant documentation and reporting of items such as restrictions, mitigation plans, off right-of-way vegetation-related outage investigation/information and other issues, all of which dilutes the focus on lines that directly impact bulk power system reliability.

Revising the standard to use general criteria or broad language for defining "Bulk Power System" transmission lines covered by the standard could become a "one size fits all" approach. If that approach were taken, the standard would cover a significant number of transmission lines that have no direct impact on bulk power system reliability under standard planning/operating conditions, resulting in a significant increase in costs for electric customers without improving "Bulk Power System" system reliability. SCE&G believes that the applicability provision of the standard should instead focus attention of the standard only on the transmission lines below 200 kV that directly impact "Bulk Power System" reliability, as the current version requires.

In sum, while SCE&G recognizes some validity in the Commission's concern, we recommend that the applicability provision of this standard should be revised only if existing system design, planning or operating reliability criteria and parameters are considered as a basis for defining the applicability of the standard. To that end, we recommend that each Regional Entity (RE) determine applicability of FAC-003-1 to those lines within the region that are between 100 kV and 200 KV if and only if they are identified as operationally significant elements of Interconnection Reliability Operating Limits ("IROLs").

IEEE Standard for Minimum Clearances:
SCE&G disagrees with objections in the FERC staff report to the use of the IEEE 516-2003 clearance as the minimum acceptable distances for "Clearance 2". The IEEE 516-2003 tables are appropriate for defining the minimum acceptable clearances to prevent flashover between conductors and vegetation under all rated electrical operating conditions. Closer minimum clearances such as the minimum length of a support insulator could have been adopted as a "lowest common denominator" clearance. However the clearance in IEEE 516-2003 was adopted to ensure an additional margin of reliability. FERC staff references ANSI Z-133 which is a safety standard that addresses worker safety as well as the safety of the general public. As such, the purpose of ANSI Z-133 is to address worker safety and is not focused on transmission line reliability, which is the purpose of FAC-003-1. OSHA, NESC and other related safety standards have clearances in excess of IEEE 516-2003. Those clearances are clearly focused on safety issues and will still apply to other aspects of design and operation of electric facilities (such as public and worker safety) but do not need to be referenced in a vegetation management reliability standard.

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

☒ Yes

☐ No

Comments: Compliance:
The SERC VMS recommends deleting reporting requirements for Category 3 outages. These outages are not controllable, not relevant to compliance, not related to grid reliability, not related to cascading blackouts, and such reporting leads to unnecessarily biasing reliability related information.

The Transmission Vegetation Management SAR Drafting Team thanks all commenters who submitted comments on the first draft of the Transmission Vegetation Management SAR. This SAR was posted for a 30 day public comment period from January 15–February 14, 2007. The Standards Committee asked stakeholders to provide feedback on the standard through a special standard Comment Form. There were 19 sets of comments, including comments from more than 80 different people from more than 63 companies representing 7 of the 10 Industry Segments as shown in the table on the following pages.

Based on the comments received, the drafting team revised the SAR to reflect these comments and improvements identified by the FERC in its Mandatory Reliability Standards for the Bulk Power System Order 693.

The following major changes were made to the SAR:

- Updated the Purpose to use language that matches the associated standard (e.g., where FAC-003 is only related to the transmission system, the term, 'bulk power system' was replaced with 'transmission system').
- Added the items NERC is required to address in compliance with FERC Order 693
- Added the following items to the list of items to review in refining the standard:
  - Review reporting criteria for Category 3 outages in the proposed technical reference material and may remove the reporting requirement of Category 3 outages in R.3 and R.4.
  - Consider deleting requirement R.4.
  - Review the reporting exemptions to include all category outages under major disasters in Requirement R3.2.
- Added a commitment to prepare a technical reference such as a "white paper" to aid in understanding the technical basis for the standard.
- The descriptions of the 'Reliability Functions' on page 3 of the SAR were updated to reflect Version 3 of the Functional Model.

In this "Consideration of Comments" document stakeholder comments have been organized so that it is easier to see the responses associated with each question. All comments received on the standards can be viewed in their original format at:

http://www.nerc.com/~filez/standards/Vegetation-Management_Project_2007-7.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Director of Standards, Gerry Adamski, at 609-452-8060 or at gerry.adamski@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

1. Do you agree that there is a reliability-related need to address the proposed revisions to FAC-003-1 — Transmission Vegetation Management? If not, please explain in the comment area.

Summary Consideration: Most commenters indicated that they do not believe there is a reliability need to revise the technical aspects of this standard. The SAR Drafting Team agrees with commenters who indicated that the original was SAR vague, and the drafting team modified the SAR to clarify that the proposed changes to this standard will address procedural updates to bring the standard into conformance with the latest version of NERC's Reliability Standards Development Procedure and the Sanctions Guidelines in the ERO Rules of Procedure, and will also address the issues raised in the FERC's March 16, 2007 Order 693 - Mandatory Reliability Standards for the Bulk Power System.

<table>
<tr><th colspan="4">Question #1</th></tr>
<tr><th>Commenter</th><th>Yes</th><th>No</th><th>Comment</th></tr>
<tr><td>Bonneville Power Administration</td><td></td><td>☑</td><td>Ok, Yes and No. The first FERC NOPR bullet needs to be addressed.
The second bullet is clearly discribed in the standard. A. 4.4.3. The reader must read the statement in context. It meets the Standard Review Guidelines.</td></tr>
<tr><td colspan="4">Response:
▪ The FERC is no longer indicating a need to develop a requirement for a minimum inspection cycle (March 16, 2007 Order 693) and stakeholders indicated they did not support this change, so it was removed from the SAR.
▪ The FERC looks to the Standard Drafting Team to determine whether a change to the applicability to <200kV is necessary.
▪ The Drafting Team does not agree that the Standard Review Guidelines have been met. For example the guidelines calls for 'time horizons' to be assigned to each requirement, and the standard currently does not have these. The standard also needs to replace its 'levels of non-compliance' with 'violation severity levels' to support the latest version of the Sanctions Guidelines.</td></tr>
<tr><td>Bandera Electric Coop.</td><td></td><td>☑</td><td>The items listed as potential revisions are vague and do not provide sufficient justification to alter the current requirements of this standard which has been in effect less than 1 year. The current standard allows for the region to determine which transmission lines are critical to reliability and should be included in a Transmission Owner's Transmission Vegetation Management Plan regardless of voltage classification. The current standard also allows each TO the flexibility to develop its plan in accordance with its specific geography and operating environment. There is no need to be more prescriptive.</td></tr>
<tr><td colspan="4">Response:
▪ The Drafting Team agrees that the first SAR draft was vague. The Drafting Team believes a revised standard is justified because it needs to include the following procedural changes:
o Re-format FAC-003-1 to conform to current Standards Development Procedure.
o Remove references to RRO in the standard and substitute a responsible entity.
o Add the compliance elements needed to support the Sanctions Guidelines, including time horizons, and violation severity levels.
▪ The FERC looks to the Standard Drafting Team to determine whether a change to the applicability to <200kV is necessary.
▪ The Standard Drafting Team will also address improvements identified by the FERC in its Order 693 - Mandatory Reliability</td></tr>
</table>

Question #1			
Commenter	**Yes**	**No**	**Comment**
Standards for the Bulk Power System.			
ITC Transmission		☑	While there may be "statutory" needs to address (e.g., FERC's request to modify particular components of the existing Standard), we do not feel there is a reliability need to do so.
Response: ▪ The Drafting Team believes a revised standard is justified because it needs to include the following procedural changes: o Re-format FAC-003-1 to conform to the current Standards Development Procedure. o Remove references to RRO in the standard and substitute a responsible entity. o Add the compliance elements needed to support the Sanctions Guidelines, including time horizons, and violation severity levels. ▪ The Standard Drafting Team will also address improvements identified by the FERC in its Order 693 - Mandatory Reliability Standards for the Bulk Power System.			
Hydro One Networks, Inc.		☑	We believe that at this time it is premature to move forward with changes to the standard that are based on voltage class issues. The Standard, as developed, applies to the BES which have been determined by a performance based methodology. NERC should wait until the BES vs. BPS issue is resolved.
Response: ▪ The Drafting Team believes a revised standard is justified because it needs to include the following procedural changes: o Re-format FAC-003-1 to conform to the current Standards Development Procedure. o Remove references to RRO in the standard and substitute a responsible entity. o Add the compliance elements needed to support the Sanctions Guidelines, including time horizons, and violation severity levels.			
Hydro-Québec TransÉnergie		☑	We believe that it is premature to move forward with changes based on voltage class. Applicability of the standard should only be to those portions of the system that are part of the Bulk Power System which have been determined by a performance based methodology.
Response: ▪ The FERC looks to the Standard Drafting Team to determine whether a change to the applicability to <200kV is necessary.			
Northeast Power Coordinating Council		☑	NPCC participating members believe that it is premature to move forward with changes based on voltage class. Applicability of the standard should only be to those portions of the system that are part of the Bulk Power System which have been determined by a performance based methodology.
Response: ▪ The FERC looks to the Standard Drafting Team to determine whether a change to the applicability to <200kV is necessary.			
American Electric Power		☑	American Electric Power believes that the current standard (when thoroughly read and understood) is completely adequate to maintain a reliable transmission system with minimum risk of vegetation-related outages.

Question #1			
Commenter	**Yes**	**No**	**Comment**
Response: ▪ The Drafting Team believes a revised standard is justified because it needs to include the following NEW procedural changes: o Re-format FAC-003-1 to conform to the current Standards Development Procedure. o Remove references to RRO in the standard and substitute a responsible entity. o Add the compliance elements needed to support the Sanctions Guidelines, including time horizons, and violation severity levels. ▪ The Standard Drafting Team will also address improvements identified by the FERC in its Order 693 - Mandatory Reliability Standards for the Bulk Power System.			
New York State Electric and Gas Corporation		☑	The current draft FAC 003 1 will provide a high level of reliability for the transmission bulk delivery system which the public now expects. After a comprehensive industry review which included industry balloting, the current Vegetation Management Standard 003 1 was approved in Feburary 2006 and several sections did not go in to effect for one year (2007). Sufficient time should be allowed so that impact of the current standard can be monitored. FAC 003 1 was designed to prevent cascading type outages and by establishing a standard for 200KV lines and above catastrophic type power outages will be eliminated. Lower volatge lines can be placed under this standard when the impact on the bulk delivery system requires tighter management as determined by local reliability organizations. Inspection cycles must be designed to meet regional needs based on local conditons, and the current standard provides this flexiblity.
Response: ▪ The Drafting Team believes a revised standard is justified because it needs to include the following NEW procedural changes: o Re-format FAC-003-1 to conform to the current Standards Development Procedure. o Remove references to RRO in the standard and substitute a responsible entity. o Add the compliance elements needed to support the Sanctions Guidelines, including time horizons, and violation severity levels. ▪ The FERC looks to the Standard Drafting Team to determine whether a change to the applicability to <200kV is necessary. ▪ The FERC is no longer indicating a need to develop a requirement for a minimum inspection cycle (March 16, 2007 Order 693) and stakeholders indicated they did not support this change, so it was removed from the SAR. ▪ The Standard Drafting Team will also address improvements identified by the FERC in its Order 693 - Mandatory Reliability Standards for the Bulk Power System.			
SERC Reliability Corporation	☑	☑	The SERC VMS is unsure how to answer the question as it is worded, but has the following comments on the SAR: The current standard contains appropriate requirements and measures to ensure the owners vegetation management program is implemented and managed to ensure the reliability of the transmission system. Mandating inspection cycle

Question #1			
Commenter	**Yes**	**No**	**Comment**
			frequencies will not enhance nor ensure reliability by inspecting more or less frequently. The minimum vegetation clearances at maximum operating conditions that are established within the owner's program, which is auditable by the ERO, will ensure reliability. Extending the requirements to lines other than those >200KV may reduce the focus on those lines and may cause the allocation of resources away from lines >200KV. Generally easements are narrower on lower voltage lines, requiring more resources and emphasis on these lines. This may have an effect on the ability to focus clearing efforts on those lines that will have a much greater impact on the bulk power system. The IEEE standard when used as the minimum clearance distance at maximum operating condition will ensure reliability when these clearances are maintained by vegetation management activities. In addition, we do not agree that a standard of zero tolerance for vegetaion-related outages in the ROW is weak on compliance.
Response: ▪ The FERC is no longer indicating a need to develop a requirement for a minimum inspection cycle (March 16, 2007 Order 693) and stakeholders indicated they did not support this change, so it was removed from the SAR. ▪ The FERC looks to the Standard Drafting Team to determine whether a change to the applicability to voltage <200kV is necessary. ▪ The Drafting Team agrees with the commenter and recognizes that the IEEE standard is applicable. ▪ The Drafting Team modified the SAR to eliminate the comment that the standard is weak on compliance as this comment was satisfied when Version 1 of the standard was developed. ▪ The Standard Drafting Team will also address improvements identified by the FERC in its Order 693 - Mandatory Reliability Standards for the Bulk Power System.			
Progress Energy		☑	The current standard contains appropriate levels of guidelines and penalties to ensure the owners vegetation management program is implemented and managed to ensure the reliability of the transmission system. Mandating inspection cycle frequencies will not enhance nor ensure reliability by inspecting more or less frequently. The minimum vegetation clearances at maximum operating conditions that are established within the owner's program that are auditable by the ERO will ensure reliability. By adding lines other than those >200KV may reduce the focus on those lines and impact the budget dollars allocated to focus on the lines >200KV. Generally easements are much more narrow on lower voltage lines, the impact on budget dollars would often require more emphasis on these lines. This may have an effect on the ability to focus clearing efforts on those lines that will have a much greater impact on the bulk power system. The IEEE standard when used as the minimum clearance distance at maximum operating condition will ensure reliability when these clearances are maintained by vegetation management activities.

Question #1			
Commenter	**Yes**	**No**	**Comment**
Response: ▪ The current version of the standard does not include 'time horizons' and uses 'levels of non-compliance' rather than 'violation severity levels' - 'time horizons' and 'violation severity levels' are needed to conform to the latest version of the Sanctions Guidelines included in the ERO Rules of Procedure. ▪ The FERC is no longer indicating a need to develop a requirement for a minimum inspection cycle (March 16, 2007 Order 693) and stakeholders indicated they did not support this change, so it was removed from the SAR. ▪ The FERC looks to the Standard Drafting Team to determine whether a change to the applicability to voltage <200kV is necessary. ▪ The Drafting Team agrees with the commenter and recognizes that the IEEE standard is applicable. ▪ The Standard Drafting Team will also address improvements identified by the FERC in its Order 693 - Mandatory Reliability Standards for the Bulk Power System.			
CenterPoint Energy Houston Electric, LLP		☑	CenterPoint Energy disagrees that there is a reliability-related need to address the proposed revisions to FAC-003-1. This SAR proposes to establish a minimum vegetation inspection cycle for transmission facilities throughout the United States. Yet, based upon the location of each utility, different vegetation and growth rates will be experienced throughout the country. Placing a time specific vegetation management cycle for all regions does not address the wide divergence of vegetation and growth rates that each utility must face. For instance, in certain areas of the country, such as desert areas, vegetation growth rates are exceedingly small; therefore, vegetation management cycles would likely be for extended periods of time. Placing a required frequent cycle will unnecessarily increase the costs to ratepayers. While in other parts of the country, vegetation can grow rapidly, and there should be shorter periods of time for the vegetation management cycle. Based upon these facts, CenterPoint Energy does not believe that adopting a standard inspection cycle that is applicable to all regions is prudent. However, CenterPoint Energy understands and supports the concept of standard requirements applicable to all regions where such standardization is practical and reasonable. In the specific case of vegetation management, it may be reasonable and practical to establish a national standard based on maximum number of allowed annual vegetation-caused outages per 100-circuit-miles of transmission. Such a standard would allow utilities flexibility to use inspection cycles and other practices that are prudent based on each utility's circumstances while still holding utilities accountable for the results.

Question #1			
Commenter	Yes	No	Comment
			The SAR also proposes to change the 200 kV threshold and use of the IEEE standard for minimum clearances. These requirements were established by a broad consensus of industry experts. CenterPoint Energy believes the broad industry consensus on these matters should be respected. CenterPoint Energy submits the following specific comments: Minimum inspection cycle, FERC NOPR Paragraph 382- CenterPoint Energy disagrees that "complete discretion left to the transmission owners in determining inspection cycles limits the effectiveness of the Reliability Standard." The standard is effective because it requires the transmission owners to balance several factors to achieve the optimum inspection cycle. It is not necessary to specify a specific inspection interval in the standard. The inspection cycle interval is one component of several conditions to be considered in FAC-003-1 Requirement R1.2.1 for establishing the required Clearance 1 of the NERC standard. Other conditions that should be considered include operating voltage, appropriate vegetation management techniques, fire risk, reasonably anticipated tree and conductor movement, species types and growth rates, species failure characteristics, local climate and rainfall patterns, line terrain and elevation, location of the vegetation within the span, and worker approach distance requirements. It is the growth rate of the vegetation coupled with the amount of clearance achieved at the time of maintenance that determines the inspection cycle interval. As such, the longer the inspection interval, the larger the clearance that must attained to achieve balance. If the utility does not achieve balance, then it will likely not avoid vegetation-related outages. It would not be necessary for a utility to be faulted based on its inspection interval, rather it would be measured for compliance under FAC-003-1 D2.3.1, D2.3.2, D2.3.3, and D2.4.1 for operational conditions regarding maintaining the minimum clearance (Clearance 2) required under FAC-003-1 Requirement R1.2.2 and any actual vegetation-related outages. FERC NOPR Paragraph 383-

Question #1			
Commenter	**Yes**	**No**	**Comment**
			CenterPoint Energy disagrees that "a one-year vegetation inspection cycle is the "norm" for the industry." The reference to "76 of 161 entities surveyed conduct ground inspections once a year" was taken from Table 3 entitled "Ground Inspection Frequency". The table can also be interpreted to indicate that 78 of 161 entities surveyed conduct ground inspections on cycles other than once a year. At best, the table shows a distribution of the varying practices of companies surveyed. The table by itself does not indicate the level of reliability provided by each of those companies. The table entries may also be incomplete because the original order under Docket EL04-52-000 under paragraph 12c asked "how often the transmission provider inspects that facility for vegetation management purposes" which did not specify ground or aerial inspection. The EEI template that many respondents used did specify ground inspection and aerial inspection separately, but the template was not used by all of the respondents as noted in the report. Interpolation of the data collected may have affected the accuracy of the results reported, so specific conclusions should consider the disparity between how the data request was worded and how the data was reported. It is important to clearly distinguish between ground inspection, aerial inspection, and pruning cycle when soliciting and interpreting industry data. Additionally, new technologies such as airborne laser surveys are coming to the market which may replace or augment other types of vegetation inspections as they become cost-effective. The industry "norm" may change as a result. FERC NOPR Paragraph 384- Although CenterPoint Energy does not agree with establishing a "one year minimum inspection cycle", it should be left to the discretion of the transmission owner as to what type of inspection is employed so that the most cost-effective methods can be utilized, depending on the system's size and terrain. It should also be made clear that "inspection cycle" is not intended to mean "pruning cycle". Remove 200kV threshold, FERC NOPR Paragraph 385- CenterPoint Energy believes the applicability of FAC-003-1 should be "to all transmission lines operated at 200kV and above and to any lower voltage lines

Question #1			
Commenter	**Yes**	**No**	**Comment**
			designated by the regional reliability organization as critical to reliability", because such a standard most closely matches the vegetation management reporting requirements from Docket EL04-52-000. Voltages below this threshold are not likely to impact the reliability of the Bulk Power System. Further, regional reliability organizations have the authority to designate lower voltages critical to reliability as appropriate. The proposed change is unnecessary. IEEE Standard as basis for minimum clearance to prevent flashover (Clearance 2) - CenterPoint Energy believes that the IEEE standard is sufficient and appropriate as a basis to determine the specific radial clearances to be maintained between vegetation and conductors under all rated electrical operating conditions (Clearance 2). Clearance 2 also must consider additional clearance for the dynamic movement of the transmission conductors to avoid vegetation related outages. Thus, the minimum clearances that a transmission owner must identify and document depend on a variety of conditions including, but not limited to, transmisison line voltage, temperature, wind velocities, and altitude.
Response: ▪ The FERC is no longer indicating a need to develop a requirement for a minimum inspection cycle (March 16, 2007 Order 693) and stakeholders indicated they did not support this change, so it was removed from the SAR. ▪ The FERC looks to the Standard Drafting Team to determine whether a change to the applicability to voltage <200kV is necessary. ▪ The Drafting Team agrees with the commenter and recognizes that the IEEE standard is applicable.			

Question #1			
Commenter	**Yes**	**No**	**Comment**
Central Hudson Gas & Electric		☑	The proposed revisions listed under the FERC NOPR do not provide proper justification to alter the requirements in the current FAC-003-1 document that was adopted one year ago. First, "a minimum vegetation inspection cycle that allows variation in physical difference" is already called for under the current standard. As stated in Section R1.1. of FAC-003-1, a schedule already should be defined under the transmission vegetation management program (TVMP). This schedule already allows for "variation in physical difference" since the current standard states that "this schedule should be flexible enough to adjust for changing conditions." Secondly, under Applicability Section 4.3., the current standard already allows for lines with lower voltage than 200kV to be "designated by the RRO as critical" and therefore applicable to the standard. Removal of the 200kV benchmark is not needed. And lastly, under the FERC staff report, the IEEE standard provides guidance in clearances and has been the industry standard for many years. If FERC objects to using this standard then they should provide clearances that can be discussed and agreed upon by the transmission owners.
Response: ▪ The FERC is no indicating a need to develop a requirement for a minimum inspection cycle (March 16, 2007 Order 693) and stakeholders indicated they did not support this change, so it was removed from the SAR. ▪ The FERC looks to the Standard Drafting Team to determine whether a change to the applicability to voltage <200kV is necessary. ▪ The Drafting Team agrees with the commenter and recognizes that the IEEE standard is applicable.			
Southern California Edison		☑	There was no empirical or anecdotal evidence presented by FERC staff to support the Commission's view that the reliability of the Bulk Power System will be enhanced with further revisions to FAC-003-1. This standard was the subject of vigorous industry debate in a previous SAR. Although it is far from perfect, the proposed revisions will not improve reliability and may very well damage existing VM programs.

Response:
▪ The Drafting Team believes a revised standard is justified because it needs to include the following NEW procedural changes:
    o Re-format FAC-003-1 to conform to the current Standards Development Procedure.
    o Remove references to RRO in the standard and substitute a responsible entity.

<tr><td>TVA</td><td>☑</td><td>☑</td><td>As worded this question is confusing however the following comments are presented on the SAR:
The current standard contains appropriate requirements and measures to ensure that vegetation related outages will not cause cascading transmission blackouts. Mandating new explicit inspection cycle frequencies will not enhance nor ensure reliability by inspecting more or less frequently. The current minimum vegetation clearances at maximum operating conditions that are established within the owner's program, which is auditable by the ERO, is sufficient to prevent vegetation related cascading transmission
blackouts. Extending the requirements to a much a larger population of lines would reduce the current focus on the most important lines (those >200 kV). The IEEE standard when used as the minimum vegetation clearance distance at maximum operating condition will ensure desired performance of the lines. A standard of zero tolerance for vegetation related outages in the ROW is not a weak standard on compliance.</td></tr>

2. Do you agree with the scope of the SAR? If not, please explain in the comment area.

Summary Consideration: Many commenters indicated there is no need to change the applicability of the requirements in this standard. The FERC indicated that the Standard Drafting Team should review and consider whether a change to the applicability to voltage <200kV is necessary.

Furthermore, some commenters expressed support for the IEEE standard's use in the FAC-003-1 Standard while the FERC declines to endorse the use of the IEEE standard as the 'only' minimum clearance. The SAR was revised to indicate that the Standard Drafting Team will seek to clarify the rationale for the use of the IEEE standard in supplemental reference material to be prepared as part of the scope of this SAR.

Question #2			
Commenter	**Yes**	**No**	**Comment**
Bonneville Power Administration	☑		Since this posting is for comment it would have been nice to provide more information as to why the FERC staff objects to the IEEE standard (since it meets the guidelines for as a North America standard. Also, why are stakeholders concerned with Reliability Coordinators vs. RRO?
Response: ▪ The Drafting Team recognizes that the IEEE standard is applicable. The FERC staff has questioned the applicability of the IEEE standard and the Drafting Team agreed to address their questions and concerns. ▪ The Drafting Team believes a revised standard is justified because it needs to include the following NEW procedural changes: o Re-format FAC-003-1 to conform to the current Standards Development Procedure. o Remove references to RRO in the standard and substitute a responsible entity. Making FAC-003 applicable to the RRO is in violation of the legislation that established the ERO. This legislation states that enforceable standards can apply only to owners, users and operators of the bulk power system. o Add the compliance elements needed to support the Sanctions Guidelines, including time horizons, and violation severity levels.			
Bandera Electric Coop.	☑	☑	As submitted, the SAR appears to completely re-open this standard negating many months of work and industry comment to reach the consensus reflected in the current FAC-003.
Response: ▪ The ERO Rules of Procedure include the latest versions of the Reliability Standards Development Procedure Manual and the Sanctions Guidelines. These documents were approved following the approval of FAC-003-1. FAC-003-1 will need to be revised to bring the standard into conformance with these documents.			
Northeast Power Coordinating Council		☑	See response to question 1, above.
Response: See the drafting team's response to your comments on question 1.			
CenterPoint Energy Houston Electric, LLP		☑	CenterPoint Energy does not agree with the scope of the SAR for the reasons discussed in response to question 1.

Question #2			
Commenter	**Yes**	**No**	**Comment**
Response: See the drafting team's response to your comments on question 1.			
Central Hudson Gas & Electric		☑	See comments above.
Response: See the drafting team's response to your comments on question 1.			
American Electric Power		☑	American Electric Power is not aware of any evidence to support a need for revising the vegetation management standard.
Response: ▪ The ERO Rules of Procedure include the latest versions of the Reliability Standards Development Procedure Manual and the Sanctions Guidelines. These documents were approved following the approval of FAC-003-1. FAC-003-1 will need to be revised to bring the standard into conformance with these documents.			
FRCC		☑	As stated in this SAR comment form, the improvements should be made to bring the standard into conformance with the Reliability Standards Development Procedure which at this time is version 6.0, adopted by NERC BOT, 11/1/2006. The SAR scope via the attached Standard Review Guidelines includes two areas not defined within the procedure. The Mitigation Time Horizons and definitions for the violation severity levels (VSLs), Lower, Moderate, High and Severe. We understand the description of Mitigation Time Horizons and definitions for VSLs are included in the SAR (the concept of Violation Time Horizons is included in the Sanctions Guidelines, appendix 4B, NERC Compliance Filing to FERC dated October 18th, 2006), but these discrepancies are part of a broader policy issue and since their use is not clearly stipulated in the NERC Reliability Standards Development Procedure, including them in the scope of the SAR is premature and will cause unnecessary confusion to stakeholders and regulators. The process is requesting the industry to comment on a scope that is defined outside the reliability standards process and as such is subject to revisions and interpretations outside the process as well. This appears inappropriate and at the extreme will lead to inconsistent understanding, measurement and enforcement of compliance actions. The Mitigation Time Horizons and VSL levels should be defined in the Reliability Standards Development Procedure prior to inclusion in the scope of a SAR. Specific Items Within Current SAR Scope:

Question #2			
Commenter	**Yes**	**No**	**Comment**
			The establishment of minimum inspection cycles has been addressed previously, in the development of the current standard and was found very problematic given the large variety of vegetative conditions throughout North America. The vegetation that was identified as a contributing cause to the 2003 Northeast Blackout had already been identified by previous inspection activities. It was the failure to take action on the known site conditions that contributed to the event. Therefore, a minimum inspection cycle would still NOT have prevented or mitigated the scope of the Blackout. The current 200 kV threshold ensures that vegetation management efforts are focused on the critical bulk power transfer lines and that TVM efforts are not diluted by including additional lower voltage lines. In practicality, the RRO designation process provides the necessary flexibility to the Regions to address localized areas where bulk power system reliability may be compromised by lower voltage vegetation outages. To note as well, Northeast Blackout related vegetation outages which initiated the cascade occurred on lines that operate at 345 kV, well above the current threshold. The FRCC supported the development of Clearance 2, as established in the current standard, as this was a consensus selection by not only the subject matter experts, but many industry participants. Picking the ANSI Z133.1 Table 1 or 2 as the NOPR suggests, could immediately place thousands of miles of transmission lines out of compliance even though operating data indicates that the lines have performed satisfactorily for years. The concern would be, the resulting dilution of valuable industry and regulator resources. The SAR includes the following stakeholder comment: "Too weak on compliance" . We caution that we feel the compliance section does need refining, but that in a world of limited resources should focus on trends in vegetation outages and not necessarily on single outages. For transmission owners, two outages on a radial 230 kV circuit should not carry the same penalty as eight outages on multiple 230 kV circuits within a network. We would recommend that compliance be refined to identify trends, relevance and risk probability to help the industry focus their resources appropriately.

Response:

- The Drafting Team believes a revised standard is justified because it needs to include the following procedural changes:

<table>

<tr><td>Hydro One Networks, Inc.</td><td></td><td>☑</td><td>To address FERC's objection to use the IEEE standard, it is necessary to clarify the objective of the Vegetation Management Standard. As we understand it, the focus of the FAC-003-1 standard is system reliability and as such, the responsibility and authority on defining and applying the safety margins is rightly assigned to the transmission owner. We request clarification on how employing safety factors will address reliability and how prescribing minimum clearances within the standard will</td></tr>
</table>

Question #2			
Commenter	**Yes**	**No**	**Comment**
			improve reliability. Please note that the Canadian Standards Association is revising standard C22.3 No. 1 - Overhead Systems. The new version will include clearances to vegetation and the proposed minimum clearances are in alignment with FAC-003-1.
Response: ▪ The Drafting Team recognizes that the IEEE standard is applicable. The FERC staff has questioned the applicability of the IEEE standard and the Drafting Team agreed to address their questions and concerns.			
SERC Reliability Corporation Progress Energy	☑	☑	Minimum Inspection Intervals: The SERC VMS (Progress Energy) believes that FAC 003-1 provides the proper amount of flexibility regarding vegetation inspection cycles and that the Standards Drafting Team should not impose minimum inspection intervals on a continent with such regional diversity in climate and plant life. The purpose of Requirement 1.1 of standard FAC-003-1 is to put the responsibility for proper inspection cycles on the entity that knows the local conditions and can best define what that inspection frequency should be, the Transmission Owner. Both NERC and the FERC staff have recognized that various local conditions can have an affect on the determination of adequate inspection frequencies. Establishing a mandatory minimum inspection frequency could have two detrimental effects on the industry. First, where a particular region is heavily forested and has heavy rainfall along with extended or year round growing seasons, a "back stop" minimum inspection frequency could lead transmission owners to conduct inspections less frequently than required by the local conditions. This could result in a Transmission Owner complying with the standard while not adequately protecting the reliability of that region's transmission system. This is a "lowest common denominator" approach which FERC has repeatedly stated is inappropriate for the reliability standards. Second, where a particular region is arid, sparsely forested or has a minimum growing season, a "back stop" minimum could require a more frequent interval than is realistically needed. This would result in increased and unnecessary costs for electric utility customers without providing an increase in system reliability. In its discussion of inspection intervals, FERC indicates that a "one-year vegetation

Question #2			
Commenter	**Yes**	**No**	**Comment**
			inspection cycle is reasonable." FERC NOPR, 10/20/2002 paragraph 383. The Commission continues by stating "a one-year inspection cycle is the 'norm' for the industry, but not the lowest common denominator…" It follows from this observation that the industry as a whole recognizes and follows appropriate inspection intervals without a need to change the standard. Further, FERC also states "some variation to a continent-wide, one-year minimum inspection cycle should be allowed due to physical differences such as climate and species of vegetation." FERC NOPR 10/20/2006, paragraph 382. FERC's express recognition that a "one size fits all" approach is not appropriate further supports the SERC VMS's contention that the existing inspection requirements in standard FAC-003-1 should remain unchanged. Finally, the performance metrics of FAC-003 require the reporting of applicable transmission interruptions that are caused by vegetation. This process should appropriately identify Transmission Owners' inspection cycles that are not adequate. In this event, the ERO has the authority to engage the Transmission Owner in enforcement compliance actions and, therefore, can remedy any vegetation-related outage that is attributed to the Transmission Owner's inspection frequency. Standard Applicability: The SERC VMS disagrees with the proposal to revise the 200 kV threshold for determining facilities subject to this standard. The majority of transmission facilities below 200 kV have significantly different design/construction/operating characteristics and have not been cited as impacting bulk power system reliability. For example, the Final Report on the August 14, 2003 Blackout in the United states and Canada: Causes and Recommendations April 2004 by the U.S.- Canada Power System Outage Task Force and all referenced major blackouts(pages 103-115) in that report, cited only outages which involved vegetation at line voltages above 200 kV. Generally applying requirements appropriate for 200 kV lines to lines less than 200 kV will result in significant documentation and reporting of items such as restrictions, mitigation plans, off right-of-way vegetation-related outage investigation/information and other issues, all of which dilutes the focus on lines that directly impact bulk power system reliability.

Question #2			
Commenter	**Yes**	**No**	**Comment**
			Revising the standard to use general criteria or broad language for defining "Bulk Power System" transmission lines covered by the standard could become a "one size fits all" approach. If that approach were taken, the standard would cover a significant number of transmission lines that have no direct impact on bulk power system reliability under standard planning/operating conditions, resulting in a significant increase in costs for electric customers without improving "Bulk Power System" system reliability. The SERC VMS believes that the applicability provision of the standard should instead focus attention of the standard only on the transmission lines below 200 kV that directly impact "Bulk Power System" reliability, as the current version requires. In sum, while the SERC VMS (Progress Energy) recognizes some validity in the Commission's concern, the SERC VMS (Progress Energy) recommends that the applicability provision of this standard should be revised only if existing system design, planning or operating reliability criteria and parameters are considered as a basis for defining the applicability of the standard. To that end, the SERC VMS recommends each Regional Entity (RE) determine applicability of FAC-003 to those lines within the region that are between 100 kV and 200 KV if and only if they are identified as operationally significant elements of Interconnection Reliability Operating Limits ("IROLs"). IEEE Standard for Minimum Clearances: The SERC VMS disagrees with objections in the FERC staff report to the use of the IEEE 516-2003 clearance as the minimum acceptable distances for "Clearance 2". The IEEE 516-2003 tables are appropriate for defining the minimum acceptable clearances to prevent flashover between conductors and vegetation under all rated electrical operating conditions. Closer minimum clearances such as the minimum length of a support insulator could have been adopted as a "lowest common denominator" clearance. However the clearance in IEEE 516-2003 was adopted to ensure an additional margin of reliability. FERC staff references ANSI Z-133 which is a safety standard that addresses worker safety as well as the safety of the general public. As such, the purpose of ANSI Z-133 is to address worker safety and is not focused on transmission line reliability, which is the purpose of FAC-003-1. OSHA, NESC and other related safety standards have clearances in excess of IEEE 516-2003. Those clearances are clearly focused on safety issues and will still apply

Question #2			
Commenter	**Yes**	**No**	**Comment**
			to other aspects of design and operation of electric facilities (such as public and worker safety) but do not need to be referenced in a vegetation management reliability standard.
Response: ▪ The FERC is no longer indicating a need to develop a requirement for a minimum inspection cycle (March 16, 2007 Order 693) and stakeholders indicated they did not support this change, so it was removed from the SAR. ▪ The FERC looks to the Standard Drafting Team to determine whether a change to the applicability to voltage <200kV is necessary. ▪ The Drafting Team recognizes that the IEEE standard is applicable. The FERC staff has questioned the applicability of the IEEE standard and the Drafting Team agreed to address their questions and concerns.			
TVA		☑	Minimum Inspection Intervals: FAC 003-1 provides the proper amount of flexibility regarding vegetation inspection cycles and that the Standards Drafting Team should not impose minimum inspection intervals on a continent with such regional diversity in climate and plant life. Requirement 1.1 of standard FAC-003-1 places the responsibility for proper inspection cycles on the entity that knows the local conditions and can best define what that inspection frequency should be, the Transmission Owner. Both NERC and the FERC staff have recognized that various local conditions can have an affect on the determination of adequate inspection frequencies. Establishing a mandatory minimum inspection frequency could have two detrimental effects on the industry. First, where a particular region is heavily forested and has heavy rainfall along with extended or year round growing seasons, a "back stop" minimum inspection frequency could lead transmission owners to conduct inspections less frequently than required by the local conditions. This could result in a Transmission Owner complying with the standard while not adequately protecting the reliability of that region's transmission system. This is a "lowest common denominator" approach which FERC has repeatedly stated is inappropriate for the reliability standards. Page 5 of 6 January 15, 2007 Second, where a particular region is arid, sparsely forested or has a minimum growing season, a "back stop" minimum could require a more frequent interval than is realistically needed. This would result in increased and unnecessary costs for electric utility customers without providing an increase in system reliability. In its

Question #2			
Commenter	**Yes**	**No**	**Comment**
			discussion of inspection intervals, FERC indicates that a “one-year vegetation inspection cycle is reasonable.” FERC NOPR, 10/20/2002 paragraph 383. The Commission continues by stating “a one-year inspection cycle is the ‘norm’ for the industry, but not the lowest common denominator…” It follows from this observation that the industry as a whole recognizes and follows appropriate inspection intervals without a need to change the standard. Further, FERC also states “some variation to a continent-wide, one-year minimum inspection cycle should be allowed due to physical differences such as climate and species of vegetation.” FERC NOPR 10/20/2006, paragraph 382. FERC’s recognition that a “one size fits all” approach is not appropriate supports maintaining the existing inspection requirements in standard FAC-003-1. Finally, the performance metrics of FAC-003 require the reporting of applicable transmission interruptions that are caused by vegetation. This process will identify Transmission Owners’ inspection cycles that are not adequate. In this event, the ERO has the authority to engage the Transmission Owner in enforcement compliance actions and, therefore, can remedy any vegetation-related outage that is attributed to the Transmission Owner’s inspection frequency. Standard Applicability: The 200 kV threshold for determining facilities subject to this standard should not be revised. The transmission facilities below 200 kV have not been cited as impacting bulk power system reliability. The Final Report on the August 14, 2003 Blackout in the United states and Canada: Causes and Recommendations April 2004 by the U.S.- Canada Power System Outage Task Force and all referenced major blackouts(pages 103-115) in that report, cited only outages which involved vegetation at line voltages above 200 kV. Generally applying requirements appropriate for 200 kV lines to lines less than 200 kV will result in significant documentation and reporting of items such as restrictions, mitigation plans, off right-of-way vegetation-related outage investigation/information and other issues, all of which dilutes the focus on lines that directly impact bulk power system reliability. Revising the standard to use general criteria or broad language for defining "Bulk Power System" transmission lines covered by the standard could become a “one size fits all” approach. If that approach were taken, the standard would cover a significant

Question #2			
Commenter	**Yes**	**No**	**Comment**
			number of transmission lines that have no direct impact on bulk power system reliability under standard planning/operating conditions, resulting in a significant increase in costs for electric customers without improving "Bulk Power System" system reliability. The SERC VMS believes that the applicability provision of the standard should instead focus attention of the standard only on the transmission lines below 200 kV that directly impact "Bulk Power System" reliability, as the current version requires. The applicability provision of this standard should be revised only if existing system design, planning or operating reliability criteria and parameters are considered as a basis for defining the applicability of the standard. To that end, each Regional Entity (RE) should determine the applicability of FAC-003 to those lines within the region that are between 100 kV and 200 KV if and only if they are identified as operationally significant elements of Interconnection Reliability Operating Limits ("IROLs"). IEEE Standard for Minimum Clearances: Page 6 of 6 January 15, 2007 The IEEE 516-2003 should continue to be used as the minimum acceptable distances for "Clearance 2". The IEEE 516-2003 tables are appropriate for defining the minimum acceptable clearances to prevent flashover between conductors and vegetation under all rated electrical operating conditions. Closer minimum clearances such as the minimum length of a support insulator could have been adopted as a "lowest common denominator" clearance. However the clearance in IEEE 516-2003 was adopted to ensure an additional margin of reliability. FERC staff references ANSI Z-133 which is a safety standard that addresses worker safety as well as the safety of the general public. As such, the purpose of ANSI Z-133 is to address worker safety and is not focused on transmission line reliability, which is the purpose of FAC-003-1. OSHA, NESC and other related safety standards have clearances in excess of IEEE 516-2003. Those clearances are clearly focused on safety issues and will still apply to other aspects of design and operation of electric facilities (such as public and worker safety) but do not need to be referenced in a vegetation management reliability standard.

<tr><th colspan="4">Question #2</th></tr>
<tr><th>Commenter</th><th>Yes</th><th>No</th><th>Comment</th></tr>
<tr><td colspan="4">The FERC is no longer indicating a need to develop a requirement for a minimum inspection cycle (March 16, 2007 Order 693) and stakeholders indicated they did not support this change, so it was removed from the SAR.
The FERC looks to the Standard Drafting Team to determine whether a change to the applicability to voltage <200kV is necessary.
The Drafting Team recognizes that the IEEE standard is applicable. The FERC staff has questioned the applicability of the IEEE standard and the Drafting Team agreed to address their questions and concerns.</td></tr>
<tr><td>Midwest Reliability Organization</td><td>☑</td><td>☑</td><td>The scope of this SAR would have been better defined if the complete Standard Review Form for the Vegetation Management Standard had been included as an attachment to the SAR. Several issues in the Standard Review Form for this SAR were excluded with this posted SAR. For example, issues related to R3.1 and R3.2.

The MRO is also not clear on the scope of the instruction to the SDrafting Team to "Expand the applicability to include transmission lines operated at 200 kV and above and other facilities as determined by the ERO so that the Reliability Standard applies to Bulk-Power System transmission lines that have an impact on reliability" It is not clear to the MRO what is meant by "as determined by the ERO". What process will the ERO use? The ERO should use stakeholder input to make this determination. The current standard is applicable to all transmission lines 200 kV and above and to any lower voltage lines designated by the RRO as critical to the electric system in the region. Will the ERO be in a position to assume the assessment of the criticality of lines less than 200 kV without input from the entities that have historically operated in each region?

Also, the MRO is not clear on what is included in the term Bulk-Power System. What guidance will the SDrafting Team have in determining what is meant by the Bulk-Power System? Since this relates to the large issue of the Bulk Electric System versus Bulk-Power System is this SAR the appropriate vehicle to address this issue? There should be a wider discussion and resolution to this issue for consistent application to all standards by all SDrafting Teams.</td></tr>
<tr><td colspan="4">Response:
The comments on R3.1 and R3.2 were developed by NERC staff in a previous version of this SAR and these have been deleted from the revised SAR. Instead, the Standard Drafting Team will apply the Standard Review Guidelines to the Standard.
The comments from the FERC NOPR were removed from the revised SAR.
The FERC looks to the Standard Drafting Team to determine whether a change to the applicability to voltage <200kV is necessary.</td></tr>
<tr><td>Florida Power and Light Company</td><td></td><td>☑</td><td>Establishing minimum inspection cycles is a very problematic given the large variety of vegetative conditions throughout North America. In reality most lines are inspected annually for all failure modes including vegetation. The trees that played a part of the North East Blackout were known and on the radar screen. The utility</td></tr>
</table>

Question #2			
Commenter	**Yes**	**No**	**Comment**
			failed to take action. The inspection did not prevent the outage from occurring. The failure to take action on the known site condition was the contributing factor to the Blackout. We do not understand the need to establish separate criteria other than the RRO's critical designation. A transmission line is either necessary to the system to prevent an overload situation or it is not. To add lines that might not be critical to the system would dilute the effort needed to insure that the critical lines are properly maintained. Since system stability is the focus of the standard, what criteria would be used to bring additional lower voltage lines under the standard. When developing Clearance 2, the committee needed to determine a distance at which a Transmission Owner could be out of compliance even though no interruption has occurred. In a sense this is the maximum 'speed limit' at which the utility would be in violation. Their criteria was "How close can a tree be and not cause an outage?" The engineers on the team reviewed scientific data and current standards. The IEEE MAID standard was the consensus selection of the sub committee. All parties need to understand that this is one of the building blocks that would be used in determining the width of an easement or ROW. Picking the ANSI Z133.1 Table 1 or 2 as the NOPR suggests could immediately place thousands of miles of transmission lines out of compliance that have performed satisfactorily for years. The ANSI tables are phase to phase safety calculations when grow-in tree interruptions are phase to ground situations.
Response: ▪ The FERCis no longer indicating a need to develop a requirement for a minimum inspection cycle (March 16, 2007 Order 693) and stakeholders indicated they did not support this change, so it was removed from the SAR. ▪ The Drafting Team believes a revised standard is justified because it needs to include the following procedural changes: o Re-format FAC-003-1 to conform to the current Standards Development Procedure. o Remove references to RRO in the standard and substitute a responsible entity. o Add the compliance elements needed to support the Sanctions Guidelines, including time horizons, and violation severity levels.			
Public Service Commission of South Carolina		☑	We are concerned that lowering the applicability threshold to all lines below 200KV will divert attention and resources from the higher voltage lines which have a higher probability of causing grid problems. The RRO and transmission owners best know which lower voltage lines should be included under the requirements of the

Question #2			
Commenter	**Yes**	**No**	**Comment**
			standard.
Response: ▪ The FERC looks to the Standard Drafting Team to determine whether a change to the applicability to voltage <200kV is necessary.			
IESO Ontario		☑	With respect to the item in the Brief Description section under FERC NOPR: "Remove the applicability to transmission lines operated at 200 kV and above so that the Reliability Standard applies to Bulk Power System transmission lines that have an impact on reliability as determined by the ERO." It is the IESO's view that requiring the ERO to make these determinations, is inappropriate. We believe the standard should remain applicable to lines 200 kV and above and lines below 200 kV as determined by the Reliability Coordinator, similar to the PRC-023 standard. The IESO also suggests that it be made clear in the SAR that it will be a complete review of the subject requirements: to include the addition, deletion and modification of requirements, as agreed to by public consensus.
Response: ▪ The FERC looks to the Standard Drafting Team to determine whether a change to the applicability to transmission voltage class <200kV is necessary. ▪ The Drafting Team removed the paragraph in the brief description of the SAR that opened the scope to other improvements. The Drafting Team concurs with consensus of the commenters that the technical elements of this standard are complete. The intent of the SAR modification is to address FERC issues and to conform to updates in the Reliability Standards Development Procedure and Sanctions Guidelines.			
Dominion - Electric Transmission		☑	We disagree with the proposal from FERC NOPR regarding removing applicability to transmission lines >200kv. The proposal to apply the Standard to lines the ERO deems to have an impact on reliability can create inconsistency between regions and is a "fill in the blank" requirement. It is not clear whether the proposed change would increase or decrease the number of transmission lines which are subject to reportable outages. In addition, we support the Standard's existing language that limits reporting to locked out lines only.
Response: ▪ The FERC looks to the Standard Drafting Team to determine whether a change to the applicability to voltage <200kV is necessary.			
Southern California Edison		☑	The Commission's reccomendation to develop a "minimum" vegetation inspection cycle is untimely and their proposal to revise the scope ignores plain language contained in the standard. In SCE's view, the Commission's incessant need to bolt on a "widget count" requirement (for minimum inspection cylcles) will likely lead to an increased number of tree-to-line contacts. Unlike the static equipment located in power plants

Question #2			
Commenter	**Yes**	**No**	**Comment**
			and substations, trees and foliage in and around Transmission ROWs are subject to uncontrolable and fairly unpredictable natural forces. Industry debate during the previous SAR and comments submitted in the recently concluded NOPR demonstrate this approach is unsound. Transmission Owners in neighboring states commented that their cycles and trimming protocols vary from year to year and sometimes circuit to circuit. Instituting a minimum inspection cycle of 3 years (for example) might appeal to certain TOs because doing so will support a case for increased rate recovery. But for others, a mandatory 3 year inspection cycle will offer a potential cost reduction opportunity because they are already following a voluntary 2 year inspection cycle. The Commission's other reccomendedation should be rejected because subsection 4.3 clearly covers transmission lines operating below 200 kV. ["….any lower voltage lines designated by the RRO as critical to the reliabilty of the electric system in the region."] FAC-003-1 requires Transmission Owners to - "define a schedule for and the type (aerial, ground) of ROW vegetation inspections". Although the Commission staff would prefer a specific time duration because it suits their "check list" style of enforcement, the prudent thing to do is allow TOs the latitude to manage their part of the bulk system and hold each accountable to the existing compliance measures in FAC-003-1. Similarly, revising subsection 4.3 in deferrence to the Commission's or staff's misinterpretation of plain text is unwarranted.
Response: ▪ The FERC is no longer indicating a need to develop a requirement for a minimum inspection cycle in its March 16, 2007 Order 693 and stakeholders indicated they did not support this change, so it was removed from the SAR. ▪ The FERC looks to the Standard Drafting Team to determine whether a change to the applicability to voltage <200kV is necessary.			
New York State Electric and Gas Corporation		☑	The current standard FAC 003 1 should be monitored for one to two full years after all segments have been implemented. February 14, 2007 is too soon to determine if a revision is required. The standard should apply to 200 KV lines and higher voltages to prevent cascading type power outages. The IEEE table 516 is referenced as a minimum guide for table 2 clearances. This table provides clear and measurable distances that can used for audits and

Question #2			
Commenter	**Yes**	**No**	**Comment**
			potential compliance issues. The current standard allows enough flexibility so that the clearance 2 distance can be expanded if a utility feels that is the correct approach in a specfic region. The physical differences between electric systems, tree growth rates, local regulations, climate, and geography make it important to provide a flexible standard, a "one size fits all" approach will not be effective in the long run.
Response: ▪ The ERO Rules of Procedure include the latest versions of the Reliability Standards Development Procedure Manual and the Sanctions Guidelines. These documents were approved following the approval of FAC-003-1. FAC-003-1 will need to be revised to bring the standard into conformance with these documents. ▪ The FERC looks to the Standard Drafting Team to determine whether a change to the applicability to voltage <200kV is necessary. ▪ The Drafting Team recognizes that the IEEE standard is applicable. The FERC staff has questioned the applicability of the IEEE standard and the Drafting Team agreed to address their questions and concerns. ▪ The Drafting Team believes a revised standard is justified because it needs to include the following procedural changes: o Re-format FAC-003-1 to conform to current Standards Development Procedure. o Remove references to RRO in the standard and substitute a responsible entity. o Add the compliance elements needed to support the Sanctions Guidelines, including time horizons, and violation severity levels. ▪ The FERC is no longer indicating a need to develop a requirement for a minimum inspection cycle (March 16, 2007 Order 693) and stakeholders indicated they did not support this change, so it was removed from the SAR.			
Manitoba Hydro		☑	The scope of the SAR is too vague on several important points. (1) There is no definition for the phrase bulk-power system - it would be therefore unclear as to what facilities would be covered by the standard. What guidance will the SDrafting Team have in determining what is meant by the bulk-power system? Since this relates to the large issue of the Bulk Electric System versus Bulk-Power System is this SAR the appropriate vehicle to address this issue? There should be a wider discussion and resolution to this issue for consistent application to all standards by all SDrafting Teams. (2)The concept of Mitigation Time Horizons has not been defined and the use of Mitigation Time Horizons has not been detailed. (3)The ERO is not the appropriate entity to determine which lines have an impact on reliability. This should be Transmission Operators in coordination with Reliability Coordinators. If this standard is to include the methodology to determine which lines have a reliability impact on the bulk-power system, the the applicability of the

<table>
<tr><th colspan="4">Question #2</th></tr>
<tr><th>Commenter</th><th>Yes</th><th>No</th><th>Comment</th></tr>
<tr><td></td><td></td><td></td><td>standard will have to include other entities besides the Transmission Owners.

(4) The SAR refers to RA, i.e., Reliability Authority. This entity no longer exists in the Functional Model but has been replaced by Reliability Coordinator.

(5) What is meant by "Too weak on compliance"?

(5) FERC objects to IEEE Standard but there is no other guidance to the standard drafting team.</td></tr>
<tr><td colspan="4">Response:
▪ The comments regarding Bulk Power System in the FERC NOPR comments were removed from the revised SAR.
▪ The ERO Rules of Procedure require the inclusion of time horizons for each standard – these are defined in the Sanctions Guidelines and are used to help determine the size of a sanction.
▪ The revised SAR does not include the language proposing that the ERO determine which lines have an impact on reliability.
▪ The reference to Reliability Authority (RA) was removed from the revised SAR.
▪ The reference, ‘Too weak on compliance’ was removed from the revised SAR as it was addressed with the development of Version 1 of this standard.
▪ The Drafting Team recognizes that the IEEE standard is applicable. The FERC staff has questioned the applicability of the IEEE standard and the Drafting Team agreed to address their questions and concerns.</td></tr>
<tr><td>Southern Company Transmission</td><td></td><td>☑</td><td>The scope of the SAR should be limited to formatting and changes of wording that recognize the formation of the ERO and its procedures.

The drafting team should not attempt to re-write the present clearance requirements, which are based on IEEE flashover distances. The clearance requirements in the orignal standard were written through extensive evaluation and input from the industry. There was strong industry consensus on the present language and the standard is serving its intended purpose very well. The clearance standard should not be revised until it is found to be ineffective or inadequate.

The drafting team should not attempt to change the applicability of the present standard. The present standard applies to all 200 KV and higher lines, plus any other line the Regional Entity deems critical. A change in wording to make the standard apply to any bulk power system transmission line deemed critical by the ERO does not provide any additional safeguard that is not already contained in the standard as presently written.</td></tr>
<tr><td colspan="4">Response:
▪ The Drafting Team recognizes that the IEEE standard is applicable. The FERC staff has questioned the applicability of the IEEE</td></tr>
</table>

Question #2			
Commenter	**Yes**	**No**	**Comment**
standard and the Drafting Team agreed to address their questions and concerns. ▪ The FERC looks to the Standard Drafting Team to determine whether a change to the applicability to voltage <200kV is necessary.			
Baltimore Gas and Electric		☑	As noted above.
Response: See response to your question #1 comment above.			
Salt River Project	☑		
Allegheny Power	☑		

3. Are there additional revisions, beyond those identified in the SAR that should be addressed within the scope of this project?

Summary Consideration: Commenters suggested a number of additional revisions to the SAR related to:
- Applicability
- Right of Way (ROW) definition
- Compliance
- Clearance requirements
- Others

The SAR Drafting Team revised the SAR to consider these suggested revisions.

Question #3			
Commenter	**Yes**	**No**	**Comment**
Bonneville Power Administration	☑		It is not clear if categroy 1 and 2 refer only to occupied ROW, or also to unoccupied area reserved by the Transmission Owner for future expansion.
Response: o Category 1 outages refer to "grow-ins" inside or outside the right-of-way regardless; while a Category 2 outage applies to "fall-ins" on land that is inside the legal bounds of the right-or-way whether occupied or not. ▪ The FERC has directed the ERO to address the definition of ROW in its Order 693. ▪ As part of the SAR, the SAR Drafting Team commits the Standard Drafting Team to prepare technical reference material such as a "white paper" to aid in understanding the technical basis for the standard and, unless the requirements in the standard are modified to add more clarity, the SAR Drafting Team will recommend that the white paper include a discussion of the differences between category 1 and category 2 to address your concern.			
FRCC	☑		Requirement 3.2, item (1), the reporting exemption for outages occuring due to natural disaters should be expanded to include all vegetation outages that occur as a result of the disaster. Currently the exemption applies to vegetation from outside the ROW. As a result of significant experience with hurricanes, our operators have found that this distinction results in a waste of post-disaster resources. The standard currently requires the owner to investigate and determine the original location of the vegetation that may have caused an outage. Restoration of circuits may be delayed and often times, determination of the original location of the vegetation is not possible.
Response: ▪ The SAR Drafting Team will review the reporting exemptions to all category outages under major disasters in Requirement R3.2.			
Northeast Power Coordinating Council	☑		Only if the Bulk Power System is determined as an impact based performance based methodology.
Response:			

Question #3			
Commenter	**Yes**	**No**	**Comment**
▪ The FERC looks to the Standard Drafting Team to determine whether a change to the applicability to voltage <200kV is necessary. The comments regarding Bulk Power System in the FERC NOPR comments were removed from the revised SAR ▪			
SERC Reliability Corporation	☑		Standard Applicability: The outage reporting requirement for the RRO should be deleted. Making FAC-003 applicable to the RRO is in violation of the legislation that established the ERO. This legislation states that enforceable standards can apply only to owners, users and operators of the bulk power system. Futher, in the NOPR on NERC standards, FERC declined to approve those standards that applied to the RROs, in part because the RROs are not owners, users or operators. Compliance: The SERC VMS recommends deleting reporting requirements for Category 3 outages. These outages are not controllable, not relevant to compliance, not related to grid reliability, not related to cascading blackouts, and such reporting leads to unnecessarily biasing reliability related information.
Response: ▪ The Drafting Team believes a revised standard is justified because it needs to include the following procedural changes: o Re-format FAC-003-1 to conform to the current Standards Development Procedure. o Remove references to RRO in the standard and substitute a responsible entity. o Add the compliance elements needed to support the Sanctions Guidelines, including time horizons, and violation severity levels. ▪ The Standard Drafting Team intends to review reporting criteria for Category 3 outages in the proposed technical reference material and may review the reporting requirement of Category 3 outages in R.3 and R.4.			
Progress Energy	☑		Standard Applicability: The outage reporting requirement for the RRO should be deleted. Making FAC-003 applicable to the RRO is in violation of the legislation that established the ERO. This legislation states that enforceable standards can apply only to owners, users and opeartors of the bulk power system. Futher, in the NOPR on NERC standards, FERC declined to approve those standards that applied to the RROs, in part because the RROs are not owners, users or operators. Compliance: Progress Energy believes that FAC-003 should focus compliance on the issues that improve system/grid reliability. The VM standard outage reporting requirements do not focus on ensuring grid/network reliability.

Question #3			
Commenter	**Yes**	**No**	**Comment**
			Category 2 outages ("Fall-ins" from vegetation within the R/W) result in a level of non-compliance (Level 2 or 3). However, "Fall-ins", either off-R/W or within the R/W, are random events. They would not occur sequentially (i.e., a fall-in causing another line section to overload resulting in another "fall-in") and would not have the potential to cascade into a widespread blackout. This is a customer reliability issue for that line, not a grid reliability issue. While it may be worthwhile to report for tracking and trending, it is not an outage that should result in non-compliance. Category 1 "Grow-ins" include outages that result from conductor side-wing would be reported as Category 1 outages, resulting in non-compliance (Level 3 or 4). However, conductor side-swing outages are random occurrences. They are not the sequential outages that would have the potential to cascade into a widespread blackout. This is a customer reliability issue for that line, not a grid reliability issue. These types of outages should be not be considered any different than numerous other random events that result in transmission line outages.
Response: ▪ The SAR Drafting Team understands the distinction between grow-in and fall-in related outages and the prediction challenges with fall-in related outages. Modifying the compliance section is included in the scope of the SAR.			
Florida Power and Light Company	☑		Requirement 3.2 exempts reporting of outages from outside the ROW when natural disasters such as tornados or hurricanes occur. Our experience with numerous hurricanes indicates that all outages during these types of events should be exempt. The focus in these situations is to get the lines back in service and restore customers. There is insufficient manpower to adequately complete the forensics necessary to determine an accurate root cause. It is not uncommon to find vegetation debris in the lines or downed trees on the ROW in this situation. In most cases it is not possible to determine the original location of these trees. In the compliance section of the document a transmission owner becomes non compliant with a single category 1 or 2 outage. This occurs regardless of the circumstances. A non compliant penalty for a single outage in a situation where no customers were affected and the system could not have been compromised is not reasonable. It is also not an indicator of a poorly maintained system. We agree that several Category 1 or 2 interruptions could be an indicator of neglect but one is not. We recommend that The compliance section be reviewed with this in mind.
Response: ▪ The Standard Drafting Team will review the reporting exemptions to all category outages under major disasters in Requirement			

Question #3			
Commenter	**Yes**	**No**	**Comment**
R3.2. ▪ Modifying the compliance section is included in the scope of the SAR.			
Midwest Reliability Organization	☑		Since the IEEE standard does not appear to be a favorable clearance requirement, minimum clearance requirements should be tied to legal documents such as easments, state statute, or permits. This will help Transmission Owners to maintain their ROWs based on their agreements with the land owners and not rely on historical ROW management practices. It would also provide flexibility in clearance requirements based on geopraphical and climatological factors that influence different regions because landowner agreements will be different depending on local influences.
Response: ▪ The Drafting Team recognizes that the IEEE standard is applicable. The FERC staff has questioned the applicability of the IEEE standard and the Drafting Team agreed to address their questions and concerns.			
TVA	☑		Standard Applicability: The outage reporting requirement for the RRO should be deleted. Making FAC-003 applicable to the RRO is in violation of the legislation that established the ERO. This legislation states that enforceable standards can apply only to owners, users and operators of the bulk power system. Further, in the NOPR on NERC standards, FERC declined to approve those standards that applied to the RROs, in part because the RROs are not owners, users or operators. Compliance: Reporting requirements for Category 3 outages should be eliminated. These outages are not controllable, not relevant to compliance, not related to grid reliability, not related to cascading blackouts, and such reporting leads to unnecessarily biasing reliability related information.
Response: ▪ The Drafting Team believes a revised standard is justified because it needs to include the following procedural changes: o Re-format FAC-003-1 to conform to the current Standards Development Procedure. o Remove references to RRO in the standard and substitute a responsible entity. o Add the compliance elements needed to support the Sanctions Guidelines, including time horizons, and violation severity levels. ▪ The Standard Drafting Team will also address improvements identified by the FERC in its Order 693 - Mandatory Reliability Standards for the Bulk Power System. ▪ The Standard Drafting Team intends to review reporting criteria for Category 3 outages in the proposed technical reference material and may review the reporting requirement of Category 3 outages in R.3 and R.4.

Nomination Form —Transmission Vegetation Management SAR Drafting Team — Modify Standard FAC-003-1

Please return this form to sarcomm@nerc.com by **January 29, 2007**. For questions, please contact Richard Schneider at 609-452-8060 or Richard.schneider@nerc.net.

The drafting team will likely meet the end of February to respond to comments on the SAR. The complete meeting schedule has not been determined yet. It is expected the teams will meet several times in 2007 including face-to-face meetings, as well as meetings facilitated through various remote meeting technologies. **All candidates should be prepared to participate actively at these meetings.**

Name:	
Organization:	
Address:	
Office Telephone:	
E-mail:	

Please briefly describe your experience and qualifications to serve on the Transmission Vegetation Management SAR Drafting Team. Candidates should have expertise in one or more of the following areas: transmission line rights-of-way (ROW) vegetation management or ROW maintenance; transmission line design and ratings; regulatory or legal considerations in ROW maintenance; or existing codes and good practices in vegetation management. Previous experience developing or applying NERC or IEEE standards is beneficial, but not a requirement.

I represent the following NERC Reliability Region(s) (check all that apply):		**I represent the following Industry Segment (check one):**
☐ ERCOT	☐	1 — Transmission Owners
☐ FRCC	☐	2 — RTOs and ISOs
☐ MRO	☐	3 — Load-serving Entities
☐ NPCC	☐	4 — Transmission-dependent Utilities
☐ RFC	☐	5 — Electric Generators
☐ SERC	☐	6 — Electricity Brokers, Aggregators, and Marketers
☐ SPP	☐	7 — Large Electricity End Users
☐ WECC	☐	8 — Small Electricity End Users
☐ NA – Not Applicable	☐	9 — Federal, State, and Provincial Regulatory or other Government Entities

	☐	10 – Regional Reliability Organizations and Regional Entities

Which of the following Function(s) do you have expertise or responsibilities:	
☐ Reliability Coordinator	☐ Transmission Service Provider
☐ Balancing Authority	☐ Transmission Owner
☐ Interchange Authority	☐ Load Serving Entity
☐ Planning Authority or Coordinator	☐ Distribution Provider
☐ Transmission Operator	☐ Purchasing-selling Entity
☐ Generator Operator	☐ Generator Owner
☐ Transmission Planner	☐ Resource Planner
☐ Compliance Monitor	☐ Market Operator
Provide the names and contact information for two references who could attest to your technical qualifications and your ability to work well in a group.

Standard Authorization Request Form

Revisions to FAC-003-1 Transmission Vegetation Management Program Project 2007-07	
Request Date Revised Date	January 9, 2007 April 2, 2007

SAR Requestor Information		**SAR Type** (*Check a box for each one that applies.*)
Name Richard Dearman	☐	New Standard
Primary Contact Richard Dearman	☒	Revision to existing Standard
Telephone (256) 851-3523 Fax	☐	Withdrawal of existing Standard
E-mail redearman@tva.gov	☐	Urgent Action

Purpose / Industry Need (Describe the purpose of the standard — what the standard will achieve in support of reliability.)

The purpose of revising this standard is to:

1. Provide an adequate level of reliability for the North American electric transmission system – by verifying that the standard is complete and that its requirements are set at an appropriate level to ensure reliability.
2. Incorporate other general improvements described in the attached Standard Review Guidelines to bring it into conformance with the latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines.
3. Consider comments received from ERO regulatory authorities and stakeholders, as noted in the attached review sheets.
4. Satisfy the standards procedure requirement for five-year review of the standards.

Detailed Description

This is a new standard that was approved in 2006. It has some 'fill-in-the-blank' components to eliminate. In addition, the following comments submitted by FERC and stakeholders need to be addressed in the refinement of the standard:

FERC Order 693 items

1. To address the issue regarding applicability:
   - The Standard DT shall work with the reliability entities and the ERO to collect and make available to the FERC, a list of critical lower voltage transmission lines. (Refer to Applicability 4.3 section of the standard.)
     - The standard DT may consider other criteria in determining applicability of the standard to sub 200kV lines.
2. To address the issue of clearances for lines on both federal and non-federal lands:
   - The standard drafting team shall collect and analyze outage data then consider defining clearances needed to avoid sustained vegetation-related outages that would apply to transmission lines crossing both federal and non-federal land.
3. To consider revising the definition of right of way to encompass required clearance areas.
4. To review the suitability of IEEE 516-2003 standard for minimum vegetation clearance.

Procedural items

5. Re-format standard to bring it into conformance with the latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines.
6. Remove references to RRO in the standard and substitute a responsible entity.
7. Add compliance elements such as time horizons, and violation severity levels.

Stakeholder items

8. The Standard DT shall prepare technical reference material such as a "white paper" to aid in understanding the technical basis for the standard.
9. The Standard DT shall review reporting criteria for Category 3 outages in the proposed technical reference material and may remove the reporting requirement of Category 3 outages in R.3 and R.4.
10. The Standard DT shall consider deleting requirement R.4.
11. The Standard DT will review the reporting exemptions to include all category outages under major disasters in Requirement R3.2.

Reliability Functions

The Standard will Apply to the Following Functions *(Check box for each one that applies.)*		
☐	Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.
☐	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports interconnection frequency in real time.
☐	Interchange Authority	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced Interchange Schedules between Balancing Authority Areas.
☐	Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area..
☐	Resource Planner	Develops a (>one year) plan for the resource adequacy of specific loads within a Planning Coordinator Area.
☐	Transmission Planner	Develops a (>one year) plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator Area.
☐	Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
☒	Transmission Owner	Owns and maintains transmission facilities.
☐	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
☐	Distribution Provider	Delivers electrical energy to the End-use customer.
☐	Generator Owner	Owns and maintains generation facilities.
☐	Generator Operator	Operates generation unit(s) to provide real and reactive power.
☐	Purchasing-Selling Entity	Purchases or sells energy, capacity, and all necessary reliability-related services as required.
☐	Market Operator	Interface point for reliability functions with commercial functions.
☐	Load-Serving Entity	Secures energy and transmission (and related reliability-related services) to serve the End-use Customer.

Reliability and Market Interface Principles

Applicable Reliability Principles *(Check box for all that apply.)*	
☐	1. Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☐	2. The frequency and voltage of interconnected bulk electric systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☐	3. Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably.
☐	4. Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.
☒	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk electric systems.
☐	6. Personnel responsible for planning and operating interconnected bulk electric systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☐	7. The security of the interconnected bulk electric systems shall be assessed, monitored and maintained on a wide area basis.

Does the proposed Standard comply with all the following Market Interface Principles? *(Select "yes" or "no" from the drop-down box.)*
1. The planning and operation of bulk electric systems shall recognize that reliability is an essential requirement of a robust North American economy. Yes
2. An Organization Standard shall not give any market participant an unfair competitive advantage.Yes
3. An Organization Standard shall neither mandate nor prohibit any specific market structure. Yes
4. An Organization Standard shall not preclude market solutions to achieving compliance with that Standard. Yes
5. An Organization Standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes

Standard Review Guidelines

Applicability

Does this reliability standard clearly identify the functional classes of entities responsible for complying with the reliability standard, with any specific additions or exceptions noted? Where multiple functional classes are identified is there a clear line of responsibility for each requirement identifying the functional class and entity to be held accountable for compliance? Does the requirement allow overlapping responsibilities between Registered Entities possibly creating confusion for who is ultimately accountable for compliance?

Does this reliability standard identify the geographic applicability of the standard, such as the entire North American bulk power system, an interconnection, or within a regional entity area? If no geographic limitations are identified, the default is that the standard applies throughout North America.

Does this reliability standard identify any limitations on the applicability of the standard based on electric facility characteristics, such as generators with a nameplate rating of 20 MW or greater, or transmission facilities energized at 200 kV or greater or some other criteria? If no functional entity limitations are identified, the default is that the standard applies to all identified functional entities.

Purpose

Does this reliability standard have a clear statement of purpose that describes how the standard contributes to the reliability of the bulk power system? Each purpose statement should include a value statement.

Performance Requirements

Does this reliability standard state one or more performance requirements, which if achieved by the applicable entities, will provide for a reliable bulk power system, consistent with good utility practices and the public interest?

Does each requirement identify who shall do what under what conditions and to what outcome?

Measurability

Is each performance requirement stated so as to be objectively measurable by a third party with knowledge or expertise in the area addressed by that requirement?

Does each performance requirement have one or more associated measures used to objectively evaluate compliance with the requirement?

If performance results can be practically measured quantitatively, are metrics provided within the requirement to indicate satisfactory performance?

Technical Basis in Engineering and Operations

Is this reliability standard based upon sound engineering and operating judgment, analysis, or experience, as determined by expert practitioners in that particular field?

Completeness

Is this reliability standard complete and self-contained? Does the standard depend on external information to determine the required level of performance?

Consequences for Noncompliance

In combination with guidelines for penalties and sanctions, as well as other ERO and regional entity compliance documents, are the consequences of violating a standard clearly known to the responsible entities?

Clear Language

Is the reliability standard stated using clear and unambiguous language? Can responsible entities, using reasonable judgment and in keeping with good utility practices, arrive at a consistent interpretation of the required performance?

Practicality

Does this reliability standard establish requirements that can be practically implemented by the assigned responsible entities within the specified effective date and thereafter?

Capability Requirements versus Performance Requirements

In general, requirements for entities to have 'capabilities' (this would include facilities for communication, agreements with other entities, etc.) should be located in the standards for certification. The certification requirements should indicate that entities have a responsibility to 'maintain' their capabilities.

Consistent Terminology

To the extent possible, does this reliability standard use a set of standard terms and definitions that are approved through the NERC reliability standards development process?

If the standard uses terms that are included in the NERC Glossary of Terms Used in Reliability Standards, then the term must be capitalized when it is used in the standard. New terms should not be added unless they have a 'unique' definition when used in a NERC reliability standard. Common terms that could be found in a college dictionary should not be defined and added to the NERC Glossary.

Are the verbs on the 'verb list' from the DT Guidelines? If not – do new verbs need to be added to the guidelines or could you use one of the verbs from the verb list?

Violation Risk Factors (Risk Factor)

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. A requirement that is administrative in nature;

or a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

Time Horizon

The drafting team should also indicate the time horizon available for mitigating a violation to the requirement using the following definitions:

- Long-term Planning — a planning horizon of one year or longer.
- Operations Planning — operating and resource plans from day-ahead up to and including seasonal.
- Same-day Operations — routine actions required within the timeframe of a day, but not real-time.
- Real-time Operations — actions required within one hour or less to preserve the reliability of the bulk electric system.
- Operations Assessment — follow-up evaluations and reporting of real time operations.

Violation Severity Levels

The drafting team should indicate a set of violation severity levels that can be applied for the requirements within a standard. ('Violation severity levels' replace existing 'levels of non-compliance.') The violation severity levels may be applied for each requirement or combined to cover multiple requirements, as long as it is clear which requirements are included.

The violation severity levels should be based on the following definitions:

- Lower: mostly compliant with minor exceptions — The responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more minor details. Equivalent score: 95% to 99% compliant.
- Moderate: mostly compliant with significant exceptions — The responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more significant elements. Equivalent score: 85% to 94% compliant.
- High: marginal performance or results — The responsible entity has only partially achieved the reliability objective of the requirement and is missing one or more significant elements. Equivalent score: 70% to 84% compliant.
- Severe: poor performance or results — The responsible entity has failed to meet the reliability objective of the requirement. Equivalent score: less than 70% compliant.

Compliance Monitor

Replace, 'Regional Reliability Organization' with 'Regional Entity'.

Fill-in-the-blank Requirements

Do not include any 'fill-in-the-blank' requirements. These are requirements that assign one entity responsibility for developing some performance measures without requiring that the performance measures be included in the body of a standard – then require another entity to comply with those requirements.

Every reliability objective can be met, at least at a threshold level, by a North American standard. If we need regions to develop regional standards, such as in under-frequency load shedding, we can always write a uniform North American standard for the applicable functional entities as a means of encouraging development of the regional standards.

Requirements for Regional Reliability Organization

Do not write any requirements for the Regional Reliability Organization. Any requirements currently assigned to the RRO should be re-assigned to the applicable functional entity.

Effective Dates

Must be 1st day of 1st quarter after entities are expected to be compliant – must include time to file with regulatory authorities and provide notice to responsible entities of the obligation to comply. If the standard is to be actively monitored, time for the Compliance Monitoring and Enforcement Program to develop reporting instructions and modify the Compliance Data Management System(s) both at NERC and Regional Entities must be provided in the implementation plan.

Associated Documents

If there are standards that are referenced within a standard, list the full name and number of the standard under the section called, 'Associated Documents'.

Functional Model Version 3

Review the requirements against the latest descriptions of the responsibilities and tasks assigned to functional entities as provided in pages 13 through 53 of the draft Functional Model Version 3.

Standard Authorization Request Form

~~Title of Proposed Standard~~ Revisions to FAC-003-1 Transmission Vegetation Management Program Project 2007-07	
Request Date	January 9, 2007
Revised Date	April 2, 2007

SAR Requestor Information	SAR Type (*Check a box for each one that applies.*)	
Name Richard ~~Schneider (To be replaced by SAR DT Chair when the SAR DT is appointed)~~Dearman	☐	New Standard
Primary Contact Richard ~~Schneider~~Dearman	☒	Revision to existing Standard
Telephone ~~609-452-8060~~(256) 851-3523 Fax	☐	Withdrawal of existing Standard
~~E-mail Richard.schneider@nerc.net~~E-mail redearman@tva.gov	☐	Urgent Action

Purpose / Industry Need (Describe the purpose of the standard — what the standard will achieve in support of reliability.)

The purpose of revising this standard is to:

1. Provide an adequate level of reliability for the North American ~~bulk power systems -~~electric transmission system – by verifying that the standard is complete and ~~the~~that its requirements are set at an appropriate level to ensure reliability.

~~2.Ensure it is enforceable as a mandatory reliability standard with financial penalties - the applicability to bulk power system owners, operators, and users, and as appropriate particular classes of facilities, is clearly defined; the purpose, requirements, and measures are results-focused and unambiguous; the consequences of violating the requirements are clear.~~

2. Incorporate other general improvements described in the attached Standard Review Guidelines to bring it into conformance with the latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines.

3. Consider comments received from ERO regulatory authorities and stakeholders, as noted in the attached review sheets.

4. Satisfy the standards procedure requirement for five-year review of the standards.

~~Brief~~Detailed Description

This is a new standard that was approved in 2006. It has some 'fill-in-the-blank' components to eliminate. In addition, the following comments submitted by FERC and stakeholders need to be addressed in the refinement of the standard:

FERC ~~NOPR~~Order 693 items

~~- Develop a minimum vegetation inspection cycle that allows variation for physical differences, as discussed above; and~~

~~- Remove the applicability to transmission lines operated at 200 kV and above so that the Reliability Standard applies to Bulk-Power System transmission lines that have an impact of reliability as determined by the ERO.~~

~~**FERC staff report**~~

~~- Objections to use of IEEE standard~~

~~**Stakeholder Comments**~~

~~- RA vs. RRO~~

~~- Too weak on compliance~~

~~- Format inconsistencies~~

1. ~~The development may include other improvements to the standards deemed appropriate by the drafting team, with the consensus of stakeholders, consistent with establishing high quality, enforceable and technically sufficient bulk power system reliability standards.~~To address the issue regarding applicability:
   - The Standard DT shall work with the reliability entities and the ERO to collect and make available to the FERC, a list of critical lower voltage transmission lines. (Refer to Applicability 4.3 section of the standard.)
     - The standard DT may consider other criteria in determining applicability of the standard to sub 200kV lines.
2. To address the issue of clearances for lines on both federal and non-federal lands:
     - The standard drafting team shall collect and analyze outage data then consider defining clearances needed to avoid sustained vegetation-related outages that would apply to transmission lines crossing both federal and non-federal land.
3. To consider revising the definition of right of way to encompass required clearance areas.
4. To review the suitability of IEEE 516-2003 standard for minimum vegetation clearance.

Procedural items

5. Re-format standard to bring it into conformance with the latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines.
6. Remove references to RRO in the standard and substitute a responsible entity.
7. Add compliance elements such as time horizons, and violation severity levels.

Stakeholder items

8. The Standard DT shall prepare technical reference material such as a "white paper" to aid in understanding the technical basis for the standard.
9. The Standard DT shall review reporting criteria for Category 3 outages in the proposed technical reference material and may remove the reporting requirement of Category 3 outages in R.3 and R.4.
10. The Standard DT shall consider deleting requirement R.4.
11. The Standard DT will review the reporting exemptions to include all category outages under major disasters in Requirement R3.2.

Reliability Functions

The Standard will Apply to the Following Functions *(Check box for each one that applies.)*		
☐	Reliability Coordinator	~~Ensures~~Responsible for the real-time operating reliability of ~~the bulk transmission system within~~ its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area~~. This is the highest reliability authority.~~ view.
☐	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within ~~its metered boundary~~a Balancing Authority Area and supports ~~system~~interconnection frequency in real time.
☐	Interchange Authority	~~Authorizes~~Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced Interchange Schedules~~.~~ between Balancing Authority Areas.
☐	Planning ~~Authority~~Coordinator	~~Plans the Bulk Electric System.~~Assesses the longer-term reliability of its Planning Coordinator Area..
☐	Resource Planner	Develops a ~~long-term~~ (>one year) plan for the resource adequacy of specific loads within a Planning ~~Authority area.~~Coordinator Area.
☐	Transmission Planner	Develops a ~~long-term~~ (>one year) plan for the reliability of ~~transmission systems~~the interconnected Bulk Electric System within its portion of the Planning ~~Authority area.~~Coordinator Area.
☐	Transmission Service Provider	~~Provides~~Administers the transmission tariff and provides transmission services ~~to qualified market participants~~ under applicable transmission service agreements (e.g., the pro forma tariff).
☒	Transmission Owner	Owns and maintains transmission facilities.
☐	Transmission Operator	~~Operates and maintains the transmission facilities, and executes switching orders.~~Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
☐	Distribution Provider	~~Provides and operates the "wires" between the transmission system and the customer.~~Delivers electrical energy to the End-use customer.
☐	Generator Owner	Owns and maintains generation ~~unit(s).~~facilities.
☐	Generator Operator	Operates generation unit(s) to provide real and ~~performs the functions of supplying energy and Interconnected Operations Services.~~reactive power.
☐	Purchasing-Selling Entity	~~The function of purchasing~~Purchases or ~~selling~~sells energy, capacity, and all necessary ~~Interconnected Operations Services~~reliability-related services as required.
☐	Market Operator	~~Integrates energy, capacity, balancing, and transmission resources to achieve an economic, reliability-constrained dispatch.~~Interface point for reliability functions with commercial functions.

☐	Load-Serving Entity	Secures energy and transmission (and related ~~generation~~reliability-related services) to serve the ~~end user.~~End-use Customer.

Reliability and Market Interface Principles

Applicable Reliability Principles *(Check box for all that apply.)*	
☐	1. Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☐	2. The frequency and voltage of interconnected bulk electric systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☐	3. Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably.
☐	4. Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.
☒	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk electric systems.
☐	6. Personnel responsible for planning and operating interconnected bulk electric systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☐	7. The security of the interconnected bulk electric systems shall be assessed, monitored and maintained on a wide area basis.

Does the proposed Standard comply with all the following Market Interface Principles? *(Select "yes" or "no" from the drop-down box.)*
1. The planning and operation of bulk electric systems shall recognize that reliability is an essential requirement of a robust North American economy. Yes
2. An Organization Standard shall not give any market participant an unfair competitive advantage.Yes
3. An Organization Standard shall neither mandate nor prohibit any specific market structure. Yes
4. An Organization Standard shall not preclude market solutions to achieving compliance with that Standard. Yes
5. An Organization Standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes

Standard Review Guidelines

Applicability
Does this reliability standard clearly identify the functional classes of entities responsible for complying with the reliability standard, with any specific additions or exceptions noted? Where multiple functional classes are identified is there a clear line of responsibility for each requirement identifying the functional class and entity to be held accountable for compliance? Does the requirement allow overlapping responsibilities between Registered Entities possibly creating confusion for who is ultimately accountable for compliance?

Does this reliability standard identify the geographic applicability of the standard, such as the entire North American bulk power system, an interconnection, or within a regional entity area? If no geographic limitations are identified, the default is that the standard applies throughout North America.

Does this reliability standard identify any limitations on the applicability of the standard based on electric facility characteristics, such as generators with a nameplate rating of 20 MW or greater, or transmission facilities energized at 200 kV or greater or some other criteria? If no functional entity limitations are identified, the default is that the standard applies to all identified functional entities.

Purpose
Does this reliability standard have a clear statement of purpose that describes how the standard contributes to the reliability of the bulk power system? Each purpose statement should include a value statement.

Performance Requirements
Does this reliability standard state one or more performance requirements, which if achieved by the applicable entities, will provide for a reliable bulk power system, consistent with good utility practices and the public interest?

Does each requirement identify who shall do what under what conditions and to what outcome?

Measurability
Is each performance requirement stated so as to be objectively measurable by a third party with knowledge or expertise in the area addressed by that requirement?

Does each performance requirement have one or more associated measures used to objectively evaluate compliance with the requirement?

If performance results can be practically measured quantitatively, are metrics provided within the requirement to indicate satisfactory performance?

Technical Basis in Engineering and Operations
Is this reliability standard based upon sound engineering and operating judgment, analysis, or experience, as determined by expert practitioners in that particular field?

Completeness
Is this reliability standard complete and self-contained? Does the standard depend on external information to determine the required level of performance?

Consequences for Noncompliance

In combination with guidelines for penalties and sanctions, as well as other ERO and regional entity compliance documents, are the consequences of violating a standard clearly known to the responsible entities?

Clear Language
Is the reliability standard stated using clear and unambiguous language? Can responsible entities, using reasonable judgment and in keeping with good utility practices, arrive at a consistent interpretation of the required performance?

Practicality
Does this reliability standard establish requirements that can be practically implemented by the assigned responsible entities within the specified effective date and thereafter?

Capability Requirements versus Performance Requirements
In general, requirements for entities to have 'capabilities' (this would include facilities for communication, agreements with other entities, etc.) should be located in the standards for certification. The certification requirements should indicate that entities have a responsibility to 'maintain' their capabilities.

Consistent Terminology
To the extent possible, does this reliability standard use a set of standard terms and definitions that are approved through the NERC reliability standards development process?

If the standard uses terms that are included in the NERC Glossary of Terms Used in Reliability Standards, then the term must be capitalized when it is used in the standard. New terms should not be added unless they have a 'unique' definition when used in a NERC reliability standard. Common terms that could be found in a college dictionary should not be defined and added to the NERC Glossary.

Are the verbs on the 'verb list' from the DT Guidelines? If not – do new verbs need to be added to the guidelines or could you use one of the verbs from the verb list?

Violation Risk Factors (Risk Factor)

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. A requirement that is administrative in nature;

or a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

~~Mitigation~~ Time Horizon

The drafting team should also indicate the time horizon available for mitigating a violation to the requirement using the following definitions:

- **Long-term Planning** — a planning horizon of one year or longer.
- **Operations Planning** — operating and resource plans from day-ahead up to and including seasonal.
- **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time.
- **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk electric system.
- **Operations Assessment** — follow-up evaluations and reporting of real time operations.

Violation Severity Levels

The drafting team should indicate a set of violation severity levels that can be applied for the requirements within a standard. (‘Violation severity levels’ replace existing ‘levels of non-compliance.’) The violation severity levels may be applied for each requirement or combined to cover multiple requirements, as long as it is clear which requirements are included.

The violation severity levels should be based on the following definitions:

- **Lower: mostly compliant with minor exceptions** — The responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more minor details. Equivalent score: 95% to 99% compliant.
- **Moderate: mostly compliant with significant exceptions** — The responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more significant elements. Equivalent score: 85% to 94% compliant.

- **High: marginal performance or results** — The responsible entity has only partially achieved the reliability objective of the requirement and is missing one or more significant elements. Equivalent score: 70% to 84% compliant.
- **Severe: poor performance or results** — The responsible entity has failed to meet the reliability objective of the requirement. Equivalent score: less than 70% compliant.

Compliance Monitor
Replace, 'Regional Reliability Organization' with '~~Electric Reliability Organization'~~Regional Entity'.

Fill-in-the-blank Requirements
Do not include any 'fill-in-the-blank' requirements. These are requirements that assign one entity responsibility for developing some performance measures without requiring that the performance measures be included in the body of a standard – then require another entity to comply with those requirements.

Every reliability objective can be met, at least at a threshold level, by a North American standard. If we need regions to develop regional standards, such as in under-frequency load shedding, we can always write a uniform North American standard for the applicable functional entities as a means of encouraging development of the regional standards.

Requirements for Regional Reliability Organization
Do not write any requirements for the Regional Reliability Organization. Any requirements currently assigned to the RRO should be re-assigned to the applicable functional entity.

Effective Dates
Must be 1st day of 1st quarter after entities are expected to be compliant – must include time to file with regulatory authorities and provide notice to responsible entities of the obligation to comply. If the standard is to be actively monitored, time for the Compliance Monitoring and Enforcement Program to develop reporting instructions and modify the Compliance Data Management System(s) both at NERC and Regional Entities must be provided in the implementation plan.

Associated Documents
If there are standards that are referenced within a standard, list the full name and number of the standard under the section called, 'Associated Documents'.

Functional Model Version 3
Review the requirements against the latest descriptions of the responsibilities and tasks assigned to functional entities as provided in pages 13 through 53 of the draft Functional Model Version 3.

Maureen E. Long
Standards Process Manager

April 10, 2007

TO: REGISTERED BALLOT BODY

Ladies and Gentlemen:

Announcement: Comment Period Opens

The Standards Committee (SC) announces the following standards actions:

SAR for Transmission Vegetation Management (Project 2007-07) Posted for 30-day Comment Period April 10–May 9, 2007

The SAR for Project 2007-07 proposes modifying the Vegetation Management Standard FAC-003-1 to address concerns raised by FERC and stakeholders and to bring the standard into conformance with the latest version of the Reliability Standards Development Procedure and the ERO Sanctions Guidelines. Please use the comment form to provide comments on the second draft of this SAR.

Standards Development Process

The *Reliability Standards Development Procedure* contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate. If you have any questions, please contact me at 813-468-5998 or maureen.long@nerc.net.

Sincerely,

Maureen E. Long

Background Information:

The SAR drafting team considered the comments submitted in response to the first posting of the SAR as well as the FERC Order 693 in preparing the revised SAR to modify FAC-003-1 — Transmission Vegetation Management.

The SAR drafting team modified the SAR to state more specifically that the revisions to the standard need to incorporate the compliance program elements of time horizons and violation severity levels to bring FAC-003-1 into conformance with the latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines.

The FERC has urged further industry consideration of a number of issues and these have been listed in the revised SAR as items to address during using standards development process to refine FAC-003-1. The SAR drafting team consensus is that a modification to FAC-003-1 to address the aforementioned items is warranted.

Please review the changes made to the Vegetation Management SAR and then respond to the questions on the following pages. Please e-mail your comments to sarcomm@nerc.net with the subject “Vegetation Management SAR” by **May 9, 2007.**

You need not answer all questions. Insert a “check” mark in the appropriate boxes by double-clicking the gray areas.

The SAR drafting team considered stakeholder comments on the first draft of this SAR and the FERC Order 693 in preparing the second draft of the SAR to modify FAC-003-1 — Transmission Vegetation Management.

The SAR drafting team modified the SAR to clarify that FAC-003-1 needs to add time horizons and violation severity levels to bring the standard into conformance with the latest version of the Reliability Standards Development Procedure and the ERO Sanctions Guidelines. (Time Horizons and Violation Severity Levels are both elements used to determine an appropriate sanction for violation of a standard.)

The SAR drafting team also modified the SAR to clarify that the scope of revisions to this standard will include addressing the issues raised by FERC in Order 693, including the following:

- Consideration of minimum clearances needed to avoid sustained vegetation-related outages that would apply to transmission lines crossing both federal land and non-federal land
- Revisions to the definition of ‘right of way’ to encompass required clearance areas
- Review of the suitability of IEEE Standard 516-2003 for minimum vegetation clearance

Several commenters indicated that the reporting requirements may need revision and the SAR was revised to include consideration of modifications to the reporting requirements.

The SAR drafting team consensus is that modification of FAC-003-1 to address the aforementioned items is needed to ensure reliability of the bulk power system.

1. **Do you agree there is a reliability need for the proposed modifications and review of the standard?**

☐ Yes

☒ No

Comments: AEP believes that the current standard (when thoroughly read and understood) is completely adequate to maintain a reliable transmission system with minimum risk of vegetation-related outages.

2. **If you are a transmission owner, have you been provided a list from a Reliability Entity (formerly RRO) of sub 200kV critical transmission lines that must comply with FAC-003-1?**

☒ Yes

☒ No

Comments: Of the three regions in which AEP has transmission facilities, only one RE has provided a listing of sub-200 kV facilities of what we consider applicable under this standard.

3. **If you are a transmission owner would you provide your methodology for determining clearance 1 and clearance 2? (As described in FAC-003-1 R1.2.1 and R1.2.2) If so, please attach.**

☒ Yes

☐ No

Comments: For Clearance 1, AEP has chosen to use the minimum approach distances set forth in ANSI Tree Care Standard Z133.1 (rev. October 2000) for persons other than qualified line-clearance arborists and qualified line-clearance arborist trainees. For Clearance 2, AEP utilizes the Z133.1 minimum approach distances for qualified line clearance arborists and qualified line-clearance arborist trainees.

4. **Are there any other comments regarding the standard, its possible modifications or the SAR?**

☒ Yes

☐ No

Comments: The SAR directs the SDT to collect and analyze outage data as part of an effort to define clearances for transmission lines on federal and non-federal lands. AEP believes that the analysis of outage data will be meaningless and unproductive. The SAR directive presupposes a cause-and-effect relationship between vegetation-related outages and federal/non-federal land status. On the contrary, AEP believes that vegetation-related data is more indicative of the effectiveness of the utility's VM program, in spite of onerous and inordinately expensive measures required on federal lands.

   ☒ Yes

   ☐ No

   Comments: Ameren does not agree that each of 11 items listed in the SAR are necessary to improve reliability. The following comments are offered for each of the 11 items identified in the SAR detail description:

   1. Standard Applicability:

   Ameren disagrees with revising the 200 kV threshold for determining facilities subject to this standard. Extending the requirements to lines other than those >200kV will dilute the focus on those lines that impact grid reliability and shift attention to facilities, <200kV. Utilities generally have an incentive to maintain reliability on lines less than 200kV. State commissions and customer expections for reliable service provide this incentive. While many facilities above 200kV directly support customer load, transmission lines below 200kV primarily support customer load, and interruptions to those facilities reduces load on the grid.

   The majority of transmission facilities below 200 kV also have significantly different design/construction/operating characteristics and have not been cited as impacting bulk power system reliability. For example, the Final Report on the August 14, 2003 Blackout in the United states and Canada: Causes and Recommendations April 2004 by the U.S.- Canada Power System Outage Task Force and all referenced major blackouts (pages 103-115) in that report, cited only outages which involved vegetation at line voltages above 200kV. Generally applying requirements that are appropriate for >200kV lines to lines less than 200kV will result in significant documentation and reporting of items such as restrictions, mitigation plans, off right-of-way vegetation-related outage investigation/ information and other issues, all of which dilutes the focus on lines that directly impact bulk power system reliability.

Revising the standard to use general criteria or broad language for defining "Bulk Power System" transmission lines covered by the standard is a “one size fits all” approach. If that approach were taken, the standard would cover a significant number of transmission lines that have no direct impact on bulk power system reliability under standard planning/operating conditions, resulting in a significant cost burden for electric customers without improving “grid” reliability. Ameren believes that the applicability provision of the standard should focus attention of the standard only on the transmission lines below 200kV that directly impact “Bulk Power System” reliability, as the current version requires.

Ameren recognizes some validity in the Commission’s concern, Ameren recommends that the applicability provision of this standard should be revised only if existing system design, planning or operating reliability criteria and parameters are considered as a basis for defining the applicability of the standard. Ameren recommends each Regional Entity (RE) determine applicability of FAC-003 to those lines within the region that are between 100kV and 200KV, if, and only if, they are identified as operationally significant elements of Interconnection Reliability Operating Limits (“IROLs”). That is, any facility below 200kV that by itself would cause an Interconnected Reliability Limit Violation should the facility
be outaged.

2. Issue of Clearances (Federal vs Non-Federal Lands):

FAC-003-1 presently requires the transmission owner (TO) “identify and document clearances between vegetation and any overhead, ungrounded supply conductors, taking into consideration transmission line voltage, the effects of ambient temperature on conductor sag under maximum design loading, and the effects of wind velocities on conductor sway.” The intent of this requirement is to ensure adequate clearances to prevent vegetation related outages. Ameren believes that only the TO has the technical information required to determine the clearances that are necessary at the time of VM work and that any “federal lands exemption” to clearances will result in inadequate clearances for the existing conditions. Consistency in application of the TO’s clearance requirements, not exceptions, is the only assurance in providing a uniform and reliable electrical system to meet the nation’s current and future energy demands.
Any exception for a case by case clearance approach to determine vegetation management activities/clearances on Federal lands will continue to drive inconsistency and/or delays associated with vegetation management decisions being driven by diverse vegetation management practices/beliefs and staff changes at the local level of Federal agencies. Vegetation-related outages have occurred on Federal lands as a result of this case by case approach, and if “Bulk Power Transmission System” lines continue to be addressed on a “case by case” basis on National Forest Service (or any other Federal lands), those lines will potentially be subject to a higher risk for vegetation-related outages, resulting in reduced reliability for the “Bulk Power System”.

Ameren believes that reliability of the “Bulk Power System” should have the same focus on Federal and private lands and that the EEI MOU with federal agencies is the appropriate vehicle for TO's to identify clearance variances on Ferderal lands, not exemption language in the standard. The standard should not be used as a mechanism by federal agencies to impose variances to proven vegetation management practices and clearances.

3. Defining Right-of-Way:

Ameren agrees that it is appropriate to further address the definition of “right-of-way”. Corridor widths beyond design clearance requirements have been acquired for a variety of reasons in the past; future use, property line buffers, etc. Vegetation in those areas that would normally fall outside of the area necessary for operation of the facility should not be considered or treated different than vegetation that is outside of a defined easement/permit area that is designed for the reliable operation of an existing single line corridor.

4. IEEE Standard for Minimum Clearances:

Ameren disagrees with objections to the use of the IEEE 516-2003 clearance as the minimum acceptable distances for “Clearance 2”. The IEEE 516-2003 tables are appropriate for defining the minimum acceptable clearances to prevent flashover between conductors and vegetation under all rated electrical operating conditions. FERC staff references ANSI Z-133 which is a safety standard that addresses worker safety as well as the safety of the general public. As such, the purpose of ANSI Z-133 is to address worker safety and is not focused on transmission line reliability, which is the purpose of FAC-003-1. OSHA, NESC and other related safety standards have clearances in excess of IEEE 516-2003. Those clearances are clearly focused on safety issues and will still apply to other aspects of design and operation of electric facilities (such as public and worker safety) but are not appropriate to be referenced in a vegetation management reliability standard.

5/6/7. Procedural Items:

Ameren agrees that the procedural items related to formatting RRO references and additional compliance elements should be addressed by the standard drafting team.

8. Technical Reference Materials:

Ameren agrees that a “white paper” that defines the technical basis for the standard is appropriate to avoid the potential for differences in interpretation of the standard’s requirements during the various region's audit processes.

9. Category 3 Outages:

Since the right to control off right-of-way vegetation is generally beyond control of the transmission owner Ameren believes that the reporting of category 3 outages should be removed from the requirements.

10. Requirement R4:

Ameren believes that requirement R4 should be deleted from the standard, based on the ERO formation and the process for delegation of authority to the regional entities.

11. Reporting Exemptions:

Ameren believes that the reporting requirement exemptions for natural disasters should include all categories of outages. It would, for example, be difficult, without delaying restoration efforts, to determine if the vegetation from high winds, hurricanes, tornadoes, etc. is from on or off the "right-of-way".

Several commenters indicated that the reporting requirements may need revision and the SAR was revised to include consideration of modifications to the reporting requirements.

The SAR drafting team consensus is that modification of FAC-003-1 to address the aforementioned items is needed to ensure reliability of the bulk power system.

1. **Do you agree there is a reliability need for the proposed modifications and review of the standard?**

   ☐ Yes

   ☒ No

   Comments: CenterPoint Energy does not agree that a revision to the TVM standard is necessary from a reliability standpoint, and believes that the existing TVM standard is adequate for that purpose.

2. **If you are a transmission owner, have you been provided a list from a Reliability Entity (formerly RRO) of sub 200kV critical transmission lines that must comply with FAC-003-1?**

   ☐ Yes

   ☒ No

   Comments:

3. **If you are a transmission owner would you provide your methodology for determining clearance 1 and clearance 2? (As described in FAC-003-1 R1.2.1 and R1.2.2) If so, please attach.**

   ☒ Yes

   ☐ No

   Comments: CenterPoint Energy has developed a methodology to determine clearance 1 and clearance 2 as described in FAC-003-1 R1.2.1 and R1.2.2. This methodology is included in a document titled "Specification for Transmission Vegetation Management Program" dated February 2007. Section 5.1 of that document covers NERC Clearance 1, and Section 5.2 covers NERC Clearance 2. Text and Tables from both Sections 5.1 and 5.2 are shown below:

   5.1 NERC CLEARANCE 1

   5.1.1 The appropriate clearance to conductors at the time of vegetation management work is established as Clearance 1 in accordance with NERC Standard FAC-003-1 Requirement R1.2.1.

   5.1.2 Clearance 1 is determined by considering transmission line voltage, the effects of ambient temperature on conductor sag under maximum design loading, the effects of wind velocities on conductor sway, and the anticipated average growth rate of the prevalent tree species within the Company’s service area over a 5-year period.

   5.1.2.1 The minimum clearance distance of IEEE Standard 516-2003 Section 4.2.2.3, Minimum Air Insulation Distances without Tools in the Air Gap, is a component of Clearance 1.

   5.1.3 Table 5.1 contains the horizontal clearance components and nominal values for Clearance 1, and Table 5.2 contains the vertical clearance components and nominal values for Clearance 1.

Table 5.1
NERC Clearance 1: Horizontal Clearance, feet
Horizontal Clearance Component, Nominal Voltage p-p

	69kV	138kV	345kV
Electrical Clearance (1)	2.46	2.95	4.40
Average 5-Year Horizontal Tree Growth	12.00	12.00	12.00
Average Mid-span Conductor Sway (2)	5.98	8.13	10.04
Total	20.44	23.08	26.44
Nominal Horizontal Value (3)	20	23	26

(1) Based on IEEE 516-2003 Table 5 for 69kV & 138kV and Table 7 for 345kV
(2) Based on NESC C2-2007 Rule 233A(1)
(3) May be reduced for site specific tree species or conductor span configuration but not less than Clearance 2.

Table 5.2
NERC Clearance 1: Vertical Clearance, feet
Vertical Clearance Component, Nominal Voltage p-p

	69kV	138kV	345kV
Electrical Clearance (1)	2.46	2.95	4.40
Average 5-Year Vertical Tree Growth	15.75	15.75	15.75
Average Conductor Final Sag Increase (2)	7.52	9.01	10.24
Total	25.73	27.71	30.39
Nominal Vertical Value (3)	26	28	30

(1) Based on IEEE 516-2003 Table 5 for 69kV & 138kV and Table 7 for 345kV
(2) Based on NESC C2-2007 Rule 233A(1)
(3) May be reduced for site specific tree species or conductor span configuration but not less than Clearance 2.

5.2 NERC CLEARANCE 2

5.2.1 The minimum radial clearance to prevent flashover between vegetation and conductors is established as Clearance 2 in accordance with NERC Standard FAC-003-1 Requirement R1.2.2.

5.2.2 Clearance 2 is determined by considering transmission line voltage, the effects of ambient temperature on conductor sag under maximum design loading, and the effects of wind velocities on conductor sway. Clearance 2 is a radial clearance, so the vertical component and the horizontal component are both calculated, and the largest clearance is selected as the prevailing clearance for Clearance 2.

5.2.2.1 The minimum clearance distance of IEEE Standard 516-2003 Section 4.2.2.3, Minimum Air Insulation Distances without Tools in the Air Gap, is a component of Clearance 2.

5.2.3 Table 5.3 contains the horizontal clearance component, Table 5.4 contains the vertical clearance component, and Table 5.5 contains the prevailing nominal values for Clearance 2.

Table 5.3

Horizontal Clearance Component, feet
Horizontal Clearance Component, Nominal Voltage p-p

	69kV	138kV	345kV
Electrical Clearance (1)	2.46	2.95	4.40
Average Mid-span Conductor Sway (2)	5.98	8.13	10.04
Total	8.44	11.08	14.44
Nominal Horizontal Value (3)	8	11	14

(1) Based on IEEE 516-2003 Table 5 for 69kV & 138kV and Table 7 for 345kV
(2) Based on NESC C2-2007 Rule 233A(1)
(3) May be reduced for site specific tree species or conductor span configuration but not less than Clearance 2.

Table 5.4

Vertical Clearance Component, feet
Vertical Clearance Component, Nominal Voltage p-p

	69kV	138kV	345kV

Electrical Clearance (1)	2.46	2.95	4.40
Average Conductor Final Sag Increase (2)	7.52	9.01	10.24
Total	9.98	11.96	14.64
Nominal Vertical Value (3)	10	12	15

(1) Based on IEEE 516-2003 Table 5 for 69kV & 138kV and Table 7 for 345kV
(2) Based on NESC C2-2007 Rule 233A(1)
(3) May be reduced for site specific tree species or conductor span configuration but not less than Clearance 2.

Table 5.5

NERC Clearance 2: Minimum Radial Clearance to Prevent Flashover, feet
Nominal Voltage p-p

69kV	138kV	345kV
10	12	15

4. Are there any other comments regarding the standard, its possible modifications or the SAR?

☐ Yes

☒ No

Background Information:

The SAR drafting team considered the comments submitted in response to the first posting of the SAR as well as the FERC Order 693 in preparing the revised SAR to modify FAC-003-1 — Transmission Vegetation Management.

The SAR drafting team modified the SAR to state more specifically that the revisions to the standard need to incorporate the compliance program elements of time horizons and violation severity levels to bring FAC-003-1 into conformance with the latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines.

The FERC has urged further industry consideration of a number of issues and these have been listed in the revised SAR as items to address during using standards development process to refine FAC-003-1. The SAR drafting team consensus is that a modification to FAC-003-1 to address the aforementioned items is warranted.

Please review the changes made to the Vegetation Management SAR and then respond to the questions on the following pages. Please e-mail your comments to sarcomm@nerc.net with the subject "Vegetation Management SAR" by **May 9, 2007.**

You need not answer all questions. Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

The SAR drafting team considered stakeholder comments on the first draft of this SAR and the FERC Order 693 in preparing the second draft of the SAR to modify FAC-003-1 — Transmission Vegetation Management.

The SAR drafting team modified the SAR to clarify that FAC-003-1 needs to add time horizons and violation severity levels to bring the standard into conformance with the latest version of the Reliability Standards Development Procedure and the ERO Sanctions Guidelines. (Time Horizons and Violation Severity Levels are both elements used to determine an appropriate sanction for violation of a standard.)

The SAR drafting team also modified the SAR to clarify that the scope of revisions to this standard will include addressing the issues raised by FERC in Order 693, including the following:

- Consideration of minimum clearances needed to avoid sustained vegetation-related outages that would apply to transmission lines crossing both federal land and non-federal land
- Revisions to the definition of 'right of way' to encompass required clearance areas
- Review of the suitability of IEEE Standard 516-2003 for minimum vegetation clearance

Several commenters indicated that the reporting requirements may need revision and the SAR was revised to include consideration of modifications to the reporting requirements.

The SAR drafting team consensus is that modification of FAC-003-1 to address the aforementioned items is needed to ensure reliability of the bulk power system.

1. **Do you agree there is a reliability need for the proposed modifications and review of the standard?**

   ☐ Yes

   ☒ No

   Comments: The current Vegetation Management Standard FAC-003-1 has been crafted in such a way as to provide crisp measurable standards that when followed will provide a high level of power quality for the bulk power delivery system. However, clearances between conductors and trees required to prevent tree related power outages must be consistent with each utility's established standards and if a transmission line passes through federal, state or locally managed areas this line placement should not impact the established clearances. Utilities should not be expected to negotiate clearances with multiple land managers.

   The IEEE 516 – 2003 table is an acceptable table to use as the minimum clearance to prevent a flash over and outages. FAC-003-1 is designed to be a reliability standard and the industry adheres to OSHA and ANSI standards to protect workers and the public.
   The IEEE 516 – 2003 table lists appropriate distances that should be used to measure compliance. The standard should continue to provide the flexibility for utility managers to increase "Clearance 2".

   The definition for right-of-way should be clarified to include only the area that is cleared and included as routine maintenance.

   We agree that there is a need to establish time horizons and clarify violation levels.

2. **If you are a transmission owner, have you been provided a list from a Reliability Entity (formerly RRO) of sub 200kV critical transmission lines that must comply with FAC-003-1?**

   ☐ Yes

   ☒ No

   Comments: The "Northeast Power Coordinating Council Facilities Notification List" may not be the correct list to be used for this standard. FAC- 003-1 should set a clear expectation the each Regional Entity will provide their transmission owners a list of critical lines including any that may be less that 200KV. Will provide list once released from NPCC.

3. **If you are a transmission owner would you provide your methodology for determining clearance 1 and clearance 2? (As described in FAC-003-1 R1.2.1 and R1.2.2) If so, please attach.**

   ☐ Yes

   ☒ No

   Comments: The clearance 2 was taken directly from IEEE Table 516 – 2003. Clearance 1 is based on "Appendix C – ISO New England Right of way Vegetation Management Standard".

4. Are there any other comments regarding the standard, its possible modifications or the SAR?

☒ Yes

☐ No

Comments: The standard FAC-003-1 is intended to create a frame work that will ensure a uniform level of reliability and at the same time must allow transmission owners to meet this objective using efficient and cost effective programs. To this end utilities must have the ability to implement “Clearance 1” distances consistently throughout their service areas.

The standard should remain focused only on 200 KV and above lines or lines listed as critical by the Regional Entity.

Inspection cycles are sufficient as listed the current version and allow flexibility to meet local variability in growth rates and other conditions. Concerns with inspection cycle length can be addressed in the compliance area

Please use this form to submit comments on the draft Transmission Vegetation Management SAR. Comments must be submitted by **May 9, 2007**. 1. **Do you agree there is a reliability need for the proposed modifications and review of the standard?**

   ☒ Yes

   ☐ No

   Comments: Modifications to capture the Commissions concerns must be addressed therefore these actions are appropriate.

2. **If you are a transmission owner, have you been provided a list from a Reliability Entity (formerly RRO) of sub 200kV critical transmission lines that must comply with FAC-003-1?**

   ☐ Yes

   ☒ No

   Comments: SERC does not currently have any sub 200 kV critical transmission lines.

3. **If you are a transmission owner would you provide your methodology for determining clearance 1 and clearance 2? (As described in FAC-003-1 R1.2.1 and R1.2.2) If so, please attach.**

   ☐ Yes

   ☐ No

   Comments:

4. **Are there any other comments regarding the standard, its possible modifications or the SAR?**

   ☒ Yes

   ☐ No

   Comments: CECD supports continuing to use the 200kV threshold for determining applicablility of vegetation management criteria. If the standard is deemed to apply to lower voltages these should only be critical lower voltage transmission facilities as determined by the Regional Entities's. CECD would also encourage the drafting team to clarify that the Vegetation Management standards are not applicable to generator interconnection facilities. In the registration process due to the NERC functional definitions, Generation Owners/Operators are required to register as Transmission Owners/Operators because of step-up transformers and other associated interconnection equipment that was not intended to be subject to the Vegetation Management program.

Several commenters indicated that the reporting requirements may need revision and the SAR was revised to include consideration of modifications to the reporting requirements.

The SAR drafting team consensus is that modification of FAC-003-1 to address the aforementioned items is needed to ensure reliability of the bulk power system.

1. **Do you agree there is a reliability need for the proposed modifications and review of the standard?**

   ☐ Yes

   ☒ No

   Comments: I'm not convinced that the elements outlined in the proposal will improve reliability and have concerns that the proposed modifications may actually reduce the flexibility that is necessary to promote system reliability or to comply with local regulations. I would prefer to see more specifics in the proposal before supporting the modifications.

2. **If you are a transmission owner, have you been provided a list from a Reliability Entity (formerly RRO) of sub 200kV critical transmission lines that must comply with FAC-003-1?**

   ☐ Yes

   ☒ No

   Comments: The reason that we do not have a list of critical lines from the RRO may be that we do not have any lines that fit the criteria.

3. **If you are a transmission owner would you provide your methodology for determining clearance 1 and clearance 2? (As described in FAC-003-1 R1.2.1 and R1.2.2) If so, please attach.**

   ☐ Yes

   ☒ No

   Comments:

4. **Are there any other comments regarding the standard, its possible modifications or the SAR?**

   ☒ Yes

   ☐ No

   Comments: We completely disagree with the proposal to eliminate reporting or off-right-of-way tree outages. In reality, off-R/W outages can cause many of the same problems that on R/W outages do if they were to occur at the most inappropriate time. Granted that they typically do not occur at times of peak load, but they could. Moreover, many off-R/W tree outages are preventable and should be addressed before they occur.

Several commenters indicated that the reporting requirements may need revision and the SAR was revised to include consideration of modifications to the reporting requirements.

The SAR drafting team consensus is that modification of FAC-003-1 to address the aforementioned items is needed to ensure reliability of the bulk power system.

1. **Do you agree there is a reliability need for the proposed modifications and review of the standard?**

   ☐ Yes

   ☒ No

   Comments: From a reliability perspective, the current standard contains appropriate requirements and measures to ensure the Transmission Owner's vegetation management program is implemented and managed to ensure the reliability of the transmission system. However the standard should be revised to address non-reliability related items that are in the SAR.

2. **If you are a transmission owner, have you been provided a list from a Reliability Entity (formerly RRO) of sub 200kV critical transmission lines that must comply with FAC-003-1?**

   ☐ Yes

   ☒ No

   Comments: The SERC region has not identified any lines below 200kV to be critical to the electrical system in the region. Since no lines have been identified as critical to the region, no list has been provided to Transmission Owners.

3. **If you are a transmission owner would you provide your methodology for determining clearance 1 and clearance 2? (As described in FAC-003-1 R1.2.1 and R1.2.2) If so, please attach.**

   ☐ Yes

   ☐ No

   Comments:

4. **Are there any other comments regarding the standard, its possible modifications or the SAR?**

   ☒ Yes

   ☐ No

   Comments: Regarding the Order 693 items, the applicability provision of the standard should focus attention of the standard only on the transmission lines 200kV and above, and those lines below 200kV that directly impact "Bulk Power System" reliability, as the current version of FAC-003 requires. Each Regional Entity (RE) must determine applicability of FAC-003 to those lines within the region that are less than 200kV. For example, transmission lines below 200kV should be considered within the scope of FAC-003 if they are identified as operationally significant elements of Interconnection Reliability Operating Limits ("IROLs"); i.e. an outage of the facility would cause an Interconnection Reliability Limit Violation.

   The Standard DT should address the issue of the necessity of maintaining consistent clearances for lines on both federal and non-federal lands.

   We agree with the use of the IEEE 516-2003 standard for for defining the minimum acceptable clearances to prevent flashover between conductors and vegetation under all rated electrical operating conditions.

We believe that the reporting requirement exemptions for natural disasters should include all categories of outages.

Please use this form to submit comments on the draft Transmission Vegetation Management SAR. Comments must be submitted by **May 9, 2007**. The SAR drafting team considered stakeholder comments on the first draft of this SAR and the FERC Order 693 in preparing the second draft of the SAR to modify FAC-003-1 — Transmission Vegetation Management.

The SAR drafting team modified the SAR to clarify that FAC-003-1 needs to add time horizons and violation severity levels to bring the standard into conformance with the latest version of the Reliability Standards Development Procedure and the ERO Sanctions Guidelines. (Time Horizons and Violation Severity Levels are both elements used to determine an appropriate sanction for violation of a standard.)

The SAR drafting team also modified the SAR to clarify that the scope of revisions to this standard will include addressing the issues raised by FERC in Order 693, including the following:

- Consideration of minimum clearances needed to avoid sustained vegetation-related outages that would apply to transmission lines crossing both federal land and non-federal land
- Revisions to the definition of 'right of way' to encompass required clearance areas
- Review of the suitability of IEEE Standard 516-2003 for minimum vegetation clearance

Several commenters indicated that the reporting requirements may need revision and the SAR was revised to include consideration of modifications to the reporting requirements.

The SAR drafting team consensus is that modification of FAC-003-1 to address the aforementioned items is needed to ensure reliability of the bulk power system.

1. Do you agree there is a reliability need for the proposed modifications and review of the standard?

☒ Yes

☐ No

Comments: The existing FAC-003-1 is flawed and needs revision.

2. If you are a transmission owner, have you been provided a list from a Reliability Entity (formerly RRO) of sub 200kV critical transmission lines that must comply with FAC-003-1?

☒ Yes

☐ No

Comments:

Yes, the Reliability Entity (SERC) has performed its duty in evaluating our transmission system. SERC has confirmed that Entergy has no lines operating below 200kV that are critical to system reliability. Entergy has received its "list," but the list is blank.

With respect to applicability, it is inappropriate to set a blunt voltage level criterion for determining which transmission lines are critical to bulk system reliability. There is no basis in engineering or in fact for voltage-based categories of applicability. Many lines operating at 200kV and higher essentially serve only local load, and there may in fact be some lines operating below 200kV where the standard should be applied. Many lines of all voltages are redundant and do not even impact local load during an outage. Therefore, the voltage criterion is overly broad.

To support this statement, Entergy supplies the following facts:

First, during the aftermath of Hurricanes Katrina and Rita, Entergy had (59) 230kV and 500kV lines out of service simultaneously. Additionally, Entergy had (85) 115kV and 161kV lines out of service simultaneously. During the aftermath of Hurricane Rita, Entergy had (41) 230kV and 500kV lines out of service simultaneously. Additionally, Entergy had (124) 115kV and 161kV lines out of service simultaneously. Dispite this overwhelming combination of simultaneous outages, no system-wide cascading blackout was initiated. Only local load was lost during restoration. This illustrates that Standard FAC-003-1, as it currently stands placing so much focus and penalty on even single-contingency outages, is overbroad, arbitrary and capricious.

Second, each year the Entergy transmission system (like all other large electric utilities) suffers numerous outages from a great number of different sources: material defects, rot and decay, animal damage, human damage, extreme wind, lightning and, vegetation. Over the years 2001 through 2006, 927 transmission lines suffered 5,688 outages from a variety of sources. Vegetation outages accounted for 7.14% of those outages. Each utility is unique, but these numbers are not unusual for a transmission system comprising 15,000 miles of line. Dispite this large number of outages, no cascading system black out has been intiated.

Finally, Entergy has had as many as 17 transmission lines outaged from a single tornado event without even losing service to local load. Standard FAC-003-1 assigns too much risk to outages in general, and too mush risk to vegetation outages in particular.

NERC and the regional reliability entities should define performance criteria that specifically define certain contingencies and certain undesireable outcomes that would classify a line as truly critical to bulk system reliability. The modeling software necessary to do this is readily available and already in use today by the Reliability Entities and their subject utilities.

If FERC has concerns about potentially devistating (albeit rare) combinations of multiple simultaneous line outage contingencies, the REs can define strict criteria for multiple contingencies. With respect to lines that result in IROLs and SOLs, these lines can also be identified with specificity, without resorting to blunt voltage distinctions.

Defining system-critical lines too broadly is actually detrimental to FERC's reliability goals. It dilutes the resources available to maintain reliability on those lines that truly affect system reliability. Utilities should employ a more focused and intelligent approach to targeted reliability. Such an approach would have benefits to the users of the transmission system and to the ratepayers that pay for it.

3. If you are a transmission owner would you provide your methodology for determining clearance 1 and clearance 2? (As described in FAC-003-1 R1.2.1 and R1.2.2) If so, please attach.

☒ Yes

☐ No

Comments:

Entergy defines four sets of clearances for vegetation approach to transmission lines.

The first set of clearances is the Vegetation Pruning Distance. This is the clearance to be achieved at the time of vegetation management work which vegetation management employees and contractors complete as part of this program. This distance varies with each line, but is set to be the EDGE OF ROW in each case. (This clearance is referred to as “Clearance 1” in the NERC Vegetation standard FAC-003-1, Cf B.R1.2.1).

The second set of clearances is the Vegetation Growth Alert Distance. This is the approach distance that triggers an alert to the Asset Management vegetation management employees that vegetation maintenance is required. Vegetation spotted on an aerial inspection that encroaches upon this clearance is noted on the inspection for future scheduling of pruning.

The third set of clearances is the Minimum Energized Pruning Distance. This is the minimum approach distance vegetation can have to energized transmission lines and still be pruned without an outage on the energized transmission line, in accordance with OSHA safety guidelines. Any vegetation that encroaches on this minimum distance must be pruned, and must be pruned during an outage on the associated transmission line.

The fourth set of clearances is the Minimum Vegetation Approach Distance. This is the absolute minimum radial approach distance to prevent flashover between vegetation and overhead ungrounded supply conductors. Under this program, vegetation should never encroach these minimum approach distances. Vegetation must be pruned prior to reaching this distance and must be pruned with an outage on the transmission line. (This distance is referred to as “Clearance 2” in the NERC vegetation standard, FAC-003-1, Cf B.R1.2.2.) These clearance distances are based upon those set forth in the Institute of Electrical and Electronics Engineers (IEEE) Standard 516-2003 (Guide for Maintenance Methods on Energized Power Lines) and as specified in Table 5.

Under this program, vegetation can encroach the Vegetation Growth Alert Distance and the Minimum Energized Pruning Distance, but it shall not encroach upon the Minimum Vegetation Approach Distance.

4. Are there any other comments regarding the standard, its possible modifications or the SAR?

☒ Yes

☐ No

Comments:

The policy to increase sanctions based on a finding of an "intentional economic decision to violate the standard" is ill-concieved:

1. Every transmission line outage that has ever occured could have been avoided if more money had been spent on SOMETHING, SOMWHERE.
2. No utility has an unlimited budget, so decisions based on risk, cost and benefit are made every day.
3. After the outage, the localized initiating cause will appear so trivial and inexpensive that it would seem that it could easily have been fixed in advance.
4. Therefore, reviewers could conclude that EVERY outage (a defacto violation of the standard), is the result of an "economic decision to violate the standard."

Economic choices are a necessary and natural part of doing business, and do not necessarily imply the existence of malicious motives or wrong-doing.

The current policy is going to create unnecessary costs to ratepayers, even to avoid inconsequential outages.

Background Information:

The SAR drafting team considered the comments submitted in response to the first posting of the SAR as well as the FERC Order 693 in preparing the revised SAR to modify FAC-003-1 — Transmission Vegetation Management.

The SAR drafting team modified the SAR to state more specifically that the revisions to the standard need to incorporate the compliance program elements of time horizons and violation severity levels to bring FAC-003-1 into conformance with the latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines.

The FERC has urged further industry consideration of a number of issues and these have been listed in the revised SAR as items to address during using standards development process to refine FAC-003-1. The SAR drafting team consensus is that a modification to FAC-003-1 to address the aforementioned items is warranted.

Please review the changes made to the Vegetation Management SAR and then respond to the questions on the following pages. Please e-mail your comments to sarcomm@nerc.net with the subject "Vegetation Management SAR" by **May 9, 2007.**

You need not answer all questions. Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

The SAR drafting team considered stakeholder comments on the first draft of this SAR and the FERC Order 693 in preparing the second draft of the SAR to modify FAC-003-1 — Transmission Vegetation Management.

The SAR drafting team modified the SAR to clarify that FAC-003-1 needs to add time horizons and violation severity levels to bring the standard into conformance with the latest version of the Reliability Standards Development Procedure and the ERO Sanctions Guidelines. (Time Horizons and Violation Severity Levels are both elements used to determine an appropriate sanction for violation of a standard.)

The SAR drafting team also modified the SAR to clarify that the scope of revisions to this standard will include addressing the issues raised by FERC in Order 693, including the following:

- Consideration of minimum clearances needed to avoid sustained vegetation-related outages that would apply to transmission lines crossing both federal land and non-federal land
- Revisions to the definition of 'right of way' to encompass required clearance areas
- Review of the suitability of IEEE Standard 516-2003 for minimum vegetation clearance

Several commenters indicated that the reporting requirements may need revision and the SAR was revised to include consideration of modifications to the reporting requirements.

The SAR drafting team consensus is that modification of FAC-003-1 to address the aforementioned items is needed to ensure reliability of the bulk power system.

1. **Do you agree there is a reliability need for the proposed modifications and review of the standard?**

☒ Yes

☐ No

Comments: FirstEnergy agrees that clarification on select issues will aid the intent of this NERC Standard.

2. **If you are a transmission owner, have you been provided a list from a Reliability Entity (formerly RRO) of sub 200kV critical transmission lines that must comply with FAC-003-1?**

☒ Yes

☒ No

Comments: ReliabilityFirst, the Reliability Entity (formerly the RRO) was requested to provided a list of lines below 200 kV deemed as crititical transmission lines that must comply with FAC-003-01. ReliabilityFirst responded "there are no lines below 200kV deemed as critical infrustructure".

3. **If you are a transmission owner would you provide your methodology for determining clearance 1 and clearance 2? (As described in FAC-003-1 R1.2.1 and R1.2.2) If so, please attach.**

☒ Yes

☐ No

Comments: For R1.2.1 (Clearance 1), FirstEnergy used our existing specification requirement "for minimum clearance to be achieved at locations with an easement or other restriction" to define the minimum exceptable clearance.

For R1.2.2 (Clearance 2), FirstEnergy uses the IEEE 516-2003 standard as the minimum as referenced in FAC-003-01. This is the minimum clearance under all operating conditions. FirstEnergy believes this is an appropriate definition.

4. **Are there any other comments regarding the standard, its possible modifications or the SAR?**

☒ Yes

☐ No

Comments:
The definition of Right-Of-Way requires modification to clarify it is the width required by engineering to operate the line. This may or may not be the legal Right-of-Way. (See previously submitted comments submitted by FE in Feb 2007 for more details).

1. **Do you agree there is a reliability need for the proposed modifications and review of the standard?**

   ☒ Yes

   ☐ No

   Comments: FPL believes the technical portion of the standard provides adequate reliability protection to the system. FPL also recognizes the need to re-format the standard to bring it into conformance with the latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines, to remove references to RRO in the standard and substitute a responsible entity and, add compliance elements such as time horizons, and violation severity levels.

2. **If you are a transmission owner, have you been provided a list from a Reliability Entity (formerly RRO) of sub 200kV critical transmission lines that must comply with FAC-003-1?**

   ☒ Yes

   ☐ No

   ☒ No

   Comments:

4. **Are there any other comments regarding the standard, its possible modifications or the SAR?**

   ☒ Yes

   ☐ No

   Comments: For the record FPL re-emphasixe its comments from the previous FAC 003-1 SAR.

   Requirement 3.2 exempts reporting of outages from outside the ROW when natural disasters such as tornados or hurricanes occur. Our experience with numerous hurricanes indicates that all outages during these types of events should be exempt. The focus in these situations is to get the lines back in service and restore customers. There is insufficient manpower to adequately complete the forensics necessary to determine an accurate root cause. It is not uncommon to find vegetation debris in the lines or downed trees on the ROW in this situation. In most cases it is not possible to determine the original location of these trees.

   In the compliance section of the document a transmission owner becomes non compliant with a single category 1 or 2 outage. This occurs regardless of the circumstances. A non compliant penalty for a single outage in a situation where no customers were affected and the system could not have been compromised is not reasonable. It is also not an indicator of a poorly maintained system. We agree that several Category 1 or 2 interruptions could be an indicator of neglect but one is not. We recommend that the compliance section be reviewed with this in mind.

The SAR drafting team considered stakeholder comments on the first draft of this SAR and the FERC Order 693 in preparing the second draft of the SAR to modify FAC-003-1 — Transmission Vegetation Management.

The SAR drafting team modified the SAR to clarify that FAC-003-1 needs to add time horizons and violation severity levels to bring the standard into conformance with the latest version of the Reliability Standards Development Procedure and the ERO Sanctions Guidelines. (Time Horizons and Violation Severity Levels are both elements used to determine an appropriate sanction for violation of a standard.)

The SAR drafting team also modified the SAR to clarify that the scope of revisions to this standard will include addressing the issues raised by FERC in Order 693, including the following:

- Consideration of minimum clearances needed to avoid sustained vegetation-related outages that would apply to transmission lines crossing both federal land and non-federal land
- Revisions to the definition of 'right of way' to encompass required clearance areas
- Review of the suitability of IEEE Standard 516-2003 for minimum vegetation clearance

Several commenters indicated that the reporting requirements may need revision and the SAR was revised to include consideration of modifications to the reporting requirements.

The SAR drafting team consensus is that modification of FAC-003-1 to address the aforementioned items is needed to ensure reliability of the bulk power system.

1. **Do you agree there is a reliability need for the proposed modifications and review of the standard?**

   ☐ Yes

   ☒ No

   Comments: It is our belief that the Standard in its current form does provide adequate provisions and drivers to minimize vegetation related outages and eliminate the likelihood of reoccurence of the August 14, 2003 blackout. However, it is recognized that the industry needs to consolidate its view on these provisions and we support the preparation of a “white paper” that will document the rationale concerning the requirements of the standard, as well as review certain aspects of the standard that have come into question.

2. **If you are a transmission owner, have you been provided a list from a Reliability Entity (formerly RRO) of sub 200kV critical transmission lines that must comply with FAC-003-1?**

   ☐ Yes

   ☒ No

   Comments: We consider that it should be the Planning Coordinator role to determine the sub 200kV critical transmission lines and even for any transmission lines irrelevent of voltage level. For that, it should follow an impact based methodology such as the one used in NPCC.

3. **If you are a transmission owner would you provide your methodology for determining clearance 1 and clearance 2? (As described in FAC-003-1 R1.2.1 and R1.2.2) If so, please attach.**

   ☒ Yes

   ☐ No

   Comments: HQT clearance methodology is not specifically based on the value specified in Clearance 1 and Clearance 2. HQT TVMP is such organized that vegetation management work minimize costs for line clearing and brush control while preventing outages from vegetation cause. As such, staff qualifications required to work near energized facilities are less than under the absolute minimum as stipulated in IEEE 516-2003, and in most cases, the work is less labour and equipment intensive. However clearances are never less than the absolute minimum stipulated in FAC-003-1 (R1.2.2).

   The above provides the basic approach used at HQT. If the Standard Drafting Team would like a copy of the HQT approach and methodology, this could be provided.

4. **Are there any other comments regarding the standard, its possible modifications or the SAR?**

   ☒ Yes

   ☐ No

   Comments: Here are some general comments on the SAR:

1. In the purpose section of the SAR, item 1, we don't understand the substitution of BPS by «electric transmission system»; it seems like there is a will to make the Standards applicable to more than the BPS. It is our understanding that NERC Standards are aimed at the reliability of the BPS. The term BPS should be retained and instead of modifying the SAR to widen the applicability, the Standard itself should be modified to specifically used the term BPS in item A.3.
2. In the detailed description section, item 1, sub-bullett , it is written that :``...the SDT may consider other criteria in determining applicability of the Standard to sub 200 kV lines...``. We think that in item 4.3 (Applicability) of the existing Standard, there is already the possibility of applying the Standard to sub 200 kV lines if determined by RRO. This could be reworded by saying:«...as determined by a methodology to define BPS element»; such as the one used by NPCC.
3. We noticed that most Definitions (e.g. RC, IA, PC, RP, TP, TOp, DP, GO, GOp, PSE, MO (not even in the Glossary), LSE) used to described the Reliability Functions in the SAR form, are somewhat different than those used in the Glossary of Terms approved with the Standards deposited at the FERC. For consistency, if the definition needs to be changed, this should be done through the right process, not just casually in the SAR Form.
4. Also, although the title in that same section of the SAR form refers to Reliability Functions, these are in fact the Responsible Entity that performs those functions; maybe a correction in the SAR form would be necessary.

Please use this form to submit comments on the draft Transmission Vegetation Management SAR. Comments must be submitted by **May 9, 2007**. You may submit the completed form by e-mail to sarcomm@nerc.net with the words **"Vegetation Management SAR"** in the subject line. ☐ Yes

☒ No

Comments: It is our belief that the Standard in its current form does provide adequate provisions and drivers to minimize vegetation related outages and eliminate the likelihood of reoccurence of the August 14, 2003 blackout. However, it is recognized that the industry needs to consolidate its view on these provisions and we support the preparation of a "white paper" that will document the rationale concerning the requirements of the standard, as well as review certain aspects of the standard that have come into question.

2. If you are a transmission owner, have you been provided a list from a Reliability Entity (formerly RRO) of sub 200kV critical transmission lines that must comply with FAC-003-1?

☐ Yes

☒ No

Comments:

3. If you are a transmission owner would you provide your methodology for determining clearance 1 and clearance 2? (As described in FAC-003-1 R1.2.1 and R1.2.2) If so, please attach.

☒ Yes

☐ No

Comments: Hydro One clearance standards are based on the Ontario Health and Safety Act (OHSA) clearances rather than the absolute minimum specified in Clearance 2. OHSA clearances at time of work minimize costs for line clearing and brush control. By maintaining OHSA clearances during normal working conditions, staff qualifications required to work near energized facilities are less than under the absolute minimum as stipulated in IEEE 515-3003, and in most cases, the work is less labour and equipment intensive. As part of work planning, qualified staff determine the amount of vegetation that has to be removed to achieve OHSA clearances at the time of the next scheduled work. As well, provisions are built into the clearances at time of work to account for conductor and tree movement during adverse weather conditions. The objective is to provide OHSA clearances under adverse conditions, but these are not always achieved, however clearances are never less than the absolute minimum stipulated in FAC-003-1.

The above provides a description of our planning process. If the Standard Drafting Team would like a copy of the Hydro One standard, this can be provided.

4. Are there any other comments regarding the standard, its possible modifications or the SAR?

☒ Yes

☐ No

Comments: We believe from a transmission system perspective, category 3 outages are no different than many of the other types of outages that take place on the system, such as hardware failures, lightning damage and station equipment outages to name a few. It is our understanding that there is no requirement to report these “other” outages which makes one wonder why the tree related outages that originate off the right of way need to be reported. We are not diminishing the importance of category 3 outages, but from a system cascading perspective, these outages are no more important than other line or station outages, and are fewer in number than the “other” random outages. To initiate system cascading as occurred during August 14, 2003, a number of the random outages would have to coincide to cause a wide spread system event, which in our opinion is a very low probability occurence. On the other hand, a category 1 outage can occur as a result of any system disturbance should there be deficiencies in clearances to vegetation, as such the importance of category 1 outages is apparent and reporting is appropriate. We support the review concerning the need to report category 3 outages and that the ultimate decision should be based on reporting rules that take into consideration the broader topic of reliability, rather than just vegetation related outages.

Please use this form to submit comments on the draft Transmission Vegetation Management SAR. Comments must be submitted by **May 9, 2007**. You may submit the completed form by e-mail to sarcomm@nerc.net with the words **"Vegetation Management SAR"** in the subject line. If you have questions please contact Harry Tom at Harry.Tom@nerc.net or by telephone at 609-452-8060.

Background Information:

The SAR drafting team considered the comments submitted in response to the first posting of the SAR as well as the FERC Order 693 in preparing the revised SAR to modify FAC-003-1 — Transmission Vegetation Management.

The SAR drafting team modified the SAR to state more specifically that the revisions to the standard need to incorporate the compliance program elements of time horizons and violation severity levels to bring FAC-003-1 into conformance with the latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines.

The FERC has urged further industry consideration of a number of issues and these have been listed in the revised SAR as items to address during using standards development process to refine FAC-003-1. The SAR drafting team consensus is that a modification to FAC-003-1 to address the aforementioned items is warranted.

Please review the changes made to the Vegetation Management SAR and then respond to the questions on the following pages. Please e-mail your comments to sarcomm@nerc.net with the subject "Vegetation Management SAR" by **May 9, 2007.**

You need not answer all questions. Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

The SAR drafting team considered stakeholder comments on the first draft of this SAR and the FERC Order 693 in preparing the second draft of the SAR to modify FAC-003-1 — Transmission Vegetation Management.

The SAR drafting team modified the SAR to clarify that FAC-003-1 needs to add time horizons and violation severity levels to bring the standard into conformance with the latest version of the Reliability Standards Development Procedure and the ERO Sanctions Guidelines. (Time Horizons and Violation Severity Levels are both elements used to determine an appropriate sanction for violation of a standard.)

The SAR drafting team also modified the SAR to clarify that the scope of revisions to this standard will include addressing the issues raised by FERC in Order 693, including the following:

- Consideration of minimum clearances needed to avoid sustained vegetation-related outages that would apply to transmission lines crossing both federal land and non-federal land
- Revisions to the definition of 'right of way' to encompass required clearance areas
- Review of the suitability of IEEE Standard 516-2003 for minimum vegetation clearance

Several commenters indicated that the reporting requirements may need revision and the SAR was revised to include consideration of modifications to the reporting requirements.

The SAR drafting team consensus is that modification of FAC-003-1 to address the

1. **Do you agree there is a reliability need for the proposed modifications and review of the standard?**

   ☒ Yes

   ☐ No

   Comments:

2. **If you are a transmission owner, have you been provided a list from a Reliability Entity (formerly RRO) of sub 200kV critical transmission lines that must comply with FAC-003-1?**

   ☐ No

   Comments:

4. **Are there any other comments regarding the standard, its possible modifications or the SAR?**

   ☒ Yes

   ☐ No

   Comments:

   1. The SAR indicates that a list of critical low voltage transmission lines will be provided to FERC. We do not interpret Order 693 to direct NERC to provide this list. Rather, we interpret that FERC asks for defining a criteria that would include low voltage transmission lines that have impact on Bulk Power System reliability. We do not think the list is required.

   2. The SAR indicates: “The standard DT may consider other criteria in determining applicability of the standard to sub 200kV lines…” Per Order 693, the criteria is quite clearly stated to be the transmission lines of less than 200 kV that could impact Bulk Power System reliability. We don't feel any other criteria would be necessary. Further, to identify the candidates that meet these criteria, we believe they should be determined by the Reliability Coordinator, similar to the PRC-023 standard, since the RC has the primary responsibility and knowledge of interconnection reliability impact.

   3. We do not understand why the SDT considers removing Category 3 incidents? In our view, Category 3 outages are important information for assessing the effectiveness of vegetation program. Since the industry started reporting vegetation related outages about 3 years ago, data collected so far indicates that of a total of 98 reported vegetation outages, 67 of them were category 3 outages. With this high percentage,

reporting of Category 3 events should be a must since the associated trends can provide valuable information to the TOs to aid its evaluation of the vegetation management program.

4. The white paper and field tests are a good idea and the SDT should be commended for these, especially the white paper.

5. Item 2 under the FERC Order 693 Items in the Detailed Description Section indicates the SDT will also collection outage data. While we understand that FERC has directed the ERO to collect outage data for transmission outages of lines that cross both federal and non-federal lands, we do not feel that it is the SDT's role to perform this task. We feel that this task should be performed by the ERO line functions or a group separate from the SDT such that the task does not add burden to the SDT which may slow down the standard development process or result in the standard development being driven by unanalyzed data and resulting in erroneous requirements.

6. With respect to reporting exemptions, our position during development of the previous version of this standard was to limit them. We commend the SDT intention to clarify the outage exemptions under major disasters, but to consider including all category outage exemptions in the standard body is too prescriptive and will add to the already extended list. It can end up with a very long list of outage exemptions, thereby reducing the coverage of the standard substantially and defeating its purpose.

It can end up with a very long list of outage exemptions, thereby reducing the coverage of the standard substatively and defeating its purpose. If this list was to be developed, they could be attached as guidelines aside of the standard.

7. The SAR DT states it will deal with "critical facilities" . The SRC suggest that the DT not use the word "critical" and adopt another term.

There is a need to define in a single standard what the term "critical" means. Standards FAC-014 (R5.1.1); IRO-002-1 (R6) and others use the term "critical" as in: critical loads, critical infrastructure, critical assets. The Veg Management Team is asked to avoid making the current situation worse.

1. **Do you agree there is a reliability need for the proposed modifications and review of the standard?**

   ☒ Yes

   ☐ No

   Comments: The definition of ROW should be clarified. The definition of a critical line should not be kept to a particular voltage threshold. However, consideration could also then be given to exempting non-critical lines operating at higher voltage levels(>200kv). Electrical clearances should be consistent whether on Federal or non-Federal land.

2. **If you are a transmission owner, have you been provided a list from a Reliability Entity (formerly RRO) of sub 200kV critical transmission lines that must comply with FAC-003-1?**

   ☐ Yes

   ☒ No

   Comments:

3. **If you are a transmission owner would you provide your methodology for determining clearance 1 and clearance 2? (As described in FAC-003-1 R1.2.1 and R1.2.2) If so, please attach.**

   ☒ Yes

   ☐ No

   Comments: Clearance 1 was developed based on the limits of approach for non-qualified people (public). At a minimum, we would clear beyond this distance during vegetation control activities. Our cycle times and management approach are adjusted for this distance, taking into account growth rates. The values will vary depending on voltage class. Clearance 2 is based on internal design standards that take into account our understanding of switching surge values for our system. The values used are more conservative than IEEE 516-2003.

4. **Are there any other comments regarding the standard, its possible modifications or the SAR?**

   ☐ Yes

   ☒ No

Background Information:

The SAR drafting team considered the comments submitted in response to the first posting of the SAR as well as the FERC Order 693 in preparing the revised SAR to modify FAC-003-1 — Transmission Vegetation Management.

The SAR drafting team modified the SAR to state more specifically that the revisions to the standard need to incorporate the compliance program elements of time horizons and violation severity levels to bring FAC-003-1 into conformance with the latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines.

The FERC has urged further industry consideration of a number of issues and these have been listed in the revised SAR as items to address during using standards development process to refine FAC-003-1. The SAR drafting team consensus is that a modification to FAC-003-1 to address the aforementioned items is warranted.

Please review the changes made to the Vegetation Management SAR and then respond to the questions on the following pages. Please e-mail your comments to sarcomm@nerc.net with the subject "Vegetation Management SAR" by **May 9, 2007.**

You need not answer all questions. Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

The SAR drafting team considered stakeholder comments on the first draft of this SAR and the FERC Order 693 in preparing the second draft of the SAR to modify FAC-003-1 — Transmission Vegetation Management.

The SAR drafting team modified the SAR to clarify that FAC-003-1 needs to add time horizons and violation severity levels to bring the standard into conformance with the latest version of the Reliability Standards Development Procedure and the ERO Sanctions Guidelines. (Time Horizons and Violation Severity Levels are both elements used to determine an appropriate sanction for violation of a standard.)

The SAR drafting team also modified the SAR to clarify that the scope of revisions to this standard will include addressing the issues raised by FERC in Order 693, including the following:

- Consideration of minimum clearances needed to avoid sustained vegetation-related outages that would apply to transmission lines crossing both federal land and non-federal land
- Revisions to the definition of 'right of way' to encompass required clearance areas
- Review of the suitability of IEEE Standard 516-2003 for minimum vegetation clearance

Several commenters indicated that the reporting requirements may need revision and the SAR was revised to include consideration of modifications to the reporting requirements.

The SAR drafting team consensus is that modification of FAC-003-1 to address the aforementioned items is needed to ensure reliability of the bulk power system.

1. **Do you agree there is a reliability need for the proposed modifications and review of the standard?**

☐ Yes

☒ No

Comments: National Grid believes that compliance with all elements of the present Standard will result in TO's achieving the reliability objectives set forth in the Standard.

2. **If you are a transmission owner, have you been provided a list from a Reliability Entity (formerly RRO) of sub 200kV critical transmission lines that must comply with FAC-003-1?**

☐ Yes

☒ No

Comments: The Reliability Entity has not provided a list of sub 200 kV lines subject to compliance with FAC-003-1. The Standard became effective in February 2007, just 3 months ago. Having no list today should not imply that the RE or the Standard has failed in any way. National Grid suggests that a revised Standard should direct the RE to produce a list of "sub 200 kV critical transmission lines" within 6 to 12 months of adoption.

3. **If you are a transmission owner would you provide your methodology for determining clearance 1 and clearance 2? (As described in FAC-003-1 R1.2.1 and R1.2.2) If so, please attach.**

☐ Yes

☒ No

Comments: Detailed methodology is not attached. In summary, National Grid used Table 5 IEEE Section 516 for determing clearance 2. These data for each voltage class were rounded to the next higher whole number. Clearance 1 was determined by adding the clearance 2 distance, conductor sag distance, and anticipated tree growth over the maintenance cycle.

4. **Are there any other comments regarding the standard, its possible modifications or the SAR?**

☒ Yes

☐ No

Comments:
1) National Grid supports amending FAC-003-1 to bring the Standard into compliance with "latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines" as discussed in the SAR Background Information.
2) We do not support amendments to the Standard to address all of the issues raised by FERC Order 693. We believe most of the FERC's concerns can be addressed by developing a "white paper" to better explain the Standard and guide its implementation.
3) National Grid does not support changing the basic approach to defining clearance from vegetation. The clearance 1 and clearance 2 concept adopts the two management approaches used by most TO's today and required in some state or ISO level

standards. National Grid supports using the reference to IEEE 516 as the basis for clearance 2 for two reasons: 1 - there is no other definitive reference for flash over distances to vegetation and 2- decades of experience by TO's acrosss the North America suggest the IEEE 516 distances are more than adequate. The well known tree caused outages in 1996 and 2003 occurred as a result of hard contact with vegetation not flashover at distances close to those in IEEE 516. Furthermore, FERC accepted IEEE 516 as appropriate for use in vegetation management in the October 2006, NOPR.
4) National Grid supports amending the definition of a right-of-way though we are not clear on what is meant in the SAR language by "to encompass required clearing areas". National Grid is concerned with the interpretation of the present definition that the right-of-way includes uncleared fee owned or easement land reserved for future construction. In many jurisdictions the TO may not be allowed to remove trees from these areas. A "white paper" could better describe the definition and prevent future compliance issues stemming from an ambiguous definition.

☐ Yes

☐ No

Comments: N/A

4. **Are there any other comments regarding the standard, its possible modifications or the SAR?**

☒ Yes

☐ No

Comments:

1. The SAR indicates that a list of critical low voltage transmission lines will be provided to FERC. We do not interpret Order 693 to direct NERC to provide this list. Rather, we interpret that FERC asks for defining a criteria that would include low voltage transmission lines that have impact on Bulk Power System reliaiblity. We do not think the list is required.

2. The SAR indicates: “The standard DT may consider other criteria in determining applicability of the standard to sub 200kV lines…” Per Order 693, the criteria is quite clearly stated to be the transmission lines of less than 200 kV that could impact Bulk Power System reliability. We don't feel any other criteria would be necessary. Further, to identify the candidates that meet this criteria, we believe they should be determined by the Reliability Coordinator, similar to the PRC-023 standard, since the RC has the primary responsibility and knowledge of interconnection reliability impact.

3. We do not understand why the SDT considers removing Category 3 incidents? In our view, Category 3 outages are important information for assessing the effectiveness of vegetation program. Since the industry started reporting vegetation related outages about 3 years ago, data collected so far indicates that of a total of 98 reported vegetation outages, 67 of them were category 3 outages. With this high percentage,

reporting of Category 3 events should be a must since the associated trends can provide valuable information to the TOs to aid its evaluation of the vegetation management program.

4. The white paper and field tests are a good idea and the SDT should be commended for these, especially the white paper.

5. Item 2 under the FERC Order 693 Items in the Detailed Description Section indicates the SDT will also collect outage data. While we understand that FERC has directed the ERO to collect outage data for transmission outages of lines that cross both federal and non-federal lands, we do not feel that it is the SDT's role to perform this task. We feel that this task should be performed by the ERO or a group separate from the SDT such that the task does not add burden to the SDT which may slow down the standard development process or result in the standard development being driven by unanalyzed data and resulting in erroneous requirements.

6. With respect to reporting exemptions, our position during development of the previous version of this standard was to limit them. We commend the SDT intention to clarify the outage exemptions under major disasters, but to consider including all category outage exemptions in the standard body is too prescriptive and will add to the already extended list. It can end up with a very long list of outage exemptions, thereby reducing the coverage of the standard substatively and defeating its purpose. If this list was to be developed, they could be attached as guidelines aside of the standard.

The SAR drafting team consensus is that modification of FAC-003-1 to address the aforementioned items is needed to ensure reliability of the bulk power system.

1. **Do you agree there is a reliability need for the proposed modifications and review of the standard?**

☐ Yes

☒ No

Comments: Proposed modifications do not increase the levels of reliability above what is already required in the current version of the Stnadard.

2. **If you are a transmission owner, have you been provided a list from a Reliability Entity (formerly RRO) of sub 200kV critical transmission lines that must comply with FAC-003-1?**

☐ Yes

☒ No

Comments: The Reliability Entity has not provided a list of facilities covered under FAC-003-1. This is not a fault of the RE as there has been no direction provided as to what factors or charateristics are required for sub-200kV lines to be included under the Standard. It is our position that the factors that will be used to develop the list of sub-200kV faciltities to be covered by the Standard be developed at the national level (NERC) and adopted by all RE's for consistency.

3. **If you are a transmission owner would you provide your methodology for determining clearance 1 and clearance 2? (As described in FAC-003-1 R1.2.1 and R1.2.2) If so, please attach.**

☒ Yes

☐ No

Comments: The methodology for determining clearance 2 is based on the requirements of FAC-003-1. The IEEE Section 516 has been considered the base minimum limits for clearances as provided under FAC-003-1 R.1.2.2. Clearances used for R.1.2.1 on the NU Transmission System comply with the requirements of ISO-NE Operating Procedure OP-3, that provides clearance levels required at the time of vegetation trimming or clearing under the various transmission voltages.

4. **Are there any other comments regarding the standard, its possible modifications or the SAR?**

☒ Yes

☐ No

Comments: NU does not support the proposed revisions based on the issues raised by FERC Order 693. The Standard has not been in effect long enough to determine if there are any shortcomings with the current requirements. It is our position that the current clearance requirements are satisfactory in that a base minimum distance as provided under IEEE Section 516 is sufficient and there is the need for variations in the second level of clearances base on Regional needs and conditions.

The revisions to the definition of "right-of-way" to encompass required clearance areas canbe problematic as this could cause significant problems with current systems. There is no detailed description on what the new defition will include or what the actual impact will be to TO's. If the definition will include defined limits or widths of rights-of-way this may affect current facilities that do not meet these distances. Second, there are areas where the company owns or possesses additional area beyond the current maintained right-of-way widths. Is it proposed that the new definition expand the limits of clearing or maintenance to include easemented or fee-owned areas beyond the current maintained limits? Until the new definition can be presented - it is difficult to support any changes at this time and we can only comment on the percevied negative impacts.

1. **Do you agree there is a reliability need for the proposed modifications and review of the standard?**

   ☒ Yes

   ☐ No

   Comments: As stated in the SAR

2. **If you are a transmission owner, have you been provided a list from a Reliability Entity (formerly RRO) of sub 200kV critical transmission lines that must comply with FAC-003-1?**

   ☒ Yes

   ☐ No

   Comments: Provided from WECC

3. **If you are a transmission owner would you provide your methodology for determining clearance 1 and clearance 2? (As described in FAC-003-1 R1.2.1 and R1.2.2) If so, please attach.**

   ☒ Yes

   ☐ No

   Comments: Will be provided to the SARDT in a separate attachment

4. **Are there any other comments regarding the standard, its possible modifications or the SAR?**

   ☒ Yes

   ☐ No

   Comments:
   1) Applicability 4.3 of the standard - PG&E believes the RE is in the best position to determine sub-200kV facilities are designated critical and covered under FAC-003-1. We suggest the ERO direct the RE to provide a list of sub-200kV lines designated critical along with methodology used to make that determination.

   2) Clearances for lines on federal and non-federal lands - PG&E believes there should be no distinction between requirements on different lands. Vegetation encroachments have the same impact regardless of land ownership.

   3) Definition of right of way - agreed

   4) Suitability of IEEE 516-2003 - PG&E believes the use of IEEE 516 as the standard for clearance requirements are adequate to ensure transmission system reliability provided the TO has an appropriate methodology for determining clearance at time of trim and an adequate cycle to prevent vegetation from encroaching within minimum distances. Use of ANSI Z133.3 or FedOSHA 1910, as suggested by FERC, is not appropriate as it is intended for worker safety and not system reliability. TO compliance with R1.2 of the standard should address concerns FERC has with maintaining minimum clearance.

   5-7) Procedural items - No comment

8) Preparation of technical manual (white paper) - agreed

9) PG&E believes the current reporting requirements under R3 of the standard should be revised. Distinction is placed on fall-in's "in and out of the ROW" and may not be the best method for determining severity for reporting purposes. PG&E believes a better distinction is (a) green/healthy/no obvious decline and (b) dead or obvious signs of disease, decay or decline. A key component of any TMVP should be hazard tree mitigation regardless if in or out of the ROW. Suggested categories:

Category 1 - Any grow-in (as currently stated).
Category 2 - Any fall-in of a dead tree or one with obvious signs of disease, decay or decline in or out of the ROW.
Category 3 - Either eliminate this category or specify healthy green tree or tree with no obvious signs of decline (if retained, be specific about this being for reporting purposes only)

PG&E recognizes that tree failures, even if dead or diseased, are not necessarily an indicator of problematic VM program and the severity level should be reflected as such. Tree density along with other factors make 100% identification not possible. However, multiple occurrences could be an indicator of substandard performance and the current standard does remains silent in respect to hazard trees other than if in or out of the ROW.

The SAR drafting team considered stakeholder comments on the first draft of this SAR and the FERC Order 693 in preparing the second draft of the SAR to modify FAC-003-1 — Transmission Vegetation Management.

The SAR drafting team modified the SAR to clarify that FAC-003-1 needs to add time horizons and violation severity levels to bring the standard into conformance with the latest version of the Reliability Standards Development Procedure and the ERO Sanctions Guidelines. (Time Horizons and Violation Severity Levels are both elements used to determine an appropriate sanction for violation of a standard.)

The SAR drafting team also modified the SAR to clarify that the scope of revisions to this standard will include addressing the issues raised by FERC in Order 693, including the following:

- Consideration of minimum clearances needed to avoid sustained vegetation-related outages that would apply to transmission lines crossing both federal land and non-federal land
- Revisions to the definition of 'right of way' to encompass required clearance areas
- Review of the suitability of IEEE Standard 516-2003 for minimum vegetation clearance

Several commenters indicated that the reporting requirements may need revision and the SAR was revised to include consideration of modifications to the reporting requirements.

The SAR drafting team consensus is that modification of FAC-003-1 to address the aforementioned items is needed to ensure reliability of the bulk power system.

1. Do you agree there is a reliability need for the proposed modifications and review of the standard?

☐ Yes

☒ No

Comments: Progress Energy Carolinas and Progress Energy Florida are providing an answer to the question as it relates to the reliability need. The current standard contains appropriate requirements and measures to ensure the Transmission Owner's vegetation management program is implemented and managed to ensure the reliability of the transmission system. In addition, we do not believe that a standard with a zero tolerance for vegetation-related outages in the ROW is in need of reliability-based revisions.

However, we do recognize the need for a revision of the standard to address non-reliability related items that are in the SAR. Procedural items such as formatting and clarifications, such as the definition of right-of-way, need to be, and should be, addressed.

2. If you are a transmission owner, have you been provided a list from a Reliability Entity (formerly RRO) of sub 200kV critical transmission lines that must comply with FAC-003-1?

☐ Yes

☒ No

Comments: The SERC and FRCC regions have not identified any lines below 200kV to be critical to the electrical system in the region. Since no lines have been identified as critical to the region, no list has been provided to Progress Energy Carolinas and Progress Energy Florida. (please note our comments on this issue in question #4)

3. If you are a transmission owner would you provide your methodology for determining clearance 1 and clearance 2? (As described in FAC-003-1 R1.2.1 and R1.2.2) If so, please attach.

☒ Yes

☐ No

Comments: Progress Energy has an individual on the Drafting Team and will share the Progress Energy Florida clearance Tables with the team.

4. Are there any other comments regarding the standard, its possible modifications or the SAR?

☒ Yes

☐ No

Comments: Progress Energy Carolinas (PEC) and Progress Energy Florida (PEF) do not agree that each of 11 items listed in the SAR are necessary to improve reliability. The following comments are offered for each of the 11 items identified in the SAR detail description:

1. Standard Applicability:

PEC and PEF believe that the current standard wording for determining facilities subject to this standard should not be revised. The standard as it is written provides for lines below 200kV, that are determined to impact the grid, to be subject to the standard.

Extending the requirements to a bright line below 200kV, such as 100kV, will dilute the focus on those lines that impact grid reliability, lines >200kV, and shift attention to facilities, those <200kV, that do not necessarily impact grid reliability. Customer reliability is an issue that impacts customer satisfaction and is generally driven by state utility commissions. While some facilities above 200kV directly support customer load, transmission lines below 200kV primarily support customer load, and interruptions to those facilities generally reduce load on the grid.

The majority of transmission facilities below 200 kV also have significantly different design/construction/operating characteristics and have not been cited as impacting bulk power system reliability. For example, the Final Report on the August 14, 2003 Blackout in the United states and Canada: Causes and Recommendations April 2004 by the U.S.- Canada Power System Outage Task Force and all referenced major blackouts (pages 103-115) in that report, cited only outages which involved vegetation at line voltages above 200kV. Generally applying requirements that are appropriate for >200kV lines to lines less than 200kV will result in significant documentation and reporting of items such as restrictions, mitigation plans, off right-of-way vegetation-related outage investigation/ information and other issues, all of which dilutes the focus on lines that directly impact bulk power system reliability.

Revising the standard to use general criteria or broad language for defining "Bulk Power System" transmission lines covered by the standard is a “one size fits all” approach. If that approach were taken, the standard would cover a significant number of transmission lines that have no direct impact on bulk power system reliability under standard planning/operating conditions, resulting in a significant cost burden for electric customers without improving “grid” reliability. PEC and PEF believe that the applicability provision of the standard should instead focus attention of the standard only on the transmission lines below 200kV that directly impact “Bulk Power System” reliability, as the current version requires.

While PEC and PEF recognize some validity in the Commission’s concern, PEC and PEF recommend that the applicability provision of this standard should be revised only if existing system design, planning or operating reliability criteria and parameters are considered as a basis for defining the applicability of the standard. To that end, PEC and PEF recommend each Regional Entity (RE) determine applicability of FAC-003 to those lines within the region that are between 100kV and 200KV, if, and only if, they are identified as operationally significant elements of Interconnection Reliability Operating Limits (“IROLs”). That is, any facility below 200kV that, by itself, would cause an Interconnected Reliability Limit Violation should the facility be outaged.

2. Issue of Clearances (Federal vs Non-Federal Lands):

FAC-003-1 presently requires the transmission owner (TO) “identify and document clearances between vegetation and any overhead, ungrounded supply conductors, taking into consideration transmission line voltage, the effects of ambient temperature on conductor sag under maximum design loading, and the effects of wind velocities on conductor sway.” The intent of this requirement is to ensure adequate clearances to prevent vegetation related outages. PEC and PEF believe that only the TO has the technical information required to determine the clearances that are necessary at the time of VM work and that any "federal lands exemption" to clearances will result in inadequate clearances for the existing conditions. Consistency in application of the TO's clearance requirements, not exceptions, is the only assurance in providing a uniform and reliable electrical system to meet the nation's current and future energy demands.

Any exception for a case by case clearance approach to determine vegetation management activities/clearances on Federal lands will continue to drive inconsistency and/or delays associated with TO vegetation management decisions being driven by diverse vegetation management practices/beliefs and staff changes at the local level of Federal agencies. Vegetation-related outages have occurred on Federal lands as a result of this case by case approach, and if "Bulk Power Transmission System" lines continue to be addressed on a "case by case" basis on National Forest Service (or any other Federal lands), those lines will potentially be subject to a higher risk for vegetation-related outages, resulting in reduced reliability for the "Bulk Power System".

PEC and PEF believe that reliability of the "Bulk Power System" should have the same focus on Federal and private lands and that the EEI MOU with federal agencies is an appropriate avenue for TO's to identify clearances on Federal lands, not an exemption in the language of a reliability standard.

3. Defining Right-of-Way:

PEC and PEF agree that it is appropriate to further address the definition of "right-of-way". Corridor widths that exceed the design clearance requirements have been acquired for a variety of reasons in the past; future use, property line buffers, etc. Vegetation in those areas that would normally be outside of the corridor width necessary for reliable operation of the facility, but within an expanded easement area, should not be considered, or treated, different than vegetation that is outside of a defined easement/permit right-of-way corridor that was designed and acquired specifically for the reliable operation of a single line.

4. IEEE Standard for Minimum Clearances:

PEC and PEF believe that the IEEE 516-2003 tables are appropriate for defining the minimum acceptable clearances to prevent flashover between conductors and vegetation under all rated electrical operating conditions. Closer minimum clearances such as the minimum length of a support insulator could have been adopted as a "lowest common denominator" clearance. However the clearance in IEEE 516-2003 was adopted to ensure an additional margin of reliability. FERC staff has made references to the use of ANSI Z-133 which is a safety standard that addresses worker safety as well as the safety of the general public. The purpose of ANSI Z-133 is to address worker safety and is not focused on transmission line reliability, which is the purpose of FAC-003-1. OSHA, NESC and other related safety standards have clearances in excess of IEEE 516-2003. Those clearances are clearly focused on safety issues and will still apply to other aspects of design and operation of electric facilities (such as public and worker safety) but are not appropriate to be referenced in a vegetation management reliability standard as a flashover clearance.

5/6/7. Procedural Items:

PEC and PEF agree that the procedural items related to formatting RRO references and revising the compliance elements to meet the new standard format should be addressed by the standard drafting team.

8. Technical Reference Materials:

PEC and PEF agree that a “white paper” that defines the technical basis for the standard is appropriate. This type of document, if crafted by the drafting team, should help to avoid the potential for differences in interpretation of the standard’s requirements by the various regions during the audit process.

9. Category 3 Outages:

Since control off right-of-way vegetation is generally beyond control of the TO and since "fall-in" outages are random events that do not threaten grid reliability, PEC and PEF believe that the reporting of category 3 outages should be removed from the requirements.

10. Requirement R4:

PEC and PEF believe that requirement R4 should be deleted from the standard, since the ERO formation provides for delegation of authority to the regional entities.

11. Reporting Exemptions:

PEC and PEF believe that the reporting requirement exemptions for natural disasters should include all categories of outages. For example, with outages caused by high winds, hurricanes, tornadoes, etc., it would be difficult (or practically impossible in some cases) to determine if the vegetation came from on, or off, the "right-of-way". In addition, the effort and time necessary to make that determination would result in delaying outage restoration efforts.

Please use this form to submit comments on the draft Transmission Vegetation Management SAR. Comments must be submitted by **May 9, 2007**. You may submit the completed form by e-mail to sarcomm@nerc.net with the words **"Vegetation Management SAR"** in the subject line. If you have questions please contact Harry Tom at Harry.Tom@nerc.net or by telephone at 609-452-8060.

Background Information:

The SAR drafting team considered the comments submitted in response to the first posting of the SAR as well as the FERC Order 693 in preparing the revised SAR to modify FAC-003-1 — Transmission Vegetation Management.

The SAR drafting team modified the SAR to state more specifically that the revisions to the standard need to incorporate the compliance program elements of time horizons and violation severity levels to bring FAC-003-1 into conformance with the latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines.

The FERC has urged further industry consideration of a number of issues and these have been listed in the revised SAR as items to address during using standards development process to refine FAC-003-1. The SAR drafting team consensus is that a modification to FAC-003-1 to address the aforementioned items is warranted.

Please review the changes made to the Vegetation Management SAR and then respond to the questions on the following pages. Please e-mail your comments to sarcomm@nerc.net with the subject "Vegetation Management SAR" by **May 9, 2007.**

You need not answer all questions. Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

The SAR drafting team considered stakeholder comments on the first draft of this SAR and the FERC Order 693 in preparing the second draft of the SAR to modify FAC-003-1 — Transmission Vegetation Management.

The SAR drafting team modified the SAR to clarify that FAC-003-1 needs to add time horizons and violation severity levels to bring the standard into conformance with the latest version of the Reliability Standards Development Procedure and the ERO Sanctions Guidelines. (Time Horizons and Violation Severity Levels are both elements used to determine an appropriate sanction for violation of a standard.)

The SAR drafting team also modified the SAR to clarify that the scope of revisions to this standard will include addressing the issues raised by FERC in Order 693, including the following:

- Consideration of minimum clearances needed to avoid sustained vegetation-related outages that would apply to transmission lines crossing both federal land and non-federal land
- Revisions to the definition of 'right of way' to encompass required clearance areas
- Review of the suitability of IEEE Standard 516-2003 for minimum vegetation clearance

Several commenters indicated that the reporting requirements may need revision and the SAR was revised to include consideration of modifications to the reporting requirements.

The SAR drafting team consensus is that modification of FAC-003-1 to address the aforementioned items is needed to ensure reliability of the bulk power system.

Background Information:

The SAR drafting team considered the comments submitted in response to the first posting of the SAR as well as the FERC Order 693 in preparing the revised SAR to modify FAC-003-1 — Transmission Vegetation Management.

The SAR drafting team modified the SAR to state more specifically that the revisions to the standard need to incorporate the compliance program elements of time horizons and violation severity levels to bring FAC-003-1 into conformance with the latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines.

The FERC has urged further industry consideration of a number of issues and these have been listed in the revised SAR as items to address during using standards development process to refine FAC-003-1. The SAR drafting team consensus is that a modification to FAC-003-1 to address the aforementioned items is warranted.

Please review the changes made to the Vegetation Management SAR and then respond to the questions on the following pages. Please e-mail your comments to sarcomm@nerc.net with the subject "Vegetation Management SAR" by **May 9, 2007.**

You need not answer all questions. Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

The SAR drafting team considered stakeholder comments on the first draft of this SAR and the FERC Order 693 in preparing the second draft of the SAR to modify FAC-003-1 — Transmission Vegetation Management.

The SAR drafting team modified the SAR to clarify that FAC-003-1 needs to add time horizons and violation severity levels to bring the standard into conformance with the latest version of the Reliability Standards Development Procedure and the ERO Sanctions Guidelines. (Time Horizons and Violation Severity Levels are both elements used to determine an appropriate sanction for violation of a standard.)

The SAR drafting team also modified the SAR to clarify that the scope of revisions to this standard will include addressing the issues raised by FERC in Order 693, including the following:

- Consideration of minimum clearances needed to avoid sustained vegetation-related outages that would apply to transmission lines crossing both federal land and non-federal land
- Revisions to the definition of 'right of way' to encompass required clearance areas
- Review of the suitability of IEEE Standard 516-2003 for minimum vegetation clearance

Several commenters indicated that the reporting requirements may need revision and the SAR was revised to include consideration of modifications to the reporting requirements.

The SAR drafting team consensus is that modification of FAC-003-1 to address the aforementioned items is needed to ensure reliability of the bulk power system.

1. Do you agree there is a reliability need for the proposed modifications and review of the standard?

☐ Yes

☒ No

Comments: The SERC VMS is providing an answer to the question as it relates to the reliability need. The current standard contains appropriate requirements and measures to ensure the Transmission Owner's vegetation management program is implemented and managed to ensure the reliability of the transmission system. In addition, we do not believe that a standard with a zero tolerance for vegetation-related outages in the ROW is in need of reliability-based revisions.

However the SERC VMS recognizes the need for a revision of the standard to address non-reliability related items that are in the SAR. Procedural items such as formatting and clarifications, such as the definition of right-of-way, need to be, and should be, addressed.

2. If you are a transmission owner, have you been provided a list from a Reliability Entity (formerly RRO) of sub 200kV critical transmission lines that must comply with FAC-003-1?

☐ Yes

☒ No

Comments: The SERC region has not identified any lines below 200kV to be critical to the electrical system in the region. Since no lines have been identified as critical to the region, no list has been provided to Transmission Owners. (please note the subcommittee's comments on this issue in question #4)

3. If you are a transmission owner would you provide your methodology for determining clearance 1 and clearance 2? (As described in FAC-003-1 R1.2.1 and R1.2.2) If so, please attach.

☐ Yes

☐ No

Comments: This question does not apply to the SERC EC Vegetation Mangement Subcommittee.

4. Are there any other comments regarding the standard, its possible modifications or the SAR?

☐ Yes

☐ No

Comments: The SERC VMS does not agree that each of 11 items listed in the SAR are necessary to improve reliability. The following comments are offered for each of the 11 items identified in the SAR detail description:

1. Standard Applicability:

The SERC VMS disagrees with revising the 200 kV threshold for determining facilities subject to this standard. Extending the requirements to lines other than those >200kV will dilute the focus on those lines that impact grid reliability and shift attention to facilities, those <200kV. The reliability of lower voltage lines involves local customers' reliability and satisfaction hence that reliability should be addressed by local and state utility commissions. The majority of the >200kV lines are solely elements of the grid and and interruptions to those lines negatively impact grid reliability. The majority of the <200kV lines primarily support customer load, and interruptions to those facilities actually reduces load on the grid.

The majority of transmission facilities below 200 kV also have significantly different design/construction/operating characteristics and have not been cited as impacting bulk power system reliability. For example, the Final Report on the August 14, 2003 Blackout in the United states and Canada: Causes and Recommendations April 2004 by the U.S.- Canada Power System Outage Task Force and all referenced major blackouts (pages 103-115) in that report, cited only outages which involved vegetation at line voltages above 200kV. Generally applying requirements that are appropriate for >200kV lines to lines less than 200kV will result in significant documentation and reporting of items such as restrictions, mitigation plans, off right-of-way vegetation-related outage investigation/ information and other issues, all of which dilutes the focus on lines that directly impact bulk power system reliability.

Revising the standard to use general criteria or broad language for defining "Bulk Power System" transmission lines covered by the standard is a “one size fits all” approach. If that approach were taken, the standard would cover a significant number of transmission lines that have no direct impact on bulk power system reliability under standard planning/operating conditions, resulting in a significant cost burden for electric customers without improving “grid” reliability. The SERC VMS believes that the applicability provision of the standard should instead focus attention of the standard only on the transmission lines below 200kV that directly impact “Bulk Power System” reliability, as the current version requires.

In sum, while the SERC VMS recognizes some validity in the Commission’s concern, the SERC VMS recommends that the applicability provision of this standard should be revised only if existing system design, planning or operating reliability criteria and parameters are considered as a basis for defining the applicability of the standard. To that end, the SERC VMS recommends each Regional Entity (RE) determine applicability of FAC-003 to those lines within the region that are between 100kV and 200KV, if, and only if, they are identified as operationally significant elements of Interconnection Reliability Operating Limits (“IROLs”). That is, any facility below 200kV that by itself would cause an Interconnected Reliability Limit Violation should the facility be outaged.

2. Issue of Clearances (Federal vs Non-Federal Lands):

FAC-003-1 presently requires the transmission owner (TO) “identify and document clearances between vegetation and any overhead, ungrounded supply conductors, taking into consideration transmission line voltage, the effects of ambient temperature on conductor sag under maximum design loading, and the effects of wind velocities on conductor sway.” The intent of this requirement is to ensure adequate clearances to prevent vegetation related outages. The SERC VMS believes that only the TO has the technical information required to determine the clearances that are necessary at the time of VM work and that any “federal lands exemption” to clearances will result in

inadequate clearances for the existing conditions. Consistency in application of the TO's clearance requirements, not exceptions, is the only assurance in providing a uniform and reliable electrical system to meet the nation's current and future energy demands.
Any exception for a case by case clearance approach to determine vegetation management activities/clearances on Federal lands will continue to drive inconsistency and/or delays associated with TO vegetation management decisions being driven by diverse vegetation management practices/beliefs and staff changes at the local level of Federal agencies. Vegetation-related outages have occurred on Federal lands as a result of this case by case approach, and if "Bulk Power Transmission System" lines continue to be addressed on a "case by case" basis on National Forest Service (or any other Federal lands), those lines will potentially be subject to a higher risk for vegetation-related outages, resulting in reduced reliability for the "Bulk Power System".

The SERC VMS believes that reliability of the "Bulk Power System" should have the same focus on Federal and private lands and that the EEI MOU with federal agencies is the appropriate vehicle for TO's to identify clearance variances on Ferderal lands, not exemption language in the standard.

3. Defining Right-of-Way:

The SERC VMS agrees that it is appropriate to further address the definition of "right-of-way". Corridor widths beyond design clearance requirements have been acquired for a variety of reasons in the past; future use, property line buffers, etc. Vegetation in those areas that would normally fall outside of the area necessary for operation of the facility should not be considered or treated different than vegetation that is outside of a defined easement/permit area that is designed for the reliable operation of an existing single line corridor.

4. IEEE Standard for Minimum Clearances:

The SERC VMS disagrees with objections to the use of the IEEE 516-2003 clearance as the minimum acceptable distances for "Clearance 2". The IEEE 516-2003 tables are appropriate for defining the minimum acceptable clearances to prevent flashover between conductors and vegetation under all rated electrical operating conditions. Closer minimum clearances such as the minimum length of a support insulator could have been adopted as a "lowest common denominator" clearance. However the clearance in IEEE 516-2003 was adopted to ensure an additional margin of reliability. FERC staff references ANSI Z-133 which is a safety standard that addresses worker safety as well as the safety of the general public. As such, the purpose of ANSI Z-133 is to address worker safety and is not focused on transmission line reliability, which is the purpose of FAC-003-1. OSHA, NESC and other related safety standards have clearances in excess of IEEE 516-2003. Those clearances are clearly focused on safety issues and will still apply to other aspects of design and operation of electric facilities (such as public and worker safety) but are not appropriate to be referenced in a vegetation management reliability standard.

5/6/7. Procedural Items:

The SERC VMS agrees that the procedural items related to formatting RRO references and additional compliance elements should be addressed by the standard drafting team.

8. Technical Reference Materials:

The SERC VMS agrees that a “white paper” that defines the technical basis for the standard is appropriate to avoid the potential for differences in interpretation of the standard’s requirements during the various region's audit processes.

9. Category 3 Outages:

Since the right to control off right-of-way vegetation is generally beyond control of the TO, the SERC VMS believes that the reporting of category 3 outages should be removed from the requirements.

10. Requirement R4:

The SERC VMS believes that requirement R4 should be deleted from the standard, based on the ERO formation and the process for delegation of authority to the regional entities.

11. Reporting Exemptions:

The SERC VMS believes that the reporting requirement exemptions for natural disasters should include all categories of outages. It would, for example, be difficult, without delaying restoration efforts, to determine if the vegetation from high winds, hurricanes, tornadoes, etc. is from on or off the "right-of-way".

Please use this form to submit comments on the draft Transmission Vegetation Management SAR. Comments must be submitted by **May 9, 2007**. Background Information:

The SAR drafting team considered the comments submitted in response to the first posting of the SAR as well as the FERC Order 693 in preparing the revised SAR to modify FAC-003-1 — Transmission Vegetation Management.

The SAR drafting team modified the SAR to state more specifically that the revisions to the standard need to incorporate the compliance program elements of time horizons and violation severity levels to bring FAC-003-1 into conformance with the latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines.

The FERC has urged further industry consideration of a number of issues and these have been listed in the revised SAR as items to address during using standards development process to refine FAC-003-1. The SAR drafting team consensus is that a modification to FAC-003-1 to address the aforementioned items is warranted.

Please review the changes made to the Vegetation Management SAR and then respond to the questions on the following pages. Please e-mail your comments to sarcomm@nerc.net with the subject "Vegetation Management SAR" by **May 9, 2007.**

You need not answer all questions. Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

The SAR drafting team considered stakeholder comments on the first draft of this SAR and the FERC Order 693 in preparing the second draft of the SAR to modify FAC-003-1 — Transmission Vegetation Management.

The SAR drafting team modified the SAR to clarify that FAC-003-1 needs to add time horizons and violation severity levels to bring the standard into conformance with the latest version of the Reliability Standards Development Procedure and the ERO Sanctions Guidelines. (Time Horizons and Violation Severity Levels are both elements used to determine an appropriate sanction for violation of a standard.)

The SAR drafting team also modified the SAR to clarify that the scope of revisions to this standard will include addressing the issues raised by FERC in Order 693, including the following:

- Consideration of minimum clearances needed to avoid sustained vegetation-related outages that would apply to transmission lines crossing both federal land and non-federal land
- Revisions to the definition of 'right of way' to encompass required clearance areas
- Review of the suitability of IEEE Standard 516-2003 for minimum vegetation clearance

Several commenters indicated that the reporting requirements may need revision and the SAR was revised to include consideration of modifications to the reporting requirements.

The SAR drafting team consensus is that modification of FAC-003-1 to address the aforementioned items is needed to ensure reliability of the bulk power system.

1. **Do you agree there is a reliability need for the proposed modifications and review of the standard?**

   ☐ Yes

   ☒ No

   Comments: We do not feel there is a reliability need for modifying the standard. However, we do agree certain modifications are needed to clarify procedural issues such as the amount of time allowed for taking corrective action when items are found to be out of compliance.

2. **If you are a transmission owner, have you been provided a list from a Reliability Entity (formerly RRO) of sub 200kV critical transmission lines that must comply with FAC-003-1?**

   ☒ Yes

   ☒ No

   Comments: We are not really sure how to answer this question. The Regional Entity has not sent us a list, but they have advised us that we do not have any sub 200 kv critical transmisison lines that must comply with FAC-003-1.

3. **If you are a transmission owner would you provide your methodology for determining clearance 1 and clearance 2? (As described in FAC-003-1 R1.2.1 and R1.2.2) If so, please attach.**

   ☒ Yes

   ☐ No

   Comments: IEEE 516-2003, Section 4.2.2.3 was adopted as the minimum allowable distance for Clearance 2, with the expectation that work would normally occur prior to Clearance 2 reaching the minimum allowable distance. Clearance 1 was determined by using the Clearance 2 value and adding a growth buffer. Sagging of conductors and their movement in wind was then considered to ensure the growth buffer is adequate.

4. **Are there any other comments regarding the standard, its possible modifications or the SAR?**

   ☐ Yes

   ☒ No

   Comments: We appreciate the efforts of the SAR Drafting Team.

Please use this form to submit comments on the draft Transmission Vegetation Management SAR. Comments must be submitted by **May 9, 2007**. You may submit the completed form by e-mail to sarcomm@nerc.net with the words **"Vegetation Management SAR"** in the subject line. If you have questions please contact Harry Tom at Harry.Tom@nerc.net or by telephone at 609-452-8060.

The SAR drafting team considered stakeholder comments on the first draft of this SAR and the FERC Order 693 in preparing the second draft of the SAR to modify FAC-003-1 — Transmission Vegetation Management.

The SAR drafting team modified the SAR to clarify that FAC-003-1 needs to add time horizons and violation severity levels to bring the standard into conformance with the latest version of the Reliability Standards Development Procedure and the ERO Sanctions Guidelines. (Time Horizons and Violation Severity Levels are both elements used to determine an appropriate sanction for violation of a standard.)

The SAR drafting team also modified the SAR to clarify that the scope of revisions to this standard will include addressing the issues raised by FERC in Order 693, including the following:

- Consideration of minimum clearances needed to avoid sustained vegetation-related outages that would apply to transmission lines crossing both federal land and non-federal land
- Revisions to the definition of ‘right of way’ to encompass required clearance areas
- Review of the suitability of IEEE Standard 516-2003 for minimum vegetation clearance

Several commenters indicated that the reporting requirements may need revision and the SAR was revised to include consideration of modifications to the reporting requirements.

The SAR drafting team consensus is that modification of FAC-003-1 to address the aforementioned items is needed to ensure reliability of the bulk power system.

1. **Do you agree there is a reliability need for the proposed modifications and review of the standard?**

   ☒ Yes

   ☐ No

   Comments: The primary needs for mocdifications to this standard are in areas to address clarifications and formatting not reliability related issues.

2. **If you are a transmission owner, have you been provided a list from a Reliability Entity (formerly RRO) of sub 200kV critical transmission lines that must comply with FAC-003-1?**

   ☐ Yes

   ☒ No

   Comments: We detemined that there are no TVA lines below 200kv that must comply to this standard due to their criticial needs in SERC.

3. **If you are a transmission owner would you provide your methodology for determining clearance 1 and clearance 2? (As described in FAC-003-1 R1.2.1 and R1.2.2) If so, please attach.**

   ☒ Yes

   ☐ No

   Comments: We utilize a clearance 2 based on IEEE 516 2003 Table 5 criteria. Our Clearance 1 is a greater amount to allow for growth between clearing and next inspection or clearance activities. We will provide our tables is requested.

4. **Are there any other comments regarding the standard, its possible modifications or the SAR?**

   ☒ Yes

   ☐ No

   Comments: We feel that the reporting of Category 3 outages should be eliminated. We agree with the need for a "white paper" to expand on definitions and intent. We feel that a defined maintainable width of right of way is more appropriate than the actual easement widths because easement widhts are not purchased or operated exclusively with or for vegetation manitenance activies. We will be pleased to share greater details on this concern if requested.

The FERC has urged further industry consideration of a number of issues and these have been listed in the revised SAR as items to address during using standards development process to refine FAC-003-1. The SAR drafting team consensus is that a modification to FAC-003-1 to address the aforementioned items is warranted.

Please review the changes made to the Vegetation Management SAR and then respond to the questions on the following pages. Please e-mail your comments to sarcomm@nerc.net with the subject "Vegetation Management SAR" by **May 9, 2007.**

You need not answer all questions. Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

The SAR drafting team considered stakeholder comments on the first draft of this SAR and the FERC Order 693 in preparing the second draft of the SAR to modify FAC-003-1 — Transmission Vegetation Management.

The SAR drafting team modified the SAR to clarify that FAC-003-1 needs to add time horizons and violation severity levels to bring the standard into conformance with the latest version of the Reliability Standards Development Procedure and the ERO Sanctions Guidelines. (Time Horizons and Violation Severity Levels are both elements used to determine an appropriate sanction for violation of a standard.)

The SAR drafting team also modified the SAR to clarify that the scope of revisions to this standard will include addressing the issues raised by FERC in Order 693, including the following:

- Consideration of minimum clearances needed to avoid sustained vegetation-related outages that would apply to transmission lines crossing both federal land and non-federal land
- Revisions to the definition of 'right of way' to encompass required clearance areas
- Review of the suitability of IEEE Standard 516-2003 for minimum vegetation clearance

Several commenters indicated that the reporting requirements may need revision and the SAR was revised to include consideration of modifications to the reporting requirements.

The SAR drafting team consensus is that modification of FAC-003-1 to address the aforementioned items is needed to ensure reliability of the bulk power system.

1. **Do you agree there is a reliability need for the proposed modifications and review of the standard?**

   ☐ Yes

   ☐ No

   Comments:

2. **If you are a transmission owner, have you been provided a list from a Reliability Entity (formerly RRO) of sub 200kV critical transmission lines that must comply with FAC-003-1?**

   ☐ Yes

   ☒ No

   Comments: VELCO has not been provided a specific list of critical lines below 200kV from the RE that need to be in compliance with FAC-003-1. VELCO suggests changing the wording in the standard to indentify those lines affected as 200 kV and great or those defined as Bulk Power System facilities.

3. **If you are a transmission owner would you provide your methodology for determining clearance 1 and clearance 2? (As described in FAC-003-1 R1.2.1 and R1.2.2) If so, please attach.**

   ☐ Yes

   ☒ No

   Comments: VELCO has defined Clearance 1 as the maximum allowed vegetation heights (12ft high) at time of maintenance. This maximum height has evolved from experience with regional growth rates and other factors. VELCO's Clearance 2 is determined by the New England ISO's Operating Procedure 3, which is slightly more stringent than IEEE 516.

4. **Are there any other comments regarding the standard, its possible modifications or the SAR?**

   ☐ Yes

   ☒ No

   Comments:

Consideration of Comments on Second Draft of Vegetation Management SAR (Project 2007-07)

The Vegetation Management SAR drafting team thanks all commenters who submitted comments on Draft 2 of the SAR. This SAR was posted for a 30-day public comment period from April 20 through May 9, 2007. The drafting team asked stakeholders to provide feedback on the SAR through a special SAR Comment Form. There were 27 sets of comments, including comments from 65 different people from more than 50 companies representing 7 of the 10 Industry Segments as shown in the table on the following pages.

Based on the comments received, the drafting team recommends that the Standards Committee advance this SAR to the standard drafting step of the standard development process. The drafting team made only one minor modification to the SAR to clarify (on page 2) that it is the ERO that will collect vegetation-related transmission outage data, not the SDT.

In this "Consideration of Comments" document stakeholder comments have been organized so that it is easier to see the responses associated with each question. All comments received on the standards can be viewed in their original format at:

http://www.nerc.com/~filez/standards/Vegetation-Management_Project_2007-7.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Director of Standards, Gerry Adamski, at 609-452-8060 or at gerry.adamski@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

The Industry Segments are:

1 — Transmission Owners
2 — RTOs, ISOs
3 — Load-serving Entities
4 — Transmission-dependent Utilities
5 — Electric Generators
6 — Electricity Brokers, Aggregators, and Marketers
7 — Large Electricity End Users
8 — Small Electricity End Users
9 — Federal, State, Provincial Regulatory or other Government Entities
10 – Regional Reliability Organizations, Regional Entities

Index to Questions, Comments, and Responses

1. **Do you agree there is a reliability need for the proposed modifications and review of the standard?**

Summary Consideration: Most commenters noted that while the FAC-003-1 Standard is technically adequate, they believed that clarification in the form of a technical white paper, and review of applicability parameters is warranted. Many of these commenters also agreed with the need to update the standard to conform to new procedural requirements and inclusion of compliance elements. The SDT shall consider producing a white paper to aid in clarifying the intent of the standard.

Question #1			
Commenter	**Yes**	**No**	**Comment**
AEP		☑	AEP believes that the current standard (when thoroughly read and understood) is completely adequate to maintain a reliable transmission system with minimum risk of vegetation-related outages.
Response: The team concurs that the technical elements are generally adequate and there is no reliability need to revise the standard. However all NERC standards must be updated to comply with new procedural requirements and inclusion of compliance elements. The Standard DT will address the issues raised in the FERC's March 16, 2007 Order 693 - Mandatory Reliability Standards for the Bulk Power System. The SDT shall consider producing a white paper to aid in clarifying the intent of the standard.			
Baltimore Gas & Electric		☑	I'm not convinced that the elements outlined in the proposal will improve reliability and have concerns that the proposed modifications may actually reduce the flexibility that is necessary to promote system reliability or to comply with local regulations. I would prefer to see more specifics in the proposal before supporting the modifications.
Response: The team concurs that the technical elements are generally adequate and there is no reliability need to revise the standard. However all NERC standards must be updated to comply with new procedural requirements and inclusion of compliance elements. The Standard DT will address the issues raised in the FERC's March 16, 2007 Order 693 - Mandatory Reliability Standards for the Bulk Power System. The SDT shall consider producing a white paper to aid in clarifying the intent of the standard.			
CenterPoint Energy		☑	CenterPoint Energy does not agree that a revision to the TVM standard is necessary from a reliability standpoint, and believes that the existing TVM standard is adequate for that purpose.
Response: The team concurs that the technical elements are generally adequate and there is no reliability need to revise the standard. However all NERC standards must be updated to comply with new procedural requirements and inclusion of compliance elements. The Standard DT will address the issues raised in the FERC's March 16, 2007 Order 693 - Mandatory Reliability Standards for the Bulk Power System. The SDT shall consider producing a white paper to aid in clarifying the intent of the standard.			
Central Maine Power		☑	The current Vegetation Management Standard FAC-003-1 has been crafted in such a way as to provide crisp measurable standards that when followed will provide a high level of power quality for the bulk power delivery system. However, clearances between

Question #1			
Commenter	**Yes**	**No**	**Comment**
			conductors and trees required to prevent tree related power outages must be consistent with each utility's established standards and if a transmission line passes through federal, state or locally managed areas this line placement should not impact the established clearances. Utilities should not be expected to negotiate clearances with multiple land managers. The IEEE 516 – 2003 table is an acceptable table to use as the minimum clearance to prevent a flash over and outages. FAC-003-1 is designed to be a reliability standard and the industry adheres to OSHA and ANSI standards to protect workers and the public. The IEEE 516 – 2003 table lists appropriate distances that should be used to measure compliance. The standard should continue to provide the flexibility for utility managers to increase "Clearance 2". The definition for right-of-way should be clarified to include only the area that is cleared and included as routine maintenance. We agree that there is a need to establish time horizons and clarify violation levels.
Response: The team concurs that the technical elements are generally adequate and there is no reliability need to revise the standard. However all NERC standards must be updated to comply with new procedural requirements and inclusion of compliance elements. The Standard DT will address the issues raised in the FERC's March 16, 2007 Order 693 - Mandatory Reliability Standards for the Bulk Power System, including a review of the definition for right-of-way. The SDT shall consider producing a white paper to aid in clarifying the intent of the standard.			
Duke Energy		☑	From a reliability perspective, the current standard contains appropriate requirements and measures to ensure the Transmission Owner's vegetation management program is implemented and managed to ensure the reliability of the transmission system. However the standard should be revised to address non-reliability related items that are in the SAR.
Response: The SAR DT agrees and thanks you for the comment.			
HQT		☑	It is our belief that the Standard in its current form does provide adequate provisions and drivers to minimize vegetation related outages and eliminate the likelihood of reoccurence of the August 14, 2003 blackout. However, it is recognized that the industry needs to consolidate its view on these provisions and we support the preparation of a "white paper" that will document the rationale concerning the requirements of the standard, as well as review certain aspects of the standard that have come into question.
Response: The SAR DT agrees and thanks you for the comment.			

Question #1			
Commenter	**Yes**	**No**	**Comment**
Hydro One Networks		☑	It is our belief that the Standard in its current form does provide adequate provisions and drivers to minimize vegetation related outages and eliminate the likelihood of reoccurence of the August 14, 2003 blackout. However, it is recognized that the industry needs to consolidate its view on these provisions and we support the preparation of a "white paper" that will document the rationale concerning the requirements of the standard, as well as review certain aspects of the standard that have come into question.
Response: The SAR DT agrees and thanks you for the comment.			
National Grid		☑	National Grid believes that compliance with all elements of the present Standard will result in TO's achieving the reliability objectives set forth in the Standard.
Response: The SAR DT agrees and thanks you for the comment.			
Northeast Utilities		☑	Proposed modifications do not increase the levels of reliability above what is already required in the current version of the Stnadard.
Response: The team concurs that the technical elements are generally adequate and there is no reliability need to revise the standard. However all NERC standards must be updated to comply with new procedural requirements and inclusion of compliance elements. The Standard DT will address the issues raised in the FERC's March 16, 2007 Order 693 - Mandatory Reliability Standards for the Bulk Power System. The SDT shall consider producing a white paper to aid in clarifying the intent of the standard.			
PGN		☑	Progress Energy Carolinas and Progress Energy Florida are providing an answer to the question as it relates to the reliability need. The current standard contains appropriate requirements and measures to ensure the Transmission Owner's vegetation management program is implemented and managed to ensure the reliability of the transmission system. In addition, we do not believe that a standard with a zero tolerance for vegetation-related outages in the ROW is in need of reliability-based revisions. However, we do recognize the need for a revision of the standard to address non-reliability related items that are in the SAR. Procedural items such as formatting and clarifications, such as the definition of right-of-way, need to be, and should be, addressed.
Response: The team concurs that the technical elements are generally adequate and there is no reliability need to revise the standard. However all NERC standards must be updated to comply with new procedural requirements and inclusion of compliance elements. The Standard DT will address the issues raised in the FERC's March 16, 2007 Order 693 - Mandatory Reliability Standards for the Bulk Power System. The SDT shall consider producing a white paper to aid in clarifying the intent of the standard.

<tr><td>Florida Power & Light</td><td>☑</td><td></td><td>FPL believes the technical portion of the standard provides adequate reliability protection to the system. FPL also recognizes the need to re-format the standard to bring it into conformance with the latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines, to remove references to RRO in the standard and substitute a responsible entity and, add compliance elements such as time horizons, and</td></tr>
</table>

Question #1			
Commenter	**Yes**	**No**	**Comment**
			violation severity levels.
Response: The SAR DT agrees and thanks you for the comment.			
IESO	☑		
IRC SRC	☑		
ISO-NE	☑		
Manitoba Hydro	☑		The definition of ROW should be clarified. The definition of a critical line should not be kept to a particular voltage threshold. However, consideration could also then be given to exempting non-critical lines operating at higher voltage levels (>200kv). Electrical clearances should be consistent whether on Federal or non-Federal land.
Response: The standard DT will review the definition of ROW. The standard DT will review applicability parameters of this standard, taking into account the comments from stakeholders such as NU, National Grid, Manitoba Hydro, First Energy, and others. The SAR DT concurs with the commenter with respect to applying this standard to Federal and non-Federal lands. The standard DT will evaluate the suitability of a case-by-case approach.			
MRO	☑		
NYISO	☑		
PGE	☑		As stated in the SAR.
Response: The SAR DT agrees and thanks you for the comment.			
PSC SC	☑		
Southern Transm.	☑		We do not feel there is a reliability need for modifying the standard. However, we do agree certain modifications are needed to clarify procedural issues such as the amount of time allowed for taking corrective action when items are found to be out of compliance.
Response: The team concurs that the technical elements are generally adequate and there is no reliability need to revise the standard. However all NERC standards must be updated to comply with new procedural requirements and inclusion of compliance elements. The Standard DT will address the issues raised in the FERC's March 16, 2007 Order 693 - Mandatory Reliability Standards for the Bulk Power System. The SDT shall consider producing a white paper to aid in clarifying the intent of the standard.			
TVA	☑		The primary needs for mocdifications to this standard are in areas to address clarifications and formatting not reliability related issues.
Response: The SAR DT agrees and thanks you for the comment.			

2. **If you are a transmission owner, have you been provided a list from a Regional Entity (formerly RRO) of sub 200 kV critical transmission lines that must comply with FAC-003-1?**

Summary Consideration: During the March 2007 SAR DT meeting, the FERC indicated they had not been presented any evidence with respect to Regional Entity (RE) critical line determinations and asked whether such lists existed. This question was posed to ascertain whether REs have determined which lines below 200 kV are critical.

Some commenters reported that their RE (SERC, FRCC, RFC) have determined there are no critical transmission lines that are under 200 kV. Some commenters (NGrid, NU, HydroOne, HQT) indicated that a list was not provided by their RE (NPCC). A commenter (MRO) noted that a list was submitted to NERC. A commenter responded that their RE (WECC) has provided such a list. On the basis of this informal poll, the SAR DT's assessment is that further specificity may be needed to aid in identifying which <200kV transmission lines should come under the purview of this standard in an attempt to standardize this criteria.. The SDT shall take under consideration other applicability parameter criteria in addition to various stakeholder proposals.

Question #2			
Commenter	**Yes**	**No**	**Comment**
IRC SRC			n/a
NYISO			n/a
Baltimore Gas & Electric		☑	The reason that we do not have a list of critical lines from the RRO may be that we do not have any lines that fit the criteria.
Response: The SAR DT thanks you for your response.			
CECD		☑	SERC does not currently have any sub 200 kV critical transmission lines.
Response: The SAR DT thanks you for your response.			
CenterPoint Energy		☑	
Central Maine Power		☑	The "Northeast Power Coordinating Council Facilities Notification List" may not be the correct list to be used for this standard. FAC- 003-1 should set a clear expectation the each Regional Entity will provide their transmission owners a list of critical lines including any that may be less that 200KV. Will provide list once released from NPCC.
Response: The SAR DT thanks you for your response.			
Dominion		☑	
Duke Energy		☑	The SERC region has not identified any lines below 200kV to be critical to the electrical system in the region. Since no lines have been identified as critical to the region, no list has been provided to Transmission Owners.
Response: The SAR DT thanks you for your response.			
HQT		☑	We consider that it should be the Planning Coordinator role to determine the sub 200kV critical transmission lines and even for any transmission lines irrelevant of voltage level.

Question #2			
Commenter	Yes	No	Comment
			For that, it should follow an impact based methodology such as the one used in NPCC.
Response: The SAR DT thanks you for your response.			
Hydro One Networks		☑	
Manitoba Hydro		☑	
MRO		☑	The MRO We have not generated a list or criteria yet. We have submitted a draft criteria to NERC
Response: The SAR DT thanks you for your response.			
National Grid		☑	The Reliability Entity has not provided a list of sub 200 kV lines subject to compliance with FAC-003-1. The Standard became effective in February 2007, just 3 months ago. Having no list today should not imply that the RE or the Standard has failed in any way. National Grid suggests that a revised Standard should direct the RE to produce a list of "sub 200 kV critical transmission lines" within 6 to 12 months of adoption.
Response: The standard DT will review applicability parameters of this standard, taking into account the comments from stakeholders such as NU, National Grid, Manitoba Hydro, First Energy, and others.			
Northeast Utilities		☑	The Reliability Entity has not provided a list of facilities covered under FAC-003-1. This is not a fault of the RE as there has been no direction provided as to what factors or charateristics are required for sub-200kV lines to be included under the Standard. It is our position that the factors that will be used to develop the list of sub-200kV faciltities to be covered by the Standard be developed at the national level (NERC) and adopted by all RE's for consistency.
Response: The standard DT will review applicability parameters of this standard, taking into account the comments from stakeholders such as NU, National Grid, Manitoba Hydro, First Energy, and others.			
PGN		☑	The SERC and FRCC regions have not identified any lines below 200kV to be critical to the electrical system in the region. Since no lines have been identified as critical to the region, no list has been provided to Progress Energy Carolinas and Progress Energy Florida. (Please note our comments on this issue in question #4.)
Response: The SAR DT thanks you for your response.			
SERC VMS		☑	The SERC region has not identified any lines below 200kV to be critical to the electrical system in the region. Since no lines have been identified as critical to the region, no list has been provided to Transmission Owners. (Please note the subcommittee's comments on this issue in question #4.)
Response: The SAR DT thanks you for your response.			
TVA		☑	We detemined that there are no TVA lines below 200kv that must comply to this standard due to their criticial needs in SERC.

Question #2			
Commenter	**Yes**	**No**	**Comment**
Response: The SAR DT thanks you for your response.			
VELCO		☑	VELCO has not been provided a specific list of critical lines below 200 kV from the RE that need to be in compliance with FAC-003-1. VELCO suggests changing the wording in the standard to identify those lines affected as 200 kV and great or those defined as Bulk Power System facilities.
Response: The standard DT will review applicability parameters of this standard, taking into account the comments from stakeholders such as NU, National Grid, Manitoba Hydro, First Energy, and others.			
Entergy Corp.	☑		Yes, the Reliability Entity (SERC) has performed its duty in evaluating our transmission system. SERC has confirmed that Entergy has no lines operating below 200kV that are critical to system reliability. Entergy has received its "list," but the list is blank. With respect to applicability, it is inappropriate to set a blunt voltage level criterion for determining which transmission lines are critical to bulk system reliability. There is no basis in engineering or in fact for voltage-based categories of applicability. Many lines operating at 200kV and higher essentially serve only local load, and there may in fact be some lines operating below 200kV where the standard should be applied. Many lines of all voltages are redundant and do not even impact local load during an outage. Therefore, the voltage criterion is overly broad. To support this statement, Entergy supplies the following facts: First, during the aftermath of Hurricanes Katrina and Rita, Entergy had (59) 230kV and 500kV lines out of service simultaneously. Additionally, Entergy had (85) 115kV and 161kV lines out of service simultaneously. During the aftermath of Hurricane Rita, Entergy had (41) 230kV and 500kV lines out of service simultaneously. Additionally, Entergy had (124) 115kV and 161kV lines out of service simultaneously. Dispite this overwhelming combination of simultaneous outages, no system-wide cascading blackout was initiated. Only local load was lost during restoration. This illustrates that Standard FAC-003-1, as it currently stands placing so much focus and penalty on even single-contingency outages, is overbroad, arbitrary and capricious. Second, each year the Entergy transmission system (like all other large electric utilities) suffers numerous outages from a great number of different sources: material defects, rot and decay, animal damage, human damage, extreme wind, lightning and, vegetation. Over the years 2001 through 2006, 927 transmission lines suffered 5,688 outages from a variety of sources. Vegetation outages accounted for 7.14% of those outages. Each

Question #2			
Commenter	**Yes**	**No**	**Comment**
			utility is unique, but these numbers are not unusual for a transmission system comprising 15,000 miles of line. Dispite this large number of outages, no cascading system black out has been intiated. Finally, Entergy has had as many as 17 transmission lines outaged from a single tornado event without even losing service to local load. Standard FAC-003-1 assigns too much risk to outages in general, and too mush risk to vegetation outages in particular. NERC and the regional reliability entities should define performance criteria that specifically define certain contingencies and certain undesireable outcomes that would classify a line as truly critical to bulk system reliability. The modeling software necessary to do this is readily available and already in use today by the Reliability Entities and their subject utilities. If FERC has concerns about potentially devistating (albeit rare) combinations of multiple simultaneous line outage contingencies, the REs can define strict criteria for multiple contingencies. With respect to lines that result in IROLs and SOLs, these lines can also be identified with specificity, without resorting to blunt voltage distinctions. Defining system-critical lines too broadly is actually detrimental to FERC's reliability goals. It dilutes the resources available to maintain reliability on those lines that truly affect system reliability. Utilities should employ a more focused and intelligent approach to targeted reliability. Such an approach would have benefits to the users of the transmission system and to the ratepayers that pay for it.
Response: The standard DT will review applicability parameters of this standard, taking into account the comments from stakeholders such as yourself and others.			
Florida Power & Light	☑		
PGE	☑		Provided from WECC
Response: The SAR DT thanks you for your response.			
AEP	☑	☑	Of the three regions in which AEP has transmission facilities, only one RE has provided a listing of sub-200 kV facilities of what we consider applicable under this standard.
Response: The SAR DT thanks you for your response.			
FirstEnergy Corp.	☑	☑	ReliabilityFirst, the Reliability Entity (formerly the RRO) was requested to provide a list of lines below 200 kV deemed as critical transmission lines that must comply with FAC-003-01. ReliabilityFirst responded "there are no lines below 200kV deemed as critical

Question #2			
Commenter	**Yes**	**No**	**Comment**
			infrastructure".
Response: The SAR DT thanks you for your response.			
Southern Transm.	☑	☑	We are not really sure how to answer this question. The Regional Entity has not sent us a list, but they have advised us that we do not have any sub 200 kv critical transmisison lines that must comply with FAC-003-1.
Response: The SAR DT thanks you for your response.			

3. If you are a transmission owner would you provide your methodology for determining clearance 1 and clearance 2? (As described in FAC-003-1 R1.2.1 and R1.2.2) If so, please attach.

Summary Consideration: This question was posed to poll transmission owners with respect to determination of Clearance 1 and Clearance 2 requirements. This information was sought to obtain examples of how industry members determine Clearance 1 since it is a qualitative requirement. Clearance 2 information was sought to evaluate the application of components of IEEE 516.

Of the 15 respondents to this poll question, some provided summary methodology for determining their Clearance 1 and Clearance 2, others have indicated that a methodology exists and is available upon request. On the basis of these responses to the poll question, the SDT shall consider reviewing IEEE 516 components to affirm their suitability in this standard and this information can assist in a white paper.

Question #3			
Commenter	**Yes**	**No**	**Comment**
IRC SRC			n/a
NYISO			n/a
SERC VMS			This question does not apply to the SERC EC Vegetation Management Subcommittee.
Response: The SAR DT thanks you for your response.			
Baltimore Gas & Electric		☑	
Central Maine Power		☑	The clearance 2 was taken directly from IEEE Table 516 – 2003. Clearance 1 is based on "Appendix C – ISO New England Right of way Vegetation Management Standard".
Response: The SAR DT thanks you for your response.			
Florida Power & Light		☑	
National Grid		☑	Detailed methodology is not attached. In summary, National Grid used Table 5 IEEE Section 516 for determing clearance 2. These data for each voltage class were rounded to the next higher whole number. Clearance 1 was determined by adding the clearance 2 distance, conductor sag distance, and anticipated tree growth over the maintenance cycle.
Response: The SAR DT thanks you for your response.			
PGN		☑	Progress Energy has an individual on the Drafting Team and will share the Progress Energy Florida clearance Tables with the team.
Response: The SAR DT thanks you for your response.			
VELCO		☑	VELCO has defined Clearance 1 as the maximum allowed vegetation heights (12ft high) at time of maintenance. This maximum height has evolved from experience with regional

Question #3			
Commenter	**Yes**	**No**	**Comment**
			growth rates and other factors. VELCO's Clearance 2 is determined by the New England ISO's Operating Procedure 3, which is slightly more stringent than IEEE 516.
Response: The SAR DT thanks you for your response.			
AEP	☑		For Clearance 1, AEP has chosen to use the minimum approach distances set forth in ANSI Tree Care Standard Z133.1 (rev. October 2000) for persons other than qualified line-clearance arborists and qualified line-clearance arborist trainees. For Clearance 2, AEP utilizes the Z133.1 minimum approach distances for qualified line clearance arborists and qualified line-clearance arborist trainees.
Response: The SAR DT thanks you for your response.			
CenterPoint Energy	☑		CenterPoint Energy has developed a methodology to determine clearance 1 and clearance 2 as described in FAC-003-1 R1.2.1 and R1.2.2. This methodology is included in a document titled "Specification for Transmission Vegetation Management Program" dated February 2007. Section 5.1 of that document covers NERC Clearance 1, and Section 5.2 covers NERC Clearance 2. Text and Tables from both Sections 5.1 and 5.2 are shown below: 5.1 NERC CLEARANCE 1 5.1.1 The appropriate clearance to conductors at the time of vegetation management work is established as Clearance 1 in accordance with NERC Standard FAC-003-1 Requirement R1.2.1. 5.1.2 Clearance 1 is determined by considering transmission line voltage, the effects of ambient temperature on conductor sag under maximum design loading, the effects of wind velocities on conductor sway, and the anticipated average growth rate of the prevalent tree species within the Company's service area over a 5-year period. 5.1.2.1 The minimum clearance distance of IEEE Standard 516-2003 Section 4.2.2.3, Minimum Air Insulation Distances without Tools in the Air Gap, is a component of Clearance 1. 5.1.3 Table 5.1 contains the horizontal clearance components and nominal values for Clearance 1, and Table 5.2 contains the vertical clearance components and nominal values for Clearance 1. Table 5.1

Question #3			
Commenter	**Yes**	**No**	**Comment**
			NERC Clearance 1: Horizontal Clearance, feet Horizontal Clearance Component, Nominal Voltage p-p 69kV 138kV 345kV Electrical Clearance (1) 2.46 2.95 4.40 Average 5-Year Horizontal Tree Growth 12.00 12.00 12.00 Average Mid-span Conductor Sway (2) 5.98 8.13 10.04 Total 20.44 23.08 26.44 Nominal Horizontal Value (3) 20 23 26 (1) Based on IEEE 516-2003 Table 5 for 69kV & 138kV and Table 7 for 345kV (2) Based on NESC C2-2007 Rule 233A(1) (3) May be reduced for site specific tree species or conductor span configuration but not less than Clearance 2. Table 5.2 NERC Clearance 1: Vertical Clearance, feet Vertical Clearance Component, Nominal Voltage p-p 69kV 138kV 345kV Electrical Clearance (1) 2.46 2.95 4.40 Average 5-Year Vertical Tree Growth 15.75 15.75 15.75 Average Conductor Final Sag Increase (2) 7.52 9.01 10.24 Total 25.73 27.71 30.39 Nominal Vertical Value (3) 26 28 30

Question #3			
Commenter	**Yes**	**No**	**Comment**
Response: The SAR DT thanks you for your response.			
Entergy Corp.	☑		Entergy defines four sets of clearances for vegetation approach to transmission lines. The first set of clearances is the Vegetation Pruning Distance. This is the clearance to be achieved at the time of vegetation management work which vegetation management employees and contractors complete as part of this program. This distance varies with each line, but is set to be the EDGE OF ROW in each case. (This clearance is referred to as "Clearance 1" in the NERC Vegetation standard FAC-003-1, Cf B.R1.2.1). The second set of clearances is the Vegetation Growth Alert Distance. This is the approach distance that triggers an alert to the Asset Management vegetation management employees that vegetation maintenance is required. Vegetation spotted on an aerial inspection that encroaches upon this clearance is noted on the inspection for future scheduling of pruning. The third set of clearances is the Minimum Energized Pruning Distance. This is the minimum approach distance vegetation can have to energized transmission lines and still be pruned without an outage on the energized transmission line, in accordance with OSHA safety guidelines. Any vegetation that encroaches on this minimum distance must be pruned, and must be pruned during an outage on the associated transmission line. The fourth set of clearances is the Minimum Vegetation Approach Distance. This is the absolute minimum radial approach distance to prevent flashover between vegetation and overhead ungrounded supply conductors. Under this program, vegetation should never encroach these minimum approach distances. Vegetation must be pruned prior to reaching this distance and must be pruned with an outage on the transmission line. (This distance is referred to as "Clearance 2" in the NERC vegetation standard, FAC-003-1, Cf B.R1.2.2.) These clearance distances are based upon those set forth in the Institute of Electrical and Electronics Engineers (IEEE) Standard 516-2003 (Guide for Maintenance Methods on Energized Power Lines) and as specified in Table 5. Under this program, vegetation can encroach the Vegetation Growth Alert Distance and the Minimum Energized Pruning Distance, but it shall not encroach upon the Minimum Vegetation Approach Distance.
Response: The SAR DT thanks you for your response.			

Question #3			
Commenter	**Yes**	**No**	**Comment**
FirstEnergy Corp.	☑		For R1.2.1 (Clearance 1), FirstEnergy used our existing specification requirement "for minimum clearance to be achieved at locations with an easement or other restriction" to define the minimum acceptable clearance. For R1.2.2 (Clearance 2), FirstEnergy uses the IEEE 516-2003 standard as the minimum as referenced in FAC-003-01. This is the minimum clearance under all operating conditions. FirstEnergy believes this is an appropriate definition.
Response: The SAR DT thanks you for your response.			
HQT	☑		HQT clearance methodology is not specifically based on the value specified in Clearance 1 and Clearance 2. HQT TVMP is such organized that vegetation management work minimize costs for line clearing and brush control while preventing outages from vegetation cause. As such, staff qualifications required to work near energized facilities are less than under the absolute minimum as stipulated in IEEE 516-2003, and in most cases, the work is less labour and equipment intensive. However clearances are never less than the absolute minimum stipulated in FAC-003-1 (R1.2.2). The above provides the basic approach used at HQT. If the Standard Drafting Team would like a copy of the HQT approach and methodology, this could be provided.
Response: The SAR DT thanks you for your response.			
Hydro One Networks	☑		Hydro One clearance standards are based on the Ontario Health and Safety Act (OHSA) clearances rather than the absolute minimum specified in Clearance 2. OHSA clearances at time of work minimize costs for line clearing and brush control. By maintaining OHSA clearances during normal working conditions, staff qualifications required to work near energized facilities are less than under the absolute minimum as stipulated in IEEE 515-3003, and in most cases, the work is less labour and equipment intensive. As part of work planning, qualified staff determine the amount of vegetation that has to be removed to achieve OHSA clearances at the time of the next scheduled work. As well, provisions are built into the clearances at time of work to account for conductor and tree movement during adverse weather conditions. The objective is to provide OHSA clearances under adverse conditions, but these are not always achieved, however clearances are never less than the absolute minimum stipulated in FAC-003-1. The above provides a description of our planning process. If the Standard Drafting Team would like a copy of the Hydro One standard, this can be provided.
Response: The SAR DT thanks you for your response.			

Question #3			
Commenter	**Yes**	**No**	**Comment**
Manitoba Hydro	☑		Clearance 1 was developed based on the limits of approach for non-qualified people (public). At a minimum, we would clear beyond this distance during vegetation control activities. Our cycle times and management approach are adjusted for this distance, taking into account growth rates. The values will vary depending on voltage class. Clearance 2 is based on internal design standards that take into account our understanding of switching surge values for our system. The values used are more conservative than IEEE 516-2003.
Response: The SAR DT thanks you for your response.			
MRO	☑		n/a
Northeast Utilities	☑		The methodology for determining clearance 2 is based on the requirements of FAC-003-1. The IEEE Section 516 has been considered the base minimum limits for clearances as provided under FAC-003-1 R.1.2.2. Clearances used for R.1.2.1 on the NU Transmission System comply with the requirements of ISO-NE Operating Procedure OP-3, that provides clearance levels required at the time of vegetation trimming or clearing under the various transmission voltages.
Response: The SAR DT thanks you for your response.			
PGE	☑		Will be provided to the SARDT in a separate attachment[TH1].
Response: The SAR DT thanks you for your response.			
Southern Transm.	☑		IEEE 516-2003, Section 4.2.2.3 was adopted as the minimum allowable distance for Clearance 2, with the expectation that work would normally occur prior to Clearance 2 reaching the minimum allowable distance. Clearance 1 was determined by using the Clearance 2 value and adding a growth buffer. Sagging of conductors and their movement in wind was then considered to ensure the growth buffer is adequate.
Response: The SAR DT thanks you for your response.			
TVA	☑		We utilize a clearance 2 based on IEEE 516 2003 Table 5 criteria. Our Clearance 1 is a greater amount to allow for growth between clearing and next inspection or clearance activities. We will provide our tables is requested.
Response: The SAR DT thanks you for your response.			

4. **Are there any other comments regarding the standard, its possible modifications or the SAR?**

Summary Consideration:
The comments were mixed with regard to:
- Whether reporting of Category 3 outages are necessary.

Most that commented agreed that:
- The 200kV applicability threshold could be clarified and the SAR DT deemed a review of applicability parameters is desirable.
- A consistent approach to both federal and non federal lands is desirable.
- A review of the definition of ROW is desirable.
- Components of the IEEE 516 standard are suitable.
- The exclusion of major disaster related events is appropriate.
- The inclusion of compliance elements and other procedural updates of the standard are needed.
- The development of a technical white paper is desirable.
- The standard DT should review the need for Requirement R4.

On the whole, the comments are supportive of the SAR as written and the SAR DT have made no changes to the second draft of the request.

Question #4			
Commenter	**Yes**	**No**	**Comment**
CenterPoint Energy		☑	
Manitoba Hydro		☑	
PSC SC		☑	
Southern Transm.		☑	We appreciate the efforts of the SAR Drafting Team.
AEP	☑		The SAR directs the SDT to collect and analyze outage data as part of an effort to define clearances for transmission lines on federal and non-federal lands. AEP believes that the analysis of outage data will be meaningless and unproductive. The SAR directive presupposes a cause-and-effect relationship between vegetation-related outages and federal/non-federal land status. On the contrary, AEP believes that vegetation-related data is more indicative of the effectiveness of the utility's VM program, in spite of onerous and inordinately expensive measures required on federal lands.
Response: The standard DT looks to receive the results of the ERO analysis and use it in developing the standard.			

Question #4			
Commenter	**Yes**	**No**	**Comment**
Ameren	☑		Ameren does not agree that each of 11 items listed in the SAR are necessary to improve reliability. The following comments are offered for each of the 11 items identified in the SAR detail description: 1. Standard Applicability: Ameren disagrees with revising the 200 kV threshold for determining facilities subject to this standard. Extending the requirements to lines other than those >200kV will dilute the focus on those lines that impact grid reliability and shift attention to facilities, <200kV. Utilities generally have an incentive to maintain reliability on lines less than 200kV. State commissions and customer expectations for reliable service provide this incentive. While many facilities above 200kV directly support customer load, transmission lines below 200kV primarily support customer load, and interruptions to those facilities reduces load on the grid. The majority of transmission facilities below 200 kV also have significantly different design/construction/operating characteristics and have not been cited as impacting bulk power system reliability. For example, the Final Report on the August 14, 2003 Blackout in the United states and Canada: Causes and Recommendations April 2004 by the U.S.-Canada Power System Outage Task Force and all referenced major blackouts (pages 103-115) in that report, cited only outages which involved vegetation at line voltages above 200kV. Generally applying requirements that are appropriate for >200kV lines to lines less than 200kV will result in significant documentation and reporting of items such as restrictions, mitigation plans, off right-of-way vegetation-related outage investigation/ information and other issues, all of which dilutes the focus on lines that directly impact bulk power system reliability. Revising the standard to use general criteria or broad language for defining "Bulk Power System" transmission lines covered by the standard is a "one size fits all" approach. If that approach were taken, the standard would cover a significant number of transmission lines that have no direct impact on bulk power system reliability under standard planning/operating conditions, resulting in a significant cost burden for electric customers without improving "grid" reliability. Ameren believes that the applicability provision of the standard should focus attention of the standard only on the transmission lines below 200kV that directly impact "Bulk Power System" reliability, as the current version requires.

Question #4			
Commenter	**Yes**	**No**	**Comment**
			Ameren recognizes some validity in the Commission's concern; Ameren recommends that the applicability provision of this standard should be revised only if existing system design, planning or operating reliability criteria and parameters are considered as a basis for defining the applicability of the standard. Ameren recommends each Regional Entity (RE) determine applicability of FAC-003 to those lines within the region that are between 100kV and 200KV, if, and only if, they are identified as operationally significant elements of Interconnection Reliability Operating Limits ("IROLs"). That is, any facility below 200kV that by itself would cause an Interconnected Reliability Limit Violation should the facility be outaged. 2. Issue of Clearances (Federal vs Non-Federal Lands): FAC-003-1 presently requires the transmission owner (TO) "identify and document clearances between vegetation and any overhead, ungrounded supply conductors, taking into consideration transmission line voltage, the effects of ambient temperature on conductor sag under maximum design loading, and the effects of wind velocities on conductor sway." The intent of this requirement is to ensure adequate clearances to prevent vegetation related outages. Ameren believes that only the TO has the technical information required to determine the clearances that are necessary at the time of VM work and that any "federal lands exemption" to clearances will result in inadequate clearances for the existing conditions. Consistency in application of the TO's clearance requirements, not exceptions, is the only assurance in providing a uniform and reliable electrical system to meet the nation's current and future energy demands. Any exception for a case by case clearance approach to determine vegetation management activities/clearances on Federal lands will continue to drive inconsistency and/or delays associated with vegetation management decisions being driven by diverse vegetation management practices/beliefs and staff changes at the local level of Federal agencies. Vegetation-related outages have occurred on Federal lands as a result of this case by case approach, and if "Bulk Power Transmission System" lines continue to be addressed on a "case by case" basis on National Forest Service (or any other Federal lands), those lines will potentially be subject to a higher risk for vegetation-related outages, resulting in reduced reliability for the "Bulk Power System". Ameren believes that reliability of the "Bulk Power System" should have the same focus on Federal and private lands and that the EEI MOU with federal agencies is the

Question #4			
Commenter	**Yes**	**No**	**Comment**
			appropriate vehicle for TO's to identify clearance variances on Ferderal lands, not exemption language in the standard. The standard should not be used as a mechanism by federal agencies to impose variances to proven vegetation management practices and clearances. 3. Defining Right-of-Way: Ameren agrees that it is appropriate to further address the definition of "right-of-way". Corridor widths beyond design clearance requirements have been acquired for a variety of reasons in the past; future use, property line buffers, etc. Vegetation in those areas that would normally fall outside of the area necessary for operation of the facility should not be considered or treated different than vegetation that is outside of a defined easement/permit area that is designed for the reliable operation of an existing single line corridor. 4. IEEE Standard for Minimum Clearances: Ameren disagrees with objections to the use of the IEEE 516-2003 clearance as the minimum acceptable distances for "Clearance 2". The IEEE 516-2003 tables are appropriate for defining the minimum acceptable clearances to prevent flashover between conductors and vegetation under all rated electrical operating conditions. FERC staff references ANSI Z-133 which is a safety standard that addresses worker safety as well as the safety of the general public. As such, the purpose of ANSI Z-133 is to address worker safety and is not focused on transmission line reliability, which is the purpose of FAC-003-1. OSHA, NESC and other related safety standards have clearances in excess of IEEE 516-2003. Those clearances are clearly focused on safety issues and will still apply to other aspects of design and operation of electric facilities (such as public and worker safety) but are not appropriate to be referenced in a vegetation management reliability standard. 5/6/7. Procedural Items: Ameren agrees that the procedural items related to formatting RRO references and additional compliance elements should be addressed by the standard drafting team. 8. Technical Reference Materials:

Question #4			
Commenter	**Yes**	**No**	**Comment**
			Ameren agrees that a "white paper" that defines the technical basis for the standard is appropriate to avoid the potential for differences in interpretation of the standard's requirements during the various region's audit processes. 9. Category 3 Outages: Since the right to control off right-of-way vegetation is generally beyond control of the transmission owner Ameren believes that the reporting of category 3 outages should be removed from the requirements. 10. Requirement R4: Ameren believes that requirement R4 should be deleted from the standard, based on the ERO formation and the process for delegation of authority to the regional entities. 11. Reporting Exemptions: Ameren believes that the reporting requirement exemptions for natural disasters should include all categories of outages. It would, for example, be difficult, without delaying restoration efforts, to determine if the vegetation from high winds, hurricanes, tornadoes, etc. is from on or off the "right-of-way".

Response:

1. The standard DT will review applicability parameters of this standard, taking into account the comments from stakeholders such as NU, National Grid, Manitoba Hydro, First Energy, and others.
2. The SAR DT concurs with the commenter with respect to applying this standard to Federal and non-Federal lands. The standard DT will evaluate the suitability of a case-by-case approach.
3. The standard DT will review the definition of ROW.
4. The SAR DT agrees with the commenter and recognizes that sections of IEEE 516 standard pertaining to minimum air insulation distances are applicable in determining minimum vegetation clearances to prevent flashovers.
5. NERC standards must be updated to comply with new procedural requirements and must include compliance elements.
6. See #5
7. See #5
8. The SDT shall consider producing a white paper to aid in clarifying the intent of the standard.
9. The SAR indicates that the Standard Drafting Team will review reporting criteria for Category 3 outages and will review the reporting requirement of Category 3 outages in R.3 and R.4.

Question #4			
Commenter	**Yes**	**No**	**Comment**
10. The standard DT will consider deletion of R.4. 11. The standard DT will review the reporting exemptions to include all category outages under major disasters in Requirement R3.2.			
Baltimore Gas & Electric	☑		We completely disagree with the proposal to eliminate reporting or off-right-of-way tree outages. In reality, off-R/W outages can cause many of the same problems that on R/W outages do if they were to occur at the most inappropriate time. Granted that they typically do not occur at times of peak load, but they could. Moreover, many off-R/W tree outages are preventable and should be addressed before they occur.
Response: The SAR indicates that the Standard Drafting Team will review reporting criteria for Category 3 outages and will review the reporting requirement of Category 3 outages in R.3 and R.4.			
CECD	☑		CECD supports continuing to use the 200kV threshold for determining applicability of vegetation management criteria. If the standard is deemed to apply to lower voltages these should only be critical lower voltage transmission facilities as determined by the Regional Entities's. CECD would also encourage the drafting team to clarify that the Vegetation Management standards are not applicable to generator interconnection facilities. In the registration process due to the NERC functional definitions, Generation Owners/Operators are required to register as Transmission Owners/Operators because of step-up transformers and other associated interconnection equipment that was not intended to be subject to the Vegetation Management program.
Response: The standard DT will review applicability parameters of this standard, taking into account the comments from stakeholders such as NU, National Grid, Manitoba Hydro, First Energy, and others. As a registered transmission owner this standard is applicable. Registration matters should be referred to the NERC organization certification program and the related regional entity.			
Central Maine Power	☑		The standard FAC-003-1 is intended to create a frame work that will ensure a uniform level of reliability and at the same time must allow transmission owners to meet this objective using efficient and cost effective programs. To this end utilities must have the ability to implement "Clearance 1" distances consistently throughout their service areas. The standard should remain focused only on 200 KV and above lines or lines listed as critical by the Regional Entity. Inspection cycles are sufficient as listed the current version and allow flexibility to meet local variability in growth rates and other conditions. Concerns with inspection cycle length can be addressed in the compliance area.

Question #4			
Commenter	**Yes**	**No**	**Comment**
Response: The SAR DT thanks you for your comments. The standard DT will review applicability parameters of this standard, taking into account the comments from stakeholders such as yourself and others. The FERC is no longer indicating a need to develop a requirement for a minimum inspection cycle (March 16, 2007 Order 693) and stakeholders indicated they did not support this change, so it was removed from the SAR.			
Dominion	☑		In response to Stakeholder item #11, we do not support exempting Category 1 or Category 2 events that occur during natural disasters.
Response: A majority of the industry stakeholder comments support natural disaster exemptions.			
Duke Energy	☑		Regarding the Order 693 items, the applicability provision of the standard should focus attention of the standard only on the transmission lines 200kV and above, and those lines below 200kV that directly impact "Bulk Power System" reliability, as the current version of FAC-003 requires. Each Regional Entity (RE) must determine applicability of FAC-003 to those lines within the region that are less than 200kV. For example, transmission lines below 200kV should be considered within the scope of FAC-003 if they are identified as operationally significant elements of Interconnection Reliability Operating Limits ("IROLs"); i.e. an outage of the facility would cause an Interconnection Reliability Limit Violation. The Standard DT should address the issue of the necessity of maintaining consistent clearances for lines on both federal and non-federal lands. We agree with the use of the IEEE 516-2003 standard for for defining the minimum acceptable clearances to prevent flashover between conductors and vegetation under all rated electrical operating conditions. We believe that the reporting requirement exemptions for natural disasters should include all categories of outages.
Response: The standard DT will review applicability parameters of this standard, taking into account the comments from stakeholders such as NU, National Grid, Manitoba Hydro, First Energy, and others. The SAR DT concurs with the commenter with respect to applying this standard to Federal and non-Federal lands. The standard DT will evaluate the suitability of a case-by-case approach. The SAR DT agrees with the commenter and recognizes that sections of IEEE 516 standard pertaining to minimum air insulation distances are applicable in determining minimum vegetation clearances to prevent flashovers.			

Question #4			
Commenter	**Yes**	**No**	**Comment**
The standard DT will review the reporting exemptions to include all category outages under major disasters in Requirement R3.2.			
Entergy Corp.	☑		The policy to increase sanctions based on a finding of an "intentional economic decision to violate the standard" is ill-concieved: 1. Every transmission line outage that has ever occured could have been avoided if more money had been spent on SOMETHING, SOMWHERE. 2. No utility has an unlimited budget, so decisions based on risk, cost and benefit are made every day. 3. After the outage, the localized initiating cause will appear so trivial and inexpensive that it would seem that it could easily have been fixed in advance. 4. Therefore, reviewers could conclude that EVERY outage (a defacto violation of the standard), is the result of an "economic decision to violate the standard." Economic choices are a necessary and natural part of doing business, and do not necessarily imply the existence of malicious motives or wrong-doing. The current policy is going to create unnecessary costs to ratepayers, even to avoid inconsequential outages.
Response: The compliance sanctions guideline addresses the matter of willful noncompliance. Refer to the Compliance program with respect to this issue. However the standard DT and Compliance Elements DT will review and assign Violation Severity Levels when modifying FAC-003-1.			
FirstEnergy Corp.	☑		The definition of Right-Of-Way requires modification to clarify it is the width required by engineering to operate the line. This may or may not be the legal Right-of-Way. (See previously submitted comments submitted by FE in Feb 2007 for more details).
Response: The standard DT will review the definition of ROW.			
Florida Power & Light	☑		For the record FPL re-emphasize its comments from the previous FAC 003-1 SAR. Requirement 3.2 exempts reporting of outages from outside the ROW when natural disasters such as tornados or hurricanes occur. Our experience with numerous hurricanes indicates that all outages during these types of events should be exempt. The focus in these situations is to get the lines back in service and restore customers. There is insufficient manpower to adequately complete the forensics necessary to determine an accurate root cause. It is not uncommon to find vegetation debris in the lines or downed trees on the ROW in this situation. In most cases it is not possible to determine the original location of these trees.

Question #4			
Commenter	**Yes**	**No**	**Comment**
			In the compliance section of the document a transmission owner becomes non compliant with a single category 1 or 2 outage. This occurs regardless of the circumstances. A non compliant penalty for a single outage in a situation where no customers were affected and the system could not have been compromised is not reasonable. It is also not an indicator of a poorly maintained system. We agree that several Category 1 or 2 interruptions could be an indicator of neglect but one is not. We recommend that the compliance section be reviewed with this in mind.
Response: The SDT will review the reporting exemptions to include all category outages under major disasters in Requirement R3.2. The SDT and Compliance Elements DT will review and assign Violation Severity Levels when modifying FAC-003-1. Note that the levels of non-compliance that are in the approved version of FAC-003 will be replaced with violation severity levels.			
HQT	☑		Here are some general comments on the SAR: 1. In the purpose section of the SAR, item 1, we don't understand the substitution of BPS by «electric transmission system»; it seems like there is a will to make the Standards applicable to more than the BPS. It is our understanding that NERC Standards are aimed at the reliability of the BPS. The term BPS should be retained and instead of modifying the SAR to widen the applicability, the Standard itself should be modified to specifically used the term BPS in item A.3. 2. In the detailed description section, item 1, sub-bullet, it is written that: "...the SDT may consider other criteria in determining applicability of the Standard to sub 200 kV lines...". We think that in item 4.3 (Applicability) of the existing Standard, there is already the possibility of applying the Standard to sub 200 kV lines if determined by RRO. This could be reworded by saying: "...as determined by a methodology to define BPS element"; such as the one used by NPCC. 3. We noticed that most Definitions (e.g. RC, IA, PC, RP, TP, TOP, DP, GO, GOP, PSE, MO (not even in the Glossary), LSE) used to described the Reliability Functions in the SAR form, are somewhat different than those used in the Glossary of Terms approved with the Standards deposited at the FERC. For consistency, if the definition needs to be changed, this should be done through the right process, not just casually in the SAR Form. 4. Also, although the title in that same section of the SAR form refers to Reliability Functions, these are in fact the Responsible Entity that performs those functions; maybe a correction in the SAR form would be necessary.

Question #4			
Commenter	**Yes**	**No**	**Comment**
Response: 1. The SAR DT used 'Bulk Electric System' because that is the term defined in the NERC Glossary. 2. The standard DT will review applicability parameters of this standard, taking into account the comments from stakeholders such as NU, National Grid, Manitoba Hydro, First Energy, and others. Furthermore the standard DT will ensure that any new terms defined for use in this standard will also be added to the Glossary of Terms. 3. The standard DT will ensure that any new terms defined for use in this standard will also be added to the Glossary of Terms. the drafting teams were directed to use the definitions for the functional model entities in the version of the Functional Model just approved by the BOT in February, 2007. The glossary will be updated to include the revised definitions for the functional entities. 4. Thanks for the comment.			
Hydro One Networks	☑		We believe from a transmission system perspective, category 3 outages are no different than many of the other types of outages that take place on the system, such as hardware failures, lightning damage and station equipment outages to name a few. It is our understanding that there is no requirement to report these "other" outages, which makes one wonder why the tree related outages that originate off the right of way need to be reported. We are not diminishing the importance of category 3 outages, but from a system cascading perspective, these outages are no more important than other line or station outages, and are fewer in number than the "other" random outages. To initiate system cascading as occurred during August 14, 2003, a number of the random outages would have to coincide to cause a wide spread system event, which in our opinion is a very low probability occurrence. On the other hand, a category 1 outage can occur as a result of any system disturbance should there be deficiencies in clearances to vegetation, as such the importance of category 1 outages is apparent and reporting is appropriate. We support the review concerning the need to report category 3 outages and that the ultimate decision should be based on reporting rules that take into consideration the broader topic of reliability, rather than just vegetation related outages.
Response: The SAR indicates that the Standard Drafting Team will review reporting criteria for Category 3 outages and will review the reporting requirement of Category 3 outages in R.3 and R.4.			
IESO	☑		1. The SAR indicates that a list of critical low voltage transmission lines will be provided to FERC. We do not interpret Order 693 to direct NERC to provide this list. Rather, we interpret that FERC asks for defining a criteria that would include low voltage transmission lines that have impact on Bulk Power System reliability. We do not think the list is required. 2. The SAR indicates: "The standard DT may consider other criteria in determining

Question #4			
Commenter	**Yes**	**No**	**Comment**
			applicability of the standard to sub 200kV lines…" Per Order 693, the criteria is quite clearly stated to be the transmission lines of less than 200 kV that could impact Bulk Power System reliability. We don't feel any other criteria would be necessary. Further, to identify the candidates that meet these criteria, we believe they should be determined by the Reliability Coordinator, similar to the PRC-023 standard, since the RC has the primary responsibility and knowledge of interconnection reliability impact. 3. We do not understand why the SDT considers removing Category 3 incidents? In our view, Category 3 outages are important information for assessing the effectiveness of vegetation program. Since the industry started reporting vegetation related outages about 3 years ago, data collected so far indicates that of a total of 98 reported vegetation outages, 67 of them were category 3 outages. With this high percentage, reporting of Category 3 events should be a must since the associated trends can provide valuable information to the TOs to aid its evaluation of the vegetation management program. 4. The white paper and field tests are a good idea and the SDT should be commended for these, especially the white paper. 5. Item 2 under the FERC Order 693 Items in the Detailed Description Section indicates the SDT will also collection outage data. While we understand that FERC has directed the ERO to collect outage data for transmission outages of lines that cross both federal and non-federal lands, we do not feel that it is the SDT's role to perform this task. We feel that this task should be performed by the ERO line functions or a group separate from the SDT such that the task does not add burden to the SDT which may slow down the standard development process or result in the standard development being driven by unanalyzed data and resulting in erroneous requirements. 6. With respect to reporting exemptions, our position during development of the previous version of this standard was to limit them. We commend the SDT intention to clarify the outage exemptions under major disasters, but to consider including all category outage exemptions in the standard body is too prescriptive and will add to the already extended list. It can end up with a very long list of outage exemptions, thereby reducing the coverage of the standard substantially and defeating its purpose
Response: 1. On the basis of the responses from stakeholders to Question #2 above, the SAR DT's assessment is that further			

Question #4			
Commenter	**Yes**	**No**	**Comment**
specificity may be needed to aid in identifying which <200kV transmission lines should come under the purview of this standard. The SDT shall take under consideration other applicability parameter criteria, various stakeholder proposals including IROL violation potential. 2. See # 1 above. 3. The SAR indicates that the Standard Drafting Team will review reporting criteria for Category 3 outages and will review the reporting requirement of Category 3 outages in R.3 and R.4. 4. The SAR DT thanks you for your comment. 5. The SDT looks to receive the results of the ERO analysis and use it in developing the standard. 6. The SDT will review the reporting exemptions to include all category outages under major disasters in Requirement R3.2.			
IRC SRC	☑		1. The SAR indicates that a list of critical low voltage transmission lines will be provided to FERC. We do not interpret Order 693 to direct NERC to provide this list. Rather, we interpret that FERC asks for defining a criteria that would include low voltage transmission lines that have impact on Bulk Power System reliability. We do not think the list is required. 2. The SAR indicates: "The standard DT may consider other criteria in determining applicability of the standard to sub 200kV lines…" Per Order 693, the criteria is quite clearly stated to be the transmission lines of less than 200 kV that could impact Bulk Power System reliability. We don't feel any other criteria would be necessary. Further, to identify the candidates that meet this criteria, we believe they should be determined by the Reliability Coordinator, similar to the PRC-023 standard, since the RC has the primary responsibility and knowledge of interconnection reliability impact. 3. Question #4			
Commenter	Yes	No	Comment
			5. Item 2 under the FERC Order 693 Items in the Detailed Description Section indicates the SDT will also collect outage data. While we understand that FERC has directed the ERO to collect outage data for transmission outages of lines that cross both federal and non-federal lands, we do not feel that it is the SDT's role to perform this task. We feel that this task should be performed by the ERO or a group separate from the SDT such that the task does not add burden to the SDT which may slow down the standard development process or result in the standard development being driven by unanalyzed data and resulting in erroneous requirements. 6. With respect to reporting exemptions, our position during development of the previous version of this standard was to limit them. We commend the SDT intention to clarify the outage exemptions under major disasters, but to consider including all category outage exemptions in the standard body is too prescriptive and will add to the already extended list. It can end up with a very long list of outage exemptions, thereby reducing the coverage of the standard substantively and defeating its purpose. If this list was to be developed, they could be attached as guidelines aside of the standard. 7. The SAR DT states it will deal with "critical facilities" . The SRC suggest that the DT not use the word "critical" and adopt another term. There is a need to define in a single standard what the term "critical" means. Standards FAC-014 (R5.1.1); IRO-002-1 (R6) and others use the term "critical" as in: critical loads, critical infrastructure, critical assets. The Veg Management Team is asked to avoid making the current situation worse.

Response:

1. On the basis of the responses from stakeholders to Question #2 above, the SAR DT's assessment is that further specificity may be needed to aid in identifying which <200kV transmission lines should come under the purview of this standard. The SDT shall take under consideration other applicability parameter criteria, various stakeholder proposals including IROL violation potential.
2. The FERC Order includes the following language which indicates that FERC would support inclusion of any circuit below 200 kV that was subject to an IROL and the SAR has been written to allow this modification..
3. The SAR indicates that the Standard Drafting Team will review reporting criteria for Category 3 outages and will review the reporting requirement of Category 3 outages in R.3 and R.4.
4. The SDT shall consider producing a white paper to aid in clarifying the intent of the standard, however a field test is not contemplated at this time.
5. The SAR was revised to clarify that it is the ERO that will collect data and the Standard DT will receive the results of

Question #4			
Commenter	**Yes**	**No**	**Comment**
the ERO analysis and use it in developing the standard. 6. The standard DT will review the reporting exemptions to include all category outages under major disasters in Requirement R3.2. 7. The FERC Order includes the following language which indicates that FERC would support inclusion of any circuit below 200 kV that was subject to an IROL and the SAR has been written to allow this modification.			
ISO-NE	☑		1. The SAR indicates that a list of critical low voltage transmission lines will be provided to FERC. We do not interpret Order 693 to direct NERC to provide this list. The SRC suggest that the DT not use the word "critical" and adopt another term. There is a need to define in a single standard what the term critical means. Standards FAC-014 (R5.1.1); IRO-002-1 (R6) and others use the term "critical" as in: critical loads, critical infrastructure, critical assets. This Team is asked to avoid making the current situation worse.

Response:

1. On the basis of the responses from stakeholders to Question #2 above, the SAR DT's assessment is that further specificity may be needed to aid in identifying which <200kV transmission lines should come under the purview of this standard. The SDT shall take under consideration other applicability parameter criteria, various stakeholder proposals including IROL violation potential.
2. The FERC Order includes the following language which indicates that FERC would support inclusion of any circuit below 200 kV that was subject to an IROL and the SAR has been written to allow this modification..
3. The Standard Drafting Team intends to review reporting criteria for Category 3 outages in the proposed technical reference material and may review the reporting requirement of Category 3 outages in R.3 and R.4.
4. The SDT shall consider producing a white paper to aid in clarifying the intent of the standard, however a field test is not contemplated at this time.
5. The standard DT looks to receive the results of the ERO analysis and use it in developing the standard.
6. The standard DT will review the reporting exemptions to include all category outages under major disasters in Requirement R3.2.
7. The FERC Order includes the following language which indicates that FERC would support inclusion of any circuit below 200 kV that was subject to an IROL and the SAR has been written to allow this modification.

Question #4			
Commenter	**Yes**	**No**	**Comment**
MRO	☑		If the Regional Reliability Organization is removed as an applicable entity, what is the Regional Entity's responsible? How will a general consensus be formed? How do you get people to participate in this formation? For good planning and application of standards, methodologies need to be consistently applied through guidelines to the drafting teams. Specifically, this standard should provide consistent methodology that provides guidance to the transmission owner. In the next revision of the standard, the MRO requests that more authority be given to the applicable entities with respect to the latitude allowed them in removing trees to the legal limits of their agreement. The MRO commends FERC on empowering NERC and the SAR DT via their Order 693 to revisit the issue of clearances for lines on both Federal and non-Federal Lands. It has come to the attention of the MRO that Federal Forest Employees as well as BLM employees have begun the practice of chemically treating noxious weeds and invasive species on Federal Lands. he MRO would like to have FERC, NERC, and the Standard DT consider meeting with Federal Land Managers to discuss, on a National Level, the issue of herbicide application by utilities on Federal Lands. At the present time there are inconsistencies regionally on this issue that allow application in some regions but not in others.
Response: 1. The term RRO is no longer in use and RE (or regional entity) is now the preferred term for the former Regional Reliability Organizations. The term RE is defined in the delegation agreements between these organizations and the ERO. 2. Such a guideline exists and is available on the NERC website entitled "Standard Drafting Team Guidelines". 3. See answer #2 above. 4. The removal of trees within the limits stated in agreements is outside the scope of this standard. 5. The coordination of the use of herbicides is outside the scope of this standard.			
National Grid	☑		1) National Grid supports amending FAC-003-1 to bring the Standard into compliance with "latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines" as discussed in the SAR Background Information. 2) We do not support amendments to the Standard to address all of the issues raised by FERC Order 693. We believe most of the FERC's concerns can be addressed by

Question #4			
Commenter	**Yes**	**No**	**Comment**
			developing a "white paper" to better explain the Standard and guide its implementation. 3) National Grid does not support changing the basic approach to defining clearance from vegetation. The clearance 1 and clearance 2 concept adopts the two management approaches used by most TO's today and required in some state or ISO level standards. National Grid supports using the reference to IEEE 516 as the basis for clearance 2 for two reasons: 1 - there is no other definitive reference for flash over distances to vegetation and 2- decades of experience by TO's acrosss the North America suggest the IEEE 516 distances are more than adequate. The well known tree caused outages in 1996 and 2003 occurred as a result of hard contact with vegetation not flashover at distances close to those in IEEE 516. Furthermore, FERC accepted IEEE 516 as appropriate for use in vegetation management in the October 2006, NOPR. 4) National Grid supports amending the definition of a right-of-way though we are not clear on what is meant in the SAR language by "to encompass required clearing areas". National Grid is concerned with the interpretation of the present definition that the right-of-way includes uncleared fee owned or easement land reserved for future construction. In many jurisdictions the TO may not be allowed to remove trees from these areas. A "white paper" could better describe the definition and prevent future compliance issues stemming from an ambiguous definition.
Response: 1. The SAR DT thanks you for your comment. 2. The SAR indicates that the SDT will produce a technical white paper to clarify intent of the standard. 3. The SAR DT agrees with the commenter not to change the basic approach and recognizes that sections of IEEE 516 standard pertaining to minimum air insulation distances are applicable in determining minimum vegetation clearances to prevent flashovers. 4. The Standard DT will review the definition of ROW. See also answer #2 above.			
Northeast Utilities	☑		NU does not support the proposed revisions based on the issues raised by FERC Order 693. The Standard has not been in effect long enough to determine if there are any shortcomings with the current requirements. It is our position that the current clearance requirements are satisfactory in that a base minimum distance as provided under IEEE Section 516 is sufficient and there is the need for variations in the second level of clearances base on Regional needs and conditions. The revisions to the definition of "right-of-way" to encompass required clearance areas can e problematic as this could cause significant problems with current systems. There is no detailed description on what the new definition will include or what the actual impact will be to TO's. If the definition will include defined limits or widths of rights-of-

Question #4			
Commenter	**Yes**	**No**	**Comment**
			way this may affect current facilities that do not meet these distances. Second, there are areas where the company owns or possesses additional area beyond the current maintained right-of-way widths. Is it proposed that the new definition expand the limits of clearing or maintenance to include easemented or fee-owned areas beyond the current maintained limits? Until the new definition can be presented - it is difficult to support any changes at this time and we can only comment on the perceived negative impacts.
Response: The SDT will review the standard to address the Commission's determinations. The standard DT will review the definition of ROW. Note that the ERO is required to respond to the FERC directives.			
NYISO	☑		1. The SAR indicates that a list of critical low voltage transmission lines will be provided to FERC. We do not interpret Order 693 to direct NERC to provide this list. Rather, we interpret that FERC asks for defining a criteria that would include low voltage transmission lines that have impact on Bulk Power System reliability. We do not think the list is required. 2. The SAR indicates: "The standard DT may consider other criteria in determining applicability of the standard to sub 200kV lines…" Per Order 693, the criteria is quite clearly stated to be the transmission lines of less than 200 kV that could impact Bulk Power System reliability. We don't feel any other criteria would be necessary. Further, to identify the candidates that meet this criteria, we believe they should be determined by the Reliability Coordinator, similar to the PRC-023 standard, since the RC has the primary responsibility and knowledge of interconnection reliability impact. 3. We do not understand why the SDT considers removing Category 3 incidents? In our view, Category 3 outages are important information for assessing the effectiveness of vegetation program. Since the industry started reporting vegetation related outages about 3 years ago, data collected so far indicates that of a total of 98 reported vegetation outages, 67 of them were category 3 outages. With this high percentage, reporting of Category 3 events should be a must since the associated trends can provide valuable information to the TOs to aid its evaluation of the vegetation management program. 4. The white paper and field tests are a good idea and the SDT should be commended for these, especially the white paper. 5. Item 2 under the FERC Order 693 Items in the Detailed Description Section indicates

<table>
<tr><th colspan="4">Question #4</th></tr>
<tr><th>Commenter</th><th>Yes</th><th>No</th><th>Comment</th></tr>
<tr><td></td><td></td><td></td><td>the SDT will also collect outage data. While we understand that FERC has directed the ERO to collect outage data for transmission outages of lines that cross both federal and non-federal lands, we do not feel that it is the SDT's role to perform this task. We feel that this task should be performed by the ERO or a group separate from the SDT such that the task does not add burden to the SDT which may slow down the standard development process or result in the standard development being driven by unanalyzed data and resulting in erroneous requirements.

6. With respect to reporting exemptions, our position during development of the previous version of this standard was to limit them. We commend the SDT intention to clarify the outage exemptions under major disasters, but to consider including all category outage exemptions in the standard body is too prescriptive and will add to the already extended list. It can end up with a very long list of outage exemptions, thereby reducing the coverage of the standard substantively and defeating its purpose. If this list was to be developed, they could be attached as guidelines aside of the standard.</td></tr>
<tr><td colspan="4">Response:
1. On the basis of the responses from stakeholders to Question #2 above, the SAR DT’s assessment is that further specificity may be needed to aid in identifying which <200kV transmission lines should come under the purview of this standard. The SDT shall take under consideration other applicability parameter criteria, various stakeholder proposals including IROL violation potential..
2. The FERC Order includes the following language which indicates that FERC would support inclusion of any circuit below 200 kV that was subject to an IROL and the SAR has been written to allow this modification..
3. The Standard Drafting Team intends to review reporting criteria for Category 3 outages in the proposed technical reference material and may review the reporting requirement of Category 3 outages in R.3 and R.4.
4. The SAR indicates that the SDT will produce a white paper to aid in clarifying the intent of the standard, however a field test is not contemplated at this time.
5. The SDT looks to receive the results of the ERO analysis and use it in developing the standard.
6. The SDT will review the reporting exemptions to include all category outages under major disasters in Requirement R3.2.</td></tr>
<tr><td>PGE</td><td>☑</td><td></td><td>1) Applicability 4.3 of the standard - PG&E believes the RE is in the best position to determine sub-200kV facilities are designated critical and covered under FAC-003-1. We suggest the ERO direct the RE to provide a list of sub-200kV lines designated critical along with methodology used to make that determination.

2) Clearances for lines on federal and non-federal lands - PG&E believes there should be no distinction between requirements on different lands. Vegetation encroachments have</td></tr>
</table>

Question #4			
Commenter	**Yes**	**No**	**Comment**
			the same impact regardless of land ownership. 3) Definition of right of way - agreed 4) Suitability of IEEE 516-2003 - PG&E believes the use of IEEE 516 as the standard for clearance requirements are adequate to ensure transmission system reliability provided the TO has an appropriate methodology for determining clearance at time of trim and an adequate cycle to prevent vegetation from encroaching within minimum distances. Use of ANSI Z133.3 or FedOSHA 1910, as suggested by FERC, is not appropriate as it is intended for worker safety and not system reliability. TO compliance with R1.2 of the standard should address concerns FERC has with maintaining minimum clearance. 5-7) Procedural items - No comment 8) Preparation of technical manual (white paper) - agreed 9) PG&E believes the current reporting requirements under R3 of the standard should be revised. Distinction is placed on fall-in's "in and out of the ROW" and may not be the best method for determining severity for reporting purposes. PG&E believes a better distinction is (a) green/healthy/no obvious decline and (b) dead or obvious signs of disease, decay or decline. A key component of any TMVP should be hazard tree mitigation regardless if in or out of the ROW. Suggested categories: Category 1 - Any grow-in (as currently stated). Category 2 - Any fall-in of a dead tree or one with obvious signs of disease, decay or decline in or out of the ROW. Category 3 - Either eliminate this category or specify healthy green tree or tree with no obvious signs of decline (if retained, be specific about this being for reporting purposes only) PG&E recognizes that tree failures, even if dead or diseased, are not necessarily an indicator of problematic VM program and the severity level should be reflected as such. Tree density along with other factors make 100% identification not possible. However, multiple occurrences could be an indicator of substandard performance and the current standard does remains silent in respect to hazard trees other than if in or out of the ROW.
Response:			

Question #4			
Commenter	Yes	No	Comment
1. On the basis of the responses from stakeholders to Question #2 above, the SAR DT's assessment is that further specificity may be needed to aid in identifying which <200kV transmission lines should come under the purview of this standard. The SDT shall take under consideration other applicability parameter criteria, various stakeholder proposals including IROL violation potential.. 2. The SAR DT concurs with the commenter with respect to applying this standard to Federal and non-Federal lands. The standard DT will evaluate the suitability of a case-by-case approach. 3. The standard DT will review the definition of ROW. 4. The SAR DT agrees with the commenter and recognizes that sections of IEEE 516 standard pertaining to minimum air insulation distances are applicable in determining minimum vegetation clearances to prevent flashovers. 5. n/a 6. n/a 7. n/a 8. The SAR indicates that the SDT will produce a technical white paper to clarify intent of the standard. 9. The SAR indicates that the SDT will review reporting criteria for Category 3 outages and will review the reporting requirement of Category 3 outages in R.3 and R.4. The SDT and Compliance Elements DT will review and assign Violation Severity Levels when modifying FAC-003-1.			
PGN	☑		Progress Energy Carolinas (PEC) and Progress Energy Florida (PEF) do not agree that each of 11 items listed in the SAR are necessary to improve reliability. The following comments are offered for each of the 11 items identified in the SAR detail description: 1. Standard Applicability: PEC and PEF believe that the current standard wording for determining facilities subject to this standard should not be revised. The standard as it is written provides for lines below 200kV, that are determined to impact the grid, to be subject to the standard. Extending the requirements to a bright line below 200kV, such as 100kV, will dilute the focus on those lines that impact grid reliability, lines >200kV, and shift attention to facilities, those <200kV, that do not necessarily impact grid reliability. Customer reliability is an issue that impacts customer satisfaction and is generally driven by state utility commissions. While some facilities above 200kV directly support customer load, transmission lines below 200kV primarily support customer load, and interruptions to those facilities generally reduce load on the grid. The majority of transmission facilities below 200 kV also have significantly different design/construction/operating characteristics and have not been cited as impacting bulk

Question #4			
Commenter	**Yes**	**No**	**Comment**
			power system reliability. For example, the Final Report on the August 14, 2003 Blackout in the United states and Canada: Causes and Recommendations April 2004 by the U.S.-Canada Power System Outage Task Force and all referenced major blackouts (pages 103-115) in that report, cited only outages which involved vegetation at line voltages above 200kV. Generally applying requirements that are appropriate for >200kV lines to lines less than 200kV will result in significant documentation and reporting of items such as restrictions, mitigation plans, off right-of-way vegetation-related outage investigation/ information and other issues, all of which dilutes the focus on lines that directly impact bulk power system reliability. Revising the standard to use general criteria or broad language for defining "Bulk Power System" transmission lines covered by the standard is a "one size fits all" approach. If that approach were taken, the standard would cover a significant number of transmission lines that have no direct impact on bulk power system reliability under standard planning/operating conditions, resulting in a significant cost burden for electric customers without improving "grid" reliability. PEC and PEF believe that the applicability provision of the standard should instead focus attention of the standard only on the transmission lines below 200kV that directly impact "Bulk Power System" reliability, as the current version requires. While PEC and PEF recognize some validity in the Commission's concern, PEC and PEF recommend that the applicability provision of this standard should be revised only if existing system design, planning or operating reliability criteria and parameters are considered as a basis for defining the applicability of the standard. To that end, PEC and PEF recommend each Regional Entity (RE) determine applicability of FAC-003 to those lines within the region that are between 100kV and 200KV, if, and only if, they are identified as operationally significant elements of Interconnection Reliability Operating Limits ("IROLs"). That is, any facility below 200kV that, by itself, would cause an Interconnected Reliability Limit Violation should the facility be outaged. 2. Issue of Clearances (Federal vs Non-Federal Lands): FAC-003-1 presently requires the transmission owner (TO) "identify and document clearances between vegetation and any overhead, ungrounded supply conductors, taking into consideration transmission line voltage, the effects of ambient temperature on conductor sag under maximum design loading, and the effects of wind velocities on

Question #4			
Commenter	**Yes**	**No**	**Comment**
			conductor sway." The intent of this requirement is to ensure adequate clearances to prevent vegetation related outages. PEC and PEF believe that only the TO has the technical information required to determine the clearances that are necessary at the time of VM work and that any "federal lands exemption" to clearances will result in inadequate clearances for the existing conditions. Consistency in application of the TO's clearance requirements, not exceptions, is the only assurance in providing a uniform and reliable electrical system to meet the nation's current and future energy demands. Any exception for a case by case clearance approach to determine vegetation management activities/clearances on Federal lands will continue to drive inconsistency and/or delays associated with TO vegetation management decisions being driven by diverse vegetation management practices/beliefs and staff changes at the local level of Federal agencies. Vegetation-related outages have occurred on Federal lands as a result of this case by case approach, and if "Bulk Power Transmission System" lines continue to be addressed on a "case by case" basis on National Forest Service (or any other Federal lands), those lines will potentially be subject to a higher risk for vegetation-related outages, resulting in reduced reliability for the "Bulk Power System". PEC and PEF believe that reliability of the "Bulk Power System" should have the same focus on Federal and private lands and that the EEI MOU with federal agencies is an appropriate avenue for TO's to identify clearances on Federal lands, not an exemption in the language of a reliability standard. 3. Defining Right-of-Way: PEC and PEF agree that it is appropriate to further address the definition of "right-of-way". Corridor widths that exceed the design clearance requirements have been acquired for a variety of reasons in the past; future use, property line buffers, etc. Vegetation in those areas that would normally be outside of the corridor width necessary for reliable operation of the facility, but within an expanded easement area, should not be considered, or treated, different than vegetation that is outside of a defined easement/permit right-of-way corridor that was designed and acquired specifically for the reliable operation of a single line. 4. IEEE Standard for Minimum Clearances:

Question #4			
Commenter	Yes	No	Comment
			PEC and PEF believe that the IEEE 516-2003 tables are appropriate for defining the minimum acceptable clearances to prevent flashover between conductors and vegetation under all rated electrical operating conditions. Closer minimum clearances such as the minimum length of a support insulator could have been adopted as a "lowest common denominator" clearance. However the clearance in IEEE 516-2003 was adopted to ensure an additional margin of reliability. FERC staff has made references to the use of ANSI Z-133 which is a safety standard that addresses worker safety as well as the safety of the general public. The purpose of ANSI Z-133 is to address worker safety and is not focused on transmission line reliability, which is the purpose of FAC-003-1. OSHA, NESC and other related safety standards have clearances in excess of IEEE 516-2003. Those clearances are clearly focused on safety issues and will still apply to other aspects of design and operation of electric facilities (such as public and worker safety) but are not appropriate to be referenced in a vegetation management reliability standard as a flashover clearance. 5/6/7. Procedural Items: PEC and PEF agree that the procedural items related to formatting RRO references and revising the compliance elements to meet the new standard format should be addressed by the standard drafting team. 8. Technical Reference Materials: PEC and PEF agree that a "white paper" that defines the technical basis for the standard is appropriate. This type of document, if crafted by the drafting team, should help to avoid the potential for differences in interpretation of the standard's requirements by the various regions during the audit process. 9. Category 3 Outages: Since control off right-of-way vegetation is generally beyond control of the TO and since "fall-in" outages are random events that do not threaten grid reliability, PEC and PEF believe that the reporting of category 3 outages should be removed from the requirements. 10. Requirement R4:

Question #4			
Commenter	**Yes**	**No**	**Comment**
			PEC and PEF believe that requirement R4 should be deleted from the standard, since the ERO formation provides for delegation of authority to the regional entities. 11. Reporting Exemptions: PEC and PEF believe that the reporting requirement exemptions for natural disasters should include all categories of outages. For example, with outages caused by high winds, hurricanes, tornadoes, etc., it would be difficult (or practically impossible in some cases) to determine if the vegetation came from on, or off, the "right-of-way". In addition, the effort and time necessary to make that determination would result in delaying outage restoration efforts.
Response: 1. On the basis of the responses from stakeholders to Question #2 above, the SAR DT's assessment is that further specificity may be needed to aid in identifying which <200kV transmission lines should come under the purview of this standard. The SDT shall take under consideration other applicability parameter criteria, various stakeholder proposals including IROL violation potential.. 2. The SAR DT concurs with the commenter with respect to applying this standard to Federal and non-Federal lands. The standard DT will evaluate the suitability of a case-by-case approach. 3. The standard DT will review the definition of ROW. 4. The SAR DT agrees with the commenter and recognizes that sections of IEEE 516 standard pertaining to minimum air insulation distances are applicable in determining minimum vegetation clearances to prevent flashovers. 5. NERC standards must be updated to comply with new procedural requirements and must include compliance elements. 6. See #5 7. See #5 8. The SAR indicates that the SDT will produce a technical white paper to clarify intent of the standard. 9. The SAR indicates that the SDT will review reporting criteria for Category 3 outages and will review the reporting requirement of Category 3 outages in R.3 and R.4. 10. The standard DT will consider deletion of R.4. 11. The standard DT will review the reporting exemptions to include all category outages under major disasters in Requirement R3.2.			
SERC VMS	☑		The SERC VMS does not agree that each of 11 items listed in the SAR are necessary to improve reliability. The following comments are offered for each of the 11 items identified in the SAR detail description: 1. Standard Applicability:

Question #4			
Commenter	**Yes**	**No**	**Comment**
			The SERC VMS disagrees with revising the 200 kV threshold for determining facilities subject to this standard. Extending the requirements to lines other than those >200kV will dilute the focus on those lines that impact grid reliability and shift attention to facilities, those <200kV. The reliability of lower voltage lines involves local customers' reliability and satisfaction hence that reliability should be addressed by local and state utility commissions. The majority of the >200kV lines are solely elements of the grid and and interruptions to those lines negatively impact grid reliability. The majority of the <200kV lines primarily support customer load, and interruptions to those facilities actually reduces load on the grid. The majority of transmission facilities below 200 kV also have significantly different design/construction/operating characteristics and have not been cited as impacting bulk power system reliability. For example, the Final Report on the August 14, 2003 Blackout in the United states and Canada: Causes and Recommendations April 2004 by the U.S.-Canada Power System Outage Task Force and all referenced major blackouts (pages 103-115) in that report, cited only outages which involved vegetation at line voltages above 200kV. Generally applying requirements that are appropriate for >200kV lines to lines less than 200kV will result in significant documentation and reporting of items such as restrictions, mitigation plans, off right-of-way vegetation-related outage investigation/ information and other issues, all of which dilutes the focus on lines that directly impact bulk power system reliability. Revising the standard to use general criteria or broad language for defining "Bulk Power System" transmission lines covered by the standard is a “one size fits all” approach. If that approach were taken, the standard would cover a significant number of transmission lines that have no direct impact on bulk power system reliability under standard planning/operating conditions, resulting in a significant cost burden for electric customers without improving “grid” reliability. The SERC VMS believes that the applicability provision of the standard should instead focus attention of the standard only on the transmission lines below 200kV that directly impact “Bulk Power System” reliability, as the current version requires. In sum, while the SERC VMS recognizes some validity in the Commission’s concern, the SERC VMS recommends that the applicability provision of this standard should be revised only if existing system design, planning or operating reliability criteria and parameters

Question #4			
Commenter	**Yes**	**No**	**Comment**
			are considered as a basis for defining the applicability of the standard. To that end, the SERC VMS recommends each Regional Entity (RE) determine applicability of FAC-003 to those lines within the region that are between 100kV and 200KV, if, and only if, they are identified as operationally significant elements of Interconnection Reliability Operating Limits ("IROLs"). That is, any facility below 200kV that by itself would cause an Interconnected Reliability Limit Violation should the facility be outaged. 2. Issue of Clearances (Federal vs Non-Federal Lands): FAC-003-1 presently requires the transmission owner (TO) "identify and document clearances between vegetation and any overhead, ungrounded supply conductors, taking into consideration transmission line voltage, the effects of ambient temperature on conductor sag under maximum design loading, and the effects of wind velocities on conductor sway." The intent of this requirement is to ensure adequate clearances to prevent vegetation related outages. The SERC VMS believes that only the TO has the technical information required to determine the clearances that are necessary at the time of VM work and that any "federal lands exemption" to clearances will result in inadequate clearances for the existing conditions. Consistency in application of the TO's clearance requirements, not exceptions, is the only assurance in providing a uniform and reliable electrical system to meet the nation's current and future energy demands. Any exception for a case by case clearance approach to determine vegetation management activities/clearances on Federal lands will continue to drive inconsistency and/or delays associated with TO vegetation management decisions being driven by diverse vegetation management practices/beliefs and staff changes at the local level of Federal agencies. Vegetation-related outages have occurred on Federal lands as a result of this case by case approach, and if "Bulk Power Transmission System" lines continue to be addressed on a "case by case" basis on National Forest Service (or any other Federal lands), those lines will potentially be subject to a higher risk for vegetation-related outages, resulting in reduced reliability for the "Bulk Power System". The SERC VMS believes that reliability of the "Bulk Power System" should have the same focus on Federal and private lands and that the EEI MOU with federal agencies is the appropriate vehicle for TO's to identify clearance variances on Ferderal lands, not exemption language in the standard.

Question #4			
Commenter	**Yes**	**No**	**Comment**
			3. Defining Right-of-Way: The SERC VMS agrees that it is appropriate to further address the definition of "right-of-way". Corridor widths beyond design clearance requirements have been acquired for a variety of reasons in the past; future use, property line buffers, etc. Vegetation in those areas that would normally fall outside of the area necessary for operation of the facility should not be considered or treated different than vegetation that is outside of a defined easement/permit area that is designed for the reliable operation of an existing single line corridor. 4. IEEE Standard for Minimum Clearances: The SERC VMS disagrees with objections to the use of the IEEE 516-2003 clearance as the minimum acceptable distances for "Clearance 2". The IEEE 516-2003 tables are appropriate for defining the minimum acceptable clearances to prevent flashover between conductors and vegetation under all rated electrical operating conditions. Closer minimum clearances such as the minimum length of a support insulator could have been adopted as a "lowest common denominator" clearance. However the clearance in IEEE 516-2003 was adopted to ensure an additional margin of reliability. FERC staff references ANSI Z-133 which is a safety standard that addresses worker safety as well as the safety of the general public. As such, the purpose of ANSI Z-133 is to address worker safety and is not focused on transmission line reliability, which is the purpose of FAC-003-1. OSHA, NESC and other related safety standards have clearances in excess of IEEE 516-2003. Those clearances are clearly focused on safety issues and will still apply to other aspects of design and operation of electric facilities (such as public and worker safety) but are not appropriate to be referenced in a vegetation management reliability standard. 5/6/7. Procedural Items: The SERC VMS agrees that the procedural items related to formatting RRO references and additional compliance elements should be addressed by the standard drafting team. 8. Technical Reference Materials: The SERC VMS agrees that a "white paper" that defines the technical basis for the

Question #4			
Commenter	**Yes**	**No**	**Comment**
			standard is appropriate to avoid the potential for differences in interpretation of the standard's requirements during the various region's audit processes. 9. Category 3 Outages: Since the right to control off right-of-way vegetation is generally beyond control of the TO, the SERC VMS believes that the reporting of category 3 outages should be removed from the requirements. 10. Requirement R4: The SERC VMS believes that requirement R4 should be deleted from the standard, based on the ERO formation and the process for delegation of authority to the regional entities. 11. Reporting Exemptions: The SERC VMS believes that the reporting requirement exemptions for natural disasters should include all categories of outages. It would, for example, be difficult, without delaying restoration efforts, to determine if the vegetation from high winds, hurricanes, tornadoes, etc. is from on or off the "right-of-way".

Response:

1. On the basis of the responses from stakeholders to Question #2 above, the SAR DT's assessment is that further specificity may be needed to aid in identifying which <200kV transmission lines should come under the purview of this standard. The SDT shall take under consideration other applicability parameter criteria, various stakeholder proposals including IROL violation potential..
2. The SAR DT concurs with the commenter with respect to applying this standard to Federal and non-Federal lands. The standard DT will evaluate the suitability of a case-by-case approach.
3. The standard DT will review the definition of ROW.
4. The SAR DT agrees with the commenter and recognizes that sections of IEEE 516 standard pertaining to minimum air insulation distances are applicable in determining minimum vegetation clearances to prevent flashovers.
5. NERC standards must be updated to comply with new procedural requirements and must include compliance elements.
6. See #5
7. See #5
8. The SAR indicates that the SDT will produce a technical white paper to clarify intent of the standard.
9. The SAR indicates that the SDT will review reporting criteria for Category 3 outages and will review the reporting requirement of Category 3 outages in R.3 and R.4.

Question #4			
Commenter	**Yes**	**No**	**Comment**
10. The standard DT will consider deletion of R.4. 11. The standard DT will review the reporting exemptions to include all category outages under major disasters in Requirement R3.2.			
TVA	☑		We feel that the reporting of Category 3 outages should be eliminated. We agree with the need for a "white paper" to expand on definitions and intent. We feel that a defined maintainable width of right of way is more appropriate than the actual easement widths because easement widhts are not purchased or operated exclusively with or for vegetation manitenance activies. We will be pleased to share greater details on this concern if requested.
Response: The SAR DT thanks you for your comments.

Standard Authorization Request Form

Revisions to FAC-003-1 Transmission Vegetation Management Program Project 2007-07	
Request Date	January 9, 2007
Revised Date	April 2, 2007

SAR Requestor Information	**SAR Type** (*Check a box for each one that applies.*)	
Name Richard Dearman	☐	New Standard
Primary Contact Richard Dearman	☒	Revision to existing Standard
Telephone (256) 851-3523 Fax	☐	Withdrawal of existing Standard
E-mail redearman@tva.gov	☐	Urgent Action

Purpose / Industry Need (Describe the purpose of the standard — what the standard will achieve in support of reliability.)

The purpose of revising this standard is to:

1. Provide an adequate level of reliability for the North American electric transmission system – by verifying that the standard is complete and that its requirements are set at an appropriate level to ensure reliability.
2. Incorporate other general improvements described in the attached Standard Review Guidelines to bring it into conformance with the latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines.
3. Consider comments received from ERO regulatory authorities and stakeholders, as noted in the attached review sheets.
4. Satisfy the standards procedure requirement for five-year review of the standards.

Detailed Description

This is a new standard that was approved in 2006. It has some 'fill-in-the-blank' components to eliminate. In addition, the following comments submitted by FERC and stakeholders need to be addressed in the refinement of the standard:

FERC Order 693 items

1. To address the issue regarding applicability:
   - The Standard DT shall work with the reliability entities and the ERO to collect and make available to the FERC, a list of critical lower voltage transmission lines. (Refer to Applicability 4.3 section of the standard.)
     - The standard DT may consider other criteria in determining applicability of the standard to sub 200kV lines.
2. To address the issue of clearances for lines on both federal and non-federal lands:
   - The standard drafting team shall collect and analyze outage data then consider defining clearances needed to avoid sustained vegetation-related outages that would apply to transmission lines crossing both federal and non-federal land.
3. To consider revising the definition of right of way to encompass required clearance areas.
4. To review the suitability of IEEE 516-2003 standard for minimum vegetation clearance.

Procedural items

5. Re-format standard to bring it into conformance with the latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines.
6. Remove references to RRO in the standard and substitute a responsible entity.
7. Add compliance elements such as time horizons, and violation severity levels.

Stakeholder items

8. The Standard DT shall prepare technical reference material such as a "white paper" to aid in understanding the technical basis for the standard.
9. The Standard DT shall review reporting criteria for Category 3 outages in the proposed technical reference material and may remove the reporting requirement of Category 3 outages in R.3 and R.4.
10. The Standard DT shall consider deleting requirement R.4.
11. The Standard DT will review the reporting exemptions to include all category outages under major disasters in Requirement R3.2.

Reliability Functions

The Standard will Apply to the Following Functions *(Check box for each one that applies.)*		
☐	Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.
☐	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports interconnection frequency in real time.
☐	Interchange Authority	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced Interchange Schedules between Balancing Authority Areas.
☐	Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area..
☐	Resource Planner	Develops a (>one year) plan for the resource adequacy of specific loads within a Planning Coordinator Area.
☐	Transmission Planner	Develops a (>one year) plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator Area.
☐	Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
☒	Transmission Owner	Owns and maintains transmission facilities.
☐	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
☐	Distribution Provider	Delivers electrical energy to the End-use customer.
☐	Generator Owner	Owns and maintains generation facilities.
☐	Generator Operator	Operates generation unit(s) to provide real and reactive power.
☐	Purchasing-Selling Entity	Purchases or sells energy, capacity, and all necessary reliability-related services as required.
☐	Market Operator	Interface point for reliability functions with commercial functions.
☐	Load-Serving Entity	Secures energy and transmission (and related reliability-related services) to serve the End-use Customer.

Reliability and Market Interface Principles

Applicable Reliability Principles *(Check box for all that apply.)*	
☐	1. Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☐	2. The frequency and voltage of interconnected bulk electric systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☐	3. Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably.
☐	4. Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.
☒	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk electric systems.
☐	6. Personnel responsible for planning and operating interconnected bulk electric systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☐	7. The security of the interconnected bulk electric systems shall be assessed, monitored and maintained on a wide area basis.

Does the proposed Standard comply with all the following Market Interface Principles? *(Select "yes" or "no" from the drop-down box.)*
1. The planning and operation of bulk electric systems shall recognize that reliability is an essential requirement of a robust North American economy. Yes
2. An Organization Standard shall not give any market participant an unfair competitive advantage.Yes
3. An Organization Standard shall neither mandate nor prohibit any specific market structure. Yes
4. An Organization Standard shall not preclude market solutions to achieving compliance with that Standard. Yes
5. An Organization Standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes

Standard Review Guidelines

Applicability

Does this reliability standard clearly identify the functional classes of entities responsible for complying with the reliability standard, with any specific additions or exceptions noted? Where multiple functional classes are identified is there a clear line of responsibility for each requirement identifying the functional class and entity to be held accountable for compliance? Does the requirement allow overlapping responsibilities between Registered Entities possibly creating confusion for who is ultimately accountable for compliance?

Does this reliability standard identify the geographic applicability of the standard, such as the entire North American bulk power system, an interconnection, or within a regional entity area? If no geographic limitations are identified, the default is that the standard applies throughout North America.

Does this reliability standard identify any limitations on the applicability of the standard based on electric facility characteristics, such as generators with a nameplate rating of 20 MW or greater, or transmission facilities energized at 200 kV or greater or some other criteria? If no functional entity limitations are identified, the default is that the standard applies to all identified functional entities.

Purpose

Does this reliability standard have a clear statement of purpose that describes how the standard contributes to the reliability of the bulk power system? Each purpose statement should include a value statement.

Performance Requirements

Does this reliability standard state one or more performance requirements, which if achieved by the applicable entities, will provide for a reliable bulk power system, consistent with good utility practices and the public interest?

Does each requirement identify who shall do what under what conditions and to what outcome?

Measurability

Is each performance requirement stated so as to be objectively measurable by a third party with knowledge or expertise in the area addressed by that requirement?

Does each performance requirement have one or more associated measures used to objectively evaluate compliance with the requirement?

If performance results can be practically measured quantitatively, are metrics provided within the requirement to indicate satisfactory performance?

Technical Basis in Engineering and Operations

Is this reliability standard based upon sound engineering and operating judgment, analysis, or experience, as determined by expert practitioners in that particular field?

Completeness

Is this reliability standard complete and self-contained? Does the standard depend on external information to determine the required level of performance?

Consequences for Noncompliance

In combination with guidelines for penalties and sanctions, as well as other ERO and regional entity compliance documents, are the consequences of violating a standard clearly known to the responsible entities?

Clear Language

Is the reliability standard stated using clear and unambiguous language? Can responsible entities, using reasonable judgment and in keeping with good utility practices, arrive at a consistent interpretation of the required performance?

Practicality

Does this reliability standard establish requirements that can be practically implemented by the assigned responsible entities within the specified effective date and thereafter?

Capability Requirements versus Performance Requirements
In general, requirements for entities to have ‘capabilities’ (this would include facilities for communication, agreements with other entities, etc.) should be located in the standards for certification. The certification requirements should indicate that entities have a responsibility to ‘maintain’ their capabilities.

Consistent Terminology

To the extent possible, does this reliability standard use a set of standard terms and definitions that are approved through the NERC reliability standards development process?

If the standard uses terms that are included in the NERC Glossary of Terms Used in Reliability Standards, then the term must be capitalized when it is used in the standard. New terms should not be added unless they have a ‘unique’ definition when used in a NERC reliability standard. Common terms that could be found in a college dictionary should not be defined and added to the NERC Glossary.

Are the verbs on the ‘verb list’ from the DT Guidelines? If not – do new verbs need to be added to the guidelines or could you use one of the verbs from the verb list?

Violation Risk Factors (Risk Factor)

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. A requirement that is administrative in nature;

or a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

Time Horizon

The drafting team should also indicate the time horizon available for mitigating a violation to the requirement using the following definitions:

- Long-term Planning — a planning horizon of one year or longer.
- Operations Planning — operating and resource plans from day-ahead up to and including seasonal.
- Same-day Operations — routine actions required within the timeframe of a day, but not real-time.
- Real-time Operations — actions required within one hour or less to preserve the reliability of the bulk electric system.
- Operations Assessment — follow-up evaluations and reporting of real time operations.

Violation Severity Levels

The drafting team should indicate a set of violation severity levels that can be applied for the requirements within a standard. (‘Violation severity levels’ replace existing ‘levels of non-compliance.’) The violation severity levels may be applied for each requirement or combined to cover multiple requirements, as long as it is clear which requirements are included.

The violation severity levels should be based on the following definitions:

- Lower: mostly compliant with minor exceptions — The responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more minor details. Equivalent score: 95% to 99% compliant.
- Moderate: mostly compliant with significant exceptions — The responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more significant elements. Equivalent score: 85% to 94% compliant.
- High: marginal performance or results — The responsible entity has only partially achieved the reliability objective of the requirement and is missing one or more significant elements. Equivalent score: 70% to 84% compliant.
- Severe: poor performance or results — The responsible entity has failed to meet the reliability objective of the requirement. Equivalent score: less than 70% compliant.

Compliance Monitor

Replace, 'Regional Reliability Organization' with 'Regional Entity'.

Fill-in-the-blank Requirements

Do not include any 'fill-in-the-blank' requirements. These are requirements that assign one entity responsibility for developing some performance measures without requiring that the performance measures be included in the body of a standard – then require another entity to comply with those requirements.

Every reliability objective can be met, at least at a threshold level, by a North American standard. If we need regions to develop regional standards, such as in under-frequency load shedding, we can always write a uniform North American standard for the applicable functional entities as a means of encouraging development of the regional standards.

Requirements for Regional Reliability Organization

Do not write any requirements for the Regional Reliability Organization. Any requirements currently assigned to the RRO should be re-assigned to the applicable functional entity.

Effective Dates

Must be 1st day of 1st quarter after entities are expected to be compliant – must include time to file with regulatory authorities and provide notice to responsible entities of the obligation to comply. If the standard is to be actively monitored, time for the Compliance Monitoring and Enforcement Program to develop reporting instructions and modify the Compliance Data Management System(s) both at NERC and Regional Entities must be provided in the implementation plan.

Associated Documents

If there are standards that are referenced within a standard, list the full name and number of the standard under the section called, 'Associated Documents'.

Functional Model Version 3

Review the requirements against the latest descriptions of the responsibilities and tasks assigned to functional entities as provided in pages 13 through 53 of the draft Functional Model Version 3.

Telephone (256) 851-3523 Fax	☐	Withdrawal of existing Standard
E-mail redearman@tva.gov	☐	Urgent Action

Purpose / Industry Need (Describe the purpose of the standard — what the standard will achieve in support of reliability.)

The purpose of revising this standard is to:

1. Provide an adequate level of reliability for the North American electric transmission system – by verifying that the standard is complete and that its requirements are set at an appropriate level to ensure reliability.
2. Incorporate other general improvements described in the attached Standard Review Guidelines to bring it into conformance with the latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines.
3. Consider comments received from ERO regulatory authorities and stakeholders, as noted in the attached review sheets.
4. Satisfy the standards procedure requirement for five-year review of the standards.

Detailed Description

This is a new standard that was approved in 2006. It has some 'fill-in-the-blank' components to eliminate. In addition, the following comments submitted by FERC and stakeholders need to be addressed in the refinement of the standard:

FERC Order 693 items

1. To address the issue regarding applicability:
   - The Standard DT shall work with the reliability entities and the ERO to collect and make available to the FERC, a list of critical lower voltage transmission lines. (Refer to Applicability 4.3 section of the standard.)
     - The standard DT may consider other criteria in determining applicability of the standard to sub 200kV lines.
2. To address the issue of clearances for lines on both federal and non-federal lands:
   - The standard drafting team shall review and analyze outage data (collected by the ERO) then consider defining clearances needed to avoid sustained vegetation-related outages that would apply to transmission lines crossing both federal and non-federal land.
3. To consider revising the definition of right of way to encompass required clearance areas.
4. To review the suitability of IEEE 516-2003 standard for minimum vegetation clearance.

Procedural items

5. Re-format standard to bring it into conformance with the latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines.
6. Remove references to RRO in the standard and substitute a responsible entity.
7. Add newly developed compliance elements such as time horizons, violation risk factors, violation severity levels, etc.

Stakeholder items

8. The Standard DT shall prepare technical reference material such as a "white paper" to aid in understanding the technical basis for the standard.
9. The Standard DT shall review reporting criteria for Category 3 outages in the proposed technical reference material and may remove the reporting requirement of Category 3 outages in R.3 and R.4.
10. The Standard DT shall consider deleting requirement R.4.
11. The Standard DT will review the reporting exemptions to include all category outages under major disasters in Requirement R3.2.

Reliability Functions

The Standard will Apply to the Following Functions *(Check box for each one that applies.)*		
☐	Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.
☐	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports interconnection frequency in real time.
☐	Interchange Authority	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced Interchange Schedules between Balancing Authority Areas.
☐	Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area..
☐	Resource Planner	Develops a (>one year) plan for the resource adequacy of specific loads within a Planning Coordinator Area.
☐	Transmission Planner	Develops a (>one year) plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator Area.
☐	Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
☒	Transmission Owner	Owns and maintains transmission facilities.
☐	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
☐	Distribution Provider	Delivers electrical energy to the End-use customer.
☐	Generator Owner	Owns and maintains generation facilities.
☐	Generator Operator	Operates generation unit(s) to provide real and reactive power.
☐	Purchasing-Selling Entity	Purchases or sells energy, capacity, and all necessary reliability-related services as required.
☐	Market Operator	Interface point for reliability functions with commercial functions.
☐	Load-Serving Entity	Secures energy and transmission (and related reliability-related services) to serve the End-use Customer.

Reliability and Market Interface Principles

Applicable Reliability Principles *(Check box for all that apply.)*	
☐	1. Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☐	2. The frequency and voltage of interconnected bulk electric systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☐	3. Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably.
☐	4. Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.
☒	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk electric systems.
☐	6. Personnel responsible for planning and operating interconnected bulk electric systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☐	7. The security of the interconnected bulk electric systems shall be assessed, monitored and maintained on a wide area basis.

Does the proposed Standard comply with all the following Market Interface Principles? *(Select "yes" or "no" from the drop-down box.)*
1. The planning and operation of bulk electric systems shall recognize that reliability is an essential requirement of a robust North American economy. Yes
2. An Organization Standard shall not give any market participant an unfair competitive advantage.Yes
3. An Organization Standard shall neither mandate nor prohibit any specific market structure. Yes
4. An Organization Standard shall not preclude market solutions to achieving compliance with that Standard. Yes
5. An Organization Standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes

Standard Review Guidelines

Applicability
Does this reliability standard clearly identify the functional classes of entities responsible for complying with the reliability standard, with any specific additions or exceptions noted? Where multiple functional classes are identified is there a clear line of responsibility for each requirement identifying the functional class and entity to be held accountable for compliance? Does the requirement allow overlapping responsibilities between Registered Entities possibly creating confusion for who is ultimately accountable for compliance?

Does this reliability standard identify the geographic applicability of the standard, such as the entire North American bulk power system, an interconnection, or within a regional entity area? If no geographic limitations are identified, the default is that the standard applies throughout North America.

Does this reliability standard identify any limitations on the applicability of the standard based on electric facility characteristics, such as generators with a nameplate rating of 20 MW or greater, or transmission facilities energized at 200 kV or greater or some other criteria? If no functional entity limitations are identified, the default is that the standard applies to all identified functional entities.

Purpose
Does this reliability standard have a clear statement of purpose that describes how the standard contributes to the reliability of the bulk power system? Each purpose statement should include a value statement.

Performance Requirements
Does this reliability standard state one or more performance requirements, which if achieved by the applicable entities, will provide for a reliable bulk power system, consistent with good utility practices and the public interest?

Does each requirement identify who shall do what under what conditions and to what outcome?

Measurability
Is each performance requirement stated so as to be objectively measurable by a third party with knowledge or expertise in the area addressed by that requirement?

Does each performance requirement have one or more associated measures used to objectively evaluate compliance with the requirement?

If performance results can be practically measured quantitatively, are metrics provided within the requirement to indicate satisfactory performance?

Technical Basis in Engineering and Operations
Is this reliability standard based upon sound engineering and operating judgment, analysis, or experience, as determined by expert practitioners in that particular field?

Completeness
Is this reliability standard complete and self-contained? Does the standard depend on external information to determine the required level of performance?

Consequences for Noncompliance
In combination with guidelines for penalties and sanctions, as well as other ERO and regional entity compliance documents, are the consequences of violating a standard clearly known to the responsible entities?

Clear Language
Is the reliability standard stated using clear and unambiguous language? Can responsible entities, using reasonable judgment and in keeping with good utility practices, arrive at a consistent interpretation of the required performance?

Practicality
Does this reliability standard establish requirements that can be practically implemented by the assigned responsible entities within the specified effective date and thereafter?

Capability Requirements versus Performance Requirements
In general, requirements for entities to have 'capabilities' (this would include facilities for communication, agreements with other entities, etc.) should be located in the standards for certification. The certification requirements should indicate that entities have a responsibility to 'maintain' their capabilities.

Consistent Terminology
To the extent possible, does this reliability standard use a set of standard terms and definitions that are approved through the NERC reliability standards development process?

If the standard uses terms that are included in the NERC Glossary of Terms Used in Reliability Standards, then the term must be capitalized when it is used in the standard. New terms should not be added unless they have a 'unique' definition when used in a NERC reliability standard. Common terms that could be found in a college dictionary should not be defined and added to the NERC Glossary.

Are the verbs on the 'verb list' from the DT Guidelines? If not – do new verbs need to be added to the guidelines or could you use one of the verbs from the verb list?

Violation Risk Factors (Risk Factor)

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. A requirement that is administrative in nature;

or a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

Time Horizon

The drafting team should also indicate the time horizon available for mitigating a violation to the requirement using the following definitions:

- **Long-term Planning —** a planning horizon of one year or longer.
- **Operations Planning —** operating and resource plans from day-ahead up to and including seasonal.
- **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time.
- **Real-time Operations —** actions required within one hour or less to preserve the reliability of the bulk electric system.
- **Operations Assessment —** follow-up evaluations and reporting of real time operations.

Violation Severity Levels

The drafting team should indicate a set of violation severity levels that can be applied for the requirements within a standard. ('Violation severity levels' replace existing 'levels of non-compliance.') The violation severity levels may be applied for each requirement or combined to cover multiple requirements, as long as it is clear which requirements are included.

The violation severity levels should be based on the following definitions:

- **Lower: mostly compliant with minor exceptions —** The responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more minor details. Equivalent score: 95% to 99% compliant.
- **Moderate: mostly compliant with significant exceptions —** The responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more significant elements. Equivalent score: 85% to 94% compliant.
- **High: marginal performance or results —** The responsible entity has only partially achieved the reliability objective of the requirement and is missing one or more significant elements. Equivalent score: 70% to 84% compliant.
- **Severe: poor performance or results —** The responsible entity has failed to meet the reliability objective of the requirement. Equivalent score: less than 70% compliant.

Compliance Monitor

Replace, 'Regional Reliability Organization' with 'Regional Entity'.

Fill-in-the-blank Requirements

Do not include any 'fill-in-the-blank' requirements. These are requirements that assign one entity responsibility for developing some performance measures without requiring that the performance measures be included in the body of a standard – then require another entity to comply with those requirements.

Every reliability objective can be met, at least at a threshold level, by a North American standard. If we need regions to develop regional standards, such as in under-frequency load shedding, we can always write a uniform North American standard for the applicable functional entities as a means of encouraging development of the regional standards.

Requirements for Regional Reliability Organization

Do not write any requirements for the Regional Reliability Organization. Any requirements currently assigned to the RRO should be re-assigned to the applicable functional entity.

Effective Dates

Must be 1st day of 1st quarter after entities are expected to be compliant – must include time to file with regulatory authorities and provide notice to responsible entities of the obligation to comply. If the standard is to be actively monitored, time for the Compliance Monitoring and Enforcement Program to develop reporting instructions and modify the Compliance Data Management System(s) both at NERC and Regional Entities must be provided in the implementation plan.

Associated Documents

If there are standards that are referenced within a standard, list the full name and number of the standard under the section called, ‘Associated Documents’.

Functional Model Version 3

Review the requirements against the latest descriptions of the responsibilities and tasks assigned to functional entities as provided in pages 13 through 53 of the draft Functional Model Version 3.

Purpose / Industry Need (Describe the purpose of the standard — what the standard will achieve in support of reliability.)

The purpose of revising this standard is to:

1. Provide an adequate level of reliability for the North American electric transmission system – by verifying that the standard is complete and that its requirements are set at an appropriate level to ensure reliability.
2. Incorporate other general improvements described in the attached Standard Review Guidelines to bring it into conformance with the latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines.
3. Consider comments received from ERO regulatory authorities and stakeholders, as noted in the attached review sheets.
4. Satisfy the standards procedure requirement for five-year review of the standards.

Detailed Description

This is a new standard that was approved in 2006. It has some 'fill-in-the-blank' components to eliminate. In addition, the following comments submitted by FERC and stakeholders need to be addressed in the refinement of the standard:

FERC Order 693 items

1. To address the issue regarding applicability:
   - The Standard DT shall work with the reliability entities and the ERO to collect and make available to the FERC, a list of critical lower voltage transmission lines. (Refer to Applicability 4.3 section of the standard.)
     - The standard DT may consider other criteria in determining applicability of the standard to sub 200kV lines.
2. To address the issue of clearances for lines on both federal and non-federal lands:
     - The standard drafting team shall ~~collect~~ review and analyze outage data (collected by the ERO) then consider defining clearances needed to avoid sustained vegetation-related outages that would apply to transmission lines crossing both federal and non-federal land.
3. To consider revising the definition of right of way to encompass required clearance areas.
4. To review the suitability of IEEE 516-2003 standard for minimum vegetation clearance.

Procedural items

5. Re-format standard to bring it into conformance with the latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines.
6. Remove references to RRO in the standard and substitute a responsible entity.
7. Add newly developed compliance elements such as time horizons, violation risk factors, violation severity levels, etc.

Stakeholder items

8. The Standard DT shall prepare technical reference material such as a "white paper" to aid in understanding the technical basis for the standard.
9. The Standard DT shall review reporting criteria for Category 3 outages in the proposed technical reference material and may remove the reporting requirement of Category 3 outages in R.3 and R.4.
10. The Standard DT shall consider deleting requirement R.4.
11. The Standard DT will review the reporting exemptions to include all category outages under major disasters in Requirement R3.2.

Reliability Functions

The Standard will Apply to the Following Functions *(Check box for each one that applies.)*		
☐	Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.
☐	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports interconnection frequency in real time.
☐	Interchange Authority	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced Interchange Schedules between Balancing Authority Areas.
☐	Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area..
☐	Resource Planner	Develops a (>one year) plan for the resource adequacy of specific loads within a Planning Coordinator Area.
☐	Transmission Planner	Develops a (>one year) plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator Area.
☐	Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
☒	Transmission Owner	Owns and maintains transmission facilities.
☐	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
☐	Distribution Provider	Delivers electrical energy to the End-use customer.
☐	Generator Owner	Owns and maintains generation facilities.
☐	Generator Operator	Operates generation unit(s) to provide real and reactive power.
☐	Purchasing-Selling Entity	Purchases or sells energy, capacity, and all necessary reliability-related services as required.
☐	Market Operator	Interface point for reliability functions with commercial functions.
☐	Load-Serving Entity	Secures energy and transmission (and related reliability-related services) to serve the End-use Customer.

Reliability and Market Interface Principles

Applicable Reliability Principles *(Check box for all that apply.)*	
☐	1. Interconnected bulk electric systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☐	2. The frequency and voltage of interconnected bulk electric systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☐	3. Information necessary for the planning and operation of interconnected bulk electric systems shall be made available to those entities responsible for planning and operating the systems reliably.
☐	4. Plans for emergency operation and system restoration of interconnected bulk electric systems shall be developed, coordinated, maintained and implemented.
☒	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk electric systems.
☐	6. Personnel responsible for planning and operating interconnected bulk electric systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☐	7. The security of the interconnected bulk electric systems shall be assessed, monitored and maintained on a wide area basis.

Does the proposed Standard comply with all the following Market Interface Principles? *(Select "yes" or "no" from the drop-down box.)*
1. The planning and operation of bulk electric systems shall recognize that reliability is an essential requirement of a robust North American economy. Yes
2. An Organization Standard shall not give any market participant an unfair competitive advantage.Yes
3. An Organization Standard shall neither mandate nor prohibit any specific market structure. Yes
4. An Organization Standard shall not preclude market solutions to achieving compliance with that Standard. Yes
5. An Organization Standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes

Standard Review Guidelines

Applicability
Does this reliability standard clearly identify the functional classes of entities responsible for complying with the reliability standard, with any specific additions or exceptions noted? Where multiple functional classes are identified is there a clear line of responsibility for each requirement identifying the functional class and entity to be held accountable for compliance? Does the requirement allow overlapping responsibilities between Registered Entities possibly creating confusion for who is ultimately accountable for compliance?

Does this reliability standard identify the geographic applicability of the standard, such as the entire North American bulk power system, an interconnection, or within a regional entity area? If no geographic limitations are identified, the default is that the standard applies throughout North America.

Does this reliability standard identify any limitations on the applicability of the standard based on electric facility characteristics, such as generators with a nameplate rating of 20 MW or greater, or transmission facilities energized at 200 kV or greater or some other criteria? If no functional entity limitations are identified, the default is that the standard applies to all identified functional entities.

Purpose
Does this reliability standard have a clear statement of purpose that describes how the standard contributes to the reliability of the bulk power system? Each purpose statement should include a value statement.

Performance Requirements
Does this reliability standard state one or more performance requirements, which if achieved by the applicable entities, will provide for a reliable bulk power system, consistent with good utility practices and the public interest?

Does each requirement identify who shall do what under what conditions and to what outcome?

Measurability
Is each performance requirement stated so as to be objectively measurable by a third party with knowledge or expertise in the area addressed by that requirement?

Does each performance requirement have one or more associated measures used to objectively evaluate compliance with the requirement?

If performance results can be practically measured quantitatively, are metrics provided within the requirement to indicate satisfactory performance?

Technical Basis in Engineering and Operations
Is this reliability standard based upon sound engineering and operating judgment, analysis, or experience, as determined by expert practitioners in that particular field?

Completeness
Is this reliability standard complete and self-contained? Does the standard depend on external information to determine the required level of performance?

Consequences for Noncompliance

In combination with guidelines for penalties and sanctions, as well as other ERO and regional entity compliance documents, are the consequences of violating a standard clearly known to the responsible entities?

Clear Language
Is the reliability standard stated using clear and unambiguous language? Can responsible entities, using reasonable judgment and in keeping with good utility practices, arrive at a consistent interpretation of the required performance?

Practicality
Does this reliability standard establish requirements that can be practically implemented by the assigned responsible entities within the specified effective date and thereafter?

Capability Requirements versus Performance Requirements
In general, requirements for entities to have ‘capabilities’ (this would include facilities for communication, agreements with other entities, etc.) should be located in the standards for certification. The certification requirements should indicate that entities have a responsibility to ‘maintain’ their capabilities.

Consistent Terminology
To the extent possible, does this reliability standard use a set of standard terms and definitions that are approved through the NERC reliability standards development process?

If the standard uses terms that are included in the NERC Glossary of Terms Used in Reliability Standards, then the term must be capitalized when it is used in the standard. New terms should not be added unless they have a ‘unique’ definition when used in a NERC reliability standard. Common terms that could be found in a college dictionary should not be defined and added to the NERC Glossary.

Are the verbs on the ‘verb list’ from the DT Guidelines? If not – do new verbs need to be added to the guidelines or could you use one of the verbs from the verb list?

Violation Risk Factors (Risk Factor)

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures;

or a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. A requirement that is administrative in nature;

or a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

Time Horizon

The drafting team should also indicate the time horizon available for mitigating a violation to the requirement using the following definitions:

- **Long-term Planning** — a planning horizon of one year or longer.
- **Operations Planning** — operating and resource plans from day-ahead up to and including seasonal.
- **Same-day Operations** — routine actions required within the timeframe of a day, but not real-time.
- **Real-time Operations** — actions required within one hour or less to preserve the reliability of the bulk electric system.
- **Operations Assessment —** follow-up evaluations and reporting of real time operations.

Violation Severity Levels

The drafting team should indicate a set of violation severity levels that can be applied for the requirements within a standard. (‘Violation severity levels’ replace existing ‘levels of non-compliance.’) The violation severity levels may be applied for each requirement or combined to cover multiple requirements, as long as it is clear which requirements are included.

The violation severity levels should be based on the following definitions:

- **Lower: mostly compliant with minor exceptions** — The responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more minor details. Equivalent score: 95% to 99% compliant.
- **Moderate: mostly compliant with significant exceptions** — The responsible entity is mostly compliant with and meets the intent of the requirement but is deficient with respect to one or more significant elements. Equivalent score: 85% to 94% compliant.

- **High: marginal performance or results** — The responsible entity has only partially achieved the reliability objective of the requirement and is missing one or more significant elements. Equivalent score: 70% to 84% compliant.
- **Severe: poor performance or results** — The responsible entity has failed to meet the reliability objective of the requirement. Equivalent score: less than 70% compliant.

Compliance Monitor
Replace, ‘Regional Reliability Organization’ with ‘Regional Entity’.

Fill-in-the-blank Requirements
Do not include any ‘fill-in-the-blank’ requirements. These are requirements that assign one entity responsibility for developing some performance measures without requiring that the performance measures be included in the body of a standard – then require another entity to comply with those requirements.

Every reliability objective can be met, at least at a threshold level, by a North American standard. If we need regions to develop regional standards, such as in under-frequency load shedding, we can always write a uniform North American standard for the applicable functional entities as a means of encouraging development of the regional standards.

Requirements for Regional Reliability Organization
Do not write any requirements for the Regional Reliability Organization. Any requirements currently assigned to the RRO should be re-assigned to the applicable functional entity.

Effective Dates
Must be 1^{st} day of 1^{st} quarter after entities are expected to be compliant – must include time to file with regulatory authorities and provide notice to responsible entities of the obligation to comply. If the standard is to be actively monitored, time for the Compliance Monitoring and Enforcement Program to develop reporting instructions and modify the Compliance Data Management System(s) both at NERC and Regional Entities must be provided in the implementation plan.

Associated Documents
If there are standards that are referenced within a standard, list the full name and number of the standard under the section called, ‘Associated Documents’.

Functional Model Version 3
Review the requirements against the latest descriptions of the responsibilities and tasks assigned to functional entities as provided in pages 13 through 53 of the draft Functional Model Version 3.

NERC

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Nomination Form —Transmission Vegetation Management Standard Drafting Team

Please return this form to sarcomm@nerc.net by **July 17, 2007** with “Trans Veg SDT Nomination” in the subject line. For questions, please contact Harry Tom at 609-452-8060 or Harry.Tom@nerc.net.

Although the meeting location hasn’t been determined, the first meeting of the standard drafting team will be August 28–30, 2007.

Name:	
Organization:	
Address:	
Office Telephone:	
E-mail:	

Please briefly describe your experience and qualifications to serve on the Transmission Vegetation Management Standard Drafting Team. Candidates should have expertise in one or more of the following areas:

- **Transmission line rights-of-way (ROW) vegetation management or ROW maintenance**
- **Transmission line design and ratings**
- **Regulatory or legal considerations in ROW maintenance**
- **Existing codes and good practices in vegetation management**

Previous experience developing or applying NERC or IEEE standards is beneficial, but not a requirement.

I represent the following NERC Reliability Region(s) (check all that apply):	I represent the following Industry Segment (check one):	
☐ ERCOT	☐	1 — Transmission Owners
☐ FRCC	☐	2 — RTOs and ISOs
☐ MRO	☐	3 — Load-serving Entities
☐ NPCC	☐	4 — Transmission-dependent Utilities
☐ RFC	☐	5 — Electric Generators
☐ SERC	☐	6 — Electricity Brokers, Aggregators, and Marketers
☐ SPP	☐	7 — Large Electricity End Users
☐ WECC	☐	8 — Small Electricity End Users
☐ NA – Not Applicable	☐	9 — Federal, State, and Provincial Regulatory or other Government Entities
	☐	10 – Regional Reliability Organizations and Regional Entities

Which of the following Function(s) do you have expertise or responsibilities:	
☐ Reliability Coordinator	☐ Transmission Service Provider
☐ Balancing Authority	☐ Transmission Owner
☐ Interchange Authority	☐ Load Serving Entity
☐ Planning Authority or Coordinator	☐ Distribution Provider
☐ Transmission Operator	☐ Purchasing-selling Entity
☐ Generator Operator	☐ Generator Owner
☐ Transmission Planner	☐ Resource Planner
☐ Compliance Monitor	☐ Market Operator

Provide the names and contact information for two references who could attest to your technical qualifications and your ability to work well in a group.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. SC approved SAR for initial posting (January 11, 2007).
2. SAR posted for comment (January 15–February 14, 2007).
3. SAR posted for comment (April 10–May 9, 2007).
4. SC authorized moving the SAR forward to standard development (June 27, 2007).

Proposed Action Plan and Description of Current Draft:

This is the initial posting of the proposed revisions to the requirements and measures in the standard. Once there is consensus on the language in the requirements and measures, the drafting team will add compliance elements to the standard.

Future Development Plan:

Anticipated Actions	Anticipated Date

7.	

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Active Transmission Line Right of Way — A strip of land that is occupied by active transmission facilities. This corridor does not include the inactive or unused part of the Right of Way intended for other facilities.

Critical Clearance Zone — The area mapped by the radial distance around a conductor specified in Table I of Attachment 1 to reliability standard FAC-003-2 — Transmission Vegetation Management Program when the conductor is energized and operating between no-load and its Rating, including the design blowout, however, the zone shall not extend beyond the limits of the Active Transmission Line Right of Way.

A. Introduction

1. **Title:** **Transmission Vegetation Management Program**

2. **Number:** FAC-003-2

3. **Purpose:** To improve the reliability of the Bulk Electric System by preventing vegetation related outages that could lead to Cascading.

4. **Applicability**

   4.1. Functional Entities:

   4.1.1. Transmission Owner

   4.1.2. Reliability Coordinator

   4.2. Facilities:

   4.2.1. Transmission lines ("applicable lines") operated at 200kV or higher, and transmission lines operated below 200kV designated by the Reliability Coordinator as being subject to this standard including but not limited to those that cross lands owned by federal[1], state, provincial, public, private, or tribal entities.

   4.2.2. Transmission lines operated below 200kV designated by the Reliability Coordinator as being subject to this standard become subject to this standard 12 months after the date the Reliability Coordinator initially designates the transmission line as being subject to this standard.

   4.2.3. Existing transmission line(s) operated at 200kV or higher that are newly acquired by a Transmission Owner and were not previously subject to this standard, become subject to this standard 12 months after the acquisition date of the transmission line(s).

5. **Effective Dates:**

   In those jurisdictions where regulatory approval is required, the first calendar day of the first calendar quarter one year after applicable regulatory authority approval for all requirements; or, in those jurisdictions where no regulatory approval is required, the first calendar day of the first calendar quarter one year following Board of Trustees adoption.

[1] EPAct 2005 section 1211c: *"Access approvals by Federal agencies"*

B. Requirements

R1. Each Transmission Owner shall have a documented transmission vegetation management program designed to control vegetation on its Active Transmission Lines' Rights of Way. The transmission vegetation management program shall:

R1.1. Specify the methodologies that the Transmission Owner uses to control vegetation.[2]

R1.2. Specify a vegetation inspection frequency of at least once per calendar year that takes into account local[3] and environmental factors.

R1.3. Require an annual plan that identifies the applicable lines to be maintained and associated work to be performed during the year. It shall be flexible to adjust to changing conditions and to findings from vegetation inspections. Adjustments to the plan within the year are permissible. The plan shall take into consideration permitting and scheduling requirements from landowners or regulatory authorities. It shall support the objectives of the transmission vegetation management program and use the methodologies outlined in the transmission vegetation management program.

R1.4. Require a process or procedure for response to imminent threats of a vegetation related Sustained Outage. The process or procedure shall specify actions which shall include immediate communication of the threat to the Transmission Operator, and may include actions such as a temporary reduction in line Rating, switching lines out of service, or other actions.

R1.5. Specify an interim corrective action process for use when the Transmission Owner is constrained from performing vegetation maintenance as planned.

R2. Each Transmission Owner shall implement its imminent threat procedure when the Transmission Owner has knowledge, obtained through normal operating practices or notification from others, that the Critical Clearance Zone is approached by vegetation to prevent an encroachment of the Critical Clearance Zone.

R3. Each Transmission Owner shall conduct inspections of all applicable lines in accordance with the frequency specified in its transmission vegetation management program.

R4. Each Transmission Owner shall prevent encroachment within the Critical Clearance Zone of its applicable lines with the following exceptions:

---

[2] ANSI A300, Tree Care Operations – Tree, Shrub, and Other Woody Plant Maintenance – Standard Practices, while not a requirement of this standard, is considered to be an industry best practice.

[3] Local factors include treatment cycle, extent and type of treatment, and their relationship to the normal growth rate.

- Encroachments of the Critical Clearance Zone that result from natural disasters.[4]
- Encroachments of the Critical Clearance Zone that result from human or animal activity.[5]

R5. Each Transmission Owner shall prevent Sustained Outages of applicable lines[6] due to vegetation growing into a conductor operating between no-load and its Rating with the following exceptions:

- Sustained Outages of applicable lines that result from natural disasters.[4]
- Sustained Outages of applicable lines that result from human or animal activity.[5]

R6. Each Transmission Owner shall prevent Sustained Outages of applicable lines[6] due to the blowing together of vegetation and a conductor within an Active Transmission Line Right of Way (operating within design blow-out conditions) with the following exception:

- Sustained Outages of applicable lines that result from sustained winds or gusts due to natural disasters.4

R7. Each Transmission Owner shall prevent Sustained Outages of applicable lines[6] due to vegetation falling into a conductor from within an Active Transmission Line Right of Way with the following exceptions:

- Sustained Outages of applicable lines that result from natural disasters.[4]
- Sustained Outages of applicable lines that result from human or animal activity.[5]

R8. Each Transmission Owner shall implement its annual work plan for vegetation management to accomplish the purpose of this standard within the extent of its easement and/or legal rights.

R9. Each Reliability Coordinator in consultation with its Transmission Owner(s) and neighboring Reliability Coordinator(s) shall jointly prepare and keep current, a list of designated applicable lines that are operated below 200kV, if any, which are subject to this standard.

R10. Each Reliability Coordinator shall document its method for assessing the reliability significance of sub-200kV lines considering all of the following:

---

[4] Examples include, but are not limited to, earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods.

[5] Examples include, but are not limited to, logging, animal severing tree, vehicle contact with tree, arboricultural activities or horticultural or agricultural activities, or removal or digging of vegetation.

[6] Multiple Sustained Outages on an individual line, if caused by the same vegetation, shall be considered as one outage regardless of the actual number of outages within a 24-hour period.

R10.1 Transmission lines whose loss would result in the exceedance of an Interconnection Reliability Operating Limit (IROL)

R10.2 Transmission lines whose loss would place the grid at an unacceptable risk of instability, separation, or cascading failures.

B. Measures

M1. The Transmission Owner has a documented transmission vegetation management program designed to control vegetation on the Active Transmission Line Right of Way. (R1)

M1.1 The Transmission Owner's transmission vegetation management program specifies the methodologies that the Transmission Owner uses to control vegetation.

M1.2 The Transmission Owner's transmission vegetation management program specifies a vegetation inspection frequency that takes into account local and environmental factors. This inspection frequency shall be at least once per calendar year.

M1.3 The Transmission Owner's transmission vegetation management program requires an annual plan and it identifies the applicable lines to be maintained and related vegetation management work to be performed during the calendar year while taking into consideration permitting and scheduling requirements from landowners or regulatory authorities.

M1.4 The Transmission Owner's transmission vegetation management program requires an imminent threat process or procedure for responding to imminent threats of a vegetation-related Sustained Outage including immediate communication of the threat to the Transmission Operator, and may include a temporary reduction in line Rating, switching lines out of service, and/or other actions that may be taken until the threat is relieved.

M1.5 The Transmission Owner's transmission vegetation management program specifies the interim corrective action process for use when the Transmission Owner is constrained from performing vegetation maintenance as planned.

M2. The Transmission Owner has evidence that it implemented its imminent threat procedure when it obtained knowledge that the Critical Clearance Zone was approached by vegetation. (R2)

M3. The Transmission Owner has evidence that it conducted vegetation inspections of all applicable transmission lines in accordance with the frequency specified in its transmission vegetation management program. (R3)

M4. The Transmission Owner has evidence such as inspection records, imminent threat reports or quality assurance reports, demonstrating there were no vegetation encroachments into the Critical Clearance Zone. (R4)

M5. The Transmission Owner has evidence that there was not a Sustained Outage of an applicable line due to vegetation growing into a conductor operating between no-load and its Rating. (R5)

M6. The Transmission Owner has evidence that there was not a Sustained Outage of an applicable line due to the blowing together of vegetation and a conductor within the Active Transmission Line Right of Way. (R6)

M7. The Transmission Owner has evidence that there was not a Sustained Outage of an applicable line due to vegetation falling into a conductor from within the Active Transmission Line Right of Way. (R7)

M8. The Transmission Owner has evidence that it is implementing, or has implemented, its annual work plan. (R8)

M9. The Reliability Coordinator has evidence that it consulted with its Transmission Owner(s) and adjacent Reliability Coordinator(s), prepared and kept current a list of designated sub-200kV transmission lines, if any, which are subject to this standard. (R9)

M10. The Reliability Coordinator has evidence that it has defined its methods for assessing the reliability significance of sub-200kV lines and has developed selection criteria for listing any sub-200kV lines. (R10)

C. Compliance (To be added)

D. Regional Differences

None identified.

FAC-003-1 Mapping to Revised NERC Reliability Standard FAC-003-2

Standard FAC-003-1 NERC Board Approved	Comment	Proposed Standard FAC-003-2
1. Title: Transmission Vegetation Management Program	**1. Title:** No Change (N/C)	**1. Title:** Transmission Vegetation Management Program
2. Number: FAC-003-1	**2. Number:** Update to latest Revision	**2. Number:** FAC-003-2
3. Purpose: To improve the reliability of the electric transmission systems by preventing outages from vegetation located on transmission rights-of-way (ROW) and minimizing outages from vegetation located adjacent to ROW, maintaining clearances between transmission lines and vegetation on and along transmission ROW, and reporting vegetationrelated outages of the transmission systems to the respective Regional Reliability Organizations (RRO) and the North American Electric Reliability Council (NERC).	**3. Purpose:** Changed electric transmission systems to Bulk Electric System. Changed to a shorter more concise purpose statement. The various explanatory objectives are now addressed within the standard's requirements.	**3. Purpose:** To improve the reliability of the Bulk Electric System by preventing vegetation related outages that could lead to widespread cascading failures.
4. Applicability: 4.1. Transmission Owner 4.2. Regional Reliability Organization 4.3. This standard shall apply to all transmission lines operated at 200 kV and above and to any lower voltage lines designated by the RRO as critical to the reliability of the electric system in the region.	**4. Applicability:** **Separated applicability between functional entities and facilities for clarity** 4.1 now is 4.4.1 No change 4.2 Removed Regional Reliability Organization and added 4.1.2 Reliability Coordinator 4.3 Clarified facility applicability in 4.2, 4.2.1, 4.2.2 and 4.2.3 as stated below 4.2.1. Added term "applicable lines" for format efficiency in the standard verbiage. Ensures that all lines are covered by the standard regardless of the owner of the over which they cross.	**4.** Applicability 4.1 Functional Entities: 4.1.1 Transmission Owner 4.1.2 Reliability Coordinator 4.2 Facilities: 4.2.1 Transmission lines ("applicable lines") operated at 200kV or higher, and transmission lines operated below 200kV designated by the Reliability Coordinator as being subject to this standard including but not limited to those that cross lands owned by federal, state, provincial, public, private, or

Standard FAC-003-1 NERC Board Approved	Comment	Proposed Standard FAC-003-2
	4.2.2 Added to identify the time frame allowed to bring sub 200kV lines into compliance with the standard after the Reliability Coordinator has determined that they are subject to the standard. 4.2.3. Added to specify the time frame allowed, for a newly acquired above 200kV line, which was not previously subject to the standard, to become subject to the standard.	tribal entities. 4.2.2 Transmission lines operated below 200kV designated by the Reliability Coordinator as being subject to this standard become subject to this standard 12 months after the date the Reliability Coordinator initially designates the transmission line as being subject to this standard. 4.2.3 Existing transmission line(s) operated at 200kV or higher that are newly acquired by a Transmission Owner and were not previously subject to this standard, become subject to this standard 12 months after the acquisition date of the transmission line(s).
Effective Dates: **5.1** One calendar year from the date of adoption by the NERC Board of Trustees for Requirement 1 and 2. **5.2** Sixty calendar days from the date of adoption by the NERC Board of Trustees for the Requirements 3 and 4.	**Effective Dates:** Reworded both 5.1 and 5.2 as one statement for consistency with standards process for a standard revision.	5. **Effective Dates:** In those jurisdictions where regulatory approval is required, the first calendar day of the first calendar quarter one year after applicable regulatory authority approval for all requirements; or, in those jurisdictions where no regulatory approval is required, the first calendar day of the first calendar quarter one year following Board of Trustees adoption.
R1. The Transmission Owner shall prepare, and keep current, a formal transmission vegetation management program (TVMP). The TVMP shall include the Transmission Owner's objectives, practices, approved procedures, and work specifications.	**R1.** Replaced "prepare, and keep current" with "have" and removed the longer series of terms with one term "designed to control vegetation". Clarified that this applies on the Active Transmission Line Right of Way. **R1.1** New language replaced the longer series that was	**R1**. Each Transmission Owner shall have a documented transmission vegetation management program designed to control vegetation on its Active Transmission Lines' Rights of Way. The transmission vegetation management program shall: **R1.1.** Specify the methodologies that the Transmission

Standard FAC-003-1 NERC Board Approved	Comment	Proposed Standard FAC-003-2
R1.1. The TVMP shall define a schedule for and the type (aerial, ground) of ROW vegetation inspections. This schedule should be flexible enough to adjust for changing conditions. The inspection schedule shall be based on the anticipated growth of vegetation and any other environmental or operational factors that could impact the relationship of vegetation to the Transmission Owner's transmission lines. **R2.** The Transmission Owner shall create and implement an annual plan for vegetation management work to ensure the reliability of the system. The plan shall describe the methods used, such as manual clearing, mechanical clearing, herbicide treatment, or other actions. The plan should be flexible enough to adjust to changing conditions, taking into consideration anticipated growth of vegetation and all other environmental factors that may have an impact on the reliability of the transmission systems. Adjustments to the plan shall be documented as they occur. The plan should take into consideration the time required to obtain permissions or permits from landowners or regulatory authorities. Each Transmission Owner shall have systems and procedures for documenting and tracking the planned vegetation management work and ensuring that the vegetation management work was completed according to work specifications.	previously implied by **R1** in version 1. **R1.1 replaced by R1.2.** Changed inspection schedule to inspection frequency and specified the frequency to be at least once per calendar year. Note also that **R3** has been added to clarify that the conduction of inspections is a separate requirement from specifying the frequency that inspections will occur. **R2** replaced by **R1.3** and **R8.** **R1.3** is the explanation of the TVMP documentation requirements changes only. See the associated remarks below under **R8** for the changes with respect to implementation of the annual plan.	Owner uses to control vegetation. **R1.2.** Specify a vegetation inspection frequency of at least once per calendar year that takes into account local[1] and environmental factors. **R1.3.** Require an annual plan that identifies the applicable lines to be maintained and associated work to be performed during the year. It shall be flexible to adjust to changing conditions and to findings from vegetation inspections. Adjustments to the plan within the year are permissible. The plan shall take into consideration permitting and scheduling requirements from landowners or regulatory authorities. It shall support the objectives of the transmission vegetation management program and use the methodologies outlined in the transmission vegetation management program.

FAC-003-1 Mapping to Revised NERC Reliability Standard FAC-003-2

Standard FAC-003-1 NERC Board Approved	Comment	Proposed Standard FAC-003-2
R1.5. Each Transmission Owner shall establish and document a process for the immediate communication of vegetation conditions that present an imminent threat of a transmission line outage. This is so that action (temporary reduction in line rating, switching line out of service, etc.) may be taken until the threat is relieved. **R1.4.** Each Transmission Owner shall develop mitigation measures to achieve sufficient clearances for the protection of the transmission facilities when it identifies locations on the ROW where the Transmission Owner is restricted from attaining the clearances specified in Requirement 1.2.1.	**R1.5** replaced by **R1.4** which requires a documented process to respond with examples of actions including immediate communications and other actions that may be taken to relieve the threat. **R1.4** replaced by **R1.5** – Now referred to as interim corrective action process to address situations where vegetation maintenance activities cannot be performed as planned. The term corrective action plan is used in lieu of mitigation plan to avoid confusion with other uses in NERC of "mitigation plan" **New R2** added to ensure that implementation of the imminent threat procedure as a stand-alone requirement. **R3.** Has been added to separate this conduct of inspections from **R1.2** documentation which specifies the frequency for inspections. **The old R1.2.** Has been changed by elimination of Clearance 1 and the replacement of Clearance 2 with the Critical Clearance Zone. See **R2** and **R4**	**R1.4.** Require a process or procedure for response to imminent threats of a vegetation related Sustained Outage. The process or procedure shall specify actions which shall include immediate communication of the threat to the Transmission Operator, and may include actions such as a temporary reduction in line rating, switching lines out of service, or other actions. **R1.5.** Specify the general interim corrective action process for use when the Transmission Owner is constrained from performing vegetation maintenance as planned. **R2.** Each Transmission Owner shall implement its imminent threat procedure when the Transmission Owner has knowledge, obtained through normal operating practices or notification from others, that the Critical Clearance Zone is approached by vegetation to prevent an encroachment of the Critical Clearance Zone. **R3**.Each Transmission Owner shall conduct inspections of all applicable lines in accordance with the frequency specified in its transmission vegetation management program.

Standard FAC-003-1 NERC Board Approved	Comment	Proposed Standard FAC-003-2
R1.2. The Transmission Owner, in the TVMP, shall identify and document clearances between vegetation and any overhead, ungrounded supply conductors, taking into consideration transmission line voltage, the effects of ambient temperature on conductor sag under maximum design loading and the effects of wind velocities on conductor sway. Specifically, the Transmission Owner shall establish clearances to be achieved at the time of vegetation management work identified herein as Clearance 1, and shall also establish and maintain a set of clearances identified herein as Clearance 2 to prevent flashover between vegetation and overhead ungrounded supply conductors. **R1.2.1.** Clearance 1 — The Transmission Owner shall determine and document appropriate clearance distances to be achieved at the time of transmission vegetation management work based upon local conditions and the expected time frame in which the Transmission Owner plans to return for future vegetation management work. Local conditions include, but are not limited to: operating voltage, appropriate vegetation management techniques, fire risk, reasonably anticipated tree and conductor movement, species type and growth rates, species failure characteristics, local climate and rainfall patterns, line terrain and elevation location of the vegetation within the span, and worker approach distance requirements, Clearance 1 distances shall be greater than those defined by Clearance 2 below under all rated electrical operating conditions.	**R1.2.1 -** Clearance 1 requirement eliminated: **R1.2.2** replaced by **R4 -** Clearance 2 has been replaced by Critical Clearance Zone. the old **R1.1.2** was a documentation requirement within the TVMP whereas **R4** specifies encroachments as violations. Under the Levels of Non-Compliance in **FAC-003-1, Level 3: 2.3.2** covered failure to "maintain…Clearance 2". Note that encroachment reporting will be addressed later in a **VSL** for **R4**	**R4** Each Transmission Owner shall prevent encroachment within the Critical Clearance Zone of

Standard FAC-003-1 NERC Board Approved	Comment	Proposed Standard FAC-003-2
R1.2.2. Clearance 2 — The Transmission Owner shall determine and document specific radial clearances to be maintained between vegetation and conductors under all rated electrical operating conditions. These minimum clearance distances are necessary to prevent flashover between vegetation and conductors and will vary due to such factors as altitude and operating voltage. These Transmission Owner-specific minimum clearance distances shall be no less than those set forth in the Institute of Electrical and Electronics Engineers (IEEE) Standard 516-2003 (*Guide for Maintenance Methods on Energized Power Lines*) and as specified in its Section 4.2.2.3, Minimum Air Insulation Distances without Tools in the Air Gap. **R1.2.2.1** Where transmission system transient overvoltage factors are not known, clearances shall be derived from Table 5, IEEE 516-2003, phase-to-ground distances, with appropriate altitude correction factors applied. **R1.2.2.2** Where transmission system transient overvoltage factors are known, clearances shall be derived from Table 7, IEEE 516-2003, phase-to-phase voltages, with appropriate altitude correction factors applied **R1.3.** All personnel directly involved in the design and implementation of the TVMP shall hold appropriate qualifications and training, as defined by the Transmission Owner, to perform their duties.	 **R1.3** – Personnel qualifications has been removed.	its applicable lines with the following exceptions: 1. Encroachments of the Critical Clearance Zone that result from natural disasters. 2. Encroachments of the Critical Clearance Zone that result from human or animal activity.
R3. The Transmission Owner shall report quarterly to	**R3** Outage reporting is now covered in **R5-R7** and	**R5** Each Transmission Owner shall prevent Sustained

Standard FAC-003-1 NERC Board Approved	Comment	Proposed Standard FAC-003-2
its RRO, or the RRO's designee, sustained transmission line outages determined by the Transmission Owner to have been caused by vegetation. **R3.1.** Multiple sustained outages on an individual line, if caused by the same vegetation, shall be reported as one outage regardless of the actual number of outages within a 24-hour period. **R3.2.** The Transmission Owner is not required to report to the RRO, or the RRO's designee, certain sustained transmission line outages caused by vegetation: (1) Vegetation related outages that result from vegetation falling into lines from outside the ROW that result from natural disasters shall not be considered reportable (examples of disasters that could create non-reportable outages include, but are not limited to, earthquakes, fires, tornados, hurricanes, landslides, wind shear, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods), and (2) Vegetation-related outages due to human or animal activity shall not be considered reportable (examples of human or animal activity that could cause a non-reportable outage include, but are not limited to, logging, animal severing tree, vehicle contact with tree, arboricultural activities or horticultural or agricultural activities, or removal or digging of vegetation). **R3.3.** The outage information provided by the Transmission Owner to the RRO, or the RRO's designee, shall include at a minimum: the name	**M5-M7** and the associated Compliance **VSLs** for **R5-R7.** Requirements **R5, R6, and R7** specify three types of Sustained Outages which shall be prevented. Exceptions have been further defined Outages in **FAC-003-1 R3** were reporting requirements and were not violations per se. In that version of the standard the **Levels of Non-Compliance 2.2.3, 2.3.1**, and **2.4.1** the Sustained Outages were assigned a level of non-compliance.	Outages of applicable lines due to vegetation growing into a conductor operating between no-load and rated conditions with the following exceptions: 1. Sustained Outages of applicable lines that result from natural disasters. 2. Sustained Outages of applicable lines that result from human or animal activity. **R6** Each Transmission Owner shall prevent Sustained Outages of applicable lines due to the blowing together of vegetation and a conductor within an Active Transmission Line Right of Way(operating within design blow out conditions) with the following exception: 1. Sustained Outages of transmission lines that result from sustained winds or gusts due to natural disasters. **R7** Each Transmission Owner shall prevent Sustained Outages of applicable lines due to vegetation falling into a conductor from within an Active Transmission Line Right of Way with the following exceptions: 1. Sustained Outages of applicable lines that result from natural disasters. 2. Sustained Outages of applicable lines that result from human or animal activity.

Standard FAC-003-1 NERC Board Approved	Comment	Proposed Standard FAC-003-2
of the circuit(s) outaged, the date, time and duration of the outage; a description of the cause of the outage; other pertinent comments; and any countermeasures taken by the Transmission Owner. **R3.4.** An outage shall be categorized as one of the following: **R3.4.1.** Category 1 — Grow-ins: Outages caused by vegetation growing into lines from vegetation inside and/or outside of the ROW; **R3.4.2.** Category 2 — Fall-ins: Outages caused by vegetation falling into lines from inside the ROW; **R3.4.3.** Category 3 — Fall-ins: Outages caused by vegetation falling into lines from outside the ROW.	Category 3 – fall-in outages are no longer reportable. . **R8** Is a new requirement which separates the implementation of the annual plan from the creation of the annual plan. See **FAC-003-2, 1.3** above.	**R8** Each Transmission Owner shall implement its annual work plan for vegetation management to accomplish the purpose of this standard within the extent of its easement and/or legal rights.
R4. The RRO shall report the outage information provided to it by Transmission Owner's, as required by Requirement 3, quarterly to NERC, as well as any actions taken by the RRO as a result of any of the reported outages.	**R4** Eliminated. The RRO, which is now the RE, is not subject to standards.	
	R9 This new requirement addresses the	**R9** Each Reliability Coordinator in consultation

Standard FAC-003-1 NERC Board Approved	Comment	Proposed Standard FAC-003-2
	identification of sub-200kV lines.	with their Transmission Owner(s) and neighboring Reliability Coordinator(s) shall jointly prepare and keep current, a list of designated applicable lines that are operated below 200kV, if any, which are subject to this standard.
		R10 Each Reliability Coordinator shall document its method for assessing the reliability significance of sub-200kV lines considering all of the following: **R10.1** Transmission lines whose loss would result in the exceedance of an Interconnection Reliability Operating Limit (IROL) **R10.2** Transmission lines whose loss would place the grid at an unacceptable risk of instability, separation, or cascading failures.

	Footnotes added to cover exceptions which were in FAC-003-1 imbedded within the standard	Footnotes on Page 4

NERC

NORTH AMERICAN ELECTRIC
RELIABILITY CORPORATION

First Draft of Standards for Vegetation Management (Project 2007-07)

First draft of the FAC-003-2 — Transmission Vegetation Management Program standard for the Vegetation Management Standard Drafting Team (Project 2007-07) is up for a 30-day comment period. Comments must be submitted through the electronic comment form by **November 25, 2008.** If you have questions please contact Harry Tom at Harry.Tom@nerc.net or by telephone at 860-550-4157

Background Information:

The Standard Drafting Team revised the Vegetation Management Standard in accordance with the Standard Authorization Request. The Standard Authorization Request scope reflects comments from the FERC Order 693 and from stakeholders as well as procedural updates. The Standard Authorization Request also specified that the revised standard incorporate compliance program elements of time horizons, violation severity levels, etc. to bring it into conformance with the latest version of the Reliability Standard Development Procedure and the ERO Sanctions Guidelines. The compliance elements are not included in this initial posting. The Standard Drafting Team has prepared a Technical Reference document to supplement the FAC-003-2 Standard and is posted along with the revised standard. This posting seeks comment on the Standard revision as well as the Technical Reference document.

You do not have to answer all questions. Enter All Comments in Simple Text Format.

Insert a "check" mark in the appropriate boxes by double-clicking the gray areas.

1. In the Purpose Statement the term "electric transmission systems" was changed to Bulk Electric System, and the Purpose statement was shortened by moving the various explanatory objectives to other locations in the revised Standard. Do you agree with the purpose statement? If not, please explain.

   ☐ Agree

   ☐ Disagree

   Comments:

2. The Reliability Coordinator was chosen as the proper entity to identify sub-200kV transmission lines to be subject to this standard (see applicability, R9, and R10). Do you agree with this choice? If not, please explain.

   ☐ Agree

   ☐ Disagree

   Comments:

3. In R1 the proposed standard replaces "*prepare, and keep current*" with "*have*", replaces the list of terms, "*objectives, practices, approved procedures, and work specifications*," with "*designed to control vegetation*", defines the "active transmission line ROW", and specifies that the transmission vegetation management program applies to that area. Do you agree with R1? If not, please explain.

   ☐ Agree

   ☐ Disagree

   Comments:

4. Documentation and implementation of the transmission vegetation management program which were previously combined in Requirement R1 are now separated in order to apply appropriate VRFs and time horizons. The implementation of some elements has been moved into standalone requirements such as inspection cycles (R3) and annual plan implementation (R8). Do you agree with these revisions and separation? If not, please explain.

   ☐ Agree

   ☐ Disagree

   Comments:

5. In R1.2 the Transmission Owner is required to have an inspection frequency of at least once per calendar year. Do you agree with R1.2? If not, please explain.

   ☐ Agree

   ☐ Disagree

   Comments:

6. In R1.3 the Standard requires that transmission vegetation management program specify an Annual Plan and specifies parameters for the plan. Implementation of the Annual Plan is separated and placed in R8. Do you agree with R1.3 and the separation of the implementation from the specification of the Annual Plan? If not, please explain.

☐ Agree

☐ Disagree

Comments:

7. In R1.4 the Standard requires the Transmission Owner to have an Imminent Threat Procedure and specifies elements to be in that procedure. Do you agree with R1.4? If not, please explain.

☐ Agree

☐ Disagree

Comments:

8. Requirement 1 section R1.5 replaces Version 1 sub-requirement R1.4. This section is now referred to as interim corrective action process. This process addresses situations where vegetation maintenance activities cannot be performed as planned. The term *corrective action plan* is used in lieu of *mitigation plan* to avoid confusion with other uses in NERC of "*mitigation plan*". Do you agree with R1.5? If not, please explain.

☐ Agree

☐ Disagree

Comments:

9. Clearance 1 in Version 1 was a "fill-in-the-blank" requirement and was removed from the standard. Do you agree? If not, please explain.

☐ Agree

☐ Disagree

Comments:

10. Personnel Qualifications in R1.3 in Version 1 was a "fill-in-the-blank" requirement and was removed from Version 2 of the standard. Do you agree? If not please explain.

☐ Agree

☐ Disagree

Comments:

11. The IEEE 516 standard distances were replaced with the Gallet equation distances. Clearance 2 was replaced by the Critical Clearance Zone. The Critical Clearance Zone is defined as the zone of all possible positions of the conductor at the line's designed operating ratings including wind factors. (Please refer to pages 22-32 in the Technical Reference Document on the Critical Clearance Zone for further background for this question.) The imminent threat procedure, R2, requires action to be taken to prevent an outage when the Critical Clearance Zone is approached. Do you agree with R2? If not please explain.

☐ Agree

☐ Disagree

Comments:

12. The Standard Drafting Team revised the spark-over (also referred to as "flashover") distance thresholds utilizing technically-equivalent Gallet equations in lieu of IEEE 516 minimum air insulation distance (MAID) calculations that were used in FAC-003-1. The rationale is that the minimum air insulation distances in IEEE 516 were safety clearances developed under laboratory conditions and thus there exists concern these distances may be too conservative to apply to lines operating in actual field conditions. Do you agree with this? If not, please explain.

☐ Agree

☐ Disagree

Comments:

13. The Standard Drafting Team applied a transient overvoltage factor (T) of 1.4 and 2.0 for ac voltage classes of 345kV and above and sub-345kV facilities, respectively. Version 1, using the IEEE 516 method, assumes a maximum transient overvoltage value. The Standard Drafting Team asserts that in this application of steady-state flashovers and due to the design attributes of higher voltage systems, a lower T factor is applicable. Do you agree with this? If not, please explain.

☐ Agree

☐ Disagree

Comments:

14. R3 has been added to clarify that conduction of inspections is a separate requirement from specifying the frequency that inspections will occur. Do you agree with R3? If not please explain.

☐ Agree

☐ Disagree

Comments:

15. Several alternatives to R4 were considered by the drafting team. The drafting team explored these significantly different alternatives at length. They are outlined below to provide background to industry during this comment period. (Please refer to pages 22-32 in the Technical Reference Document on the Critical Clearance Zone for further background for this question.)

    - As written, R4, a new requirement, stipulates that the Transmission Owner is in violation if an encroachment of the Critical Clearance Zone occurs at any time. If vegetation enters the Critical Clearance Zone, a violation will have occurred, regardless of the actual proximity of the vegetation to the conductor at the time. Evidence will be required to prove that no encroachments of the Critical Clearance Zone have occurred anywhere at any time during the annual compliance period. This will require the time and effort to postpone vegetation maintenance to perform field investigations and document all possible encroachments.

    - One alternative to R4 required immediate removal of the vegetation or immediate implementation of the imminent threat procedure upon discovery of a possible encroachment of the Critical Clearance Zone, thereby proactively preventing an outage. A violation would have occurred only if the imminent threat process was not successfully implemented.

- Another alternative was a tiered approach. This tiered approach involved a "per thousand mile" metric to determine when a violation had occurred and the severity of the violation. This metric was an attempt to equitably account for varying exposures that exist due to widely ranging system sizes.

Do you agree that R4 is written in the most effective way to achieve the purpose of the standard? If not, what do you propose as an alternative to R4 that would ensure a level of reliability equal to or better than FAC-003-1?

☐ Agree

☐ Disagree

Comments:

16. Requirements R5, R6, and R7 define that Sustained Outages due to vegetation growing into, blowing together with, and falling into transmission lines are violations (subject to certain exemptions). Therefore, all such outages must be reported as violations of the standard. Do you agree with this change? If not, please explain.

☐ Agree

☐ Disagree

Comments:

17. R8 is a new requirement which separates the implementation of the annual plan from the requirement to have an annual plan. Do you agree with R8? If not please explain.

☐ Agree

☐ Disagree

Comments:

18. If you have further suggestions for improving this standard or the technical reference document, please offer them.

Transmission Vegetation Management

NERC Standard FAC-003-2 Technical Reference

Prepared by the

North American Electric Reliability Corporation

Vegetation Management Standard Drafting Team

OCTOBER 20, 2008

Table of Contents

Introduction

This document is intended to provide supplemental information and guidance for complying with the requirements of Reliability Standard FAC-003-2. It is a supporting document and provides explanatory background to the requirements of the Standard.

The purpose of the Standard is to improve the reliability of the Bulk Electric System by preventing vegetation related outages that could lead to Cascading.

Compliance with the Standard is mandatory and enforceable.

Disclaimer

This supporting document may explain or facilitate implementation of reliability standard FAC-003-2 — Transmission Vegetation Management but does not contain mandatory requirements subject to compliance review.

Definition of Terms

Active Transmission Line Right of Way* — A strip of land that is occupied by active transmission facilities. This corridor does not include the inactive or unused part of the Right-of-Way intended for other facilities.

Examples of active and inactive portions of corridors include:

1) Where portions of the right of way are occupied by active facilities and other portions are acquired to accommodate future facilities. Power plant exits are examples where large rights-of-way are obtained for maximum corridor utilization and may currently have fewer structures constructed (see Figure 1 on page 6).
2) Rights of way where corridor edge zones are provided for vegetation to exist (see Figure 2 on page 7).
3) Where double-circuit structures are installed but only one circuit is currently strung with conductors (see Figure 3 on page 8).

Critical Clearance Zone* — The area mapped by the radial distance around a conductor specified in Table I of Attachment 1to the reliability standard FAC-003-2 — Transmission Vegetation Management Program when the conductor is energized and operating between no-load and its Rating, including the design blow-out, however the zone shall not extend beyond the limits of the Active Transmission Line Right of Way.

Sustained Outage** — The deenergized condition of a transmission line resulting from a fault or disturbance following an unsuccessful automatic reclosing sequence and/or unsuccessful manual reclosing procedure.

Cascading ** — The uncontrolled successive loss of system elements triggered by an incident at any location. Cascading results in widespread electric service interruption that cannot be restrained from sequentially spreading beyond an area predetermined by studies.

Rating ** — The operational limits of a transmission system element under a set of specified conditions.

*To be added to the NERC glossary of terms with final approval of this standard revision
** Currently defined in the NERC glossary of terms

Applicability of the Standard

4. *Applicability:*

   4.1. Functional Entities:

   4.1.1. Transmission Owner

   4.1.2. Reliability Coordinator

   4.2. Facilities:

   4.2.1. Transmission lines ("applicable lines") operated at 200kV or higher, and transmission lines operated below 200kV designated by the Reliability Coordinator as being subject to this standard including but not limited to those that cross lands owned by federal[1], state, provincial, public, private, or tribal entities.

   4.2.2. Transmission lines operated below 200kV as designated by the Reliability Coordinator as being subject to this standard become subject to this standard 12 months after the date the Reliability Coordinator initially designates the Transmission Line as being subject to this standard.

   4.2.3. Existing transmission line(s) operated at 200kV or higher that are newly acquired by a Transmission Owner and were not previously subject to this standard, become subject to this standard 12 months after the acquisition date of the transmission line(s).

The reliability objective of this NERC Vegetation Management Standard ("Standard") is to prevent vegetation-related outages which could lead to Cascading by effective vegetation maintenance while recognizing that certain outages such as those due to vandalism, human errors and acts of nature are not preventable. Operating experience clearly indicates that trees that have grown out of specification could contribute to a cascading grid failure, especially under heavy electrical loading conditions.

Serious outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations. To properly reduce and manage this risk, it is necessary to apply the Standard to applicable lines on any kind of land or easement, whether they are Federal Lands, state or provincial lands, public or private lands, franchises, easements or lands owned in fee.

The Standard addresses vegetation management along applicable overhead lines that serve to connect one electric station to another. However, it is not intended to be applied to lines sections inside the electric station fence or other boundary of an electric station or underground lines.

The Standard is intended to reduce the risk of Cascading involving vegetation. It is not intended to prevent customer outages from occurring due to tree contact with all transmission lines and

[1] EPAct 2005 section 1211c: *"Access approvals by Federal agencies"*

voltages. For example, localized customer service could be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. This Standard is not written to address such isolated situations which have little impact on the overall Bulk Electric System.

Vegetation growth is constant and always present. Unmanaged vegetation poses an increased outage risk when numerous transmission lines are operating at or near their Rating as a result of increased sags incurred. This poses a significant risk of multiple line failures and Cascading. On the other hand, most other outage causes (such as trees falling into lines, lightning, animals, motor vehicles, etc.) are statistically intermittent. The probability of occurrence of these events is not dependent on heavy loads. There is no cause-effect relationship which creates the probability of simultaneous occurrence of other such events. Therefore these type events are highly unlikely to cause large-scale grid failures.

In preparing the original vegetation management standard in 2005, industry stakeholders set the threshold for applicability of the standard at 200kV. This was because an unexpected loss of lines operating at above 200kV has a higher probability of initiating a widespread blackout or cascading outages compared with lines operating at less than 200kV.

The original NERC vegetation management standard also allowed for application of the standard to “critical” circuits (critical from the perspective of initiating widespread blackouts or cascading outages) operating below 200kV. While the percentage of these circuits is relatively low (at one major U.S. utility, only 3% of its thousands of sub-200kV circuits are considered critical), it remains a fact that there are sub-200kV circuits whose loss could contribute to a widespread outage. Given the very limited exposure and unlikelihood of a major event related to these lower-voltage lines, it would be an imprudent use of resources to apply the Standard to all sub-200kV lines. The drafting team selected, after evaluating several alternatives, the Reliability Coordinator as the best entity to determine applicable lines below 200 kV that are subject to this standard.

Transmission Vegetation Management Program

R1. *Each Transmission Owner shall have a documented transmission vegetation management program designed to control vegetation on its Active Transmission Lines' Rights of Way. The transmission vegetation management program shall:*

The purpose of the Standard is to prevent vegetation-related outages that can result in Cascading. Under Requirement R1, each Transmission Owner is required to have a transmission vegetation management program designed to control vegetation on the Active Transmission Line Right of Way. The transmission vegetation management program is an important component of the Standard because it is the formal document that Transmission Owners use to manage vegetation to achieve the purpose of the Standard. An adequate transmission vegetation management program formally establishes the guidelines that are used by the Transmission Owner to plan and perform vegetation work that is necessary to prevent transmission outages and minimize risk to the transmission system.

It should be noted that Requirement R1 is concerned with the content of the transmission vegetation management program and supporting documents, but does not address implementation of the elements of the transmission vegetation management program. Other requirements address implementation of the transmission vegetation management program. For example, sub-part 1.4 requires Transmission Owners to establish an imminent threat procedure. However, sub-part 1.4 does not address implementation or execution of the imminent threat procedure. This is addressed in Requirement R2. These situations will be reviewed in the following discussion.

Methodology to Control Vegetation

R1.1. *Specify the methodologies that the Transmission Owner uses to control vegetation*[2]

Transmission Owners are required to specify the methodologies or management methods used to control vegetation on applicable lines in the transmission vegetation management program. The methods specified in the transmission vegetation management program under this requirement are the methods that will be applied to the development and implementation of the annual work plan (R1.3 and R8).

The intent of this sub-part is for the Transmission Owner to list and generally describe the vegetation management methods that are used on its Active Transmission Line Right of Way. Transmission Owners are not required to deploy each of the methods listed in every situation. Nor are they required to provide a detailed description of each method, although these may exist in the Transmission Owner's specifications. Instead, the methods listed under this requirement are intended to provide a menu of vegetation management options that the Transmission Owner may deploy when developing and implementing the annual work plan based upon the many different circumstances that are typically encountered.

It should be emphasized that pruning is an ineffective maintenance method. Removal is always superior to pruning in ensuring tree conflicts do not occur.

In general, the best management practice for the Transmission Owner is to always exercise its maximum legal rights to achieve the objectives of the transmission vegetation management program. This minimizes the possibility of conflicts between energized conductors and vegetation. Since this is not always possible, the Transmission Owner's strategy should be to use its prescribed vegetation maintenance methods to work towards or achieve the maximum use of the Active Transmission Line Right of Way.

The following are several examples of how methodologies could be specified in the transmission vegetation management program under this requirement. These are offered as examples only and it is recognized that numerous other methodologies could be included in the transmission vegetation management program. It is also recognized that more detailed descriptions would typically be included in the Transmission Owner's internal specifications and procedures. The "average" tree does not usually cause a Sustained Outage. It is above-average growth that creates the greatest risk. In summary, methods must be applied in a sound biological manner

<u>Mechanical Clearing</u> — Remove all trees and brush in the Active Transmission Line Right of Way. Cut or mow all stumps to 3 inches or less above grade. De-limb and windrow on the edge of the right of way those larger trees that could be obstructive to other line maintenance activities.

<u>Selective Mechanical Tree Removal</u> — Selectively remove with chain saws or mechanized equipment all tall-growing species of trees, as listed in the specifications. Chemically treat the stumps of re-sprouting trees with the herbicide mixtures identified in the specification within one

---

[2] *ANSI A300, Tree Care Operations — Tree, Shrub, and Other Woody Plant Maintenance – Standard Practices, while not a requirement of this standard, is considered to be an industry best practice.*

hour of making the cut. All low-growing species of shrubs and trees, as listed in the specification, will be preserved unless otherwise noted.

<u>Low-Volume Foliar Selective Herbicide Treatment</u> — Selectively treat with herbicide <u>all</u> tall-growing species of trees as listed in the specification which are less than ten feet in height, using the low-volume foliar herbicide mixture and application process listed in the specification. All low-growing species of shrubs and trees, as listed in the specification will be preserved unless otherwise noted.

<u>Side Pruning</u> — Prune trees adjacent to the Active Transmission Line Right of Way that have grown to an extent that they have encroached upon or will soon encroach upon the clearances listed in the specification. In cases where specified clearances can not be achieved due to Active Transmission Line Right of Way width restrictions, remove branches to prevent entry into the Active Transmission Line Right of Way.

ANSI A300 – Best Management Practices for Tree Care Operations

Transmission Owners have the option of adopting the procedures and practices contained in an industry-recognized ANSI Standard known as A300 for use as a central component of its vegetation management program. The following is a description of A300.

Introduction

Integrated Vegetation Management (IVM) is a best management practice conveyed in the American National Standard for Tree Care Operations, Part 7 (ANSI 2006) and the International Society of Arboriculture's *Best Management Practices: Integrated Vegetation Management* (Miller 2007). IVM is consistent with the requirements in FAC-003-02, and it provides practitioners with what industry experts consider to be the most appropriate techniques to apply to electric right-of-way projects in order to exceed those requirements.

IVM is a system of managing plant communities whereby managers set objectives, identify compatible and incompatible vegetation, consider action thresholds, and evaluate, select and implement the most appropriate control method or methods to achieve set objectives. The choice of control method or methods should be based on the environmental impact and anticipated effectiveness, along with site characteristics, security, economics, current land use and other factors.

Planning and Implementation

Best management practices provide a systematic way of planning and implementing a vegetation management program. While designed primarily with transmission systems in mind, it is also applicable to distribution projects. As presented in ANSI A300 part 7 and the ISA best management practices, IVM consists of 6 elements:

1) Set Objectives
2) Evaluate the Site
3) Define Action Thresholds
4) Evaluate and Select Control Methods

5) Implement IVM
6) Monitor Treatment and Quality Assurance

The setting of objectives, defining action thresholds, and evaluating and selecting control methods all require decisions. The planning and implementation process is cyclical and continuous, because vegetation is dynamic and managers must have the flexibility to adjust their plans. Adjustments may be made at each stage as new information becomes available and circumstances evolve.

Set Objectives

Objectives should be clearly defined and documented. Examples of objectives can include promoting safety, preventing outages caused by vegetation growing into electric facilities and minimizing them from trees growing outside the right of way, maintaining regulatory compliance, protecting structures and security, restoring electric service during emergencies, maintaining access and clear lines of sight, protecting the environment, and facilitating cost effectiveness.

Objectives should be based on site factors, such as workload and vegetation type, in addition to human, equipment and financial resources. They will vary from utility to utility and project to project, depending on line voltage and criticality, as well as topographical, environmental, fiscal and political considerations. However, where it is appropriate, the overriding focus should be on environmentally-sound, cost effective control of species that potentially conflict with the electric facility, while promoting compatible, early successional, sustainable plant communities.

Work Load Evaluations

Work-load evaluations are inventories of vegetation that could have a bearing on management objectives. Work load assessments can capture a variety of vegetation characteristics, such as location, height, species, size and condition, hazard status, density and clearance from conductors. Assessments should be conducted considering voltage, conductor sag from ambient temperatures and loading, and the potential influence of wind on line sway.

Evaluations can be comprehensive or point sample, and can be done to obtain information on an entire program or an individual project. Comprehensive evaluations account for vegetation that could potentially affect management objectives, including hazard trees. Program-level comprehensive evaluations can be made of all target vegetation on a system, while project-level evaluations focus on vegetation relevant to a specific job. Comprehensive evaluations provide the advantage of supplying a complete set of data upon which to base management decisions. On the other hand, comprehensive surveys can be impractical for utilities with large numbers of trees, limited human and financial resources, or both.

Point sampling offers an alternative for utilities for which comprehensive inventories are impractical. Point sampling is cost effective, and has a proven track record for reasonable accuracy. A common method involves dividing a management area (a system or project) into equal-sized units and selecting a random sample sufficient to statistically represent the total work quantity. Random selection eliminates the chance of bias on the part of the investigator. Every plant or plant community of interest within each selected area is inventoried, with collected data used to forecast the total workload.

Evaluate and Select Control Methods

Control methods are the process through which managers achieve objectives. The most suitable control method best achieves management objectives at a particular site. Many cases call for a combination of methods. Managers have a variety of controls from which to choose, including manual, mechanical, herbicide and tree growth regulators, biological, and cultural options.

Manual Control Methods

Manual methods employ workers with hand-carried tools, including chainsaws, handsaws, pruning shears and other devices to control incompatible vegetation. The advantage of manual techniques is that they are selective and can be used where others may not be. On the other hand, manual techniques can be inefficient and expensive compared to other methods. If pruning is necessary, it should comply with ANSI A300 Part 1 (ANSI 2001) and ISA best management practices for utility pruning (Kempter 2004).

Mechanical Control Methods

Mechanical controls are done with machines. They are efficient and cost effective, particularly for clearing dense vegetation during initial establishment, or reclaiming neglected or overgrown right of way. On the other hand, mechanical control methods can be non-selective and disturb sensitive sites.

Tree Growth Regulator and Herbicide Control Methods

Tree growth regulators and herbicides are essential for effective vegetation management. Tree growth regulators (TGRs) are designed to reduce growth rates by interfering with natural plant processes. TGRs can be helpful where removals are prohibited or impractical by reducing the growth rates of some fast-growing species.

Herbicides control plants by interfering with specific botanical biochemical pathways. Herbicide use can control individual plants that are prone to re-sprout or sucker after removal. When trees that re-sprout or sucker are removed without herbicide treatment, dense thickets develop, impeding access, swelling workloads, increasing costs, blocking lines-of-site, and deteriorating wildlife habitat. Treating suckering plants allows early successional, compatible species to dominate the right-of-way and out-compete incompatible species, ultimately reducing work.

Cultural Control Methods

Cultural methods modify habitat to discourage incompatible vegetation and establish and manage desirable, early successional plant communities. Cultural methods take advantage of seed banks of native, compatible species lying dormant on site. In the long run, cultural control is the most desirable method where it is applicable.

A cultural control known as cover-type conversion provides a competitive advantage to short-growing, early successional plants, allowing them to thrive and eventually out-compete unwanted tree species for sunlight, essential elements and water. The early successional plant community is relatively stable, tree-resistant and reduces the amount of work, including herbicide application, with each successive treatment.

Wire-Border Zone

The wire-border zone technique is a management philosophy that can be applied through cultural control. W.C. Bramble and W.R. Byrnes developed it in the mid-1980s out of research begun in 1952 on a transmission right-of-way in the Pennsylvania State Game Lands 33 Research and Demonstration project (Yahner and Hutnik (2004).

The wire zone is the section of a utility transmission right-of-way directly under the wires and extending outward about 10 feet on each side. The wire zone is managed to promote a low-growing plant community dominated by grasses, herbs and small shrubs (under 3 feet in height at maturity). The border zone is the remainder of the right-of-way. It is managed to establish small trees and tall shrubs (under 25 feet in height at maturity). When properly managed, diverse, tree-resistant plant communities develop in wire and border zones. The communities not only protect the electric facility and reduce long-term maintenance, but also enhance wildlife habitat, forest ecology and aesthetic values.

Although the wire-border zone is a best practice in many instances, it is not necessarily universally suitable. For example, standard wire-border zone prescriptions may be unnecessary where lines are high off the ground, such as across low valleys or canyons, so the technique can be modified without sacrificing reliability.

One way to accommodate variances in topography is to establish different regions based on wire height. For example, over canyon bottoms or other areas where conductors are 100 feet or more above the ground, only a few trees are likely to be tall enough to conflict with the lines. In those cases, trees that potentially interfere with the transmission lines can be removed selectively on a case-by-case basis.

In areas where the wire is lower, perhaps between 50-100 feet from the ground, a border zone community can be developed throughout the right-of-way. Note that in many cases, conductor attachment points are more than 50 feet off the ground, so a border zone community can be cultivated near structures. Where the line is less than 50 feet off the ground, managers could apply a full wire-border zone prescription.

An environmental advantage of this type of modification is stream protection. Streams often course through the valleys and canyons where lines are likely to be elevated. Leaving timber or border zone communities in canyon bottoms helps shelter this valuable habitat, enabling managers to achieve environmentally sensitive objectives.

Implement IVM

All laws and regulations governing IVM practices and specifications written by qualified vegetation managers must be followed. Integrated vegetation management control methods should be implemented on regular work schedules, which are based on established objectives and completed assessments. Work should progress systematically, using control measures determined to be best for varying conditions at specific locations along a right-of-way. Some considerations used in developing schedules include the importance and type of line, vegetation clearances, work loads, growth rate of predominant vegetation, geography, accessibility, and in some cases, time lapsed since the last scheduled work.

Clearances Following Work

The Transmission Owner should establish and document appropriate minimum clearance distances to be achieved at the time of work. Clearances following work should be sufficient to meet management objectives, including reducing preventing trees from entering the Critical Clearance Zone, electric safety risks, service-reliability threats and cost.

Monitor Treatment and Quality Assurance

An effective program includes documented processes to evaluate results. Evaluations can involve quality assurance while work is underway and after it is completed. Monitoring for quality assurance should begin early to correct any possible miscommunication or misunderstanding on the part of crewmembers. Early and consistent observation and evaluation also provides an opportunity to modify the plan, if need be, in time for a successful outcome.

Utility vegetation management programs should have systems and procedures in place for documenting and verifying that vegetation management work was completed to specifications. Post-control reviews can be comprehensive or based on a statistically representative sample. This final review points back to the first step and the planning process begins again.

Summary

Integrated vegetation management offers a systematic way of planning and implementing a vegetation management program as presented in ANSI A300 Part 7. This methodology enables a program to comply with the NERC *Transmission Vegetation Management Program* standard (FAC-003-2). Managers should select control options to best promote management objectives. Tree-resistant plant communities can be a desirable objective to reduce long-term work loads and costs because, once established, they out-compete incompatible plants. When effectively implemented, IVM is a systematic, preventive strategy that results in site-specific treatments to meet management objectives. A sound program includes documented processes to evaluate results, which should involve both monitoring for quality assurance while work is underway and after it is completed. However, the overriding focus should be on environmentally-sound, cost effective control of species that potentially conflict with the electric facility while promoting compatible, early successional, sustainable plant communities where appropriate.

Vegetation Inspection Frequency

R1.2. *Specify a vegetation inspection frequency of at least once per calendar year that takes into account local* [3] *and environmental factors.*

The transmission vegetation management program shall specify the frequency of inspection. The inspection frequency shall be at least once per calendar year. Transmission Owners should consider factors that could warrant more frequent inspection including growth studies, the need to insure individual fast-growing trees have not encroached into the Critical Clearance Zone, the need to identify excessive spring growth, and the need to identify seasonally occurring hazard trees.

[3] Local factors include treatment cycle, extent and type of treatment, and their relationship to the normal growth rate.

Annual Plans

R1.3. *Require an annual plan that identifies the applicable lines to be maintained and work to be performed during the year. It shall be flexible to adjust to changing conditions and to findings from vegetation inspections. Adjustments to the plan within the year are permissible. The plan shall take into consideration permitting and scheduling requirements from landowners or regulatory authorities. It shall support the objectives of the transmission vegetation management program and use the methodologies outlined in the transmission vegetation management program.*

The work plan is not intended to be a “span-by-span” detailed description of all work to be performed. It is intended to require the Transmission Owner to plan and schedule vegetation work to avoid encroachment into the Critical Clearance Zone.

The reference in the standard to "implement the annual work plan for vegetation management to accomplish the purpose of this standard within the extent of its easement and/or legal rights" is intended to address the importance of maintaining all locations on the Active Transmission Line Right of Way for reliability purposes in lieu of making special exceptions.

- Property owners and other interested parties occasionally request special considerations to leave undesirable vegetation conditions. It is recognized that such considerations must never be allowed to impact reliability.
- These undesirable vegetation conditions require more frequent work or inspections than other locations with similar vegetation threats and similar easement rights which are not subject to the special property requests
- The Transmission Owner's vegetation maintenance work necessary to implement the annual work plan is most effective when performed to the maximum extent allowed by any legal and/or easement rights.
- The Transmission Owner should, therefore, endeavor to maintain its Active Transmission Line Right of Way to the full extent of its legal rights at all times and in all cases.

This approach is superior to incremental management over the long term because it reduces overall encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient at all locations on the Active Transmission Line Right of Way .

Imminent Threat Procedure

> ***R1.4.*** *Require a process or procedure for response to imminent threats of a vegetation related Sustained Outage. The process or procedure shall specify actions which shall include immediate communication of the threat to the Transmission Operator, and may include actions such as a temporary reduction in line Rating, switching lines out of service, or other actions.*

The term "imminent threat" refers to a vegetation condition which is placing the transmission line at a significant risk of a Sustained Outage.

Examples of imminent threats may include vegetation that is rapidly approaching or has encroached within the Critical Clearance Zone or a tall tree which has been uprooted and is leaning precariously toward transmission conductors which could draw an arc when the tree falls. Both cases represent imminent threats due to the high probability that they could cause a Sustained Outage.

Two key elements of an acceptable imminent threat procedure are outlined below:

- Upon discovery of an imminent threat, the operating authority (operating authority refers to personnel with direct responsibility for operating the transmission lines, including but not limited to ordering the de-rating or de-energization of transmission lines) will be notified of the condition so that action (such as temporary reduction in line Rating, switching the line out of service, etc.) may be taken until the threat is relieved.
- The protocol for contacting the operating authority should be defined. For example, some Transmission Owners' processes may require a call directly to the operating authority, while other Transmission Owners may require a call to a supervisor or field forester. The process should be explicit for the expectations of actions upon the individual discovering the imminent threat.

The urgency of addressing imminent threats may be contrasted with the longer time frames of corrective action plans which are developed from a corrective action process as defined in R1.5. The communication of imminent threats should typically be done in a matter of minutes or hours, whereas corrective action plans may require months or years (see requirement R1.5).

All serious conditions are not necessarily considered as imminent threats under the Standard. For example, Transmission Owners may assign a high priority to the removal of trees that have been designated for removal under a danger tree identification program, but not yet encroached within the Critical Clearance Zone. These trees are not considered imminent threats under the Standard because there is not a high probability that they will grow sufficiently before treatment to encroach into the Critical Clearance Zone or immediately fall and subsequently cause a Sustained Outage.

Some encroachments may be found within the Critical Clearance Zone at a time when there exists sufficient safety clearance distance from the conductors to allow their safe removal. If so their removal may not require switching the line out of service, de-rating the line temporarily or other actions.

Interim Corrective Action Process

> ***R1.5.*** *Specify an interim corrective action process for use when the Transmission Owner is constrained from performing vegetation maintenance as planned.*

Each Transmission Owner is required to specify an interim corrective action process in its transmission vegetation management program. The purpose of this sub-part is to ensure that Transmission Owners have in place a process to develop a corrective action plan that identifies and mitigates risk to the reliability of transmission lines when the Transmission Owner is constrained from performing vegetation maintenance work as planned.

Constraints to performing vegetation maintenance work as planned could result from legal injunctions filed by property owners, the discovery of easement stipulations which limit the Transmission Owner's rights, or other circumstances. The Standard recognizes that numerous circumstances resulting in work constraints can occur, and that numerous ways to identify and mitigate the associated risks to line reliability can be developed. Thus, the requirement is such that the Transmission Owner must specify a general, flexible corrective action process which provides a framework that can be applied over a wide range of situations to ensure line reliability.

A general interim corrective action process may include the following steps:

- Determine and understand the constraint
- Determine the degree of risk to line reliability due to the constraint
- Determine a specific interim corrective action plan to mitigate the risk
- If applicable, determine the time frame for the corrective action plan to be in effect

Implement Imminent Threat Procedure

R2. *Each Transmission Owner shall implement its imminent threat procedure when the Transmission Owner has knowledge, obtained through normal operating practices or notification from others, that the Critical Clearance Zone is approached by vegetation to prevent an encroachment of the Critical Clearance Zone.*

Determining Clearance Distances for Vegetation near Transmission Lines

A vital component of an effective vegetation management program is maintaining an adequate distance between energized transmission line conductors and vegetation. Maintaining a minimum separation can prevent inadvertent Sustained Outages caused by direct contact of the conductors and the vegetation or sparkover between the conductors and the vegetation.

The Gallet Equation is a well known method of computing the required strike distance for proper insulation coordination, and has the ability to take into account various air gap geometries, as well as non-standard atmospheric conditions. When the Gallet Equation and conservative probabilistic methods are combined, i.e. deterministic design, sparkover probabilities of 10^{-6} or less are achieved. This approach is well known for its conservatism and was used to design the first 500 kV and 765 kV lines in North America [1]. Thus, the deterministic design approach using the Gallet Equation is used for the standard to compute the minimum strike distance between transmission lines and the vegetation that may be present in or along the transmission corridor.

Method Explanation (Gallet Equation)

In 1975 G. Gallet published a benchmark paper that provided a method to compute the critical flashover voltage (CFO) of various air gap geometries [4]. The Gallet Equation uses various “gap factors” to take into account various air gap geometries. Various gap factor values are provided in [1]. If the vegetation in a transmission corridor, e.g. a tree, is assumed electrically to be a large structure then the CFO of such an air gap geometry can be computed for dry or wet conditions using a well established equation proposed by Gallet [1],[2],[4],

$$CFO_A = k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} \qquad (1)$$

where,

k_w is defined as the factor that takes into account wet or dry conditions (dry = 1.0 and wet = 0.96) and phase arrangement (multiply by 1.08 for outside phase), e.g. outside phase and wet conditions = (0.96)(1.08) = 1.037,

k_g is defined as the gap factor (1.3 for conductor to large structure),

D	is the strike distance (m),
CFO_A	is the CFO for the relative air density (kV).
δ	is defined as the relative air density and is approximately equal to (2) where A is the altitude in km,

$$\delta = e^{-\frac{A}{8.6}} \tag{2}$$

$$m = 1.25G_0\left(G_0 - 0.2\right) \tag{3}$$

$$G_0 = \frac{CFO_s}{500 \cdot D} \tag{4}$$

$$CFO_s = k_w \cdot k_g \cdot \frac{3400}{1 + \frac{8}{D}} \tag{5}$$

where CFO_S is the CFO for standard atmospheric conditions (kV). Using (1)-(5), the required CFO_A can be computed using an iterative process.

Once the CFO_A is known, deterministic methods can be used to determine the required clearance distance. If we let the maximum switching overvoltage be equal to the withstand voltage of the air gap (CFO_A - 3σ) then the CFO_A can be written as (6).

$$CFO_A = \frac{V_m}{1 - 3\left(\frac{\sigma}{CFO_A}\right)} \tag{6}$$

where

V_m is equal to the maximum switching overvoltage, i.e. the value that has a 0.135% chance of being exceeded,

σ is the standard deviation of the air gap insulation,

CFO_A is the critical flashover voltage of the air gap insulation under non-standard atmospheric conditions.

The ratio of σ to the CFO_A given in (6) can be assumed to be 0.05 (5%) [1]. Thus, (6) can be written as (7).

$$CFO_A = \frac{V_m}{0.85} \tag{7}$$

Substituting (7) into (1) we arrive at (8).

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1 + \frac{8}{D}} \tag{8}$$

Equation 8 relates the maximum transient overvoltage, V_m, to the air gap distance, D. Using (8) to compute the required clearance distance for the specified air gap geometry (conductor to large structure) results in a probability of flashover in the range of 10^{-6}.

Transient Overvoltage

In general, the worst case transient overvoltages occurring on a transmission line are caused by energizing or re-energizing the line with the latter being the extreme case if trapped charge is present. The intent of FAC-003 is to keep a transmission line that is *in service* from becoming de-energized (i.e. tripped out) due to sparkover from the line conductor to nearby vegetation. Thus, the worst case scenarios that are typically analyzed for insulation coordination purposes (e.g. line energization and re-energization) can be ignored. For the purposes of FAC-003-2, the worst case transient overvoltage then becomes the maximum value that can occur with the line energized. Determining a realistic value of transient overvoltage for this situation is difficult because the maximum transient overvoltage factors listed in the literature are based on a switching operation of the line in question. In other words, these maximum overvoltage values (e.g. the values listed in [2], [3] and [5]) are based on the assumption that the subject line is being energized, re-energized or de-energized. These operations, by their very nature, will create the largest transient overvoltages. Typical values of transient overvoltages of in-service lines, as such, are not readily available in the literature because the resulting level of overvoltage is negligible compared with the maximum (e.g. re-energizing a transmission line with trapped charge). A conservative value for the maximum transient overvoltage that can occur anywhere along the length of an in-service ac line is approximately 2.0 p.u.[2]. This value is a conservative estimate of the transient overvoltage that is created at the point of application (e.g. a substation) by switching a capacitor bank without a pre-insertion device (e.g. closing resistors). At voltage levels where capacitor banks are not very common (e.g. 362 kV), the maximum transient overvoltage of an “in-service” ac line are created by fault initiation on adjacent ac lines and shunt reactor bank switching. These transient voltages are usually 1.5 p.u. or less [2]. It is well known that these theoretical transient overvoltages will not be experienced at locations remote from the bus at which they were created; however, in order to be conservative, it will be assumed that all nearby ac lines are subjected to this same level of overvoltage. Thus, a maximum transient overvoltage factor of 2.0 p.u. for 242 kV and below and 1.4 p.u. for ac transmission lines 362 kV and above is used to compute the required clearance distances for vegetation management purposes.

The overvoltage characteristics of dc transmission lines vary somewhat from their ac counterparts. The referenced empirically derived transient overvoltage factor used to calculate the minimum clearance distances from dc transmission lines to vegetation for the purpose of FAC-003-2 will be 1.8 p.u.[3].

Example Calculation

An example calculation is presented below using the proposed method of computing the vegetation clearance distances. It is assumed that the line in question has a maximum operating voltage of 550 kV_{rms} line-to-line. Using a per unit transient overvoltage factor of 1.4, the result is a peak transient voltage of 629 kV_{crest}. It is further assumed that the line in question operates at a maximum altitude of 7000 feet (2.134 km) above sea level.

The required withstand voltage of the air gap must be equal to or greater than 629 kV_{crest}. Since the altitude is above sea level, (1) - (5) have to be iterated on to achieve the desired result. Equation (9) can be used as an initial guess for the clearance distance.

$$D_i = \frac{8}{\dfrac{3400 \cdot k_w \cdot k_g}{\left(\dfrac{V_m}{0.85}\right)} - 1} \tag{9}$$

For our case here, V_m is equal to 629 kV, k_w = 1.037 and k_g = 1.3. Thus,

$$D_i = \frac{8}{\dfrac{3400 \cdot k_w \cdot k_g}{\left(\dfrac{V_m}{0.85}\right)} - 1} = \frac{8}{\dfrac{3400 \cdot 1.037 \cdot 1.3}{\left(\dfrac{629}{0.85}\right)} - 1} = 1.535m \tag{10}$$

Using (2)-(5) and (8) the withstand voltage of the air gap is next computed. This value will then be compared to the maximum transient overvoltage.

$$CFO_S = k_w \cdot k_g \cdot \frac{3400}{1 + \dfrac{8}{D}} = 1.037 \cdot 1.3 \cdot \frac{3400}{1 + \dfrac{8}{1.535}} = 737.7kV \tag{11}$$

$$\delta = e^{-\frac{A}{8.6}} = e^{-\frac{2.134}{8.6}} = 0.78 \tag{12}$$

$$G_O = \frac{CFO_S}{500 \cdot D} = \frac{737.7}{(500) \cdot (1.535)} = 0.961 \tag{13}$$

$$m = 1.25 \cdot G_O (G_O - 0.2) = 1.25 \cdot 0.961(0.961 - 0.2) = 0.915 \tag{14}$$

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1 + \dfrac{8}{D}} = (0.85)(1.037)(1.3)(0.78)^{0.915} \left(\frac{3400}{1 + \dfrac{8}{1.535}} \right) = 499.8kV \tag{15}$$

The calculated V_m is less than 629 kV; thus, the clearance distance must be increased. A few iterations using (2)-(5) and (8) are required until the computed $V_m \geq$ 629 kV. For this case it was found that D = 1.978 m (6.49 feet) yielded V_m = 629.3 kV. Using this clearance distance the following values were computed for the final iteration.

$$CFO_S = k_w \cdot k_g \cdot \frac{3400}{1 + \dfrac{8}{D}} = 1.037 \cdot 1.3 \cdot \frac{3400}{1 + \dfrac{8}{1.978}} = 908.5kV \tag{16}$$

$$\delta = e^{-\frac{A}{8.6}} = e^{-\frac{2.134}{8.6}} = 0.78 \tag{17}$$

$$G_O = \frac{CFO_S}{500 \cdot D} = \frac{908.5}{(500)\cdot(1.978)} = 0.919 \tag{18}$$

$$m = 1.25 \cdot G_O(G_O - 0.2) = 1.25 \cdot 0.919(0.919 - 0.2) = 0.825 \tag{19}$$

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} = (0.85)(1.037)(1.3)(0.78)^{0.825}\left(\frac{3400}{1+\frac{8}{1.978}}\right) = 629.3kV \tag{20}$$

Therefore, the minimum vegetation clearance distance for a maximum line to line ac operating voltage of 550 kV at 7000 feet above sea level is 1.978 m (6.49 feet). Table I provides calculated distances for various altitudes and maximum system operating ac voltages.

TABLE I — Minimum Vegetation Clearance Distances
For Alternating Current Voltages

1500	16.55ft (5.04m)	16.9ft (5.15m)	17.27ft (5.26m)	17.62ft (5.37m)	17.97ft (5.48m)
1200	12.3ft (3.75m)	12.62ft (3.85m)	12.92ft (3.94m)	13.24ft (4.04m)	(13.54ft 4.13m)
1000	9.82ft (2.99m)	10.1ft (3.08m)	10.38ft (3.16m)	10.65ft (3.25m)	10.92ft (3.33m)
800	6.15ft (1.87m)	6.36ft (1.94m)	6.57ft (2.00m)	6.77ft (2.06m)	6.98ft (2.13m)
500	4.5ft (1.37m)	4.66ft (1.42m)	4.83ft (1.47m)	5ft (1.52m)	5.17ft (1.58m)

Critical Clearance Zone

The best management practice for the Transmission Owner is to always exercise its maximum legal rights with regards to Active Transmission Line Right of Way vegetation clearing work. Doing so minimizes the possibility of incurring any conflicts between energized conductors and vegetation. Since this is not always possible, Table I in FAC-003-2 identifies the minimum radial distances, derived using the Gallet equations, which are required to prevent a flashover (sparkover) at the corresponding line voltage ratings.

The minimum radial distance values in Table I represent a radial zone (or shell) around a conductor within which there is a high probability that a flashover event will occur. However, the minimum radial distance concept should not be mistaken to suggest that a static condition is being managed; in fact, the reality is a very dynamic situation. The use of the Critical Clearance Zone concept as set forth by the Standard attempts to simplify and address this complex dynamic management requirement to aid in field applications.

The conductor's position in space at any point in time is continuously changing as a reaction to a number of different loading variables affecting the conductor's movement within each line span. Changes in vertical and horizontal conductor positioning are the result of thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation. Physical loading applied to the conductor affects sag and swing by combining physical factors such as ice and wind loading.

As a consequence of these loading variables, the conductor's position in space is dynamic and continuously moving. Over some period of time, the conductor will ultimately pass through all possible positions it can occupy in space. This full range of positions can be thought of as the conductor's "flight path".

As the conductor moves throughout its flight path, the minimum clearance shell surrounding the conductor obviously moves with it. Therefore, this shell also maps out an area in space called the "Critical Clearance Zone". Any conductive item (such as a tree) that has encroached within this Critical Clearance Zone has the potential to cause flashover when the conductor enters a corresponding location in its flight path.

The shape and size of the Critical Clearance Zone around the conductor is irregular and will change depending on where a conductor segment is located within the span. At mid-span, where the potential for conductor movement is the greatest due to sag and wind deflection, the corresponding Critical Clearance Zone is also the largest and most irregular. Conversely, the Critical Clearance Zone is at its smallest near the conductor attachment to the transmission line structure insulator assembly. In the most extreme case, the Critical Clearance Zone again becomes a simple radial circle at a rigidly fixed insulator attachment point such as with a V-string or standoff insulator type of installation. Figures 4 through 7 below demonstrate these concepts.

With the size, shape and area of the Critical Clearance Zone dramatically changing as one progresses along a span, identifying the precise location and boundary of the Critical Clearance Zone around the conductor in the field becomes very problematic. First, all the variables involved make it very complicated and difficult to calculate the exact shape and size of the Critical Clearance Zone at any particular location in any one, and ultimately all, of the many spans of a transmission line. Second, at the time of field measurement, it is very difficult to precisely know where the conductor is within its wide range of all possible flight path positions.

Therefore, even if the exact size and shape of the Critical Clearance Zone is known, it becomes nearly impossible to field correlate and accurately "superimpose" the Critical Clearance Zone around the conductor.

There are also operational adjustments that must be made to the Critical Clearance Zone as well when managing vegetation. When transmission lines are initially designed, basic engineering assumptions and calculations are made with regard to the maximum environmental and physical forces to which the facility will be exposed as well as anticipated electrical loads. Again, these assumptions include the consideration of things like the maximum wind and ice loading, thermal heating and dissipation, span lengths, conductor strength, associated stringing and sagging conditions, etc. All of these design considerations are combined to define the anticipated "design flight path" for the conductor within each span. However, transmission facilities are not always available to be operated at their full Rating for numerous reasons. For example, transmission facilities can sometimes be built to a higher design voltage than they are currently operated at to reserve capacity that will be utilized with other future system upgrades. Consequently in cases such as these that do not subject a facility to its maximum design capacity, the "operational flight path" of the conductor can be anticipated to be somewhat smaller than the full range of the "designed flight path". Subsequent decisions regarding vegetation management, therefore, need only be made with regard to ensuring the integrity of the actual anticipated operational flight path for the conductor.

Given all of the complicated considerations outlined above, vegetation management around near the Critical Clearance Zone can be very challenging. It is important that the full conductor flight path, within the appropriate limits defined by the lesser of the design parameters or the operational constraints for the line, be available at all times to accommodate the full range of power system operational requirements. Even with the best planning and execution of the vegetation management program, including the use of frequent inspections, vegetation can still unintentionally approach or even encroach into the Critical Clearance Zone without a Transmission Owner's immediate awareness. Such an event does not always result in a flashover if the conductor is not simultaneously occupying that same area of the Critical Clearance Zone. An example of this would be when the conductor is not currently being blown to the extreme edge of its designed flight path from a maximum anticipated wind loading event. However, in such a case it is imperative - and required by the Standard - that the Transmission Owner's Imminent Threat process be implemented immediately upon discovery to correct the approaching or encroaching situation. Failure to do so is a violation of Requirement R2 of the standard.

An accurate representation of the Critical Clearance Zone in the field, correctly positioned around the conductor, is critically important if the Critical Clearance Zone is to be used as an essential parameter for vegetation management and Standards regulation. Because of all of the variables and difficulties in determining the Critical Clearance Zone, as well as the consequences associated with Requirement R4 for failure to maintain Critical Clearance Zone clearances, it is anticipated and expected that Transmission Owners will manage vegetation at distances greater than the Critical Clearance Zone. Given the variation of the Critical Clearance Zone's size and shape at various locations along the line span, it is anticipated that many Transmission Owners will establish a work trigger well outside the Critical Clearance Zone.

Further, to ensure adequate field monitoring and detection of incompatible vegetation conditions, Standard FAC 003-2 requires inspections on a frequency that is appropriate to verify and ensure there are no undiscovered Critical Clearance Zone approaches or encroachments. The anticipated growth rates of the vegetation surveyed in relationship to its speed of approach and distance from the Critical Clearance Zone is a very important consideration during inspection. At a minimum, the inspection frequency can not be less than once per year.

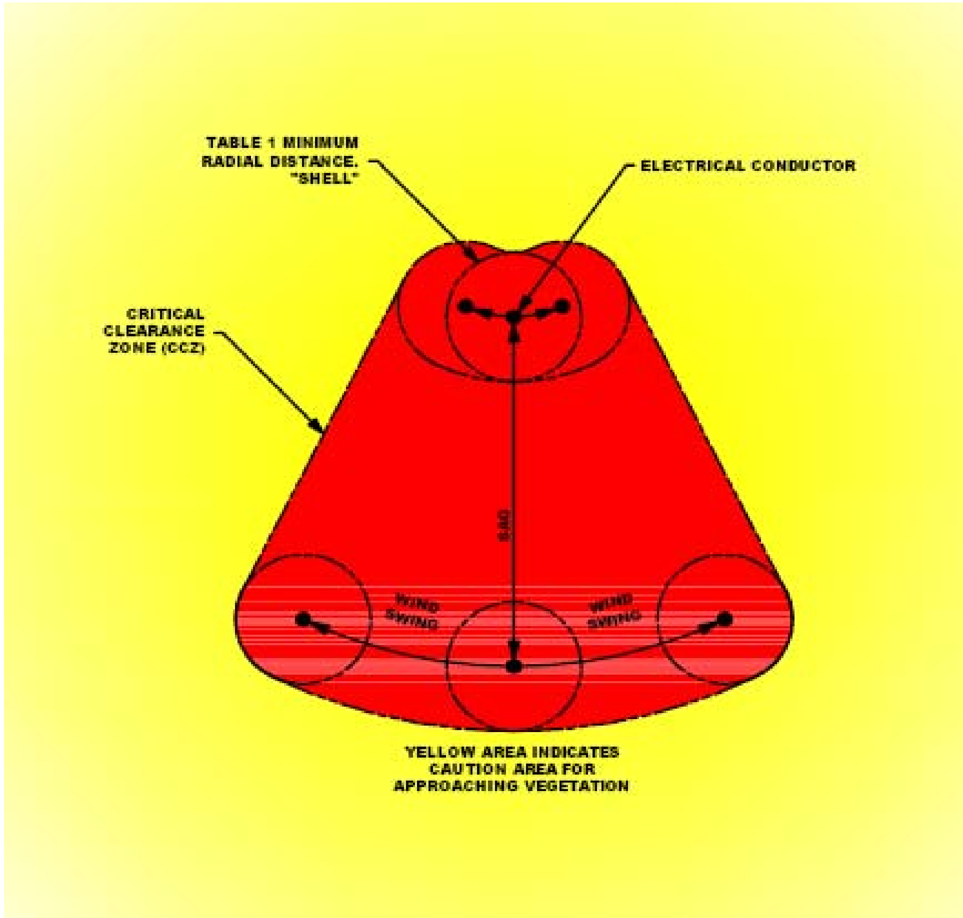

Figure 4

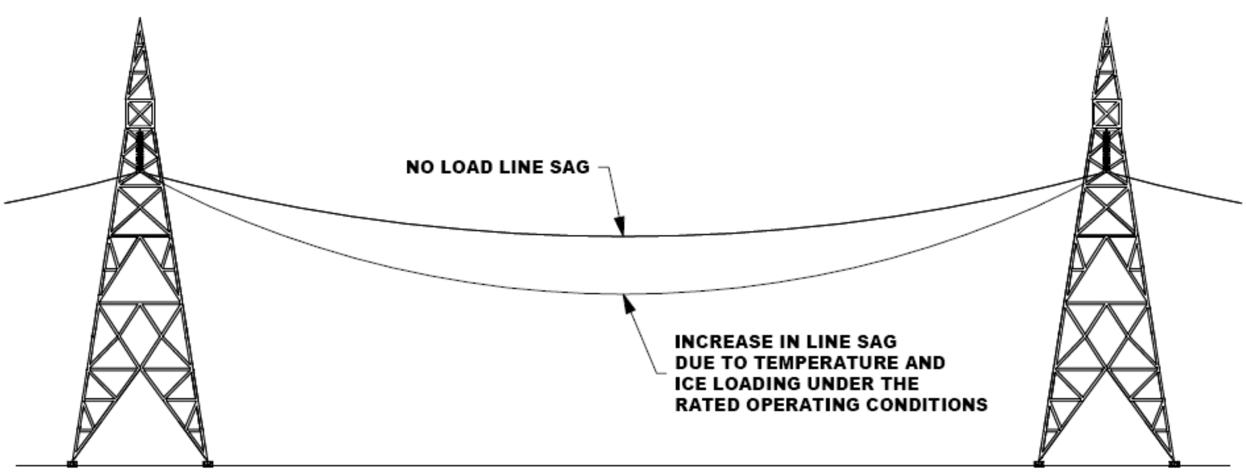

Figure 5

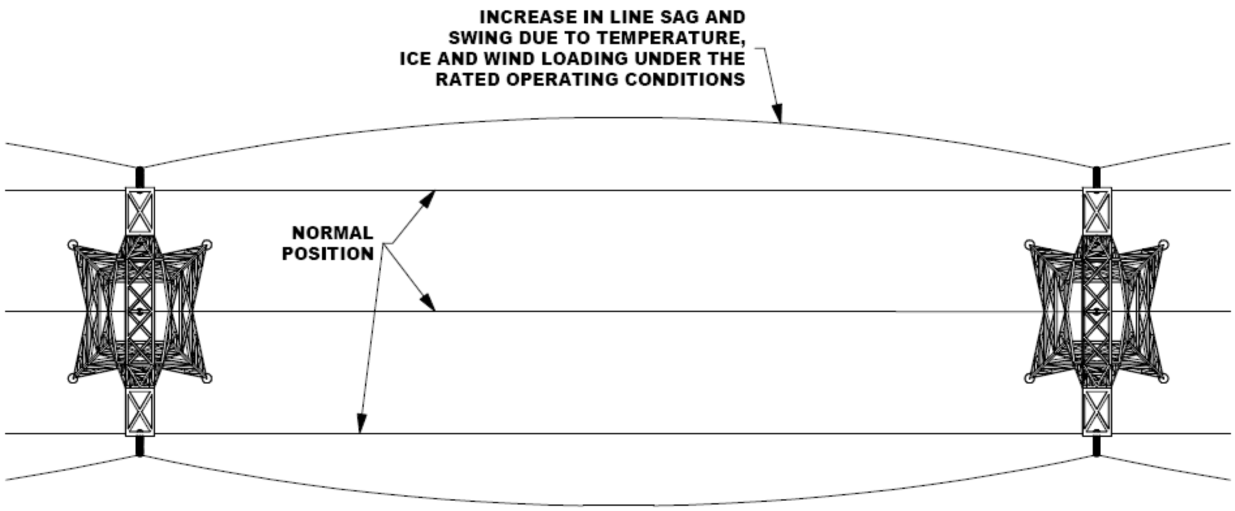

Figure 6

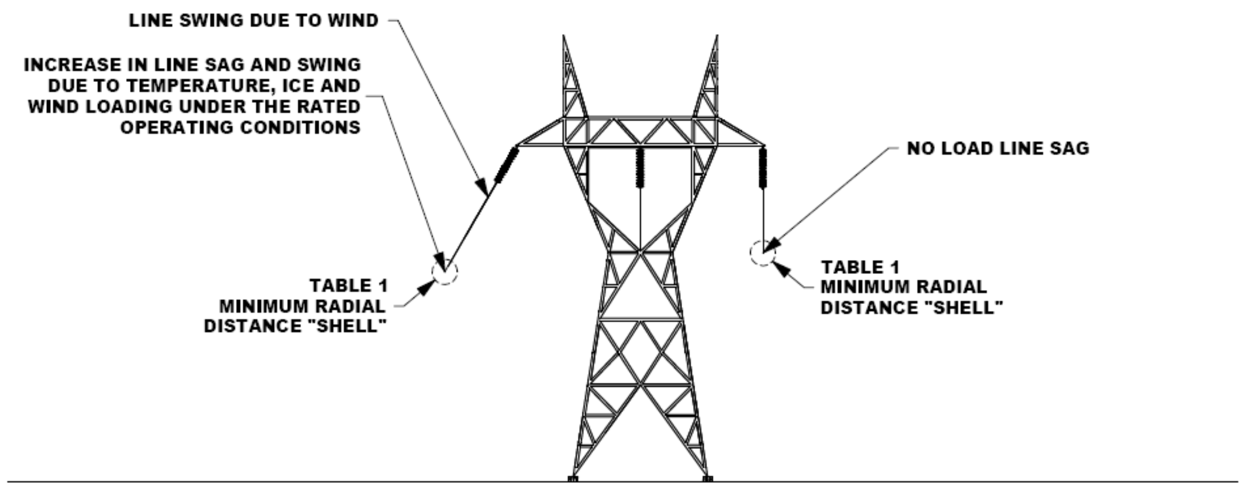

Figure 7

Conduct Vegetation Inspections

R3. *Each Transmission Owner shall conduct inspections of all applicable lines in accordance with the frequency specified in its transmission vegetation management program.*

The Requirement is self explanatory and no additional information is necessary.

Encroachments within Critical Clearance Zone

R4. *Each Transmission Owner shall prevent encroachments within the Critical Clearance Zone of its applicable transmission lines with the following exceptions:*
1. Encroachments of the Critical Clearance Zone that result from natural disasters[4]
2. Encroachments of the Critical Clearance Zone that result from human or animal activity[5]

The presence of vegetation in the Critical Clearance Zone presents a state of reduced transmission system reliability and is a violation of Requirement R4. A Critical Clearance Zone encroachment incident is defined as the presence in the Critical Clearance Zone of vegetation from a single tree, or a group of trees or vegetation in a single span or adjacent spans. The exposure to Critical Clearance Zone encroachment incidents varies widely among transmission systems owned by large and small Transmission Owners.

[4] Examples include, but are not limited to, earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods.

[5]Examples include, but are not limited to, logging, animal severing tree, vehicle contact with tree, arboricultural activities or horticultural or agricultural activities, or removal or digging of vegetation.

Sustained Outages— Vegetation Growth

> ***R5.*** *Each Transmission Owner shall prevent Sustained Outages of applicable lines*[6] *due to vegetation growing into a conductor operating between no load and its Rating with the following exceptions:*
>
> 1. *Sustained Outages of applicable lines that result from natural disasters.*
> 2. *Sustained Outages of applicable lines that result from human or animal activity.*

The most significant vegetation related reliability risk to the transmission system involves Sustained Outages due to vegetation growing into transmission lines. This is commonly referred to as a grow-in or sag-in. These events could lead to widespread cascading failures, such as the August 10, 1996 West Coast Blackout and the August 14, 2003 US-Canada blackout.

These blackouts occurred during the summer months when the transmission system is more vulnerable to cascading events which can lead to blackouts. A review of NERC disturbance reports related to blackouts indicates that most major blackouts attributed to vegetation were caused by grow-in or sag-in events during the summer.

Since grow-in events have historically resulted in several major blackouts the standard recognizes that they present a high risk to the system. Sustained Outages due to sag-ins that occur due to natural disasters are beyond the control of the Transmission Owner. In addition it is often not possible in the aftermath of a natural disaster to do the forensics to determine what happened. Therefore such outages are not considered violations of this requirement.

Sustained Outages due to sag-ins that occur due to human (such as new plantings of tall vegetation, automobile collisions into towers) or animal activity are beyond the control of the Transmission Owner. Therefore such Sustained Outages are not considered violations of this requirement.

The standard recognizes that multiple Sustained Outages on an individual line can be caused by the same vegetation. As such, the Standard recognizes these events as a single Sustained Outage. For example a Sustained Outage could be caused by a tree but be mistakenly attributed to something else (e.g. contaminated insulator string or a different tree). After that situation is addressed the line would be re-energized and would suffer another Sustained Outage from contact with the tree.

Investigations are often hampered by weather conditions, darkness and/or other factors that lead to a misdiagnosis of the cause of the fault as noted in the above example.

[6] Multiple Sustained Outages on an individual line, if caused by the same vegetation, shall be considered as one outage regardless of the actual number of outages within a 24-hour period.

Sustained Outages— Blowing Vegetation

R6. *Each Transmission Owner shall prevent Sustained Outages of applicable lines[6] due to the blowing together of vegetation and a conductor with Active Transmission Line Right of Way (operating within design blow-out conditions) with the following exception:*

1. *Sustained Outages of applicable lines that result from sustained winds or gusts due to natural [4]*

[4]

Unlike grow-ins which are addressed in Requirement R5, a review of NERC disturbance reports related to blackouts indicates major blackouts were rarely if ever attributed to vegetation-related Sustained Outages due to blowing together of vegetation and transmission conductors. These events are known as blow-ins.

The standard recognizes that multiple Sustained Outages on an individual line can be caused by the same vegetation. As such, the Standard considers these multiple events caused by the same vegetation as a single Sustained Outage.

Sustained Outages— Falling Vegetation

R7. *Each Transmission Owner shall prevent Sustained Outages of applicable lines*[6] *due to vegetation falling into a conductor from within an Active Transmission Line Right of Way with the following exceptions:*

1. *Sustained Outages of applicable lines that result from natural disasters.*[4]
2. *Sustained Outages of applicable lines that result from human or animal activity.*[5]

Unlike grow-ins which are addressed in Requirement R5, a review of NERC disturbance reports related to blackouts indicates major blackouts were rarely if ever attributed to vegetation-related Sustained Outages due to vegetation falling into transmission lines. These events are known as fall-ins.

Sustained Outages due to fall-ins resulting from natural disasters are beyond the control of the Transmission Owner. In addition, it is often not possible in the aftermath of a natural disaster to perform the forensics necessary to determine what happened. Therefore, such Sustained Outages are not considered violations of this requirement.

Sustained Outages due to fall-ins that occur due to human or animal activity are beyond the control of the Transmission Owner. Therefore, such Sustained Outages are not considered violations of this requirement.

The Standard recognizes that multiple Sustained Outages on an individual line can be caused by the same vegetation. As such, the Standard recognizes these events as a single Sustained Outage.

Implement Annual Work Plan

R8. *Each Transmission Owner shall implement its annual work plan for vegetation management to accomplish the purpose of this standard within the extent of its easement and/or legal rights.*

This standard requires that the Transmission Owner implement the annual work plan and document this implementation. The annual work plan should allow sufficient time for reasonable procedural requirements to permit work on federal, state, provincial, public, tribal lands, such as permits for National Forest, Department of Transportation work, etc.

This Standard requires that the annual work plan be flexible to allow the Transmission Owner to change priorities during the year as conditions or situations dictate. For example, weather conditions (drought) could make herbicide application ineffective during the plan year. Another situational variance could be a major storm that redirects local resources away from planned maintenance. This situation may also include complying with mutual assistance agreements by moving resources off the Transmission Owner's system to work on another system. Examples of documented adjustments may include deferrals or additions to the annual work plan.

A measure for how this requirement was met may include documentation or other evidence of the work performed. Documentation may consist of signed-off work orders, signed contracts, printouts from work management systems, spreadsheets of planned versus completed work, timesheets, QA work form, paid invoices, etc. to verify that the work has been completed. In addition, documentation of planned work that was deferred or not completed is needed. Documentation of deferred or incomplete work may include the reasons that the planned work was not completed. Where specific work on a line or lines was postponed, the expected completion date of the work may be included, if known. Other evidence may include photographs, inspection reports, walk-throughs, etc.

Designating Sub-200kV Lines

_R9._ *Each Reliability Coordinator in consultation with its Transmission Owner(s) and neighboring Reliability Coordinator(s) shall jointly prepare and keep current, a list of designated applicable lines that are operated below 200kV, if any, which are subject to this standard.*

Requirement R9 assigns to the Reliability Coordinator the task of designating sub-200kV lines that are subject to this standard. It can be seen that this Standard has departed from use of the term “critical” and replaced it with criteria that are more descriptive of the large disturbances this Standard intends to prevent.

The Standard places the responsibility on the Reliability Coordinator for the identification of specific sub-200kV circuits to which the Standard is to be applied. Identification of such sub-200kV circuits is to be done in consultation with the Reliability Coordinator’s Transmission Owners and neighboring Reliability Coordinators.

Reliability Coordinators can offer documentation that they have consulted with their Transmission Owners and neighboring Reliability Coordinators and that they have kept current a list of designated sub-200kV transmission lines that are subject to the Standard. Documentation may include letters, e-mails, spreadsheets, etc.

Documenting Method of Identifying Sub-200kV Lines

R10. *Each Reliability Coordinator shall document its method for assessing the reliability significance of sub-200kV lines considering all of the following:*

R10.1 *Transmission lines whose loss would result in the exceedance of an Interconnection Reliability Operating Limit (IROL)*

R10.2 *Transmission lines whose loss would place the grid at an unacceptable risk of instability, separation, or cascading failures.*

Requirement R10 assigns to the Reliability Coordinator the task of documenting its methods for assessing the reliability significance of sub-200kV lines.

Standards Announcement

Comment Period Open
October 27–November 25, 2008

Now available at:
http://www.nerc.com/filez/standards/Vegetation-Management_Project_2007-07.html

First Draft of FAC-003-2 and Reference Document (Project 2007-07)

The Vegetation Management Standard Drafting Team (Project 2007-07) has posted its first draft of standard FAC-003-2 — Transmission Vegetation Management Program and an associated technical reference document for a 30-day comment period. The comment period is now **open until 8 p.m. on November 25, 2008**.

The drafting team revised the vegetation management standard in accordance with the Standard Authorization Request, which reflects comments from the FERC Order 693 and from stakeholders as well as procedural updates. The compliance elements, which are also part of the Standard Authorization Request, are not included in this initial posting. The drafting team has prepared and posted a technical reference document to supplement the FAC-003-2 standard along with a document comparing FAC-003-1 to FAC-003-2.

Please use this electronic form to submit comments. If you experience any difficulties in using the electronic form, please contact Barbara Bogenrief at 609-452-8060.

The status, purpose, and supporting documents for this project — including an off-line, unofficial copy of the questions listed in the comment form — are posted at the following site:

http://www.nerc.com/filez/standards/Vegetation-Management_Project_2007-7.html

Standards Development Process

The Reliability Standards Development Procedure contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

For more information or assistance, please contact Shaun Streeter,
Standards Program Administrator, at shaun.streeter@nerc.net or at 609.452.8060.

JAMES W. SMITH
ITC HOLDINGS
Disagree
ITC does not agree with the new purpose statement. The NERC Glossary of terms states that the BES â€¦.generally operated at voltages of 100kV or higher and the Applicability in Section 4 clearly states the standard is intended to apply to all line voltages of 200kV and above and those lines designated by the Reliability Coordinator (4.2.1) as being subjected to this standard. Using the term Bulk Electric System (BES) clearly sends a confusing message and should be eliminated. Thus the term of "electric transmission system" is appropriate for the standard
Agree
ITC agrees that the Reliability Coordinator is the appropriate entity to identify and designate any sub - 200kV lines deemed applicable to the standard with the concurrence of the Transmission Owner.

Agree
The standard doesn't actually explain or define the Active Transmission Line Right of Way.
Agree
Agree
Agree
Disagree
Agree & Disagree with the question: Agree with the need to have an Imminent Threat Procedure and upon discovery of an IT, the Transmission Operations (TO) should be notified. We Disagree however, with the requirement as written as its too prescriptive and is open to interpretation, from an audit perspective, with use of the term â€œimmediateâ€□ communication and a partial list of activities that the TO may consider. Decisions on what specific system operating actions that could be taken are beyond the responsibility of the vegetation management personnel. Disagree with the need to implement the imminent threat procedure merely because a CCZ is being approached. It is possible that the CCZ is being approached by vegetation at the lowest point of the CCZ where the conductor may be at its highest point in the CCZ, (potentially 20 or 30 feet from vegetation) and wouldnâ€™t necessitate notification to the TO. Is there a desired distance from the CCZ where this procedure must be implemented since all vegetation within a Right-of-Way will approach the CCZ as it grows? R1.4 should be changed to â€œRequire a process for response to vegetation related imminent threat to applicable lines and not the CCZ
Agree
Agree
Agree
Disagree
Just because vegetation is approaching the CCZ doesn't represent an imminent threat and should not be set to an imminent threat procedure. Implementation of R2 would require field personnel to determine the speculative position of the line during inspections to decide whether to engage the imminent threat procedures. While we agree that an imminent threat procedure should be implemented to address vegetation related imminent threats as soon as they are identified, we believe that an approach of the CCZ should not be used to generate implementation. The term "approached" does not identify a specific distance, so itâ€™s not clear to what extend vegetation would have to approach the CCZ to require implementation of the imminent threat process. ITC agrees that the implementation of an imminent threat procedure may be a valid concept, but visualization of the CCZ and determining approaching vegetation is a practice in hypothetical conductor locations in real time. This may be a good imaginary concept in understanding conductor movement but it's impractical for field applications.
Agree
Agree
Agree
Disagree
First, itâ€™s impossible to determine that no encroachments into the CCZ have occurred at any time and determination of the CCZ from the field perspective is problematic. The standard is ambiguous and it seems like clear cutting is the underlining message that is wanted. Determining an encroachment into the CCZ is problematic due to the need for survey accuracy measurements and engineering evaluations. This will also lead to questions about the ability to audit this requirement.

The CCZ changes in size and shapes continuously in each and every span and will be difficult to monitor. This would require field personnel to spend numerous hours estimating and attempting to measure potential encroachments of the CCZ. The way R4 is currently written the Transmission Owners would be required to self-certify compliance with R4, and which we donâ€™t think this is possible. This will lead to audit issues with more scrutinizing and potentially more penalties or fines. It is important to recognize that the ultimate goal of the standard is to ensure that vegetation management is conducted in order to maintain an adequate level of reliability, and not to precisely measure clearance zones. Alternative 2 would be the most logical choice, depending on easement/legal rights, with changes that would eliminate any reference to a trigger point into the encroachment zone of the CCZ to; measuring encroachment to a fix distance (Gallet tables) observed by field personnel
Agree
Agree
Clarifying the intent for the annual plan is to focus on the Active Rights of Way will prevent interpretation conflicts
V1 was a better written standard and had clear requirements on reporting and who was to report violations etc. When and how are violation to be reported is not mentioned in the V2. The standard should clearly identify all reporting requirements. Standard development should focus on practicality for the field personnel in terms of implementing the standard and enforceability. Version 2 is not as user friendly for field personnel and ambiguous at best which requires an impractical and unrealistic level of performance from the industry. This standard needs to stress that it applies to vegetation within the Active Transmission Right of Way. Vegetation from outside the active ROW, falling through the CCZ should not be a violation. V2 needs further clarification of the definition of the active ROW.

Tennessee Valley Authority
Disagree
TVA feels the use of the term Bulk Electric System will cause unnessesary confusion to the industry concerning applicability of this standard. TVA recommends the continued use of the undefined term "electric transmission systems. TVA recommends changing the phrase "by preventing vegetation-related outages that could lead to Cascading" to "by preventing those vegetation-related outages that could lead to Cascading", this removes the improper inference that each vegetation-related outage leads to Cascading
Agree
TVA agrees with Comment question 2
Agree
TVA agrees with Comment Question 3
Agree
TVA agrees with Comment Question 4
Disagree
TVA suggests that R1.2 be changed by adding "except in cases where lines or significant sections of lines are over terrain which is void of vegetation(such as bodies of deep water)or over terrain void of any vegetation that can grow to a mature height that could threaten the conductors, then longer cycles will be acceptable". This would avoid unecessary expenses in such cases.
Agree
TVA agrees with Comment Question 6 and proposes that the Annual Plan be a defined term.
Disagree
TVA recommends that R1.4 and R2 both be removed from this Standard. This is a "zero tolerance" Standard with significant penalties for outage violations. These penalty conditions are the necessary and sufficient conditions for the Transmission Owner to immediately react to any discovered threats to prevent potential outages.
Agree

TVA agrees with Comment Question 8
Agree
TVA agrees with Comment Question 9
Agree
TVA agrees with Comment Question 10
Disagree
TVA recommends that R2 be removed from this standard. Since this is a "zero tolerance" standard there is a very significant incentive for the Transmission Owner to inspect and plan maintenance to prevent potential outages. The Gallet Equations should be kept within the white paper solely for the TO to reference for developing maintenance and inspection cycles.
Disagree
TVA agrees with this concept however as stated in Comment Question 11 response, this should be an element of the White Paper and should not be in the Standard Requirement.
Disagree
TVA agrees with this concept however as stated in Comment Question 11 response, this should be an element of the White Paper and should not be in the Standard Requirement.
Agree
TVA agrees with Comment Question 14
Disagree
TVA recommends that R4 be removed from this standard. Since this is a "zero tolerance" standard with substantial penalties for controllable vegetation related outages there is an overwhelming incentive for the Transmission Owner to proactively perform inspections, preventative maintenance, inpections and corrective maintenance to prevent potential outages. As such, R4 does not add any value to improving reliablity while causing numerous unresolvable problems.
Agree
TVA agrees with Comment Question 16.
Agree
TVA agrees with Comment Question 17
Group
Associated Electric Cooperative Inc.
John Neagle
Associated Electric Cooperative Inc.
Disagree
The definition of Bulk Electric System includes most transmission lines operated at 100 kv and above. While Section A.4.2.1 limits the applicability of FAC-003-2 to 200 kv and higher transmission lines, the use of the term Bulk Electric System could cause unnessary confusion. Associated Electric Cooperative Inc recommends the continued use of the term "electric transmission systems."
Disagree
Associated Electric Cooperative Inc does not believe the Reliability Coordinator (RC) is the appropriate entity to determine whether or not selected sub-200 kv transmission lines should be subject to this standard. The planning horizon for the RC is typically much shorter than the time needed to incorporate a sub-200 kv transmission line into a vegetation management program. Associated recommends Planning Coordinator be designated as the applicable functional entity and be substituted wherever Reliability Coordinator appears in the Standard.
Disagree
Associated Electric Cooperative Inc agrees with the changes described in Question 3 except for the definition of Active Transmission Line Right of Way. Associated suggests the term be revised to "Active Right-of-Way" for consistency with the present Glossary term "Right-of-Way" and that the definition of Active Right-of-Way be revised to explicitly permit the Transmission Owner to solely determine the appropriate width. A suggested definition is "Active Right-of-Way: The portion of Right-of-Way utilized for active transmission facilities. The width of the Active Right-of-Way, as determined

by the Transmission Owner, shall be consistent with the Transmission Ownerâ€™s normal standards and practices and shall be consistent with good utility practice for other transmission lines of similar voltage and configuration. Inactive or unused portions of the Right-of-Way, intended for future transmission lines or other facilities, may be excluded from the Active Right-of-Way."
Agree
Disagree
While Associated Electric Cooperative Inc agrees with this requirement in general, there may be areas (e.g. highly arid terrain, open water, etc.) where an annual interval is unnecessary and adds little or nothing to reliability.
Agree
Disagree
The language in R1.4, requiring notification of the Transmission Operator, is inconsistent with the Applicability in Section A.4.1.1 which designates the Transmission Owner as the responsible entity.
Agree
Agree
Agree
Disagree
The phrase â€œâ€¦Critical Clearance Zone is approachedâ€¦â€☐ in R2 is nebulous and probably unenforceable. The determination and visualization of the Critical Clearance Zone and approaching vegetation encroachment, under field conditions, is a practice in application of theoretical conductor locations in real time. Would the Transmission Owner be found in noncompliance if evidence showed vegetation had â€œapproachedâ€☐ within 20 feet, 2 feet, 2 inches or some other arbitrary distance of the CCZ and the TO failed to implement its imminent threat procedure?
Agree
Agree
Agree
Disagree
Associated Electric Cooperative Inc believes this requirement, as written, is unreasonable since it would prevent (or at least result in noncompliance) the intrusion within the Critical Clearance Zone (CCZ) of anything or anyone, including qualified line workers and their tools. It is suggested the words â€œof vegetationâ€☐ be added between encroachment and within. The requirement would then read, â€œEach Transmission Owner shall prevent encroachment of vegetation within the Critical Clearance Zone of its applicable lines with the following exceptions:â€☐ The complexity of determining an encroachment into the Critical Clearance Zone is overly burdensome, requiring engineering calculations and possibly the need for precision measurements. The Transmission Owner (TO) cannot demonstrate compliance with the Requirement and its companion Measure, M4, since a negative cannot be proven. Therefore, since the TO must demonstrate compliance (guilty until proven innocent), it is automatically in violation of the Standard.
Disagree
Requirements 5, 6 and 7, as written, compel the Transmission Owner to allocate precious resources to ensuring a vegetation related outage will NEVER occur on any applicable transmission line, regardless of the line's true importance to maintaining electric transmission system reliability. All lines are not created equal; only those which are an IROL or contribute to IROLs should be held to a zero tolerance standard.

Agree
R9 and R10: Associated Electric Cooperative Inc does not believe the Reliability Coordinator (RC) is the appropriate entity to determine whether or not selected sub-200 kv transmission lines should be subject to this standard. The planning horizon for the RC is typically much shorter than the time needed to incorporate a sub-200 kv transmission line into a vegetation management program. Associated recommends Planning Coordinator be designated as the applicable functional entity and be substituted wherever Reliability Coordinator appears in the Standard. M1.4: The language in M1.4, requiring immediate communication of an imminent threat to the Transmission Operator, is inconsistent with the Applicability in Section A.4.1.1 which designates the Transmission Owner as the responsible entity. M4: The preparation and retention of inspection reports, imminent threat reports, quality assurance reports, etc. is appropriate. These reports would not, however, absolutely demonstrate the Transmission Owner had experienced no vegetation encroachments into the Critical Clearance Zone. A negative cannot be proven. M6 and M7: The Transmission Owner is again expected to demonstrate a negative to prove compliance. Section C: Associated Electric Cooperative Inc recognizes the Standard, as posted, is a first draft for comments and will likely be revised before submittal for ballot. However, the Compliance section should be posted for an adequate comment period prior to balloting.

NPCC
Guy Zito
NPCC
Agree
Disagree
While we agree with the suggested changes, we believe that the TVMP should be focused on removal of incompatible vegetation from the Active Right of Way. We recommend using the following phrase in R1: "designed to remove incompatible vegetation on its Active Transmission Lines' Rights 0f Way" instead of "designed to control vegetation on its Active Transmission Lines' Rights of Way". Incompatible vegetation should be defined as any vegetation which has the potential to grow tall enough to jeopardize the integrity of an applicable transmission line by growing into the CCZ or falling into the CCZ. This would provide clear guidance to all stakeholders, support long term vegetation management philosophies, and complement methods such as IVM where incompatible vegetation is completely removed, and compatible vegetation is encouraged to proliferate, thereby helping to control incompatible vegetation in an environmentally positive manner. Removal of incompatible vegetation is superior to pruning, topping, and trimming in terms of short and long term reliability of the Bulk Electric System. This language would also serve to align NERC and FERC with Transmission Owners who attempt achieve the highest degree of reliability by exercising their full easement rights in cases where strong opposition from landowners and public officials is encountered. If such language is adopted it should apply to R1 and the TVMP. It should be made clear in the technical reference document that removal, rather than pruning of incompatible vegetation is the philosophy that must be incorporated into the TVMP. It must be clearly explained that Transmission Owners have the flexibility to perform removals gradually over several treatment cycles in sensitive areas as long as pruning is performed as an interim measure to ensure that CCZ encroachments and on-Right of Way fall overs do not occur. It must also be made clear that the presence of incompatible vegetation on the Right of Way will always occur and does not in itself constitute a violation of the Standard.
Agree
Disagree
There were differing opinions within the group. Those entities with extensive overhead transmission felt the once a year requirement was overly prescriptive and would not improve reliability, others were in agreement with the "at least once per calendar year" requirement.
Disagree

R1.2 and R1.3 should specifically state calendar year, and the Annual Plan and inspection follow the same calendar year timing.
Disagree
While we strongly agree that an imminent threat procedure should be required in the TVMP, we disagree with some specific wording in R1.4. R1.4 requires immediate communication of an imminent threat to the Transmission Operator, which we would normally agree with. R2 however requires that the imminent threat procedure be implemented when the Critical Clearance Zone (CCZ) is approached by vegetation. "Approached" is not defined as a specific distance, so this part of the requirement is left up to the individual's interpretation. In cases where the CCZ is approached by vegetation no threat to the system is possible if the vegetation is removed before it actually grows into the CCZ. In many cases the vegetation can be removed without taking clearance outages because the CCZ is large, and the conductor and vegetation are still relatively far apart. In such cases there is no need to notify the Transmission Operator, although there is a need to remove the vegetation immediately. We recognize that the opposite is also true, and that in some cases it will be necessary to notify the Transmission Operator because a clearance outage or line de-rating may be required to remove the vegetation. We therefore suggest a simple change to the wording of the second sentence of R1.4. Change "â€¦. specify actions which shall include immediate communication of the threat to the Transmission Operator, and may include actions such as a temporary reduction in line Rating, switching lines out of service, or other actions" to "... specify actions which may include immediate communication of the threat to the Transmission Operator, a temporary reduction in line Rating, switching lines out of service, or other actions". This change will address the issue which is described above and will allow each Transmission Operator to develop an imminent threat procedure that best fits their system. It should also be noted that many Transmission Operators have imminent threat procedures in place to address all imminent threats to their transmission system, not just threats due to vegetation. It makes sense for Transmission Owners to have only one imminent threat process, therefore the flexibility that can be achieved in the context of this standard would be helpful.
Agree
Agree
We agree but believe that the TVMP should target removal of all incompatible vegetation on the Active Right of Way as described in the response to question 3.
Agree
Agree
Agree
Agree
Agree
Disagree
The purpose of the standard is "To improve the reliability of the Bulk Electric System by preventing vegetation related outages that could lead to Cascading". We believe that R4 is not the most effective way to achieve this purpose because it does not provide incentive for Transmission Owners to take advantage of modern technology, such as aerial laser survey (ALS) using Light Detection and Ranging technology (LIDAR), that is capable of accurately identifying vegetation which is approaching the CCZ or has encroached into it. In fact R4 provides an incentive not to utilize this technology because Transmission Owners who identify encroachments would be in violation of R4 for each identified encroachment. On the other hand, Transmission Owners who choose to be less proactive often would not identify such encroachments because the CCZ and encroachments of it are generally not easy to determine without taking precise measurements. Unless the line is heavily loaded or the vegetation is significantly overgrown, encroachments of the CCZ would not be readily noticed. In most cases these Transmission Owners would simply remove or cut back incompatible vegetation without taking

measurements. The threat to the line would have been eliminated with no encroachment having been identified. R4 presents a dilemma for Transmission Owners that are considering making the significant investment in ALS technology. While the technology would allow them to identify any potential grow-in or fall-in conditions, it would also expose them to the risk of identifying violations of R4, that would otherwise not have been identified. Violation Risk Factors (VRFs), Violation Severity Levels (VSLs), and Time Horizons are not included in this Draft, but after making a significant investment in ALS, Transmission Owners could be faced with significant additional cost in terms of NERC penalties. In addition, even if the penalties were relatively low they would be exposing themselves to violations that less proactive Transmission Owners would not be exposed to. In our view R4 as written would, in some cases, have the opposite effect of what is intended because the business case for using ALS is more difficult to make. This will result in less use of ALS and other emerging technology that is likely to be developed. This would result in fewer problems being identified, a small percentage of which will not be discovered until they result in a line trip. Still we believe that the concept of the CCZ is a good one and recommend that R4 be changed so that Transmission Owners are provided with an incentive to invest in the best technology available in order to ensure the highest level of reliability. The opportunity exists to develop the standard in a manner that encourages the industry to take advantage of new technology and manage vegetation in a very proactive way. We recommend that R4 be changed as follows: Modify R4 to require Transmission Owners to immediately implement the imminent threat process defined in R1.4 when they identify instances where the CCZ is approached or encroached upon. Failure to do so would be a violation of R4. Eliminate encroachment of the CCZ as a violation of R4. This would eliminate R2 and incorporate implementation of the imminent threat process into R4. Require Transmission Owners to report to the Regional Entity on a quartely basis any instances where the imminent threat process was implemented due to an encroachment of the CCZ. This would add a reporting requirement for Transmission Operators. Require Transmission Owners to report to the Regional Entity on a quarterly basis any instances where either a momentary or sustained outage was caused by grow-ins, Active Transmission Line Right of Way blow-ins, or Active Transmission Line Right-of-Way fall-ins. This would add three additional reporting requirements for Transmission Operators. Require Regional Entities to perform additional audits of Transmission Owners that exceed metrics for violations of the CCZ . The metrics would be established in this Standard based upon 100 circuit miles of applicable lines. This would add an additional requirement for Regional Entites. This concept would result in a more rigorous standard than FAC-003-01 because of the additional reporting and auditing requirements. It would drive proactive behavior throughout the industry and provide a significant incentive for Transmisison Owners to invest in new technology such as ALS that is capable of accurately identifying vegetation that has approached or encroached upon the CCZ. We believe that this change would result in the identification of more incipient vegetation-related problems and fewer vegetation-related outages as soon as it was implemented and would best support the purpose of the Standard.
Disagree
NPCC participating members request clarification if violations of R5, R6, and R7 result in outages that must be reported.
Agree
NPCC requests that the Standard Drafting Team review the compliance and reporting requirements for consistency and adequacy.
Individual
Chris Scanlon
Exelon
Agree
Agree
Agree
Agree
Refer to footnotes in R1.1 and 1.2. Are applicable entities to be held accountable to ANSI A300

(footnote 2) and for providing documentation to support analysis that "local factors" were accounted for (footnote 3)? These footnotes should be requirements or they should be removed and included in a Reference Document not subject to compliance audit.
Agree
Agree
Agree
Agree
Disagree
We do not understand the reference to "fill in the blank" requirement for Clearance 1. As commonly understood, a "fill in the blank" standard /requirement is one that was assigned to the RRO. Clearance 1 in FAC-003-1 is a TO requirement. The reference to a clearing zone should be retained, as each TO will need to define this in their program so as to avoid encroachments into the CCZ.
Agree
Agree but same comment as above,we do not understand the reference to "fill in the blank" requirement for R1.3. As commonly understood, a "fill in the blank" standard /requirement is one that was assigned to the RRO.
Disagree
Comments: 1) In spite of the rigor associated with the Gallet equations, the definition of CCZ is imprecise as the Ratings to be used are not specified. In addition, Exelon is concerned that it will be difficult to determine the CCZ for each span under all possible operating conditions. Implementing an imminent threat procedure (R2) in combination with the CCZ may be unworkable under actual field conditions. 2) We are concerned that CCZ is only fully defined in the Technical Reference documentation and not in the standard itself. As stated in the NERC Standards Process Manual, Elements of a Reliability Standard, "Supporting documents to aid in the implementation of a standard may be referenced by the standard but are not part of the standard itself." There needs to be enough specificity as to the definition of CCZ in FAC-003-2 so that adequate documentation and evidence of compliance can be developed.
Disagree
Comments: By using the Gallet equations, the draft standard appears to support reducing the clearance requirements as compared to IEEE 516. Given what we believe would be the difficulties in applying the clearances as developed using the Gallet equation method, we question if dropping the IEEE 516 guidance could have the unintended consequence of reducing reliability.
Disagree
We disagree with the T factors that are proposed as our design is more conservative.
Agree
Disagree
The first bullet is unworkable in the real world. It will be virtually impossible to prove that "no encroachments of the CCZ have occurred anywhere at any time during the compliance period". The effort to do this will not enhance reliability. In fact, in may harm reliability by requiring unnecessary investments and O&M expenditures that could be better spent on real reliability enhancements. Exelon agrees, subject to the development of a workable definition of the CCZ, that the second bullet is the preferred approach.
Disagree
It appears to Exelon that the requirements of the standard have been written and modified at different times and as a result the document lacks a degree of consistency and coherence. While the Standard mentions encroachment of the CCZ and Sustained Outages as potential violations, it is completely silent on how momentary outages should be addressed. Exelon views the following events as a risk continuum that should be addressed in the Standard and handled as a part of the VRFs and

VSLs - encroachment of the air gap distance, momentary outages and Sustained Outages.
Disagree
Strike "within the extent of it's easement and / or legal rights." This is unnecessary and will cause confusion. The annual work plan as required to be developed per R1.3 requires consideration of permitting, scheduling and regulatory limitations.
Applicability. 4.2.2 is unclear. If 4.2.2 is intended to cover Generator Owner interconnections, say so uniquivocally. Do not rely on future changes to the NERC Registry Criteria or other "global" solutions if the intent is to make the standard applicable to Generation Owners who own generator leads. Exelon would like to reemphasize our concern with implementing the requirements if the Gallet equation derived CCZ is used. ANSI A300 part 1 and part 7 should be part of the standard as they provide independently recognized valid methods and guidance to conduct maintenance on the ROW corridor.
Individual
Weston Davis
Central Maine Power Company
Disagree
Central Maine Power suggests that a definition be provided for Bulk Power.
Agree
Agree
Agree
Agree
Agree
Agree
Agree
Disagree
Central Maine Power Company disagrees with removal of clearance 1. The clearance 1 was included so that professional arborists could establish the clearanace necessary for a transmission owner to reduce the risk of a tree caused power outage. The transmission owner should use ANSI- Standard A300, including PART 7, and other publications to develop best management practices which include clearances at time of maintenance. Clearance 1 provides leverage for Transmission Owners to achieve the clearances stated in their TVMP.
Disagree
Central Maine Power Company disagrees with the removal of the qualification statement. The individual responsible for this critical program must be qualified through experience, training, and education. The International Society of Arboriculture has a certification program that can help with guidelines for qualified arborists.
No comment
Agree
Agree
Agree
Disagree
Central Maine Power Company suggests the second alternative to R4 as recommended above, which

is to require immediate removal of the vegetation or immediate implementation of the imminent threat procedure upon discovery of a possible encroachment of the critical clearance zone, thus preventing an outage. This alternative is similar to R2, therfore R4 may not be required.
Agree
Central Maine Power Company suggests that R8 read as A Transmission Owner shall implement its annual work plan within the Active Right of Way to the the extent of its easements or legal rights.
The White paper is an important support document and should remain as an attached reference to FAC 003. The white paper should clarify that capable tree species should always be removed from the border zone, except in selected areas where topography includes deep ravines.
Individual
Thad Ness
American Electric Power (AEP)
Disagree
American Electric Power ("AEP") does not agree with this purpose statement. First, it is clear from the Applicability (in Section 4) that the standard applies only to certain lines, not to the entire Bulk Electric System (BES). Reference to the BES in the Purpose statement tends to muddy the water, potentially leading to an assumption that the Standard indeed applies to the entire BES. AEP suggests that the term BES used herein be replaced with "electric transmission system" or "transmission grid". Second, the phrase "by preventing vegetation-related outages that could lead to Cascading" should be changed to "by preventing those vegetation-related outages that could lead to Cascading", to remove any suggestion that all vegetation-related outages could lead to Cascading.
Agree
AEP concurs with the drafting team that the Reliability Coordinator is the appropriate entity for identifying sub-200kV lines (if any) that would be subject to the Standard.
Agree
While Requirement R1 does not actually define "Active Transmission Line Right of Way" (it is defined on page 2 of the Standard), AEP concurs with R1, except as noted below for R1.4.
Agree
AEP agrees with these changes from Version 1.
Agree
AEP agrees with this change.
Agree
AEP agrees with these changes.
Disagree
AEP agrees with the need for a TO to have an Imminent Threat Procedure and that the Transmission Operator should be immediately notified of imminent threats. However, AEP disagrees with the requirement that the Transmission Operator be notified merely because the Cricitical Clearance Zone (CCZ) has been approached. It is possible that the CCZ is encroached by vegetation at the lowest point of the CCZ whereas the conductor may be at its highest point in the CCZ (potentially 20 or 30 feet away from the vegetation). This situation does not merit notification to the Transmission Operator. Please also refer to our comments regarding CCZ in AEP's responses to Questions 15 and 18.
Agree
Agree
AEP agrees with the removal of Clearance 1 from the Standard.
Agree
AEP agrees that the Standard should not stipulate or require personnel qualifications.
Disagree
AEP agrees with the need for a TO to have an Imminent Threat Procedure and that the Transmission Operator should be immediately notified of imminent threats. However, AEP disagrees with the

requirement that the Transmission Operator be notified merely because the CCZ has been approached. Vegetation approaching the CCZ does not necessarily constitute an imminent threat. It is possible that the CCZ is encroached by vegetation at the lowest point of the CCZ whereas the conductor may be at its highest point in the CCZ (potentially 20 or 30 feet away from the vegetation). This situation does not merit notification to the Transmission Operator. Please also refer to our comments regarding CCZ in AEP's responses to Questions 15 and 18.
Agree
AEP agrees that the Gallet Equation method is a reasonable and appropriate replacement for the IEEE 516 method.
Agree
AEP agrees that the choice of transient overvoltage factors is sufficiently sound.
Agree
AEP agrees with this change.
Disagree
AEP disagrees with the proposed requirement that violations be automatically declared if the CCZ is encroached. Instead, AEP would support a standard utilizing the first alternative proffered in these comment questions. While the CCZ is an interesting theoretical concept, it is not realistically feasible in the field to implement a concept that depends on accurate measurements and calculations. Further, the proposed requirement offends common notions of reliable maintenance methods, because it demands that forestry crews stop work if they see a potential encroachment and that surveyors and engineers be brought in to take detailed measurements and perform complex calculations to determine whether an encroachment has in fact occurred. The need for a reliable transmission grid would be much better served by a standard utilizing the first alternative, in which no violation occurs in the event of an encroachment as long as the TO implements its imminent threat procedure and removes the vegetation. While seemingly technically appealing, the CCZ concept is fraught with implementation difficulties. It should not be used as a Pass/Fail zero-tolerance decision point to determine whether a violation has occurred. After all, a zero-defect condition has not been achieved in many other aspects of electric utility operation. For instance, the utility industry attempts every year to conduct its business without any workplace deaths, yet deaths occur every year. Many millions of dollars are spent by North American utilities to promote safety programs and safe work procedures, but some work-related vehicle accidents and personal injuries still occur. Also, utilities aggressively investigate electric switching errors and have instituted rigorous dispatcher-training programs, but a few switching errors still occur. For an industry in which billions of stems of vegetation must be managed, even a high six-sigma level of quality would still result in a few cases annually of imperfectly managed vegetation. It is unreasonable to expect zero-tolerance perfection with the CCZ concept. Also, with the way R4 is worded, a tree falling from outside the right of way would result in a violation if it passed through the CCZ, whether it resulted in an outage or not. It is not appropriate to place a burden on the TO for such circumstances outside the TO's control. As R4 is written, it appears that there is no way that a TO could certify at the end of the year that it has maintained a CCZ free of encroachments, even if no outages occurred. AEP believes a more effective and reliability-centered approach would be one where TOs are expected to implement their imminent threat procedure if vegetation is encroaching upon the Gallet equation distance. If TOs act accordingly and remove the vegetation without incurring an outage, then they would not be in violation. However, if the TOs knew of vegetation encroaching upon the Gallet equation distance but failed to implement their imminent threat process, they would be in violation and be obliged to report the event.
Agree
AEP is in agreement with these changes.
Agree
AEP agrees with this change.
The definition for Critical Clearance Zone (CCZ) on page 2 of the proposed draft Standard does not specify the Rating (summer, winter, normal, emergency, etc.). This suggests that different CCZs apply at different times of the year and thus that vegetation in the area might be outside the CCZ at certain times of the year and inside the CCZ at other times. AEP suggests that this may not have been the intent of the drafting team. Also, the term "design blowout" is not defined; thus, it appears that it will be up to the TO and the auditor to determine the bounds of the CCZ. AEP again suggests

that this may not have been the intent of the drafting team. Requirement R8 contains the clause "within the extent of its easement and/or legal rights". This intent of this clause is unclear and its rationale is not obvious. AEP suggests that this clause be removed or at least reworded for clarity.

Deborah Schaneman
Platte River Power Authority
Agree
The use of the approved terminology, Bulk Electric System, from the NERC Glossary of Terms is better than the undefined term electric transmission systems.
Agree
The Reliability Coordinator is better able to identify lines under 200 kv that would exceed an Interconnection Reliability Operating Limit (IROL), cause instability, uncontrolled separation, or cascading outages resulting from a vegetation related outage than the Regional Entity.
Agree
The list of terms, "objectives, practices, approved procedures and work specifications," from version 1 provides more clarity thatn the one word "methodology" and should bot be replaced. The newly defined term "active transmission line ROW" provides clarity to the portion of the ROW requiring vegetation management and is a valuable addition to the standard.
Agree
The separation allows lower sanctions and penalties to be assessed for weak documentation and higher sanctions and penalties to be assessed for weak inspection programs and weak vegetation management. However, the standard would be easier to follow if the two elements were kept together in the document.
Agree
The inspection frequency is reasonable.
Agree
Under the new working in R1., the TVMP no longer has a requiremnt to include objectives. However, there is a phrase in R1.3. to "support the objectives... and methodologies outlined in the TVMP". R1.3. should be consistent with the wording in R1.
Agree
Imminent threat is not a defined term in the NERC Glossary of Terms so it could be construed as a fill-in-the-blank requirement by FERC as each Transmission Owner could define Imminent Threat differently. Imminent threat should be defined or the requirement should be reworded to define what types of situations would require a procedure. Also, the language, "and may include actions such as a temporary reduction in line rating, switching lines out of service, or other actions" should be removed from the standard but could be included in the imminent threat procedure or definition.
Agree
The term corrective action plan adds clarity.
Disagree
Clearance 1 could be defined in the standard in tables developed using IEEE Standards for various voltages, line spans and altitudes. Clearance 1 provides justification and leverage for operational clearances when dealing with organizations such as municipalities. Without Clearance 1, utilities could be mandated in specific situations to clear so that the vegetation is just beyond the CCZ at all times. This could result in pruning at six month intervals, which is not feasible or cost-effective.
Agree
The requirement should be removed because it is a "fill-in-the-blank" requirement. Defining the proper amount of personnel qualifications and training would be too prescriptive for utilites with small vegetation management programs and not prescriptive enough for utilities with large vegetation management programs.
Disagree
Changing to the Gallet equation will not have a large impact on vegetation management operations, keeping Clearance 1 and 2 with tables developed using IEEE Standards for various voltages, line spans and altitudes is preferable. Actions should be taken to prevent an outage when vegetation

encroaches Clearance 2.
Agree
Changing this will not have a large impact on vegetation management operations, so we have no concerns.
Agree
Changing this will not have a large impact on vegetation management operations, we have not concerns.
Agree
The separation allows lower sanctions and penalties to be assessd for a weak schedule and higher sanctions and penaltites to be assessed for not implementing schedules. However, we feel that the sandard itself would be easier to follow if it was re-organized so that the requirement to have the schedule is kept together with the requirement to implement it.
Disagree
This requirement should be removed completely. It is too stringent and it is impossible to prove compliance through documentation. Encroachemnt of Clearance 2 (or CCZ) should be addressed in the imminent threat procedure.
Disagree
The requirement under R7 should be changed from "shall prevent sustained outages" to "shall minimize sustained outages due to vegetation falling into a conductor." We note the word "minimize" was present in earlier drafts of the docuement. We are concerned about the requirement for utilities to prevent sustained outages from vegetation falling into the conductor from within the active transmission ROW. It is operationally almost impossible to know precisely where the edge of the ROW is in all situations under all conditions. This could lead to an incident where utilities are charged unreasonably - for example, for an outage from a tree that was one foot within the active ROW line. We should not be held liable when reasonable due diligence is practiced.
Agree
The separation allows lower sanctions and penalities to be assessed for a weak plan and higher santions and penalties to be assessed for not implementing an annual plan. However, we feel that the standard itself would be easier to follow if it was re-organized so that the requirement to have a plan is kept together with teh requirement to implement it.
The white paper ensures consistent interpretation of the standard. Perhaps the lack of such a paper in the first version of the standard contributed to the varying interpretations.

Agree
Agree
Agree
Agree
See Question 6 and 17.
Disagree
While TAL's specific conditions and current process would meet this requirement, I can envision where some conditions may not require an annual inspection. These might include desert conditions, crop fields, over water, etc. To dictate a specific one-year requirement could be burdensome to some utilities with no improvement to the relibility of the BES.
Disagree
While I can agree with a separate requirement (R8) to implement the plan developed in R1.3, they need to both have the flexibility desired in R1.3. I do not see that flexibility in R8. See response to question 17.
Agree
Disagree
The use of the term "interim corrective action" implies that a permanent solution or return to the original plan must be pursued. I would change this to "alternate maintenance" process to prevent non-compliance if the TO is constrained and has reached an agreement with the land owner that

works to maintain the reliability of the line.
Agree
Agree

Agree
Disagree
VEHEMENTLY DISAGREE! The purpose of the standard is to prevent vegetation related outages. A violation should occur if an outage occurs. As written, R4 and M4 would be impossible to prove or disprove. It is not like we can get up there with a tape measure and measure it. R2 requires action if the CCZ is "approached". This is undefined and subject to a myriad of interpretations. Evidence is hard enough to obtain to the satisfaction of the Compliance Monitor. To require sufficient evidence to prove that something didn't occur is a tremendous burden and is not a wise expenditure of vegetation management dollars. Let us spend the money on trimming and not on paperwork. As an alternative replace "encroachment within the Critical Clearance Zone" with "vegetation caused outages". This would allow the same exceptions and is much easier to prove or disprove with a breaker operation. Although this would result in the cause of every breaker operation being tracked, it is a tangible evidence requirement and leaves very little room for interpretation. The levels of fines have already shown that vegetation management is a serious standard and we had better comply.
Agree
Why have we gone backwards with only "Sustained Outages" being a violation? Even a momentary outage indicates that a violation has occured if the cause was vegetation related (with the same exceptions). This would seem to contradict the proposed R4. If it wasn't a Sustained Outage it wasn't a violation? If you have a sustained outage due to vegetation, you must have violated the CCZ.
Disagree
Combined with Question 6. R8 needs to have the same flexibility that R1.3 has. As written, it could be argued that you have to do everything in your annual plan, AND anything in addition due to the changing conditions. This contradicts what is put forth in the white paper. I would add "as modified per R1.3" after "implement it's annual work plan for vegetation management"
Attachment I. Titles are different between page 8 and 9. Page 8 should have (D) after Distances. Page 9 should have indication that it is "continued" since the table spans multiple pages.

Agree
Agree
Disagree
Use of the term "have" is a notable and unnecesssary weakening versus the terms "prepare and keep current". One of the key lessons learned from past vegetation related outages and subsequent investigations and reports is that successful UVM programs must continually adapt to changing circumstances which means practices and procedures must be kept current. Why weaken this expectation in the standard? Also, I disagree with the elimination from the revised standard the present requirement R1 that all TVMPs include certain essential components (objectives, practices, approved procedures & work specifcations). Why make changes that imply TVMP's without these key components are acceptable?
Agree
I agree with the seperation and re-ordering of documenation and implementation requirements into two distinct groups. This is a welcome improvement to the standard.
Agree

Disagree
I disagree with the elimination of the present requirement R2 (last sentence) that requires a TO to have proper quality control (QC) systems and procedures in place to document & track planned UVM work so as to verify it was completed properly to work specifications. The need for this requirement was demonstrated as recently as last year when a grow-in outage occurred at BG&E due to a contractor trimming the wrong tree at the wrong location, a situation that could have been prevented with effective QC.
Agree
Disagree
The existing R1.4 is focused on identifying where vegetation clearance objectives cannot be met at the time UVM work is performed due to restrictions outside of the TO's immediate control. The proposed revised standard is focused on situations where work scheduled in the annual plan cannot be performed as planned for any reason. Can a constraint on planned work be internal such as budget related? Why bother with a corrective process for constrained planned work if the work not completed as planned poses no risk of causing an outage? I stongly believe that the sole focus of this provision must specifically address individual locations where, due to restrictions outside of the TO owner's control, vegetation clearances specified in the TVMP cannot be obtained. This section of the standard should be about trees being closer to conductors than they should be due to factors beyond the TO's control, rather than whether or not planned work was performed.
Disagree
I am strongly opposed to the removal of Clearance 1 from the standard. Being able to point to this provision has been invaluable to internal communications with upper management and external discussions with land owners and the public concerning UVM. In fact, other than the patrol/inspection requirements, no other provision in the standard has been as essential to preventing grow-in tree contacts than Clearance 1. It has forced TO's across the country to re-claim overgrown ROW and re-commit to consistent UVM practices. We all know how easy it is for TO's to get weak in the knees in the face of public opposition to proper and prudent UVM work even when it is clear what needs to be done. This dynamic is what led us to the 2003 blackout to begin with. I would like to see the drafting team consider expanding upon the existing model and create three clearances: 1. A clearance at the time work is performed, 2. An action threshold clearance which would trigger the TO would take immediate action to clear encroaching vegetation posing an unacceptable outage risk, and 3. A no closer than clearance in which vegetation would never be allowed to encroach in order to prevent flashover.
Disagree
If the standard continues to allow T.O.'s to design and implement their own TVMPs and expect them to use BMPs, ANSI A300, develop menthods and practices, adapt schedules and plans to changing conditions, etc., then it is reasonable to expect that T.O. personnel responsible for the TVMP to be experts in the field of utility vegetation management with appropriate training, certifications, licenses and credentials. I do not agree with eliminating this requirement. Quite the opposite, I believe that the requirement needs to be more specific as to minimum qualifications key personnel must meet. There are more requirements & qualifications to drive a semi-truck than to design and implement a program (UVM) critical to the operation of the nation's electric grid. Does that make sense?
Disagree
While I agree with the argument that the Gallet equatiion is a better technical or scientific method than IEEE 516 for determining realistic conductor to tree flashover distances, I do not agree that the new proposed clearance tables serve any useful purpose as a vegetation clearance standard from an operational perspective. The FAC-003-2 Technical Reference itself points to this fact when it states, "even if the exact size and shape of the C.C.Z. is known, it becomes nearly impossible in the field to correlate and accurately superimpose the C.C.Z. around the conductor." The Tech. Ref. goes on to say that "it is anticipated that many T.O.s will establish a work trigger well outside the C.C.Z." I agree wholeheartedly with that concept and believe that the Gallet clearance tables should be used by TO's to develop the more important "work trigger" or "action threshhold" clearances. This revision is overly focused on C.C.A.'s that have no practical operational application while being silent to the more critical to reliability issue of "work trigger/action threshold" clearances. This needs to be addressed if we hope to be successful at achieving the goal of zero preventable tree related outages.

Disagree
If T.O.'s are serious about public safety and potential electrical hazards or are required to comply with NESC/IEEE safety standards, then the greater, more conservative clearance distances must apply. On an complex issue where the aerial distances between live conductors and trees are dynamic and changing, I would prefer to be on the side of caution and on the side of safety. Given the history of cascading blackouts due to preventable tree contacts, there is a need to be conservative with the standards. I don't see it being in the public interest to argue that established minimum air insulation distances are inappropriately restrictive when applied to UVM.
No comment.
Agree
Disagree
It will be impossible for a T.O. to provide "evidence" that no encroachments of the C.C.Z. occured at any time during the year. This approach will be a compliance nightmare and is unworkable. How does one prove this never happens? You can't monitor every span of every line at all times. Obviously, whenever a T.O. has a preventable outage, that should be a violation. To address the issue of preventing outages before they occur and penalizing T.O.'s who don't take proper steps to prevent them, I prefer the approach of immediate removal of threatening vegetation that encroaches within a "threat trigger/action threshold" clearance distance per the T.O.'s formal imminent threat procedure. This "threat trigger/action threshold" clearance would be established by the T.O. and be a specific requirement under a revised FAC-003.
Agree
While being more specific & explicit, I don't interpret the overall requirement as being any different from the current standard.
Agree
While I very much respect the industry commitment and expertise of the drafting team members, the resulting revised standard reflects an effort to "revolutionize" the standard, when an "evolution" of the current standard would better serve the interests of system reliability. The kinds of wholesale changes proposed in this revision evoke real concerns about governmental regulations being a moving target and in many aspects, backs away from requirements that have led to real progress in UVM made since the 2003 blackout. For example, our company has invested tens of thousands of dollars and countless man-hours to comply with provisions of the existing standard only to see them simply done away with under the proposed revised standard. These investments were made based on an industry consensus standard as well as a realization that the requirements were reasonable and essential to improving system reliability. Where is the evidence that the current standard is not working as intended? What has changed in the last few years to warrant a complete re-write of the current standard? Most UVM professionals will agree there are some changes that need to be made to address FERC's concerns and to clarify intent. However, as presently written, I will recommend our T.O. vote against adoption of FAC-003-2.

Western Area Power Administration, Upper Great Plains Region
Jerry Paulson
Western Area Power Administration, Upper Great Plains Region
Agree
Western (UGPR) agrees with the objective of using the FERC/NERC defined term "Bulk Electric System", but believe that the FERC/NERC definition includes lines above 100 kV. It needs to be clearly understood that use of the generic term in the Purpose section does not supersede the specific definitions (greater than 200 kV, etc.) contained in the Facilities section.
Agree
Western's (UGPR) agreement is contingent upon maintaining the requirements for consulting with Transmission Owners and neighboring Reliability Coordinator(s) and documenting the method for assessing the reliability significance of each included line as contained in R9 and R10.
Agree

A question that has surfaced during discussions within the industry is "Can the Transmission Owner designate an active R/W width that is less than the easement width even with a single-circuit line with no R/W set aside for vegetation buffer or future development?" OR, does the easement width equate to "Active T-Line ROW" under the situation described above.
Agree
Agree
Agree
The description of the annual plan now appears to require a detailed plan for each line. Under FAC-003-1, Western (UGPR) identified higher priority vegetation during aerial inspection and handled those expediciously. We then addressed a percentage of the lower priority trees based upon a number of agency defined factors (vegetation priority, ground conditions, resource availability, etc). The less rigid annual plan allowed us the freedom to cut the lower priority trees that made the best sense to cut. We are concerned that the additional rigidity will create a ever-changing annual plan because we may have to adjust dozens of lines based on inspections. We question whether it is prudent to occupy finite resources in continually modifying the annual plan when the real benefits accrue from actually performing the vegetation management activities.
Agree
Agree
Agree
While Western (UGPR) agrees with the removal of Clearance 1, we believe it is advantageous for Transmission Owners to have a "trigger distance" in order to have some additional time to plan and schedule vegetation work. The trigger distance is advantageous only if the Regulators do NOT interpret it to be an extended CCZ and do NOT enforce based on "trigger distance" instead of the CCZ.
Agree
Disagree
The CCZ as defined would very specifically outline a zone that needs to remain clear of vegetation to avoid a violation, but that specificity could be an overly burdensome concept to implement and/or monitor. Theoretically, there could be an infinite number of allowable vertical and horizontal (for outside phases) clearances depending on your location within each span. Theoretically, you may need to clear cut at mid-span (depending on retreatment intervals, growth rate, etc.) while allowing a 40 foot tree closer to the structure, along with everyting in between depending on your location within the span. To fully comply with the CCZ as defined, each Transmission Owner would have to have a table of allowable vertical and horizontal clearances for every few feet on every available span length within each line section. Producing such tables would be a significant burden to each Transmission Owner, but without them, the Transmission Owner could not verify that vegetation had not encroached within the CCZ. In order to produce the tables outlined above, the Transmission Owner would need to identify what design parameter(s) are applicable for the "correct" CCZ? We remain concerned that weather conditions in excess of those parameters could lead to a vegetation contact/outage and proving that weather conditions were in excess of design criteria would be extremely difficult or impossible for all spans on a lengthy transmission line. It is not uncommon to have weather stations 50 or more miles away from points on our transmission system. In order to certify/verify compliance, the Transmission Owner would have to physically take their table to the field and verify vertical and horizontal clearances from the edge of the theoretical envelope (not the actual conductor position) for all vegetation within the span. This would be a time-consuming, burdensome, cumbersome process if Regulators are going to require specific evidence in order for the Transmission Owner to document their annual certification.
Agree

Agree
Agree
Disagree
R4 as proposed would do nothing to improve the reliability of the BES. In fact, we believe that R4 (as currently proposed) would impose significantly more stringent requirements than most Transmission Owners have interpreted FAC-003-1 to require. We believe that if the proposed interpretation would have been offered under FAC-003-1 that there would have be a great backlash against that Standard. It is our believe that current annual certifications of compliance for FAC-003-1 by Transmission Owners don't use "any infringement of the CCZ by any piece of vegetation at any time" as their measure for compliance. It could be argued that this proposal would actually do more to curtail accurate reporting of potential violations. We believe that making an infringement into the CCZ a violation and having that violation carry a six (or seven) figure fine would do more to discourage accurate reporting than any other system under discussion. Making the Transmission Owner prove that an incursion into the CCZ didn't happen would force an inventory of every inch of the R/W which is a gigantic waste of resources. Being tasked with proving that something didn't happen could be compared with our justice system declaring suspects will be considered guilty until they are proven innocent. This is a flawed and blatantly unfair concept and not a productive way of attaining the Purpose stated in this document. Western (UGPR) is disappointed by the "zero tolerance" nature of this document and its interpretation that "any infringement of the CCZ by any piece of vegetation at any time" constitutes a violation. We are not aware of any other NERC standard that is zero tolerance and question why vegetation is singled out to bear the brunt when several other factors could contribute to a system cascading event (i.e. relay problems, system configuration, operator issues, etc). In summation, we believe that a zero tolerance document being applied with "guilty until proven innocent" principles would do much to create an increasingly adversarial relationship between regulators and the industry.
Agree
Agree
1) Proactive utilities are implementing policies that call for the removal of all vegetation that could grow into the CCZ. Such policies are not without resistance from landowners, environmental groups, etc. One of the arguments used by such groups is that NERC/FERC do not require removal of the trees. It would very helpful if this document included the practice of removing vegetation capable of encroaching within the CCZ as a reasonable or acceptable practice under this Standard. 2) We can forsee a possible public backlash if this Standard is adopted as written. We see many utilities needing rate increases to cover the additional costs of implementing and monitoring the more stringent requirements of this proposal. We also believe that the more stringent requirements will have no noticeable impact on reliability. So you'll have the public paying more and seeing no change in reliability and questioning why.
Group
SERC Vegetation Management Subcommittee (VMS)
Jack Gardner (Chairman) Joe Spencer (SERC staff)
SERC Reliability Corporation
Disagree
The definition of the Bulk Electric System generally does not include radial transmission lines directly serving load and, in addition, includes all lines operated at 100 kV and above. Use of the term Bulk Electric System will cause unnecessary confusion to the industry concerning applicability of this standard. Therefore, we recommend the continued use of the undefined term "electric transmission systems."
The SERC Vegetation Management Subcommittee (VMS) abstains on this question. However, we believe that this comment form should provide an option to abstain in addition to the options to agree/disagree.

Agree
Agree
Agree
While the SERC VMS agrees in general, there may be areas (i.e. desert terrain) where an annual interval would be unnecessary and not cost effective.
Agree
Disagree
The Requirement as written is too prescriptive and is open to interpretation, from an audit perspective, with use of the term â€œimmediateâ€□ communication and a partial list of activities. Many conditions or threats, requiring immediate removal, would not require communication with the Transmission Operator, who is not an applicable entity for this standard. The SERC VMS recommends that R1.4 be deleted. Since this is a "zero tolerance" standard any Transmission Owner will remove any discovered threats to prevent outages. If R1.4 is not deleted, the SERC VMS believes that imminent threats should be a defined term. The definition should be as follows: â€œImminent Threat: A vegetation condition which, if not addressed, will place a transmission line at a significant risk of a Sustained Outage.â€□
Agree
Agree
Agree
Disagree
The SERC VMS recommends that R2 be deleted. Since this is a "zero tolerance" standard any Transmission Owner will remove any discovered threats to prevent outages. While we agree that the implementation of an imminent threat procedure may be a valid concept, visualization of the Critical Clearance Zone (CCZ) and determining an approaching encroachment is a practice in application of theoretical conductor locations in real time.
Agree
Developing minimum sparkover distances in this standard is a superior approach for the stated reason in question 12. In addition, referring to tables and values in another standard is problematic if the referenced standard is revised and the tables are re-numbered or deleted altogether. We suggest that the tables based on the Gallet equations be removed from the standard and be kept in the technical white paper solely to assist in developing a common understanding of the threshold for taking actions.
Agree
See comments in #12 above.
Agree
Disagree
The concept of the CCZ is useful as a mental model to visualize required vegetation management work. While this is a good conceptual tool to drive consistent terminology and proper vegetation management practices, it remains theoretical in nature and impractical to measure on a span by span basis. The complexity of determining an encroachment into the CCZ is overly burdensome due to the need for survey accuracy measurements and engineering evaluations. In addition, this complexity leads to questions about the ability to audit this requirement. These complexities introduce reliability and audit issues when encroachments into this conceptual area are defined as violations. The SERC VMS believes the Sustained Outage, as defined by other measures in this standard, should be the non-compliance measure. We suggest that the CCZ concept be kept in the technical white paper and that all references to the CCZ be removed from the body of the standard.
Agree

Disagree
While the SERC VMS agrees in principle, we believe that the Requirement, as written, is â€œopen endedâ€☐ and could be interpreted to be in conflict with the "Active Rights of Way" concept. Clarifying the intent for the annual plan to focus on the Active Rights of Way will prevent incorrect interpretations. The SERC VMS suggest that the Requirement be reworded to read: â€œEach Transmission Owner shall implement its annual work plan for vegetation management within the Active Right of Way to accomplish the purpose of this standard within the extent of its easements and or legal rights.â€☐
Group
Progress Energy Florida
John Pinney
Transmission Operations and Planning Department
Disagree
The intent of the revision of the standard was to bring clarity to the standard. Referring to the BES in the purpose creates confusion as to the applicability of the standard. Therefore, Progress Energy recommends the continued use of the term "electric transmission systems."
Agree
While Progress Energy agrees that the RC is the appropriate entity, the drafting team should consider including a dispute resolution requirement for those instances when the Transmission Owner and the Reliability Coordinator disagree as to which lines below 200 kV should be included.
Agree
Disagree
The sub-requirements should be moved up to requirement level if the team desires to have different VRFs and VSLs.
Agree
Agree
Annual Plan should be a defined term in the standard. Without a definition, the term may be interpreted differently by industry and the regulator. The drafting team should raise the prominence of annual plan and define the attributes of an annual plan.
Disagree
Progress Energy agrees with the need for a Transmission Owner to have an Imminent Threat Procedure and that the Transmission Operator should be immediately notified of imminent threats but only when it is appropriate as defined by the TO's imminent threat procedure. We disagree with the requirement to immediately communicate with the Transmission Operator whenever the Critical Clearance Zone is approached. Not every scenario is an issue that requires action by the Transmission Operator: It is possible that the CCZ is being approached by vegetation at the lowest point of the CCZ whereas the conductor may be at its highest point in the CCZ (potentially 30 feet away from the vegetation) -- This typical situation does not merit notification to the Transmission Operator (which is required by FAC-003-2 as currently written).
Agree
Agree
Agree
Disagree
The Critical Clearance Zone as currently defined is too academic. Implementation of R2 would require field operations staff to determine the theoritical position of the line during inspections to decide

whether to engage the imminent threat procedures. The academic/theoretical aspects of the Critical Clearance Zone definition are not practical or enforceable. The criteria for a violation needs to be limited to the position of the conductor in real time.
Agree
Agree
Disagree
The standard has established a threshold of compliance. For consistency, compliance should be measured at the threshold not a Registered Entities program requirement.
Disagree
The definition of Critical Clearance Zone includes too many academic and theoretical elements. It is impossible to provide evidence that vegetation did not encroach into the the Critical Clearance Zone during TVMP cycles. Furthermore, the operations staff performing periodic ground and aerial inspections would need to determine the CCZ for each foot of transmission line to assure compliance with the standard as it is currently written. The CCZ concept can neither be implemented or enforced as written. The CCZ refers to Ratings which is defined in the Glossry of Terms as "The operational limits of a tranmsission system element under a set of specified condiditons." This definition is too broad to be a consistently enforceable term from one utilitly or region to the next. As it is currently written, no exemption exists for vegetation falling from outside the Active Transmission Line Right of Way into, or lodging in, the theoretical CCZ.
Agree
Agree
While Progress Energy agrees with the change, the term â€˜annual planâ€™ should be a defined term including threshold elements.
To avoid interpretation errors and provide clarity, the Applicability section for Facilities (4.2) of FAC-003 should include a statement that the standard only applies to vegetation within the Active Transmission Line Right of Way. For example, a fall-in from outside of the Active Transmission Line Right of Way that causes a sustained outage is not a violation of this standard. Any encroachment/outage initiated by vegetation falling from outside of the Active Transmission Line Right of Way should be excluded from violations. The CCZ concept is academically elegant, but when applied in the field, it presents significant implementation, interpretation and enforcement issues: the complexity of determining compliance could have the unintended negative consequences to reliability; removal of vegetation will likely be delayed because of the complexity and accuracy required to determine compliance prior to tree removal; certification that no violations have occurred will require lengthy and costly calculations and survey measurements; the standard refers to Ratings in the determination of line sags and Ratings is not a tightly defined term, PRC-023 requires relays to hold lines in beyond the line Ratings; how will PRC-023 requirements be factored into the CCZ concept. The CCZ concept introduces more complexity and ambiguity into the standard than it resolves. The drafting team needs to develop an alternative to the CCZ concept that is simple, easy to apply and clearly defines at what point a violation occurs. There are over 158,000 line miles of AC Transmission above 200kV in the United States, covering a Right of Way area potentially as large as 3,000 to 4,000 square miles (an area roughly equivalent to Rhode Island and Delaware combined). With billions of stems of managed vegetation, in and along the right of way, even six-sigma performance would result in a number of outages on a system this large. With countless VM processes and assessments that take place daily, it is unrealistic/unreasonable to expect zero-tolerance for random vegetation events (the transmission system is planned/operated to handle at least any single contingency).

As proposed, Requirement R4 and corresponding Measure M4 will be highly subjective and impractical for the industry to implement. The determination of a violation due to encroachments into the Critical Clearance Zone will be subjective in nature due to field judgments, is random and not initiated by a known system event. It also will not be feasible for utilities to fulfill R4 requirements to ensure and provide evidence that any encroachments into Critical Clearance Zones have not occurred on their system throughout the year. Requirement R4 is not required since in the remaining requirements of FAC-003-2 contain the principal elements for compliance in ensuring the reliability of the bulk power system related to vegetation management of the transmission system. Specifically, the remaining requirements provide that a transmission vegetation plan be maintained, implemented and regularly reviewed whereby utilities must perform the requisite vegetation clearance work in order to prevent any sustained outages on the bulk power system. A sustained outage due to vegetation is a known, measurable event to which a penalty sanction will be invoked and therefore provides the required impetus for adherence to standard FAC-003-2. Requirement R4 and the associated measure M4 should therefore be removed from the proposed standard language.
Disagree
Exceptions should include flying debris including vegetation.
Agree
The title and explanation for Table 1 in Attachment 1 is not clear as to itâ€™s usage and applicability. It is being confused with the correlation with a minimum clearance and not as a component or building block of the Critical Clearance Zone. Under R10, there may be other methods for

consideration of assessing reliability significance of the sub-200 kV lines other than what is listed. Suggest the Drafting Team consider other criteria that an RC should condsider in its processes. R10.2 is redundant with R10.1. IROL by definition are those operating limits that represent instability, uncontrolled seperation or cascading. Suggest removing R10.2. Under M1.3 the measure requires the annual plan to cover a calendar year. An annual plan may cover a cycle growing season to growing season using the inspection to verify the next seasons work. Suggest removing the language for calendar year. M5, M6, M7 The measures should be requesting the evidence that it has violated the requirements. Good standing programs should not have to defend good practice by providing useless reports. The FAC-003-1 existing requirement R4 for reporting sustained outages is a reasonable and sustainable method that should be retained. R9 should include a periodic review period of annually. Any requirement to maintain current documentation should have a review period.

Disagree
NERC glossary of terms defines the Bulk Electric System as "the electrical generation resources, transmission lines, interconnections with neighboring systems, and associated equipment, generally operated at voltages of 100 kV or higher." This, at a mimimum, could lead to confusion over what impacts the reliability of the Grid by potentially including facilities less than 200 kV.

TECO aggres with the need for the Imminent Threat Procedure. However, the use of the new Critical Clearance Zone could create a "fill in the blank" standard. We we need to lock these clearances down as an industry so as to define what is an imminent threat and what the CCZ is in terms of specific distances.
Disagree
The phrasing above references a "corrective action plan". However, the standard as written is stated as an "interim corrective action process". These are not one and the same. Interim implies a truly temporary condition. As described on page 21 of the Technical reference, however,some of these operational issues may not be "interim".
Agree
Agree
While we agree with the removal of "fill-in the blank" requirements, we recommend the inclusion of professional qualifications for staff involved in this Standard. Reading the 42 page technical reference and the attached comment form, all involved need to really understand the Standard as well as industry practices.
Disagree
This is a good start. The Critical Clearance Zone (CCZ) is a very real and practical concept; however, it is not transferable to field conditions. This could result in a "fill in the blank" standard relative to what the Critical Clearance Zone will be in terms of distance. As I read this, it will be a sliding scale from insulator to mid span and back for each designated line voltage. The max wind speed to be used and other assumptions behind the determination of this zone may be as involved a Gallet's formula. This will lead to complications during operational inspection and verificaiton of these clearances.

Good start. R8 must also address the flexability which is addressed in R1.3. As written, R8 does not do this. In addition, R8 states "within the extent of its easement and/or legal right...". This could create another set of conflicting criteria, where the utility has a long term "interim corrective action plan".
Good start. However, this will need additional work and reivew predicated on the above comments.
Individual
Edward Bedder
Orange and Rockland Utilities Inc.
Disagree
The use of the term "Bulk Electric System" (BES) could lead to confusion. In most regions BES includes lines with operating voltages equal to or greater than 100kV. The Standard is intended to apply to all lines with operating voltages equal to or greater than 200kV, and only those sub-200kV lines which are designated by the Reliability Coordinator (paragraph 4.2.1). Use of the words "electric transmission systems" rather than BES would eliminate this potential source of confusion.
Agree
Agree
Agree
Agree
Agree

While we agree that the imminent threat procedure should be included in the TVMP, the requirement is overly prescriptive and should be revised to allow Transmission Owners flexibility to develop imminent threat procedures which best fit their systems and protocols. We recommend that R1.4 be reworded as follows: "Require a process or procedure for response to vegetation-related imminent threats to applicable lines. The imminent threat procedure shall require action to eliminate vegetation-related imminent threats, and shall be implemented upon discovery of such conditions". In addition, the definition of "Imminent Threat" should be defined. We suggest the following: "A condition which places a transmission line at significant risk of an outage in the very near term". An example of a vegetation-related imminent threat would be an uprooted tree leaning precariously toward a conductor which is certain to make contact with the conductor as the tree falls. Many Transmission Operators have imminent threat procedures in place to address all imminent threats to

their transmission systems, not just imminent threats due to vegetation. In many cases it would make sense for Transmission Owners to have one imminent threat process that covers all imminent threat conditions. The flexibility being recommended would facilitate this.
Agree
Agree
We generally agree, however please see comments included in question 18.
Agree
Disagree
While we agree that the imminent threat procedure should be implemented to address vegetation-related imminent threats as soon as they are identified, we believe that an "approach" of the CCZ should not be used to trigger implementation. The term "approached" does not identify a specific distance, so it is not clear to what extent vegetation would have to approach the CCZ in order to require implementation of the imminent threat process. This is left to the discretion of individual interpretation, is confusing to field personnel, and presents compliance and auditing problems. Imminent threats which are based on vegetation clearances should be identified based on specific clearances, not undefined approach distances. In practical field application the CCZ is an invisible area that changes shape and size along the length of the conductor. It is impossible to readily identify in the field without engineering calculations and precise measurements or the use of technology such as Aerial Laser Survey (ALS) using Light, Detection and Ranging (LIDAR) technology. Therefore under normal circumstances the location, size, and shape of the CCZ and vegetation encroachments of the CCZ can only be roughly estimated. Even with the use of ALS, which is relatively accurate, information is often not available for months after the survey flight. We believe that under normal circumstances imminent threats which are based on vegetation clearances should be identified in terms of specific distances from the conductor. While it is not possible for an inspector to readily identify a vegetation encroachment of the CCZ in the field, an inspector could more easily estimate a specified short distance between a conductor and vegetation in real time and initiate implementation of the imminent threat procedure based on that assessment. This assessment would be significantly more accurate than attempting to measure the distance between vegetation and the CCZ, which is not visible and constantly changes size and shape throughout the span. In cases where the Transmission Owner chooses to deploy ALS, the CCZ rather than the conductor could be used as the reference because in most cases the CCZ could be identified relative to approaching vegetation with a reliable degree of accuracy. Still a specific distance should be used to trigger implementation of the imminent threat procedure because of the issues previously raised with the use of the word "approached".
Agree
Agree
Agree
Disagree
We believe that R4 is not the most effective way to achieve the purpose of the Standard. As previously stated the CCZ and encroachments of it are generally not possible to identify in the field without taking precise measurements. The CCZ changes in size and shape continuously throughout each and every span. In many cases the CCZ can be very large, and the position of the conductor with respect to encroaching vegetation within the CCZ can be relatively far apart. Such cases would typically not be identified as encroachments of the CCZ by visual inspections. Only those instances where the vegetation is significantly overgrown would be readily identifiable. R4, as written presents a problem in terms of compliance, certification of compliance, and auditing because precise measurements of every span are impractical and costly to perform. Certification of compliance would require field personnel to spend valuable time estimating and attempting to measure potential encroachments of the CCZ. R4 does not provide incentive for Transmission Owners to deploy modern technology that is better able to identify encroachments of the CCZ with a reasonable amount of

accuracy, such as ALS and LIDAR which are described in the response to Question 11. In fact R4 might provide an incentive not to utilize this technology because Transmission Owners who identify encroachments using ALS which would otherwise not have been identified would be in violation of R4. Transmission Owners that choose to be less proactive often would not identify such encroachments and would be at less risk of violating R4. The effect could be less frequent use of ALS and other technology that may emerge. This would result in fewer problems being identified, a small percentage of which may not be discovered until they result in a line trip. We believe that the best way to achieve the purpose of this Standard is to encourage proactive behavior which prevents vegetation-related outages throughout the entire industry. R4 does not achieve this in the most effective way. We recommend the following: Eliminate encroachment of the CCZ as a violation of R4. Require Transmission Owners to immediately implement the imminent threat process defined in R1.4 when they identify instances where vegetation has grown within a specific distance as described in the response to Question 11 regarding R2. This would essentially combine R2 and R4. Require Transmission Owners to report to the Regional Entity any instances where the imminent threat process was implemented due to a vegetation-related clearance encroachment. This would add a reporting requirement for Transmission Owners. Require Regional Entities to perform additional audits of Transmission Owners that exceed metrics for vegetation-related clearance encroachments. The metrics should be established in the Standard based upon 1000 circuit miles of applicable lines. This would add an additional requirement for Regional Entites. Modify R5, R6, and R7 to include include preventing momentary outages as well as Sustained Outages. We believe that this concept would result in a more rigorous standard because of the additional requirements, but would focus the industry's attention in a more effective fashion. We believe it would result in fewer vegetation-related interruptions and a higher level of reliability soon after implementation, and would therefore best support the purpose of the Standard.
Agree
We agree, but recommend that momentary outages be included as violations of all three requirements as well. Also, the Standard does not directly require reporting of vegetation-related outages although implicitly, outages which are violations of the Standard must be reported. This has lead to some confusion during this comment phase and we suggest that the reporting requirements be directly stated in the Standard.
Agree
Clearance 1 has been eliminated from this draft. Version 2 as drafted only requires that Transmission Owners address vegetation that approaches the CCZ. This is essentially equivalent to Clearance 2 in version 1, a minimum clearance. Although unlikely this could result in some Transmission Owners adopting a just in time vegetation management concept that focuses on maintaining minimum clearances, rather than removing incompatible vegetation or achieving greater clearances. Although R1 requires Transmission Owners to design their TVMPs to control vegetation there is no clear requirement to address incompatible vegetation early and aggressively. The drafting team should revisit this and consider returning to some form of Clearance 1 or requiring the TVMP to address removal of incompatible vegetation within their easement rights

Disagree
ATC disagrees with changing the term "electric transmission systems" to "Bulk Electric System". This standard applies to 200 kV and higher transmission lines not all BES facilities. Suggested Purpose statement: To maintain the reliability of the electric transmission system by requiring entities to have and implement a transmission vegetation management plan.
Disagree
Requirements 9 and 10 should be deleted and replaced with the following language. Proposed Language The TO shall include those transmission lines below 200 kV that that are associated with an established IROL. (This language could either be uses as a requirement or inserted into the Applicability section.) Our statement provides a clear decision on which lower voltage lines have to be included in an entities transmission vegetation management program.

Agree
We agree with the idea but the term "active transmission facilities" needs additional clarity. This clarity could be accomplished with a footnote. Proposed Footnote: A transmission facility that contains a transmission line to which FAC-003 is applicable. The proposed footnote aids in the indentification of applicable transmission facilities.
Agree
Agree
We agree with a minimum inspection frequency, but believe that the additional verbiage "â€¦ that takes into account local and environmental factors" should be deleted. The additional verbiage does not provide greater reliability only more documentation. Proposed Language: Specify a vegetation inspection frequency of at least once per calendar year.
Agree
ATC agrees with separating the implementation Requirements from the Annual Plan Requirements.
Disagree
We agree that entities should have a Vegetation Imminent Threat Procedure, but that the term should be defined. Also see related comments to Question #11.
Agree
ATC agrees with the concept but disagrees with the proposed language. ATC believes the term "interim" should be removed from R 1.5. In some cases, a corrective action can end up being a long term/normal fix. Proposed Language: Specify a corrective action process that will be used when estabilshed clearances or methodologies are altered.
Agree
Agree
Disagree
ATC believes that the Critical Clearance Zone (CCZ) is a good theoretical concept to aid industy in understanding the overall movement of conductors, but it is an impractical concept for field application. Due to the variability in the size of the CCZ as you move along a conductor, as well as changes from span to span or even line to line due to design parameters, loading or weather-related issues, the CCZ concept should not be tied to an imminent threat procedure. Vegetation approaching the CCZ does not constitute an imminent threat. It may be months to years before this vegetation ever gets to a proximity distance from the conductor to be within a "spark-over" distance as defined by the Gallet equations. Requirement R2 should support the purpose of this standard by requiring implementation of the Vegetation Imminent Threat Procedure when the Transmission Owner has visual, field knowledge that vegetation is encroaching upon a conductor within some specific distance that is a multiple of the Gallet distances referenced in Table I of FAC-003-2 (to be conservative we suggest two to three times the Gallet distances). Failure to implement the Vegetation Imminent Threat Procedure in such instances would be a violation of R2. As R2 is currently written, a Transmission Owner cannot comply with R2 unless the imminent threat procedure is continuously being implemented or monitored, because vegetation that is growing is always approaching the CCZ. "Approaching the CCZ" cannot be the trigger for implementation of the Vegetation Imminent threat Procedure. Instead, the trigger should be an encroachment within some observed field distance. Requirement R2 could be rewritten as follows: â€œEach Transmission Owner shall implement its Vegetation Imminent Threat Procedure when the Transmission Owner has knowledge, obtained through normal operating practices or notification from others, that vegetation is encroaching upon a conductor within a distance that is twice the Gallet clearance distances referenced in Table I." Using a multiple of the Gallet distances provides a safety factor. Assessing a violation for failure to appropriately implement the Vegetation Imminent Threat Procedure or for a sustained vegetation-related outage would promote the proper behavior.
Agree

Disagree
While the CCZ is valuable to understanding the movement of conductors, it cannot be readily applied in the field. This field application challenge is noted in the Technical Reference Document (pages 29 & 30). The way R4 is currently stated, the Transmission Owner would be in violation of R4 for any CCZ encroachment not due to natural disasters or human or animal activity. This would include a tree falling from outside the right of way corridor that passes through the theoretical CCZ. Furthermore, Transmission Owners would be required to self-certify compliance with R4, and ATC does not think there is a practical way to do that. Clearly, the approach of assessing violations for CCZ encroachment is unworkable. ATC believes that R4 should be deleted.
Agree
Agree
ATC agrees with the requirement to implement the annual work plan, but recommends striking the words "within the extent of its easement and/or legal rights". The emphasis for this requirement is to execute the annual work plan. The white paper already speaks to the point that it is a best practice for utilities to exercise their legal rights. If we agree that the goal is to prevent outages, then we can simply end this requirement with "implement its annual work plan for vegetation management." Propose Changes to R8: Each Transmission Owner shall implement its annual work plan for vegetation management.
FAC-003-1 lacks clarity that is essential for understanding what is necessary for compliance. The proposed FAC-003-2 needs to be simplified to aid with field implementation and compliance interpretation. Currently, it does not provide the clarity and simplification needed by Transmission Owners and regulatory bodies to enhance reliability. Requirement 1.3: The proposed requirement does not allow enough flexibility for making changes to the Annual Plan. We believe that changes to the Annual Plan should be allowed even if that means delaying something until the next Annual Plan. Our Proposed Changes: Have an annual plan that identifies the applicable lines to be maintained and associated work to be performed. Adjustments to the annual plan are permissible. We believe that our proposed language accomplishes the SDT's intent while allowing for appropriate flexibility.

Use of the general term Bulk Electrical System creates unintentional confusion regarding the applicability of this standard to lines operated at 200 kV or higher and designated lines operated below 200 kV.
Agree
Agree
Agree
Disagree
Some areas such as highly developed urban areas, deserts, or grassland prairie may not be conducive to tall vegetation growth and require frequent (annual) inspection.
Agree
Agree
The Technical Reference document could be expanded to explain that a well rounded Imminent Threat Procedure should contain many mitigation alternatives to appropriately address a wide range of field situations, including a "no immediate field action is required" option. For example, further investigation of a potential imminent threat situation may reveal that the situation has been

erroneously reported or incorrectly measured and therefore no immediate vegetation removal actions are required. A utility's Imminent Threat Procedure may also address situations beyond just vegetation related incidents.
The specifics of a "plan" as required by R1.4 in version 1 of the Standards has been replaced with the generalities of a "process" required by R1.5 in version 2 of the Standards. At the time of an audit, the adequacy of a general process is harder to measure than the adequacy of the specific mitigation measures that were previously required by R1.4 in version 1 of the Standards. It is unclear what an auditor will be looking for to determine compliance with R1.5 - will the auditor be looking for generalities or specifics? Further, if a utility has documented their interim corrective action process, but it is not followed, is this a violation of the Standards?
Agree
Agree
Disagree
As discussed in the Technical Reference document, the CCZ is a complicated theoretical envelope surrounding all rated operating positions of the conductor. Its dynamic shape is constantly changing and is contingent upon location within the span. Calculation of the size and shape of CCZ is based, in part, upon the design parameters of the transmission facility. However, as-built or long term maintenance conditions can often diverge from the original design requirements over time. Ground elevations can also change as a result of man made or natural causes from the original design elevations recorded on plan and profile engineering drawings. Consequently, precise field measurement of the as-built CCZ is extremely problematic and strategies that utilize the calculation of allowable right-of-way tree heights can be hindered by unrecorded deviations from the original design criteria. Allowable tree height strategies also become increasingly more difficult and impractical with increasing extremes in terrain. While the CCZ is a very important concept for an effective vegetation management program it is far to theoretical, dynamic, and impractical to field measure for use as a clear and precise boundary for regulatory purposes. In addition, the R2 requirement for action when the imprecise and theoretical CCZ boundary is "approached" by vegetation is an even more subjective and unmeasurable. The "rate of approach" is really the key issue of concern. The rate of vegetation approach is a function of many variables including species type and site specific growing conditions. For example, a Century Plant which can grow six inches a day is obviously a much greater concern than a Lodgepole Pine on a dry mountain top which grows only a few inches a year. As such, there is no practical way to define or measure for regulatory purposes those "approach" situations that legitimately require immediate action from those "approach" situations that do not. The wording and concepts of R2 are therefore to imprecise to be used as clear requirements for Standards compliance.
Agree
Agree
Agree
Disagree
As discussed in the Technical Reference document and question #11 above, the CCZ is a complicated theoretical envelope surrounding all rated operating positions of the conductor. Its dynamic shape is constantly changing and is contingent upon location within the span. Calculation of the size and shape of CCZ is based, in part, upon the design parameters of the transmission facility. However, as-built or long term maintenance conditions can often diverge from the original design requirements over time. Ground elevations can also change as a result of man made or natural causes from the original design elevations recorded on plan and profile engineering drawings. Consequently, accurate field measurement of the as-built CCZ is extremely problematic and strategies that utilize the calculation of allowable right-of-way tree heights can be hindered by unrecorded deviations from the original design criteria. Allowable tree height strategies also become increasingly more difficult and impractical with increasing extremes in terrain. While the CCZ is a very important concept for an

effective vegetation management program it is far to theoretical, dynamic, and impractical to field measure for use as a clear and precise boundary for regulatory purposes. As such, R4 as written should be deleted from the Standards. Further, the requirement to provide evidence of something that has not occurred (no vegetation encroachments of the CCZ) is also impractical. General industry interpretation of R1.2.2 in version 1 of the Standards is that the specific Clearance 2 distance is the precise boundary that is not to be encroached verses the broader area that is ultimately mapped out as the conductor moves through "all rated electrical operating conditions". Only the Clearance 2 distance value is a clear, precise number that can be accurately observed and measured in the field. If there is a persistence to retain the CCZ concept as a requirement within the Standards, the second bullet option above regarding the initiation of the imminent threat process upon discovery of a possible encroachment is the preferred option. Since a potential encroachment into the CCZ is not a violation under this option, exact determination of the CCZ boundary is no longer as essential. Rather, the focus is on triggering mitigation to vegetation problems to prevent outages. However, as with question #11 above, there is still no practical way to determine for regulatory purposes those "potential encroachment" situations that legitimately require initiation of the imminent threat process from those "potential encroachment" situations that do not. Under this option the utility is really motivated to initiate the imminent threat process to avoid an impending outage. As such, the occurrence of an outage becomes the only clear, precise and observable means to determine a Standards violation. A proposed alternative to ensure a level of reliability equal to or better than FAC-003-1 is to retain the Clearance 2 requirement (without the imprecise "all rated electrical operating conditions" language) in combination with the sustained outage requirements of R5, R6 and R7. If an additional margin of safety is determined to be required, industry performance can be adjusted to become more proactive by increasing the minimum Clearance 2 distance to a value greater than the proposed version 2 Gallet equation (table 1) values. Thinking in terms of the CCZ concept, it is obvious that a larger Clearance 2 value translates into a larger CCZ envelope. A larger CCZ envelope in turn triggers mitigation for possible CCZ encroachments sooner.
Agree
Agree
1. Further clarification of the definition of the active right-of-way appears to be required. For example, if a tree falls from an area controlled by the utility which is outside of the normal width of the actively managed right-of-way, but this area is not reserved or "intended for other facilities", could this be a violation of a Standards requirement? The narrative discussion within the white paper seems to imply that it is not, but the "intended for other facilities" requirement within Standards definition implies that it would be. 2. As currently presented, FAC-003-2 requires an impractical and unrealistic level of performance from the industry. This level of performance is unwarranted for the overwhelming number and expanse of transmission facilities to which the Standards are applicable. Many of these facilities, such as radial load lines, are not critical TOT or IROL facilities and have a minimal impact on overall grid reliability. The rigorous zero tolerance level of performance is only warranted for those lines that are critical TOT or IROL facilities. 3. The Standards should clearly identify any and all reporting requirements.

We propose adding the following language to the end of the definition for "Active Transmission Line Right of Way": OR OTHER PURPOSES, REGARDLESS OF THE PREMISES DIMENSIONS IN ANY EASEMENT, LICENSE AGREEMENT OR OTHER LAND RIGHT DOCUMENT.
Disagree
Add a note of exception to the requirement for inspections on those lines that do not have vegetation management issues (e.g. lines that traverse desert areas only).
Disagree
The way this requirement is written may require a utility to prove a negative. In other words, prove that we did not have trees encroaching into the CCZ at any time. This is impossible to prove. We propose the following language: â€œThe TO shall not have a encroachment within the CCZ which was not dealt with by utilizing the imminent threat procedure before experiencing a Sustained Outage, with the following exceptions 1) Encroachment of the CCZ that result for natural disasters 2) Encroachment of the CCZ that result from human or animal activity."
Agree
We agree, however please add a reference to â€œwind gusts 45 miles per hour or greaterâ€□ to the exception note for this requirement. The exception would read â€œ1) Sustained Outages of transmission lines that result from sustained winds (45 miles per hour or greater) or gusts due to natural disasters.â€□
Attachment 1, Table I- Change the title of the table from "Proposed Minimum Vegetation Clearance Distances" to "Critical Clearance Zone Distances". The reason being is that the general public could

interpret this table to mean that this is all the clearance that is required by a utility at the time of pruning. Section C, Violation Severity Levels- There is some inconsistency between the C.2 chart and the contents of the Standard and the White Paper. For example, the White Paper specifies that an exception to an R6 blowing together violation would exist for sustained winds of gusts of 45 miles per hour or greater. As to R7, the Standard itself notes that a violation only occurs if the vegetation falling into the line is from within the ROW â€“ C 2 does not incorporate that requirement. There are two approaches: either note the exemptions within the C 2 chart, or add a footnote to the chart along these lines: "This chart summarizes various provisions, the details of which are more fully set forth in the Standard and White Paperâ€□. We would recommend the later approach. General suggestions: 1) It appears that the FAC-003 Standard is the only "zero tolerance" standard, in some respects. Is this reasonable? 2) There appears to be "advisory" language in this version of the Standard. This type of language should be part of the White Paper, not the Standard itself. 3) Utilities need more support from FERC to deal with regional roadblocks within the USFS regarding the implementation of IVM. The Memorandum of Understanding is not universally accepted within all regions of the USFS.

Disagree
By definition, the capitilized term, Bulk Electric System, is defined to include most facilities 100 kV and above. The previous version of this standard appropriately restricted the applicability of the standard to those facilities operating above 200kV and any additional facilites identified by the Regional Reliability Organization as critical. This new version of the standards attempts to limit the 100-200 kV class applicability by having the RC identify the critical facilities. We believe the change creates unnecessary and undesirable confusion in that one requirement of the standard says that it applies to all the BES and then another requirement limits the application. Leaving the term "electric transmission systems" in the definition is preferable to that proposed.
Disagree
While the RC would seemingly have the wide area view to make the assignment appropriate, the standard is really trying to determine the entity who can assess the risk to the BES of a vegetation-related outage. The management of that risk is in the venue of the Transmission Planner who, in the long term, designs the system and, in the Operating Horizon, establishes the parameters of operation that will lead to reliability. Certainly, the RC is preferable to the RE (RRO). However, the TP is preferable to the RC.
Agree
Agree
This is a good change from a compliance perspective; the documentation requirements can now be assigned lower VRFs than the implementation requirements
Agree
Agree
Disagree
Transmission Owners should have a Vegetation Imminent Threat Procedure, and "Vegetation Imminent Threat" should be a defined term, defined as: "Vegetation observed in the field encroaching upon a conductor within a distance defined in the Vegetation Management plan." In this case, the threat would require an immediate response and would include communication to the Transmission Operator. From there, the actions that the operator decides to take will be dependent on the incident and system conditions. We do not need to be prescriptive with this requirement but rather allow the Transmission Operator and appropriate field personnel the flexibility to make the right decisions to safely, promptly and appropriately remove the vegetation threat. From a Transmission Owner's perspective, many situations can constitute an imminent threat but this approach will clearly define a "Vegetation Imminent Threat" as it relates to the Purpose of this standard. While a definition of "Vegetation Imminent Threat - Vegetation observed in the field encroaching upon a conductor within

a distance that is twice the Gallet clearance distances referenced in Table I of the draft standard FAC-003-2" would be acceptable and far superior to that which is proposed, it will still be difficult for field personnel to identify, at each foot of a transmission circuit, wherein twice the Gallet distance would be found. See comment on #11 below.
Agree
Agree
Agree

Agree
Disagree
The second bulleted alternative above is the best approach, but it should be improved by changing the imminent threat trigger from "encroachment of the CCZ" to "encroachment within some observed, field distance that is defined in the Plan. This would allow Transmission Owners to define for field personnel a CCZ that accomplishes some multiple of the Gallet distances referenced in Table I" but is easy to determine and apply. We have recommended changes to accomplish this in Requirement R2 (see our response to Question #11 above), and R4 should simply be deleted. While the CCZ is valuable to understanding the movement of conductors, it cannot be readily applied in the field. This field application challenge is noted in the Technical Reference Document (pages 29 & 30). The way R4 is currently stated, the Transmission Owner would be in violation of R4 for any CCZ encroachment not due to natural disasters or human or animal activity. This would include a tree falling from outside the right of way corridor that passes through the theoretical CCZ. Furthermore, Transmission Owners would be required to self-certify compliance with R4, and we don't think there's any way to do that. Clearly the approach of assessing violations for CCZ encroachment is unworkable. Likewise, the third alternative listed above is untenable. The tiered approach could have a mitigating effect on violations, but it would require the same inspection effort and postponement of vegetation management that makes the first alternative unworkable. Both the first and third alternatives would require very significant additional expenditures for surveys and documentation in an impossible attempt to certify compliance - money that would be better spent controlling vegetation.
Agree
Agree

We recommend striking, or modifying, the words "within the extent of its easement and/or legal rights" as they may be introducing an unintended compliance quagmire. For example, if the easement is extraordinarily wide but reliability and the work plan do not dictate that the work plan apply to the entire easement, how will compliance be measured? The work plan should recognize easement or legal rights issue. Therefore, the emphasis for this requirement shoudl be to execute the annual work plan. The white paper already speaks to the point that it is a best practice for utilities to exercise their legal rights. By tagging the words on to the requirement, we are adding unnecessary compliance validation to this requirement for both industry and the regulators. If a clarifying sentence is required, we would suggest that R8 stop with the word standard and a new sentence be added, "The work plan should address easement or legal/rights"
While FAC-003-1 lacks clarity that is essential for understanding what is necessary for compliance, the proposed FAC-003-2 needs to be simplified to aid with field implementation and compliance interpretation. Currently, it does not provide the clarity and simplicity needed by Transmission Owners to implement and regulatory bodies to monitor in a manner that will enhance reliability.
Individual
John Humphrey
Nebraska Public Power District
Disagree
NPPD disagrees with the change to bulk electric system, because it creates confusion on the applicability. This standard only applies to certain lines and not the entire (bulk) system.
Agree
NPPD agrees that the Reliability Coordinator is the correct body for identification of any sub 200kV lines that would be subject to this standard.
Agree
Agree
Agree
Agree
Disagree
NPPD agrees that a Transmission Owner should have an imminent threat procedure and the TO be immediately notified of any threats. NPPD disagrees with prescribing what needs to be done as a result of the threat. This is condition based and staff can make the right decision as to what corrective actions are necessary.
Agree
Agree
Agree
Disagree
The CCZ is a good concept to explain the flight path of a conductor under all conditions but it would be impractical to use in the field. There are too many variables to consider and an encroachment does not constitute an immediate threat.
Agree
Agree
Agree

Disagree
NPPD disagree with an encroachment being a violation. A lot of time would need to be spent to determine if an encroachment occured and in a self regulating environment, reporting would be miminal if any. The Transmission Owner would be in violation for any non natural event. Even a tree falling into the ROW passing through CCZ would be in voilation of R4. Difficult at best to enforce. We need to spend time keeping the ROW cleared and less time inspecting for possible encroachments.
Agree
Agree
Group
Progress Energy Carolinas
Jack Gardner
Transmission Operations and Planning Department
Disagree
The intent of the revision of the standard was to bring clarity to the standard. Referring to the BES in the purpose creates confusion as to the applicability of the standard. Therefore, Progress Energy recommends the continued use of the term "electric transmission systems."
Agree
While Progress Energy agrees that the RC is the appropriate entity, the drafting team should consider including a dispute resolution requirement for those instances when the Transmission Owner and the Reliability Coordinator disagree as to which lines below 200 kV should be included.
Agree
Disagree
The sub-requirements should be moved up to requirement level if the team desires to have different VRFs and VSLs.
Agree
Agree
Annual Plan should be a defined term in the standard. Without a definition, the term may be interpreted differently by industry and the regulator. The drafting team should raise the prominence of annual plan and define the attributes of an annual plan.
Disagree
Progress Energy agrees with the need for a Transmission Owner to have an Imminent Threat Procedure and that the Transmission Operator should be immediately notified of imminent threats but only when it is appropriate as defined by the TO's imminent threat procedure. We disagree with the requirement to immediately communicate with the Transmission Operator whenever the Critical Clearance Zone is approached. Not every scenario is an issue that requires action by the Transmission Operator: It is possible that the CCZ is being approached by vegetation at the lowest point of the CCZ whereas the conductor may be at its highest point in the CCZ (potentially 30 feet away from the vegetation) -- This typical situation does not merit notification to the Transmission Operator (which is required by FAC-003-2 as currently written).
Agree
Agree
Agree

Disagree
The Critical Clearance Zone as currently defined is too academic. Implementation of R2 would require field operations staff to determine the theoritical position of the line during inspections to decide whether to engage the imminent threat procedures. The academic/theoretical aspects of the Critical Clearance Zone definition are not practical or enforceable. The criteria for a violation needs to be limited to the position of the conductor in real time.
Agree
Agree
Disagree
The standard has established a threshold of compliance. For consistency, compliance should be measured at the threshold not a Registered Entities program requirement.
Disagree
The definition of Critical Clearance Zone includes too many academic and theoretical elements. It is impossible to provide evidence that vegetation did not encroach into the the Critical Clearance Zone during TVMP cycles. Furthermore, the operations staff performing periodic ground and aerial inspections would need to determine the CCZ for each foot of transmission line to assure compliance with the standard as it is currently written. The CCZ concept can neither be implemented or enforced as written. The CCZ refers to Ratings which is defined in the Glossry of Terms as "The operational limits of a tranmsission system element under a set of specified condiditons." This definition is too broad to be a consistently enforceable term from one utilitly or region to the next. As it is currently written, no exemption exists for vegetation falling from outside the Active Transmission Line Right of Way into, or lodging in, the theoretical CCZ.
Agree
Agree
To avoid interpretation errors and provide clarity, the Applicability section for Facilities (4.2) of FAC-003 should include a statement that the standard only applies to vegetation within the Active Transmission Line Right of Way. For example, a fall-in from outside of the Active Transmission Line Right of Way that causes a sustained outage is not a violation of this standard. Any encroachment/outage initiated by vegetation falling from outside of the Active Transmission Line Right of Way should be excluded from violations. The CCZ concept is academically elegant, but when applied in the field, it presents significant implementation, interpretation and enforcement issues: the complexity of determining compliance could have the unintended negative consequences to reliability; removal of vegetation will likely be delayed because of the complexity and accuracy required to determine compliance prior to tree removal; certification that no violations have occurred will require lengthy and costly calculations and survey measurements; the standard refers to Ratings in the determination of line sags and Ratings is not a tightly defined term, PRC-023 requires relays to hold lines in beyond the line Ratings; how will PRC-023 requirements be factored into the CCZ concept. The CCZ concept introduces more complexity and ambiguity into the standard than it resolves. The drafting team needs to develop an alternative to the CCZ concept that is simple, easy to apply and clearly defines at what point a violation occurs. There are over 158,000 line miles of AC Transmission above 200kV in the United States, covering a Right of Way area potentially as large as 3,000 to 4,000 square miles (an area roughly equivalent to Rhode Island and Delaware combined). With billions of stems of managed vegetation, in and along the right of way, even six-sigma performance would result in a number of outages on a system this large. With countless VM processes and assessments that take place daily, it is unrealistic/unreasonable to expect zero-tolerance for random vegetation events (the transmission system is planned/operated to handle at least any single contingency).

Agree
Q1: SCE agrees in part with the proposed revisions to the purpose statement. However, we believe the phrase "vegetation related outages" is unnecessarily vague. Based on the content of certain requirements in Version 2, the intent of this standard is and should be to prevent sustained outages due to vegetation-to-line contacts. SCE respectfully suggests the purpose statement (A3) be revised to read: "To improve the reliability of the Bulk Electric System by preventing vegetation-to-line contacts that could lead to Cascading.â€□
Agree
Q2: No comments.
Agree
Q3: No Comments.
Disagree
Q4: SCE does not agree with separating the documentation and implementation aspects of the TVMP into separate requirements R3 and R8 (respectively). SCE believes that proposed R3 and corresponding M3 should be eliminated and replaced with a modified version of proposed R8. SCE respectfully suggests that proposed R8 be revised to read: "Each Transmission Owner shall implement and follow its Vegetation Management Program to the extent allowed by existing easement and/or legal rights."
Disagree
Q5: SCE does not agree with imposing a one-size-fits-all inspection frequency of â€œat least once per calendar yearâ€□ upon all U.S. Transmission Owners. The associated technical paper presents no credible evidence or statistical corroboration to support the proposed inspection frequency. Until such time as a thorough industry study or similar evidence is presented that demonstrates the proposed inspection frequency is cost effective and will enhance system reliability, Transmission Owners should be allowed to establish their own inspection frequency rate. Regarding the enforcement of a non-standardized inspection frequency, should a Transmission Owner incur a vegetation-to-line contact that results in a Sustained Outage, upon review of the investigation results, the responsible Reliability Coordinator and/or NERC could then impose a more stringent inspection frequency requirement upon the infracting Transmission Owner. The imposition of more stringent inspection frequencies could be applied on a temporary or permanent basis, depending on the severity of the outage, but lacking a demonstrated need, good performing Transmission Owners should be allowed to establish their own inspection frequencies based upon their individual needs and operating conditions. SCE respectfully suggests R1.2 be revised to read: "Specify a vegetation inspection frequency that takes into account local and environmental factors."
Agree
Q6: SCE agrees in part. Proposal R1.3, requiring Transmission Owners to establish an annual maintenance plan is generally acceptable. However, SCE disagrees with including peripheral information in R1.3 and the institution of a separate implementation requirement (R8). Further, we note that some portions of FAC-003-1 (R2) appear to have been transplanted into proposed R1.3 and that the word â€œshallâ€□ has been replaced with the word â€œshouldâ€□. SCE believes that inserting the word â€œshallâ€□ into statements that are clearly advisory in nature does not necessarily create enforceable requirements. As proposed, an enforcement auditor might incorrectly determine that the new â€œrequirementâ€□ statements in proposed R1.3, describing the need for â€œflexibilityâ€□, â€œconsideration of permitting and scheduling requirementsâ€□, and self-determined â€œmethodologiesâ€□ is a comprehensive list of items for the maintenance plan. Because this list of program elements is not complete, SCE recommends all text following the opening sentence be removed from R1.3 and inserted into the supporting technical paper. SCE respectfully suggests that R1.3 be revised to read: "Specifies a plan that identifies the applicable lines to be maintained and associated work to be performed."
Agree
Q7: SCE agrees in part with the content of R1.4 because of its similarity to existing requirement R1.5 in FAC-003-1. However, we disagree with the drafterâ€™s inclusion of peripheral information following the first sentence. We also note that the second sentence of proposed R1.4 includes both a requirement and a recommendation. SCE believes this and similar recommendations are best suited for the supporting technical paper. SCE respectfully suggests that R1.4 be revised to read: "Specify a

process or procedure for communicating an impending vegetation-to-line contact that may result in a sustained outage and the appropriate response measures.â€☐
Agree
Q8: SCE agrees in part with the revisions to R1.5, including the proposed phrase "corrective action process". However, we do not believe it is necessary to include the term "Transmission Owner" in the sentence because the entire standard is clearly applicable to Transmission Owners. SCE respectfully suggests that proposed R1.5 be revised to read: "Specify an interim corrective action process for use when planned vegetation maintenance is deterred."
Agree
Q9: No comments.
Agree
Q10: No comments.
Agree
Q11: SCE agrees in part with proposed R2. The use of the Gallet equation and the replacement of the existing Clearance 2 requirement with the Critical Clearance Zone is acceptable. However, SCE strongly disagrees with establishing a separate requirement for implementing an imminent threat procedure should there be an encroachment of the Critical Clearance Zone because it forms the basis of an unnecessary zero-tolerance enforcement policy. Read in context with corresponding Measure 2, R2 appears to require Transmission Owners to prove that a Critical Clearance Zone encroachment did or did not occur and also prove that that an imminent threat procedure was or was not properly invoked. Although SCE agrees that CCZ encroachments should be addressed timely, we disagree with the notion and underlying assumption that a CCZ incursion will always lead to a flash-over or a vegetation-to-line contact. If the goal of FAC-003-2 is to prevent sustained outages (due to vegetation-to-line contacts) that could lead to Cascading, emphasizing â€œpreventionâ€☐ is understandable, however, enforcing prevention measures is an entirely different matter. Under the proposed requirements, a vegetation-to-line contact could conceivably represent two distinct violations of FAC-003-2. SCE believes this type of regulatory double jeopardy is patently unfair and forcing Transmission Owners to prove a CCZ encroachment did or did not occur is equally unfair and unenforceable. Because R1.4 adequately addresses the Transmission Ownerâ€™s responsibility regarding the implementation of an imminent threat procedure, SCE respectfully recommends that proposed R2 and corresponding M2 be removed from FAC-003-2.
Agree
Q12: No comments.
Agree
Q13: No comments.
Disagree
Q14: SCE does not agree with the inclusion of proposed R3 and believes it should be replaced with a modified version of proposed R8. SCE respectfully suggests that proposed R8 be revised to read: "Each Transmission Owner shall implement and follow its Vegetation Management Program to the extent allowed by existing easement and/or legal rights."
Disagree
Q15: SCE does not agree that proposed R4 was written in the most effective way because it establishes a zero tolerance enforcement policy. SCE agrees that a CCZ incursion should be addressed promptly, but we do not agree that a CCZ incursion is equivalent to a vegetation-to-line contact, or that a CCZ incursion represents an imminent threat of flash-over. As written, proposed R4 would require Transmission Owners to prove that a Critical Clearance Zone incursion has not occurred. Short of a daily ground or aerial inspection of every applicable transmission line, it is clearly impossible for a Transmission Owner to monitor their active Right of Way on a 24/7/365 basis to ensure a CCZ incursion will not or has not occurred. Bearing in mind that even the most robust of Transmission VM programs may occasionally identify an anomalous condition (in or outside the active ROW) that left untreated could lead to a flash-over or vegetation-to-line contact, the identification of such conditions typically occur during scheduled aerial or ground patrols and addressed timely. Of the two alternatives offered, SCE finds the first option (second bullet item) to be the most palatable. However, even that option leaves significant doubt as to practical enforcement, because a Transmission Owner could still be found in violation of two separate requirements (R4 and R5, R4 and R6 or R4 and R7) should a

vegetation-to-line contact (resulting in a sustained outage) occur. This situation amounts to regulatory double jeopardy. SCE believes that by any reasonable legal or regulatory measure, requiring a Transmission Owner to prove that a CCZ incursion did not occur is impractical and virtually impossible to enforce in a fair and impartial manner. Further, SCE believes that proposed R4 and corresponding M4 detracts from the purported goal of FAC-003-2 and should be removed.
Agree
Q16: SCE agrees in part with the establishment of R5, R6 and R7, however, we note that the opening of each requirement repeats a slightly altered version of the FAC-002-2 purpose statement. We find such repetitiveness unnecessary and note that as written, Requirements 5-7 presents a near identical compliance conundrum for Transmission Owners as Requirement 4. Again, Transmission Owners would be required to prove that they did not incur a sustained outage due to a vegetation caused flash-over or vegetation-to-line contact whether it be a grow-in, blow-in or fall-in. Although proving a sustained outage (for cause) did not occur will be difficult and unwieldy, it is not impossible. The simple difference between a Transmission Owner disproving the occurrence of a CCZ incursion and their disproving vegetation caused sustained outages, is that Transmission Owners do in fact keep records of â€œoutagesâ€☐. Because a Transmission Ownerâ€™s record keeping prowess is the only viable option for proving a vegetation caused outage did not occur, SCE respectfully suggests R5, R6 and R7 be revised to read: R5 - "Each Transmission Owner shall document Sustained Outages of applicable lines due to vegetation growing into a conductor operating within its Rating with the following exceptions:" R6 - "Each Transmission Owner shall document Sustained Outages of applicable lines due to vegetation blowing into a conductor operating within its Rating and located within an Active Transmission Line Right of Way with the following exceptions:" R7 - "Each Transmission Owner shall document Sustained Outages of applicable lines due to vegetation falling into a conductor operating within its Rating and located within an Active Transmission Line Right of Way with the following exceptions:" We also note that Footnote 6 is misplaced in the draft and should follow the word â€œOutagesâ€☐ in each of these requirements.
Agree
Q17: SCE agrees in part with the inclusion of R8, however, we believe R8 should be revised and renumbered to replace proposed R3. In SCEâ€™s view, the act of implementing a Transmission VM program encompasses both inspection and maintenance activities. SCE respectfully suggests that proposed R8 be revised to read: "Each Transmission Owner shall implement and follow its Vegetation Management Program to the extent allowed by existing easement and/or legal rights."
SCE notes that Section C (Compliance) is incomplete and that the associated levels of Non-Compliance listed in FAC-003-1 may be different from those proposed for FAC-003-2. SCE reserves the right to revise its initial comments and submit additional comments regarding the requirements, measures and compliance portions of FAC-003-2.
Group
SERC OC Standards Review Group
Jim Griffith
Southern Company
Disagree
The following comments are supplied by the SERC OC Standards Review Group (OCSRG): The definition of the Bulk Electric System generally does not include radial transmission lines directly serving load. The current standard covers all 200 kV and above transmission lines along with those lower voltage lines designated by the RRO while the BES includes all lines 100 kV and above. Use of the term Bulk Electric System will cause unnessesary confusion to the industry concerning applicability of this standard. Therefore, the SERC OCSRG recommends the continued use of the undefined term "electric transmission systems."
Disagree
The SERC OCSRG does not believe that the RC is the appropriate entity to identify sub-200 kV transmissions to be subject to this standard. Vegetation Management programs are longer than the normal operating horizons of RCs. We believe that the proper function to identify sub-200 kV transmission lines subject to this standard is the Planning Coordinator. This must be consistent with PRC-023, Requirement 3. We also recommend that a process be established for dispute resolution. NERC should develop a comprehensive approach to the determination of "critical" facilities rather than

pushing a piecemeal approach as evidenced by this standard and PRC-023, among others.
Agree
Agree
Disagree
While the SERC OCSRG agrees with this requirement in general, there may be areas (e.g., desert terrain) where an annual interval would be unnecessary and not cost effective.
Agree
Disagree
The Requirement as written is too prescriptive and is open to interpretation from an audit perspective with use of the term â€œimmediateâ€☐ communication and a partial list of activities. Due to limitations of communication capabilities in the field, "immediate" may not be practical. While the White Paper provides insight into what is accceptable communications to the Transmission Operator, the standard is less prescriptive in describing what is an acceptable communication path to the Transmission Operator. We recommend better descriptions in VSLs, measures and the RSAW as to what is acceptable. Many conditions or threats, requiring immediate removal, would not require communcation with the Transmission Operator, who is not an applicable entity for this standard. The SERC OCSRG recommends that R1.4 be deleted. Since this is a "zero tolerance" standard any Transmission Owner will remove any discovered threats to prevent outages. If R1.4 is not deleted, the SERC OCSRG believes that imminent threats should be a defined term. The definition should be as follows: â€œImminent Threat: A vegetation condition which, if not addressed, will place a transmission line at an immediate risk of a Sustained Outage.â€☐
Agree
Agree
Agree
Disagree
The SERC OCSRG recommends that R2 be deleted. Since this is a "zero tolerance" standard any Transmission Owner will remove any discovered threats to prevent outages. While we agree that the implementation of an imminent threat procedure may be a valid concept, visualization of the Critical Clearance Zone and determining an approaching encroachment is a practice in application of theoretical conductor locations in real time.
Agree
Developing minimum sparkover distances in this standard is a superior approach for the stated reason in question 12. In addition, referring to tables and values in another standard is problematic if the referenced standard is revised and the tables are re- numbered or deleted altogether. The SERC OOCSRG suggests that the tables based on the Gallet equations be removed from the standard and be kept in the technical white paper solely to assist in developing a common understanding of the threshhold for taking actions.
Agree
See comments in #12 above.
Agree
Disagree
The requirement, as written, compels the Transmission Operator to allocate precious resources to ensuring that a vegetation encroachment NEVER will occur on any transmission line, regardless of that line's true importance to maintaining electric transmission system reliability. All lines are not created equal; only those that are involved in IROLs should be held to a zero tolerance standard. R4, if retained, should begin with "Subject to its legal rights," and insert the word "vegetation" between

prevent and encroachment. Vegetation, which falls through the Critical Clearance Zone or falls to lodge within the Critical Clearance Zone, should not be included as violations of the Critical Clearance Zone. The concept of the Critical Clearance Zone is useful as a mental model to visualize required vegetation management work. While this is a good conceptual tool to drive consistent terminology and proper vegetation management practices, it remains theoretical in nature and impractical to measure on a span by span basis. The complexity of determining an encroachment into the Critical Clearance Zone is overly burdensome due to the need for survey accuracy measurements and engineering evaluations. In addition, this complexity leads to questions about the ability to audit this requirement. These complexities introduce reliability and audit issues when encroachments into this conceptual area are defined as violations. The SERC OCSRG believes the Sustained Outage, as defined by other measures in this standard, should be the non-compliance measure. We suggest that the Critical Clearance Zone concept be kept in the technical white paper and that all references to the Critical Clearance Zone be removed from the body of the standard. R5, R6, and R7 ensure that version 2 of the standard has reliability requirements equal to version 1; therefore R4 should be removed.
Disagree
R5, R6 and R7 should begin with "Subject to its legal rights,". The requirements, as written, compel the Transmission Operator to allocate precious resources to ensuring that a vegetation outage NEVER will occur on any transmission line, regardless of that line's true importance to maintaining electric transmission system reliability. All lines are not created equal; only those that are involved in IROLs should be held to a zero tolerance standard. R5, R6, and R7 ensure that version 2 of the standard has reliability requirements equal to version 1; therefore R4 should be removed.
Disagree
The SERC OCSRG suggests that the Requirement be reworded to read: â€œEach Transmission Owner shall implement its annual work plan for vegetation management within the Active Rights of Way." Any further verbiage is confusing, ambigious or unnecessary.
The SERC OCSRG recommends that the definition of "Active Rights of Way" be revised as follows: "A strip of land, designated by the Transmission Owner, that is occupied by active transmission facilities. This corridor does not include the inactive or unused part of the Right of Way set aside by the Transmission Owner for other facilities or uses." The SERC SOSRG recommends that this standard should exclude radial to load facilities and, for consistency, all 200 kV and above lines should not be included in the standard unless they meet the same requirements as sub 200 kV lines.

Agree
Agree
Agree
Agree
Agree
Disagree
The Standard is about preventing outages and having an effective program. An effective program should allow for the identification of a threat and the removal of the threat prior to a vegetation caused outage. I prefer alternative 2. If a vegetation caused outage should occur or if the Regional Entity determines a violation occurred based on a compliance investigation then the entity is in violation of this requirement.
Agree
Agree
1) Disagree with R1.1. The proposed standard is too lenient on the program documention required for an effective program. R1.1 should include the words " the program will document the program objectives, method of site evaluation, the definition of action thresholds, the control methodologies, and how the monitoring program is established". There is a wide gulf between listing IVM methodologies and a vegetation proram implementing A300. 2) CHANGE: Within Applicable Facilities listed in section 4.2 the phrase Transmission Line should be changed to Overhead Transmission Line. The NERC Glossary definition of transmission Line is: " A system of structures, wires, insulators and associated hardware that carry electric energy from one point to another in an electric power system. Lines are operated at relatively high voltages varying from 69 kV up to 765 kV, and are capable of transmitting large quantities of electricity over long distances." The accompanying white paper states the standard is addressing the impact of vegetation growth on overhead transmission lines. The intent of this standard is the development and imlementation of a vegetation management program for overhead transmission lines only. By specifically stating "overhead transmission lines in Section 4.2 there will be no possibility of an occurrence of an auditor requesting a vegetation management program for underground lines.

Robert (Bob) B. Suedkamp
USDA Forest Service, Southwestern Region, Regional Office for AZ and NM
Agree
Agree
Agree
My disagreement with R1
Agree
Disagree
It would seem also that the T.O. should be expected to react to circumstances that create the need for a more frequent inspection cycle such as conditions that cause widespread vegetation mortality such as drought and/or beetle infestations.
Disagree
I think that the Transmission Owner should be able to specify the effective period of the plan whether

it is one year or ten years. Arizona utilities are starting to think in terms of multi-year corridor management plans. A one year planning period could be specified as the minimum planning period.
Agree
The USFS would be expecting the Transmission Owner to be documenting the imminent threat procedures in an operating plan or corridor management plan that would be approved by the designated USFS decision maker. If such procedures are documented in the Transmission Owner's TVMP and are compatible with USFS resource management direction, then the imminent threat procedures could be incorporated in the agency-approved operating plan by reference. If the Transmission Owner disputes any restrictions that are placed by the USFS on the imminent threat procedures, the USFS has an administrative appeals process which the Transmission Owner can use, but those procedures can be time-consuming and probably would not be perceived by the Transmission Owner as being neutral for negotiation purposes. It might help if a third federal party like NERC could help resolve disputes between the Transmission Owner and the USFS on the imminent threat procedures. Although the USFS would object to unreasonable intrusion of NERC into normal USFS land management prerogatives, imminent threat procedures would seem to be a topic for which NERC should take a very strong position, especially with a standard that identifies minimum vegetation clearances as related to prevention of arcing potential, or in other words, vegetation that should be considered hazardous and in immediate need of treatment.
Agree
In my opinion, problems between the Transmission Owner and the USFS over the TVMP should be worked out before a TVMP is ever finalized. A dispute resolution process outside the control of either party would be very helpful and would probably facilitate quicker solutions than if the Transmission Owner and the USFS are left to work out problems on their own. If a TVMP is prepared in a vacuum, the problems may not come to light until some kind of outage actually occurs. It would be much better to flush any disagreements and deal with them before any outages actually occur.
Disagree
If it is possible for NERC to identify minimum clearance standards as related to arcing potential for hazardous vegetation, it would definitely help USFS field administrators to have some kind of hard and fast standards. If that kind of approach is not reasonable in light of the need to adjust standards for various load conditions and vegetation growth rates, then a prescribed formula for calculating minimum clearances would be the next best thing.
Disagree
Perhaps standard M8 could be expanded or clarified to require the Transmission Owner to describe how employees, especially field supervisors, are trained to implement the plan and to prove that the training was actually provided. Some problems have arisen in the USFS Southwestern Region because some Transmission Owners are not providing adequate supervision of field work.
Agree
Attachment 1 is very conservative. I think that the clearance distances shown on the attachment should be expanded to create, in effect, a standard that reflects maximum line loading and maximum line sag. I would also like to see some flexibility built into the process so that the Transmission Owner and the USFS could negotiate some consideration for vegetation growth rates. The end result would generate a standard that would give the Transmission Owner the security of knowing that vegetation would not grow into the potential arcing zone for some reasonable amount of time - some kind of entry cycle.
Agree
See comment for Question 11.
Don't know!
Agree
Disagree

The wording appears too strong. Who can predict the unforeseen circumstances that inevitably arise. If the standards require the reporting of encroachments, the ensuing report can help determine if the Transmission Owner did everything reasonable to avoid the problem. It seems like the standard should be written to require the Transmission Owner to do everything reasonable to avoid the problem. A judgement call would still be needed to evaluate the performance.
Disagree
I believe that the text for each element should be re-written with the general philosophy that the Transmission Owner shall do everything reasonable to prevent such problems in line with the comment for section 15. Problems should be reported and investigated and a judgement call should be made about whether the Transmission Owner did everything reasonable to avoid the problem.
Disagree
This standard needs to be broadened to include evaluation of the good faith efforts by the Transmission Owner to coordinate with the USFS on development of the work plan. A mechanism should be developed to allow the Transmission Owner to evaluate the good faith efforts of the USFS.
I'm having trouble getting comments to "stick" in this section of the form. I have a general concern with the opening paragraph of R1. The wording seems to encourage a Transmission Owner to develop a TVMP in a vacuum. The US Forest Service defintely wants input into the development of an annual work plan and USFS land use authorizations include a requirement for USFS approval of vegetation management plans. It seems much more reasonable to require the TVMP to reflect USFS or any other landowner resource management considerations. This tactic would require more "up front" work, but the end result is a plan which would reflect reasonable landowner input and where the disagreements could be settled ahead of time rather than being left for the night shift. I also believe that some kind of dispute resolution process is needed outside the control of either the Transmission Owner or the USFS. I think that NERC could fill that role very well.
Individual
Kris Manchur
Manitoba Hydro
Disagree
Manitoba Hydro disagrees with changing "electric transmission systems" to "Bulk Electric System" because BES applies to facilities 100kV and above which may not have an impact on system reliability.
Disagree
Manitoba Hydro disagrees that the RC is appropriately positioned to identify and designate any sub-200kV lines that should be subject to this standard. Lines below 200kV should include only those that are currently classified as Interconnection Reliability Operating Limit (IROL) lines which are already defined and listed for registered entities. As such R9 and R10 should be eleiminated from this standards along with the RC in the applicability section.
Agree
Agree
Agree
Agree
Agree with the seperation - but suggest that the time horizon of one year be removed as some changes may push the work beyond the curent planning year.
Agree
Suggest removing, "and may include actions such as a temporary reduction in line rating, switching lines out of service, or other actions", as this is outside the scope of a vegetation management program.
Disagree
Agree with the change in terminology - but would suggest that wording clarify that this is not only for situations where the utiity is unexpectedly prevented from implementing its annual plan - but also for

areas where it is unable to implement its clearance requirements due to property rights limitations.
Agree
Agree
Disagree
The imminent threat process trigger should be well defined, and the vague "approaching" terminology needs to be changed. Imminent threat implies and that an elevated risk of contact exists. That is not the case if the vegetation is merely approaching the CCZ. The objective of the overall Vegetation Management program is to prevent an encroachment. The imminent threat procedure should be triggered by discovery of an encroachment into the CCZ. Even when an actual encroachment into the CCZ occurs - while the odds of an outage event have increased - the likelihood of a contact is still minimal, as other environmental factors still need to be in place (ie. high temperature and/or high wind conditions). If this approach to an imminent threat process trigger, then the violation of this requirement implies a violation of R4, which prohibits the encroachment of the CCZ, and therefore either R2 or R4 could be removed, or they could be combined into one requirement.
Agree
Disagree
Manitoba Hydro has historically designed the ROW clearance requirements based on an operating limitation of not switching during extreame wind conditions, therefore, beyond a wind presure of 230 Pa, our design doesnot account for switching surge overvoltages. We do howerver, agree with the use of overvoltage factors as described above for wind conditions of less than 230 Pa.
Agree
Disagree
Manitoba Hydro asserts that the reliablity of the system is measured by outage, not by the possiblity of an outage, and therefore if the overall vegetation management system (plan-patrol-discover-mitigate) is effetive in preventing an outage, then the reliablity of the system has been maintained, and the intnent of the reliablity standard achieved. Therefore, we propose that the second bullet above is the prefered alternative, and that R2 and R4 be combined as the violation of R4 would then imply a violation of R2.
Agree
Agree with splitting the various events. We note that there is no specific requirement to actually report an outage. The Requirements say that we should Prevent Sustained Outages, but not actually report sustained outages should they occur. In version 1, R3 clearly stated that the Transmission Owner shall report.
Agree
Individual
Jianmei Chai
Consumers Energy Company
Disagree
Consumers Energy disagrees with changing the current "electric transmission systems" to "bulk electric system". This change will create confusion and can lead to a discrepency concerning lines operating below 200kV that may be included in the "bulk electric system" but are otherwise excluded from this standard.
Agree
Agree

Agree
Disagree
FERC required NERC in Order 693 to develop appropriate inspection cycles based on local factors. Potential annual tree growth varies considerably within the geography of the United States and FAC-003-1 recognized this factor and left it up to the utility to determine the most appropriate inspection cycle for their system. This was in lieu of having proper data readily available to determine inspection cycles for various areas that could be incorporated into the standard. FAC-003-2 greatly decreases the minimum separation distance between conductors and vegetation. Table 1 shows the minimum distance at sea level for a 345 kV line a 3.12 feet. This is considerably less than the potential annual growth rate of many tree species in many areas of the United States. Therefore, the annual inspection cycle would not be acceptable to identify tree growth that can violate the minimum distance before it occurs. Consumers Energy strongly believes that using the Gallet formula to determine the minimum clearance between conductors and vegetation will decrease the reliability of the system compared to the minimum clearance requirements in FAC-003-1.
Agree
Disagree
Consumers Energy believes that each Transmission Owner/Operator should have a Vegetation Imminent Threat Procedure. We disagree with this requirement because "vegetation imminent threat" is not defined in the standard. As interperted, the "vegetation imminent threat" is only what is needed to avoid violating the Gallet formula minimum distance which would allow vegetation approaching close to 3 feet of separation on 345 kV conductors. At this distance, removal of the tree cannot occur without removing the line from service per OSHA rules. Therefore, the tree can "cause" an outage but be acceptable under this standard. Consumers Energy believes that vegetation must be maintained so that extraordinary measures needed to remove the vegetation threat do not have to occur in order to complete the work. Thus, the minimum distance to "trigger" an imminent threat must be greater than the OSHA minimum working distance and therefore the Gallet formula does not provide the protection that FERC demands. During high load periods options a system operator may have to mitigate the vegetation threat may not be available; you may not be able to remove the line from service, derate the line, etc., so the operator must "hope" to get through the high load period without the vegetation causing a outage. Allowing vegetation to approach the Gallet formula distance is unacceptable and severely decreases the reliability of the system.
Agree
Agree
Agree
Disagree
Absolutely disagree! The Gallet formula distances do not provide adequate protection of the system. The "Critical Clearance Zone" concept is not workable in the field. Every foot of every span would have a different CCZ that cannot be measured in the field without survey type equipment and knowledge of current line loadings. The clearance requirement needs to be uniform along the span for field crews to effectively achieve compliance. It appears that the drafting team hopes to minimize violations of vegetation violating FAC-003-1 Clearance 2 distances by decreasing the clearance distance between the conductor and vegetation using the Gallet formula. If NERC believes that FAC-003-1 Clearance 2 distances are too conservative, then the Gallet formula distance needs to be increased by some multiplier (2 or3) to achieve adequate safeguard for growing vegetation. Most trees in the United States in the size range that could exist beneath conductors achieve height growth of 3 feet or more annually. A tree in May may have adequate clearance per the proposed CCZ and in July violate that clearance causing an outage. Therefore, if the CCZ is to remain as is then the transmission owner/operator must have a defined imminent threat distance considerably greater than the CCZ and must be great enough that field personnel can safely remove the threat without de-energizing or de-rating the line.

Disagree
The Gallet distances severely lessen the reliability of the tranmission system since there is not a define imminent threat distance and the Clearance 1 distances have been removed from this draft. The IEEE 516 distances provided a safety margin to allow for vegetation to grow and not be a reliability risk. A transmission owner/operator of a moderate size could not effectively inspect often enough during the growing season to protect lines from outages when trees are permitted to approach the Gallet formula distance and not be a violation. Such close distances would permit utility management to severely cut vegetation management budgets and allow trees to grow for 1-2 years beyond their scheduled maintenance cycle and not be in violation. But, 2-3 years after the budget cut, the field operation would be faced with an insurmountable amount of trees needing addressed and limited timeframes to complete the work. This is basically how the blackout occurred and this standard decreases the requirements to allow this to happen again.
Agree
Agree
Disagree
The CCZ does not provide adequate clearance and the imminent threat procedure if successfully implemented only works IF YOU KNOW ABOUT THE VEGETATION THAT THREATENS THE CCZ which cannot be ensured with yearly inspections. Consumers Energy believes that the Clearance 2 distances in FAC-003-1 provide more reliability than the CCZ proposed in this draft or any of the alternatives disussed above.
Disagree
R5, R6 and R7 should be rewritten as a single requirment for vegetation within the "Active Transmission Line Right of Way" and the exceptions listed. Additionally, a requirement for hazardous trees outside of the "Active Transmission Line Right of Way" should be incorporated into this draft and similar exceptions listed for natural disasters, third-party, and animal causes.
Agree
The annaul work plan should be designed to avoid vegetation growing into a violation of the CCZ or whatever minimum distance is acceptable. Since the plan can change throughout the year, it needs to be flexible, it should be stated that the plan at a minimum must provide adequate funding to prevent vegetation growth from violating the minimum clearance distance. The flexibility of change should be limited to changing to address emergent needs for vegetation management and not reductions in funding that delay maintenance in the hopes that additional funding at some future point in time will be adequate to remove the backlog of vegetation maintenance. The Purpose of the standard should be revised to state "(To maintain minimum clearance sufficient to avoid any vegetation-related Sustained Outages for all applicable conditions) for all Transmission Lines covered by this Standard" as provided by FERC in Order 693, Paragraph 731. The purpose as stated in FAC-003-2 waters down the intent of FERC to "improve the reliability" and is only applicable to "outages that could lead to cascading".
Individual
Dawn Travalini
National Grid
Disagree
Use of the term Bulk Electric System will cause unnessesary confusion to the industry concerning applicability of this Standard.
Disagree
No opinion.
Agree
Defining "Active Transmission Line Right-of-Way" solves the Right-of-Way definition problem within the SAR.
Agree

These revisions and separation make it easier to match requirements and measures.
Disagree
R1.2, M1.2 and M1.3 in the Standard all refer to calendar year. National Grid objects to inspections being based on a calendar year. Transmission Owners should be able to define their own "year". (See Question No. 18.)
Agree
Agree
Disagree
National Grid agrees replacing mitigation plan with corrective action process. However, National Grid questions the use of "interim" for a corrective action process in R1.5, and suggests striking "interim".
Disagree
National Grid takes exception to the term "fill-in-the-blank". National Grid disagrees with the elimination of Clearance 1. The Clearance 1 requirement in FAC-003-1 was meant to allow a Transmission Owner to establish clearances to be achieved at the time of vegetation management work, and be sensitive to local and regional conditions. National Grid believes that Clearance 1 is needed for public education and safety reasons. Clearance 1 standards allow utilities to specify a cyclic programmatic approach, and gives the utility leverage with local and state regulators and the public to achieve significantly larger than minimal clearances.
Disagree
National Grid takes exception to the term "fill-in-the-blank". National Grid would like Personnel Qualifications to remain in Standard FAC-003-2.
Agree
Agree
Disagree
No opinion.
Agree
Agree
National Grid agrees that there should be no encroachments into the CCZ. However, encroachments in the CCZ should NOT be considered a violation. Violations should only be for sustained transmission outages.
Agree
National Grid agrees with the proposed change, however, Standard FAC-003-2 does not provide outage reporting requirements in R5, R6, R7, or anywhere else in the Standard.
Agree

National Grid has the following comments: 1. Transmission Owners should be able to define their own inspection "year" and not be locked into a calendar year time frame. National Grid performs inspections at least once per vegetation growth year. Under our Vegetation Management Program, growth years are not skipped, and our inspections occur prior to new growth every year. For example, a transmission right-of-way may be inspected in December 2008 and the right-of-way is next inspected in February 2010. Under this scenario, the inspections occurred 14 months apart, but only one growth year occurred between inspections, and each inspection is ahead of the next year's growth. Transmission Owners need this flexibility to deal with regional growth rate differences and climate. 2. Section C., Compliance, of Draft Standard FAC-003-2 states "To be added". Issuance of Draft Standard FAC-003-2 should have been delayed for comments until all sections were complete. This section is likely to include the outage reporting and self-certification requirements. Transmission Owners need the opportunity to comment on these items. 3. With the elimination of Clearance 1 and reducing Clearance 2 clearances, there is concern that FERC will view Standard FAC-003-2 as a watered down version of Standard FAC-003-1.

Pacific Gas & Electric Co.
Agree
Agree
Agree
Agree
Agree
This requirement is appropriate to ensure adequate inspection frequencies, however, a clear definition of "inspection" should be contained in either the standard or white paper.
Agree
Agree
PG&E agrees an imminent threat procedure is a critical component of the standard and should be contained in the TVMP. See additional comments for Q11.
Agree
Agree
Agree
Disagree
PG&E agrees the Gallet equation is superior to IEEE 516 and the imminent threat procedure is a critical component of the standard but disagrees that initiation of the procedure be based on such ambigous language as "approaching the CCZ". Approaching could be any and all vegetation that is live and growing and CCZ is a theoritical calculation not a real time event. As written, the standard would require the TO to initiate an emergency action when such action may not be warrented or necessary to prevent an outage. PG&E recommends using a clearly defined and measureable threshold to determine when the imminent threat procedure must be initated. A reasonable threshold would be 3 times the Gallet clearance distances referred to in Table 1 or when vegetation is threatening to fall into or otherwise impact a line.
Agree
Agree

Agree
Disagree
PG&E believes a "minimum clearance distance" or "do not encroach zone" is a critical element of this standard and necessary to achieve the stated purpose of preventing vegetation caused outages. Preventing vegetation encroachments will prevent outages. However, PG&E disagrees with using the CCZ as a minimum clearance requirement because it is ambigous and subject to wide variations and intrepretation. CCZ is a good concept to aid in understanding movement of conductors but is a theoretical calculation and would be very difficult if not impossible to enforce. PG&E suggests using a clearly defined distance such as Gallet equation plus a safety margin to assure there is no chance of spark over. Two times Gallet would be a reasonable clearance requirement to assure a spark over does not occur and eliminate the ambiguity of the CCZ as the "do not encroach zone".
Agree
M5, M6 and M7 do not explcity exclude the exceptions in R5, R6 and R7 and should do so.
Agree
PG&E agrees with the requirement to implement the annual work plan, but recommends removing the language "within the extent of its easement and/or legal rights".
1) The standard should be clear that it applies to all Federal and Non-Federal land. PG&E further recommends additional language specifically dealing with Federal land such as application of ANSI A300. 2) The standard should specify applicability inside substations.

Western Utility Arborists
Agree
Yes, we agree.
Agree
Yes, we agree.
Agree
Yes, we agree, subject to the qualification about â€œactiveâ€☐ rights-of-way under Comment #16. Under R1.1, it says â€œSpecify the methodologies that the Transmission Owner uses to control vegetation.â€☐ The single word â€œmethodologiesâ€☐ does not adequately replace â€œobjectives, practices, approved procedures, and work specifications.â€☐ The Western Utilities recommends keeping the original wording. We would also like to point out that the original intent of the standard was to ensure that utilities had a complete vegetation management program. The new standard is evolving towards an outage control program, and no longer encourages programs or behaviours that would ensure the causes of outages are prevented long before they become a problem. The standard now redirects efforts to avoiding outages instead of managing vegetation.
Although itâ€™s important to have these two separate aspects â€“ documentation and implementation â€“ separating them spatially in the document itself makes the standard longer than necessary and creates redundancy. It seems obvious that if you prepare elements of the TVMP, they also need to be implemented. The document would be easier to follow if the two elements were kept together.
Clarification is required on exactly what an inspection is, which should perhaps be outlined in the white paper. There are areas where inspections are not necessary at all, such as lines over a parking lot, or in a remote desert area. The Western Utilities need some assurance that this inspection will not constitute a dedicated, comprehensive vegetation management inspection. Inspections are currently often part of a routine line patrol, where the lineman looks for vegetation concerns in addition to undertaking maintenance work. Therefore, the Transmission Owner needs the ability within their TVMP to define what an inspection is in the context of their utility operations.
The document would benefit from keeping the two requirements together, since they relate to the same topic. Under the new wording in R1, the TVMP no longer has a requirement to include

objectives. However, there is a phrase in R1.3 to â€œsupport the objectivesâ€¦and methodologiesâ€¦outlined in theâ€¦program.â€☐ To be consistent with R1.3, the Western Utilities recommends that R1.1 be reworded to specify the methodologies and objectives that the Transmission Owner uses to control vegetation.
Agree
We agree with 1.4, with the following qualification: Any standard that is developed should not contain advisory-type languageâ€”it should be declarative in tone. For example, in R1.4, the ending clause that begins â€œâ€¦and may include actionsâ€¦â€☐ should be removed because it is advisory in nature. The suggested actions are not even the responsibility of the vegetation management program.
Agree
Yes, we agree.
Disagree
The Western Utilities do not agree with the removal of Clearance 1. We recommend adding it back to the document, but reworded and moved to include it as a measurement (M), rather than a requirement (R) under the new standard. Many utilities feel that Clearance 1 provides justification and leverage for operational clearances when dealing with organizations such as municipalities. Without Clearance 1, utilities could be mandated in specific situations to clear so that the vegetation is just beyond the CCZ at all times. This could result in pruning at six month intervals, which is not feasible or cost-effective.
Agree
The Western Utilities are in agreement with the elimination of this requirement. However, we feel strongly there must be appropriate knowledge to do the work, and that Transmission Owners must at least have internal standards related to personnel qualifications.
The Western Utilities feel that changing to the Gallet equation will not have a large impact on its vegetation management operations, so we have no concerns. We agree with R2, but feel that this clause makes R4 redundant, as per our discussion under Comment # 15 below. We recommend the removal of R4 entirely from the standard.
Agree
The Western Utilities feel that changing this will not have a large impact on its vegetation management operations, so we have no concerns.
Agree
The Western Utilities feel that changing this will not have a large impact on its vegetation management operations, so we have no concerns.
The Western Utilities understands that itâ€™s possible to have a schedule and not implement it. However, we feel that the document itself would be easier to follow if it was re-organized so that the requirement to have the schedule is kept together with the requirement to implement it.
The new requirement in R4 stipulates that the Transmission Owner is in violation if an encroachment of the CCZ occurs at any time. However, the CCZ changes with each foot of the transmission line from the insulator to the mid-span, depending on loading, actual operating temperature, wind loading, ice loading, maximum design rating, maximum operating load, and so on. Further, measure M4 requires that the Transmission Owner has evidence demonstrating there were no vegetation encroachments into the CCZ. To provide evidence demonstrating there were no vegetation encroachments into the CCZ would be an extremely onerous task and an expensive requirement for the Utilities. The Western Utilities strongly supports the alternative to R4 as recommended in the Comment Form (#15), which is to require immediate removal of the vegetation or immediate implementation of the imminent threat procedure upon discovery of a possible encroachment of the CCZ, thereby proactively preventing an outage. This means a violation would occur only if the imminent threat process is not successfully implemented. This alternative is essentially the same as R2. Therefore, the Western Utilities recommend removing R4 from the standard entirely.
The Western Utilities strongly recommend that the requirement under R7 be changed from â€œshall prevent sustained outagesâ€☐ to â€œshall minimize sustained outages due to vegetation falling into a conductor.â€☐ We note that the word â€œminimizeâ€☐ was present in earlier drafts of the document. We are concerned about the requirement for utilities to prevent sustained outages from vegetation falling into the conductor from within the active transmission ROW. It is operationally

almost impossible to know precisely where the edge of the ROW is in all situations under all conditions. This could lead to an incident where utilities are charged unreasonably â€“ for example, for an outage from a tree that was one foot within the active ROW line. We should not be held liable when reasonable due diligence is practiced. Further, it is not economically feasible for utilities to survey every ROW in the U.S. and Canada to determine precise clearance zones.
The Western Utilities understands that itâ€™s possible to have an annual plan and not implement it. However, we feel that the document itself would be easier to follow if it was re-organized so that the requirement to have the plan is kept together with the requirement to implement it.
Any standard that is developed should not contain advisory-type languageâ€”it should be declarative in tone. For example, in R1.4, the ending clause that begins â€œâ€¦and may include actionsâ€¦â€□ should be removed because it is advisory in nature. The suggested actions are not even the responsibility of the vegetation management program. ADDITIONAL COMMENTS We have prepared, and will submit via email, additional comments regarding our online submission. If the ability to submit them electronically is not available on this website, we will send the complete document via email to Harry Tom and would ask that it be reviewed and considered by the drafting team.

Transmission Operations
Disagree
The Purpose Statement of any regulation or standard should be completely consistent with the body of regulation or standard. Here the use of Bulk Electric System (which is defined as 100 kV and above) is inconsistent with the language of the Standard that states this Standard applies to 200 kV and above. One of the primary purposes of re-drafting a Reliability Standard is to clear up any previous confusion -- here the Purpose Statement instead of adding to clarity, adds an uncessary element of confusion. Thus, the Purpose Statement should be re-written to state 200 Kv and above.
Agree
Agree
Agree
Agree
Agree
Disagree
The definition of Imminent Threat procedure should be included in the Standard. As FERC has stated with regard to the definition of sabotage, the industry should come up with a standard definition and it should not vary from company-to-company. FPL further disagrees with defining Imminent Threat only in a white paper as proposed by some. The Standard should not refer to other reference documents, especially when it is to add clarity and should define the Imminent Threat procedure as well as its requirements within the body of the Standard.
Agree
FPL neither agrees or disagrees with this removal but provides the following comment. FPL's experience regarding Clearance 1 is that it was an effective way of demonstrating a measurable requirement for compliance when dealing with public entities. The use of a corrective action process to mitigate instances where this clearance was not met before violations ocurred is also very effective in promoting reliability and safety in the Standard.
Agree
Disagree

FPL agrees that the Gallet equation is a better method to determine a Critical Clearance Zone. However, FPL does not agree with the application of the zone for several reasons outlined below. â€¢ There are many environmental and engineering variables and assumptions included in the calculation of the Critical Clearance Zone. â€¢ These assumptions are not clearly defined in the standard. â€¢ Unless there is a significant intrusion into the Critical Clearance Zone, an engineer and surveyor would be necessary at all times to determine a violation. â€¢ The success of this standard lies with a standard the field personnel can implement. When making actual trimming or removal decisions, the field personnel are not adequately skilled to do much more than make a rough guess at the Critical Clearance Zone. This standard must establish measurable and auditable parameters for field operations. â€¢ In Requirement R2, determination of when to activate the Imminent Threat Procedure becomes unclear due to the difficulty in determining when the Critical Clearance Zone is encroached. â€¢ As written, off ROW trees falling through the Critical Clearance Zone become a violation of Requirement R4. Unless an outage occurred, how would the utility determine that a violation occurred? In FAC 003-1 an outage of this nature is defined as Category 3 and is not a violation. Since fall-in tree interruptions have never been contributors to cascading events or blackouts they should not be a violation of a NERC standard. Consequently, as written, it is highly questionable whether this Standard is sufficiently specific and clear to be enforceable. The many questions and levels of confusion introduced with the application of the Critical Clearance Zone concept suggests that neither the industry nor NERC will ever know if compliance is met. Such a high level of ambiguity requires that the Critical Clearance Zone concept be revisited and most likely replaced with a measure that is workable for both the industry and NERC. To further this effort, FPL has outlined some alternative suggestions described in the answer to question 18.
Agree
Agree
Agree
Disagree
NERC standards require the Transmission Owner certify annually that they are in compliance to the standard for the entire year. Since there is no way that a Transmission Owner could monitor every span of line every minute of every day, Requirement R4 cannot be certified. A Transmission owner can only certify that at the time inspected the system met the specification in the standard and that implementation of its Transmission Vegetation Management Plan maintains these specifications. As stated earlier, the Critical Clearance Zone is difficult to accurately identify in the field and without an outage it would be difficult for an auditing body to find and validate. Requirements R4-R7 are reactive in nature. They are violations after the event has occurred or when the tree - wire relationships are so close that emergency action is the only recourse for the Transmission Owner. The standard needs to drive the Transmission Owner to identify and remove trees threatening the system in a proactive fashion. A Transmission Owner should never be in violation for timely action to remove a threat to the system.
Disagree
As currently written, Requirements R5, R6 and R7 demand perfection. The only acceptable number for all 150K miles of affected transmission line in the US is 0. The standard should be achievable and enable proactively addressing potential threats to facilities from vegetation. Even using a Six Sigma level of quality and control, processes can achieve a level of 3.4 defects per million opportunities for defect. Each tree on the ROW represents one of those opportunities. FPL has outlined an alternative proposal in response to Question 18.
Disagree
The standard goes to great length to specify the Active Transmission Right-of-Way but omits its reference in requirement R8. The inclusion of this term in Requirement R8 adds consistency to the application of the standard. FPL suggests the following change: "Each Transmission Owner shall implement its annual work plan for vegetation management to accomplish the purpose of this standard within the extent of its easement ans/or legal rights in the Active Transmission Line Right-of-Way."

FPL believes the Vegetation Management standard should concentrate on grow-in tree issues that contribute to cascading or blackout events as stated in the purpose statement. Fall-in trees from either on or off ROW do not in-and-of themselves cause cascading or blackout events. Transmission systems are appropriately designed to handle incidental outages under N-1 conditions which are the case in fall-in type outages. Requirements relating to fall-in and blow-in outages (R6 and R7), which deal with incidents resulting from force majeure or acts of God, should be removed to allow resources to be allocated to addressing events related to grow in interruptions. Because of an utter lack of control or such situations, no Standard or regulation places a duty on one to control force majeure or acts of God, yet that is precisely what R6 and R7 intend to do. If R6 and R7 stay in its current form, this will be yet another reason why this Standard as written will be unenforceable. FPL recommends the following approach. The entire US Transmission system was built under the National Electric Safety Code (C2). That code uses the Reference Component as the initial building block for establishing the lowest height of a conductor for all operating and designed environmental conditions. Over most open land this distance is 14 feet. FPL recommends creating a new requirement to clearly define a trimming standard. New Requirement At time of trimming, trees under conductors should be trimmed or removed so that the average growth would remain below the Reference Component of Rule 232 in the National Electric Safety Code C2. The wire zone should extend to the blowout distance calculated at 39 miles per hour (Fresh Gale) not to exceed the Active Transmission Right-of-Way. Where the Transmission Owner can not achieve that clearance, they shall have a permanent (ex. raised conductor) or interim (ex. short trim cycles) corrective action plan in place to prevent tree wire conflicts. Permanent corrective action plans should reside in the Transmission Owner's vegetation program record keeping system (database) for application when that line is maintained or inspected. Trees to the side of the ROW should be maintained at the edge of the Active Transmission Right-of-Way. The value in this approach is in its application by arborists and tree trimmers in field conditions. This approach is clear and measurable without a surveyor or an engineer present. The line design calculations were made to the NESC Standard at the time the line was built and incorporate all potential conductor locations within its flight path. As it stands now if there is a violation to R4, R5, R6, or R7 it is already too late. The standard should seek to identify and correct poor performers before they create a reliability threat to the system. In the field, a poor performer has many trees close to the line and will have to do many emergency cuts. It will also have more momentary interruptions before it has a single Sustained interruption. Sustained Interruptions have a history of contributing to cascading and blackout events. The standard should measure performance and penalize poor performance. The changes below reflect performance measurements with a graduated penalty applied to the metric. Change R2 to read Each Transmission Owner shall implement its Imminent Threat procedure when the Transmission Owner has knowledge, obtained through normal operating practices or notification from others, that the tree / conductor distance is less than the minimum clearance distance as specified in Table 2 of ANSI Z133.1-2006 (the minimum approach distance for qualified line-clearance arborists or qualified line-clearance trainees). Transmission Owners are to document and report activation of the Imminent Threat Procedure for violation of Table 2. Activation of the Imminent Threat Procedure for other causes shall not be reportable. The Violation Severity level should read: Activation of the Imminent Threat Procedure for encroachment of Table 2 of ANSI Z133.1-2006 (the minimum approach distance for qualified line-clearance arborists or qualified line-clearance trainees) has the following severity level: Lower â€“ Greater than 5 per 1000 miles of line and less than 7 Moderate â€“ Greater than 7 per 1000 miles of line and less than 9 High - Greater than 9 per 1000 miles of line and less than 13 Severe - Greater than 13 per 1000 miles of line Trees inside of Table 2 can only safely be trimmed under a clearance from the system operator, using special techniques under a line right of way from the system operator, or by a lineman with a live line permit from the system operator. No utility wants to let a tree get so close to energized lines such that it has to take the line out of service for a tree trim. It should be noted that Table 2 represents an established industry standard which is normally found placarded on the side of every tree trimming easement truck and bucket truck. It is minimum knowledge for every qualified line-clearance tree person under OSHA regulations. This is a distance that field personnel understand. New R5 to read: Each Transmission Owner shall minimize Momentary Outages of applicable lines due to vegetation growing into a conductor with the following exceptions: â€¢ Sustained Outages of applicable lines that result from natural disasters. â€¢ Sustained Outages of applicable lines that result from human or animal Activity. The Violation Severity level should read: Lower â€“ Having Momentary Outages Greater than 3 per 1000 miles of line and less than 6 Moderate â€“ Having Momentary Outages Greater than 6 per 1000 miles of line and less than 8 High - Having Momentary

Outages Greater than 8 per 1000 miles of line and less than 12 Severe - Having Momentary Outages Greater than 12 per 1000 miles of line New R6 to read: Each Transmission Owner shall minimize Sustained Outages of applicable lines due to vegetation growing into a conductor with the following exceptions: â€¢ Sustained Outages of applicable lines that result from natural disasters. â€¢ Sustained Outages of applicable lines that result from human or animal Activity. The Violation Severity level should read: Lower â€“ Moderate â€“ High - Having Sustained Outages Greater than 1 per 1000 miles of line Severe - Having Sustained Outages of 2 or greater per 1000 miles of line These VSL's listed above constitute a strawman for discussion. The drafting team could request historical performance data from Transmission Owners to statistically evaluate where the VSL should be set. As time progresses, future performance data could be re-evaluated to reset the limits. These changes bring the standard back in line with measurable and auditable requirements which provide practical field measurements to the personnel who can make the difference. These parameters provide measurements to indicate the tree health of the system. On a separate note, FPL believes that clarifying information captured in footnotes within the standard should specifically be referenced and made part of the standard. These notes add clarity and better define the standard requirements.

Agree
Agree
Yes, we agree, subject to the qualification about â€œactiveâ€☐ rights-of-way under Comment #16. We would also like to point out that the original intent of the standard was to ensure that utilities had a complete vegetation management program. The new standard is evolving towards an outage control program, and no longer encourages programs or behaviours that would ensure the causes of outages are prevented long before they become a problem. Instead, it redirects efforts to avoiding outages instead of managing vegetation. If this is now the preferred approach, the term TVMP is no longer valid and should perhaps be changed to the Transmission Vegetation Outage Prevention Program. Under R1.1, it says â€œSpecify the methodologies that the Transmission Owner uses to control vegetation.â€☐ The single word â€œmethodologiesâ€☐ does not adequately replace â€œobjectives, practices, approved procedures, and work specifications.â€☐ We recommend that the SDT retain the original wording.
Disagree
Although itâ€™s important to have these two separate aspects â€“ documentation and implementation â€“ separating them spatially in the document itself makes the standard longer than necessary and creates redundancy. It seems obvious that if you prepare elements of the TVMP, they also need to be implemented. The document would be easier to follow if the two elements were kept together.
Disagree
Clarification is required on exactly what an inspection is, which should perhaps be outlined in the white paper. There are areas where inspections are not necessary at all, such as lines over a parking lot, or in a remote desert area. We need some assurance that this inspection will not constitute a dedicated, comprehensive vegetation management inspection. Inspections are currently often part of a routine line patrol, where the lineman looks for vegetation concerns in addition to undertaking maintenance work. Therefore, the Transmission Owner needs the ability within their TVMP to define what an inspection is in the context of their utility operations.
Disagree
The document would benefit from keeping the two requirements together, since they relate to the same topic. Under the new wording in R1, the TVMP no longer has a requirement to include objectives. However, there is a phrase in R1.3 to â€œsupport the objectivesâ€¦and methodologiesâ€¦outlined in theâ€¦program.â€☐ To be consistent with R1.3, we recommend that R1.1 be reworded to specify the methodologies and objectives that the Transmission Owner uses to control vegetation.

Agree
We agree with 1.4, with the following qualification: Any standard that is developed should not contain advisory-type languageâ€”it should be declarative in tone. For example, in R1.4, the ending clause that begins â€œâ€¦and may include actionsâ€¦â€□ should be removed because it is advisory in nature. The suggested actions are not even applicable under the scope of a vegetation management program.
Agree
Disagree
We do not agree with the removal of Clearance 1. We recommend adding it back to the document, but reworded and moved to include it as a measurement (M), rather than a requirement (R) under the new standard. Many utilities feel that Clearance 1 provides justification and leverage for operational clearances when dealing with organizations such as municipalities. Without Clearance 1, utilities could be mandated in specific situations to clear so that the vegetation is just beyond the CCZ at all times. This could result in pruning at six month intervals, which is not feasible or cost-effective.
Agree
We are in agreement with the elimination of this requirement, but not without some qualifications. We feel strongly there must be appropriate knowledge to do the work, and that Transmission Owners must at least have internal standards related to personnel qualifications. It is unfortunate that this important requirement for an effective vegetation management program has been removed due to concerns with the auditing program.
Agree
We feel that changing to the Gallet equation will not have a large impact on its vegetation management operations, so we have no concerns. We agree with R2, but feel that this clause makes R4 redundant, as per our discussion under Comment # 15 below. We recommend the removal of R4 entirely from the standard.
Agree
We feel that changing this will not have a large impact on its vegetation management operations, so we have no concerns.
Agree
We feel that changing this will not have a large impact on its vegetation management operations, so we have no concerns.
Disagree
We understand that it is possible to have a schedule and not implement it. However, we feel that the document itself would be easier to follow if it was re-organized so that the requirement to have the schedule is kept together with the requirement to implement it.
Disagree
The new requirement in R4 stipulates that the Transmission Owner is in violation if an encroachment of the CCZ occurs at any time. However, the CCZ changes with each foot of the transmission line from the insulator to the mid-span, depending on loading, actual operating temperature, wind loading, ice loading, maximum design rating, maximum operating load, and so on. Further, Measure M4 requires that the Transmission Owner has evidence demonstrating there were no vegetation encroachments into the CCZ. These requirements may result in having to LIDAR the lines annually, to prove that trees have not encroached upon the CCZ. This would be an extremely onerous and expensive requirement for utilities. NV Energy strongly supports the alternative to R4 as recommended in the Comment Form (#15), which is to require immediate removal of the vegetation or immediate implementation of the imminent threat procedure upon discovery of a possible encroachment of the CCZ, thereby proactively preventing an outage. This means a violation would occur only if the imminent threat process is not successfully implemented. This alternative is essentially the same as R2. Therefore, we recommend removing R4 from the standard entirely.
Disagree
We strongly recommend that the requirement under R7 be changed from â€œshall prevent sustained outagesâ€□ to â€œshall minimize sustained outages due to vegetation falling into a conductor.â€□ We note that the word â€œminimizeâ€□ was present in earlier drafts of the document. We are

concerned about the requirement for utilities to prevent sustained outages from vegetation falling into the conductor from within the active transmission ROW. It is operationally almost impossible to know precisely where the edge of the ROW is in all situations under all conditions. This could lead to an incident where utilities are charged unreasonably â€“ for example, for an outage from a tree that was one foot within the active ROW line. We should not be held liable when reasonable due diligence is practiced. Further, it is not economically feasible for utilities to survey every ROW in the U.S. and Canada to determine and document precise clearance zones. Such costly effort would not produce any benefit to the reliabililty of the bulk electric system.
Disagree
We understand that it is possible to have an annual plan and not implement it. However, we feel that the document itself would be easier to follow if it was re-organized so that the requirement to have the plan is kept together with the requirement to implement it.
These comments were made with collaboration with other Western Utilities in a conference on this topic held in Denver. Any standard that is developed should not contain advisory-type languageâ€”it should be declarative in tone. For example, in R1.4, the ending clause that begins â€œâ€¦and may include actionsâ€¦â€☐ should be removed because it is advisory in nature. The suggested actions are not even the responsibility of the vegetation management program. NV Energy and the other Western Utilities support the development of this white paper as a way to help ensure consistent interpretation of the standard. Perhaps the lack of such a paper in the first version of the standard contributed to the varying interpretations by the auditors. The utilities understand however that this document is not a legal document and is not binding.

Agree
Agree
Agree
Yes, we agree, subject to the qualification about "active" rights of way under comment 16. Under R1.1 it says "Specify the methodologies that the Transmission Owner uses to control vegetation." The single word "methodologiees" does not adequately replace "objectives, practices, approved procedures, and work specifications." We recommend keeping the original wording.
Disagree
The document would be easier to follow if kept together. Separation of the recommendations and implementation will make this a redundant process, because both will say the same thing.
Agree
The term "inspection" needs to be better defined, as well as the term "calendar year."
Agree
To be consistent with R1.3, we recommend that R1.1 be reworded to specify the methodologies and objectives that the Transmission Owner uses to control vegetation.
Agree
We recommend that any advisory language be removed, and replaced with a declaration to the utilities.
Agree
Disagree
We do not agree with the removal of Clearance 1. We recommend that it be added back into the document, but reworded and moved so it be included as a measurement, rather than a requirement. Without Clearance 1, utilities could be mandated in specific situations to clear so that vegetation is just beyond the Critical Clearance Zone at all times, which is not feasible or cost effective.
Disagree
We feel there must be appropriate knowledge to do the work, and that Transmission Owners must at

least have internal standards related to personnel qualifications.
Disagree
We do not agree with replacing Clearance Zone 2 with the Critical Clearance Zone. We recommend the removal of R4 entirely from the standard.
Agree
Agree
Disagree
The information should not be separated. It will be much easier to follow if the requirement to have the schedule is kept together with the requirement to implement it.
Disagree
The new requirement in R4 stipulates that the Transmission Owner is in violation if an encroachment of the Critical Clearance Zone (CCZ) occurs at any time. However, the CCZ changes with each foot of the transmission line from the insulator to the mid-span, depending on loading, actual operating temperature, wind loading, ice loading, maximum design rating, maximum operating load, and so on. Further, Measure M4 requires that the Transmission Owner have evidence demonstrating there were no vegetation encroachments into the CCZ. These requirements may result in having to LIDAR the lines annually to prove that trees have not encroached upon the CCZ. This would be an extremely oerous and expensive requirement for utilities. We strongly support the alternative to R4 as recommended in the Comment Form, which is wto require immediate removal of the vegetation or immediate implementation of the imminent threat procedure upon discovery of a possible encroachment of the CCZ, thereby proactively preventing an outage. This means a violation would occur only if the imminent threat process is not successfully implemented. This alternative is essentially the same as R2. Therefore, we recommend removing R4 from the standard entirely.
Disagree
We recommend that the requirement under R7 be changed from "shall prevent sustained outages" to "shall minimize sustained outages due to vegetation falling into a conductor." The word minimize was present in earlier drafts of the document. We are concerned with the requirement for utilities to prevent sustained outages from vegetation falling into the conductor from within the active transmission Right of Way. It is operationally almost impossible to know precisely where the edge of the ROW is in all situations under all conditions. This could lead to an incident where utilities are charged unreasonably.
Disagree
We feel that the document itself would be easier to follow if it was re-organized so that the requirement to have the plan is kept together with the requirement to implement the plan.
We feel that any advisory-type language should be removed from the standard and replaced with wording that is in a declarative tone. We support the development of the white paper as a way to help ensure consistent interpretation of the standard.

Agree
Agree
Disagree
We agree in changing the text as proposed only if R1 is expanded as suggested below. The standard as written is primarily, if not exclusively focussed on outage prevention through one means, to keep vegetation out of the Critical Clearance Zone. The burden to accomplish this is placed on the Transmission Owner/Operator as it should be. The first section highlights that a program is required, but does not provide a requirement above this simplistic view, and from our perspective the Measures do not introduce any further rigour. This simplistic approach, in our opinion, does not adequately

address the reliability risks associated with the various methodologies of managing vegetation. The White Paper notes removal is superior to pruning in ensuring tree conflicts do not occur. The White Paper includes elements of vegetation management risks, but the revised standard for the most part excludes this issue. One could argue that the audits and fines will manage reliability risks, but we are not convinced that this will do so in a consistent and adequate manner. There are numerous clearance risk factors associated with managing vegetation on rights of way. Some of these are: accurate measurement of conductor sag, accurate measurement of vegetation, vegetation growth rate, conductor sway, tree movement. If one looks at Table 1, the Clearance Distances are to the nearest cm or 1/100 of a foot. This makes one wonder, how realistic are the expectations laid out in the standard? To manage the risks around the Critical Clearance Zone the Standard requires each Transmission Owner to work with these precise numbers and build in a margin of safety to manage the situation. Will each Transmission Owner use identical criteria to trigger work? This doubtful, so this leads one to believe that the standard has not been designed to produce consistent results, which in our opinion is the case. So one has varied field conditions that are difficult to nail down, precise clearance requirements to the nearest 1/100â€™ and the likelihood of inconsistent margins of safety. We realize that the audit process will help to assess these situations, but it may not be enough to achieve a somewhat uniform risk profile across the transmission systems. Other standards that we are familiar with include a margin of safety such as added clearance above the absolute minimum recognizing that it may not be practical to work to such precise measures. Examples of standards that use this approach to ensure consistent and reliable results include OHSA and the Canadian Standards Association. We are not advocating that this standard follows an identical approach, but do want to highlight that the standard may fall short in the area of managing vegetation management risks which in turn have a direct impact on reliability. Considering the above, it is suggested that the aspect of managing vegetation reliability risks be added to the White Paper to allow Transmisison Owners to develop somewhat consitent criteria. Further on the topic of managing risk. We believe that reliability risks are directly related to the amount of incompatible vegetation on a right of way that is approaching the Critical Clearance Zone. Incompatible vegetation would be vegetation that has the potential to grow into the Critical Clearance Zone at full growth. We suggest that risks could be reduced significantly by including direction in the standard concerning the management of incompatible vegetation. This would drive a greater degree of consistency among Transmission Owners and would reduce the amount of vegetation on rights of way that have the potential to cause flashover. In addition, this would reinforce the reliability risks associated with vegetation, not just from a clearance perspective but also from a volume perspective, and would provide a more comprehensive view for the public and interest groups. In order to respond to what we consider a shortcoming of the proposed standard, our suggestion would be to expand R1.1 similar to the following: Specify the methodologies that the Transmission Owner uses to control vegetation and demonstrate that the removal of non-compatible vegetation is a focus within the plan. It is recognized that reliability risks increase appreciably with an increase in incompatible vegetation on an active right of way, and the Transmission Owner is required to remove incompatible vegetation at a point no later in time when it poses a threat to the reliability of the transmission line. Exceptions include vegetation used for designated visual screens, trees of a historic significance, vegetation to control erosion, agreements made at the time of environmental approval for construction, â€¦â€¦â€¦etc.
Agree
Disagree
Clarification is required on the requirements. The frequency and need for inspection is based on a number of factors that include: type of vegetation on a right of way, change in growing conditions and the Transmission Ownerâ€™s clearance standards (i.e., if the clearance standards are well above the Critical Clearance then the risk to reliability may be very low, so why inspect for vegetation clearances on an annual basis?) This being the case, clarification is needed on inspection requirements relative to the overall approach used to manage vegetation clearances. For example, Hydro One conducts routine line inspections on an annual basis and identifies clearance issues. Would this meet the requirements of the standard?
Agree
Agree

Agree
Disagree
We would agree only if the standard is revised to include the removal of incompatible vegetation as outlined in our response to question 3 above. If not, then added direction or requirements are needed to introduce the elements that combine (to a greater degree than exists under the revised standard) reliability and vegetation management. Clearance 1 accomplished this to some degree.
Agree
Agree
Agree
Agree
Agree
Disagree
A statement is needed that this requirement applies to the active right of way. Outside of the active right of way there is no guarantee that this can be achieved. As noted in the question above, it may be very difficult with the first alternative to provide adequate evidence that no encroachment had occurred over the compliance period, as the situation is very difficult to assess along each span to the accuracies (1/100 of a foot) spelled out for the CCZ. It may be more meaningful that the Transmission Owners be able to demonstrate processes, methodologies and actions that can support that vegetation has not entered the CCZ. Another alternative for R4 could then be: Each Transmission Owner shall demonstrate that adequate actions and processes are in place to prevent vegetation from entering the CCZ. The effectiveness of the process can then be evaluated based on methods used for field assessment and performance, i.e., outages and imminent threat reporting. It appears that the second alternative noted above can be combined with R2. It is not clear why there needs to be a separate requirement. Hydro One is not in favour of alternative 3, as this would create added administration with a situation that will be difficult to prove to the accuracy required. LIDAR may be the only means available to provide evidence of a quality needed to produce meaningful statistics, and in many cases this may not be the most efficient use of the limited funding that is available.
Disagree
A further exception would be a sustained outage where the conductor has moved outside of the critical clearance zone. This could occur under conditions of heavy icing, operating outside the line rating or excessive wind. These would not necessarily be the result of a natural disaster. Also, it is recommended that the requirement for R7 be revised to â€œEach Transmission Owner shall minimize (â€œminimizeâ€☐ replacing â€œpreventâ€☐) Sustained Outages of applicable lines due to vegetation falling into a conductorâ€¦.. A fall in is a random occurrence and the likelihood that this would be the cause or contribute to a cascading event is very remote. These types of outages are rare and can be considered similar in nature to an insulator flashover or a hardware failure, which have not been given any association with cascading events. The purpose of the standard is to prevent cascading events and it is suggested that this remain the focus and not introduce other types of outages on a selective basis.
Agree
Please see our comments on question 3.
Individual
David Dworzak
Edison Electric Institute
Disagree

The purpose of the standard should be revised to state 'To maintain minimum clearances sufficient to avoid any vegetation-related Sustained Outages for all applicable conditions.' This is the identical wording taken from Order No. 693, Paragraph 731.
Agree
Agree
Agree
Agree
Agree
Agree
Agree
Agree
Agree
Agree
Agree
Agree
Disagree
Consistent with previous comments, NERC should respond to FERC Order No. 693 Paragraph 721 regarding compliance audit procedures to identify appropriate inspection cycles.
Disagree
Encroachment without a Sustained Outage should not be construed as a violation. The proposed R4 requirement should be removed. EEI strongly believes that this requirement, if approved, is unenforceable. The alternative, to require implementation of the imminent threat procedure, should be considered as a practical approach. In particular, this concern applies to a requirement to prove that no encroachments have existed. This will require extensive work by field personnel, who will be required to make subjective judgments. In addition, determining actual clearance zones in the field would require a span-by-span analysis to be conducted with the rigor of survey level measurements. Calculations made to determine the clearance zones are based on undefined terms and subject to wide variation. Enforcement authorities will be required to make interpretations. EEI believes that the costs of conducting such work will not deliver sufficient benefit to warrant the requirement. Ultimately, there is no basis for determining whether the theoretical clearance zones included in the proposed standard will increase, or even maintain, an adequate level of reliability as provided by the existing standard.
Agree
Agree
Overall Comments EEI strongly believes that companies are responding assertively to the requirements in FAC-003-1 and that the existing standard is effective in supporting an adequate level of reliability. The central issue with FAC-003-1 and the draft version 2 centers on circumstances

where vegetation encroachments into clearance zones take place and do not result in interruptions. EEI understands that a potentially broad range of interpretations are being applied to the existing standard, resulting in potential violations due to clearance encroachments of any possible design position of the conductor being violations, as well as Sustained Outages. Version 2 should clarify this issue in the context of focusing the industry in the direction that is most effective in establishing an adequate level of reliability. The technical comments provided by EEI seek to address this critical issue. Quantitative analysis on vegetation-related line outages or violations made publicly available do not support the need for a substantive revision of the standard. Analysis needs to recognize a broader range of facts in a consistent manner. Analysis needs to consider whether violations resulted in a Sustained Outage, whether all outages and vegetation encroachment were voluntarily reported prior to enactment of Section 215, or the facts and circumstances surrounding violations. For example, while some entities may perceive a decline in industry performance, it may be that companies are reporting much more completely than in the past. Much more rigorous analysis is needed before concluding that the existing standard must be made tougher. Rather than focusing on whether the standard should be more stringent, EEI believes that the emphasis in the standard development process should focus on practicality, both for field personnel in terms of implementing the standard, and enforceability. Revisions to the existing standard should therefore seek to a) respond to issues raised by FERC in Order No. 693 b) where possible, clarify ambiguities in the requirements, and c) improve industry understanding, practicality, and enforceability. For example, it is impractical to seek development of a â€˜bright lineâ€™ set of performance requirements. The standard needs to recognize both the diversity of the continent in terms of geography, topography, and climate, and the critical need to provide field personnel with workable performance requirements. Bottom line; it is very important to recognize that the ultimate goal of the standard is to ensure that vegetation management is conducted in order to maintain an adequate level of reliability, and the industry is achieving this goal. The standard should aim for increasing clarity in the requirements without sacrificing flexibility, since companies expect high monetary penalties associated with Sustained Outages caused by vegetation. In addition, a continued â€˜zero toleranceâ€™ approach to vegetation management will emphasize operational excellence. Seeking â€˜zero toleranceâ€™ on momentary outages is equivalent to pursuit of operational perfection, which is achievable only at extraordinary expense to customers. Therefore, the Standard will be most effective if its elements encourage proactive behavior and provide incentives for Transmission Owners to identify and address vegetation clearance issues before they result in momentary interruptions or Sustained Outages. Vegetation Outage Data In Order No. 693, Pargraph 732, FERC ordered NERC to collect and analyze transmission outage data to inform development of the revised standard. EEI encourages the drafting team and NERC Standards Committee to request that NERC collect and analyze this critically important information. Such analysis provides an important foundation for determining whether the standard can ensure an adequate level of reliability as required by Section 215. Applicability Order No. 693, Paragraph 708, directs NERC to 'develop an acceptable definition that covers facilities that impact reliability but balances extending the applicability of this standard against unreasonably increasing the burden on transmission owners.' In the order, FERC appears to accept the 200-kv threshold, however, continues to ask about these other critical facilities. EEI recommends that the drafting team develop a definition of 'sub- 200kv critical facilities' for use in the standard. Reliance on Reliability Coordinators for developing their own definition raises the likelihood of inconsistent approaches and applications of the term. In addition, the drafting team should consider whether such critical facilities might require expanding applicability to entities other than Transmission Owners. Annual Plan as a Defined Term In order to aid in compliance enforcement and industry compliance, the term 'annual plan' should be a defined term.

Agree
Disagree
The RC should not define applicable lines that are operated below 200 kV. PRC023 requires the Planning Coordinator to define transmission lines operated at 100 kV to 200 kV that are considered

critical to the reliability of the Bulk Electric System. Multiple lists will lead to confusion among electric utilities.
Agree
Agree
Agree
Agree
Agree
Agree
Agree
Agree
Agree
Agree
Agree
Agree
Disagree
Recommend replacing the word "prevent" in R4 to "monitor". The first alternative that requires immediate removal of vegetation or immediate implementation of the imminent threat procedure would be a Requirement that could be measured. In addition, if an encroachment is found it needs to be eliminated and the first alternative specifies immediate removal. If R4 is left as written, how can you provide evidence that there has been no encroachments within the Critical Clearance Zone.
Disagree
Recommend removing R7 because current and proposed standards do not require the entire right-of-way or Active Transmission Line Right of Way to be clear of vegetation. In this case, a utility should not be penalized if a tree falls from within the right-of-way or Active Transmission Right-of-Way as long they are meeting all the other standards (e.g., minimum vegetation clearance distances). Since fall-ins from just outside of the right-of-way is currently not a compliance issue, it makes sense that a fall-in from within the right-of-way be treated the same. This is especially true for a utility who has elected to acquire a wider right-of-way than another utility. That utility may have a tree(s) growing just inside the right-of-way but still maintains a better clearance distance between trees and conductors than a utility with a narrower right-of-way and no tree encroachment.
Agree
The SDT should clarify that Transmission lines operated at 200 kV and above is for lines that are network facilities. Radial load transmission facilities operated at 200 kV and above should not be subject to this standard as they would not lead to SOLs or IROLs. M2 requires evidence that a TO implemented its imminent threat procedure upon knowledge of a Critical Clearance Zone breach. M4 requires evidence that there were NO encroachments into the Critical Clearance Zone. These two measures are in conflict with one another. If a utility provides evidence for M2 then they are in violation based upon M4. M4 and M5 requires a utility to provide "proof to the negative". These measures should be removed from the standard. R9, R10, M9, and M10 should be removed from this

standard as critical facilities are identified through the PRC standards.
Individual
George Czerniewski
Consolidated Edison Company of New York (CECONY)
Disagree
The phrase "Bulk Electric System" (BES) is somewhat misleading. BES includes transmission voltages greater than 100kV but this Standard addresses transmission lines with operating voltages at or above 200kV and only those lines below 200kV designated by the Reliability Coordinator. Use of the phrase "electric transmission circuits" or something similar rather than BES would reduce confusion.
Agree
CECONY agrees provided that R9 remains the same as is currently written. This states that the Reliability Coordinator, in consultation with the Transmission Owner, shall jointly prepare and keep current, a list of designated applicable lines.
Agree
Agree
Agree
Agree
Disagree
CECONY currently has procedures that mandate response to imminent threats. The Standard should be made more general and not identify the specific actions that shall be taken in the procedure. The second sentence of R1.4 should be deleted and the first sentence should read, 'Require a process or procedure to respond to vegetation-related imminent threats." This adds the necessary flexibility that utilities require and avoids additional redundant processes or procedures from being developed.
Agree
Agree
Agree
Disagree
CECONY is in favor of using the Gallet equations as they provide a more realistic clearance distance for vegetation. We understand and agree that establishing a Critical Clearance Zone (CCZ) would provide the specific area that a conductor could possibly travel through during various field and weather conditions but we do not agree that this is the most practical approach. The main issue is that the wording '...the Critical Clearance Zone is approached by vegetation.....' is very vague and left open to wide interpretation which causes inconsistency and confusion throughout the industry. The CCZ changes throughout the length of each conductor in each span so a field inspector's job and an auditor's job become much more complicated when trying to confirm compliance when vegetation is present in the Actiove ROW. We feel that the time spent trying to measure and calculate the CCZ and then confirm compliance would be better spent initiating a response plan to safely remove the vegetation. The imminent threat procedure would only be implemented if vegetation encroaches beyond a specific distance from the conductor, not as it approaches the theoretical CCZ. Advanced technology would be required if a vegetation approach distance to the CCZ was to be calculated in the field. This is a very costly and time consuming requirement and does not efficiently meet the Standard's goal of ensuring reliability.
Agree
Agree

Agree
Disagree
CECONY disagrees with R4 as currently written. As mentioned in the response to Question 15, performing a field measurement of the CCZ and a field measurement of the vegetation encroaching into the CCZ are complicated, time-consuming efforts. As the CCZ changes along the conductor, so too may the Active ROW dimensions, the vegetation clearances at multiple points, and elevation levels to name a few. Certifying compliance that no encroachments have occurred would be very difficult for auditors and field inspectors. Modern laser technology would have to be deployed to take these measurements and CECONY is concerned that, if an encroachment of the CCZ constitutes a violation, utilities would not consider investing in this technology knowing that multiple violations could potentially be found within a single span. Enhanced reliability is achieved when utilities invest in the best available technology and perform proactive inspections on their systems but, as written, R4 would not effectively motivate a utility to follow through with these initiatives. We recommend that the term 'momentary outage' or the phrase 'all outages' be used in R5, R6, and R7 instead of 'Sustained Outages' to avoid confusion throughout the industry. Momentary outages identify a potential failure of the utility's vegetation management program and stating it directly in the Standard clearly sends the message to utilities that all vegetation outages are unacceptable. In summary, we do not agree that encroachments are violations but we do recommend that when a utility identifies vegetation-related imminent threats and takes immediate action, they report this to their Reliability Coordinator. The Reliability Coordinator (RC) could then identify the utilities that have had multiple issues or have exceeded acceptable pre-established reporting limits which, in turn, would help the RC prioritize auditing efforts. This, in our opinion, would enhance reliability more effectively.
Agree
CECONY agrees that outages caused by the factors mentioned are violations of R5, R6, and R7 but we recommend that either the phrase 'momentary outage' be incuded in the wording or the phrase 'All Outages' replace 'Sustained Outages' to make the requirements clearer.
Agree
CECONY does not feel that, as currently written, the Standard would effectively enhance reliability throughout the industry. We recommend that stricter language be used in the Standard specifically requiring the industry to remove incompatible species on Active ROWs. This should reduce the number of outages resulting from vegetation grow-ins and vegetation fall-ins from inside the Active ROW and help maintain a higher level of reliability. This is currently done at the state level (in NY) and the revised wording in the Federal Standard may help promote consistency industry-wide and avoid confusion. Also, the concept of the CCZ is theoretically strong but it needs to be made simpler for the auditors and field inspectors.

Tom Mathews and Steve Rueckert
WECC
Agree
Disagree
WECC believes the Regional Entity should remain the proper entity to identify sub-200kV transmission lines subject to this standard. The Regional Entity is in the best position to work with Transmission Owners (TOs) and Reliability Coordinators across the interconnection to determine critical sub-200kV transmission lines.
Agree
Agree
Agree

Agree
Agree
But for clarity, "Imminent Threat Procedure" should be replaced with "Vegetation Imminent Threat Procedure".
Agree
Agree
Agree
Agree
Yes but the wording is ambiguous. Vegetation under a transmission line is always "approaching" or growing towards the transmission line. Entities should define a specific distance greater than the Critical Clearance Zone when they are required to implement their Imminent Threat Procedures.
Agree
Agree
Agree
Agree
Yes, R4 as written provides clear guidence to TOs on the minimum radial distance, dependant on line voltage that vegetation is allowed to approach energized conductors. These industry standardized distances will ensure a level of reliability equal to or better than FAC-003-1.
Agree
However reporting requirments are not identified in the standard. WECC believes that sustained outages caused by vegetation should be reported to the Regional Entity using the existing reporting requirments in FAC-003-1
Agree
Reporting requirments are not identified in the standard. WECC believes that sustained outages caused by vegetation should be reported to the Regional Entity using the existing reporting requirments in FAC-003-1 (Transmission Owners report outages to the Regional Entity). Reports of sustained outages to the Reliability Coordinator should be made for reliability purposes and not compliance purposes. The Reliability Coordinator should not be required to report vegetation outages of individual Transmission Owners to the compliance department.
Individual
Sreenath Thota
Arizona Public Service Company
Disagree
APS suggest the following change; To improve the reliability of the Bulk Electric System by preventing vegetation related outages. This is a reliability standard APS would suggest removing "that could lead to widespread cascading failures" from the purpose statement.
Agree
Agree
Agree

Agree
Clarification is required on exactly what an inspection is, which should perhaps be outlined in the white paper. There are areas where inspections are not necessary at all, such as lines over a parking lot, or in a remote desert area. APS needs some assurance that this inspection will not constitute a dedicated, comprehensive vegetation management inspection. Inspections are currently often part of a routine line patrol, where the forester or lineman looks for vegetation concerns in addition to undertaking maintenance work. Therefore, the Transmission Owner needs the ability within their TVMP to define what an inspection is in the context of their utility operations.
Disagree
The document would benefit from keeping the two requirements together, since they relate to the same topic. Under the new wording in R1, the TVMP no longer has a requirement to include objectives. However, there is a phrase in R1.3 to â€œsupport the objectivesâ€¦and methodologiesâ€¦outlined in theâ€¦program.â€☐ To be consistent with R1.3, APS recommends that R1.1 be reworded to specify the methodologies and objectives that the Transmission Owner uses to control vegetation.
Agree
APS agrees with 1.4, with the following qualification: Any standard that is developed should not contain advisory-type languageâ€"it should be declarative in tone. For example, in R1.4, the ending clause that begins â€œâ€¦and may include actionsâ€¦â€☐ should be removed because it is advisory in nature. The suggested actions are not even the responsibility of the vegetation management program.
Agree
Disagree
APS disagrees with removal of clearance one. Clearance one should be achieved at time of maintenance which is part of the vegetation program. This gives leverage with dealing with state and federal agencies, tribal and private landowners. This isn't a fill in the blank requirement, however it should be based on sound science in regards to vegetation management. A professional arborist/forester can determine the appropriate amount of vegetation that needs to be obtained at the time of maintenance. APS suggest the following language change for clearance 1. The Transmission Owner shall maintain ROW on Federal, State, Tribal and Private lands in accordance with ANSI-Standard A300 (Part 1)-2001 and (Part 7)-2006 in consultation with companion publication Best Management Practices: Integrated Vegetation Management, 2007. If all utilities followed this standard this would increase the reliability of the bulk electric system and reduce the risk of vegetation outages.
Disagree
APS disagrees with the removal of personnel qualifications. The person responsible for vegetation management program should have experience and training in vegetation management and system operations. The International Society of Arboriculture has an ISA Certified Arborist and Utility Specialist certification. This requires the credential holder to have minimal qualifications before sitting for the certification and on going training to maintain the credential. The industry has already responded by providing the information as part of the current standard FAC-003-1. It makes no sense to remove personnel qualifications from the revision.

APS understands that itâ€™s possible to have a schedule and not implement it. However, we feel that the document itself would be easier to follow if it was re-organized so that the requirement to have the schedule is kept together with the requirement to implement it.
Disagree

APS agrees with alternative one.The new requirement in R4 stipulates that the Transmission Owner is in violation if an encroachment of the CCZ occurs at any time. However, the CCZ changes with each foot of the transmission line from the insulator to the mid-span, depending on loading, actual operating temperature, wind loading, ice loading, maximum design rating, maximum operating load, and so on. Further, Measure M4 requires that the Transmission Owner has evidence demonstrating there were no vegetation encroachments into the CCZ. These requirements may result in having to LIDAR the lines annually, to prove that trees have not encroached upon the CCZ. This would be an extremely onerous and expensive requirement for utilities. APS strongly supports the alternative to R4 as recommended in the Comment Form (#15), which is to require immediate removal of the vegetation or immediate implementation of the imminent threat procedure upon discovery of a possible encroachment of the CCZ, thereby proactively preventing an outage. This means a violation would occur only if the imminent threat process is not successfully implemented. This alternative is essentially the same as R2. Therefore, APS recommends removing R4 from the standard entirely.
Disagree
APS strongly recommends that the requirement under R7 be changed from â€œshall prevent sustained outagesâ€□ to â€œshall minimize sustained outages due to vegetation falling into a conductor.â€□ We note that the word â€œminimizeâ€□ was present in earlier drafts of the document. We are concerned about the requirement for utilities to prevent sustained outages from vegetation falling into the conductor from within the active transmission ROW. It is operationally almost impossible to know precisely where the edge of the ROW is in all situations under all conditions. This could lead to an incident where utilities are charged unreasonably â€“ for example, for an outage from a tree that was one foot within the active ROW line. We should not be held liable when reasonable due diligence is practiced. Further, it is not economically feasible for utilities to survey every ROW in the U.S. and Canada to determine precise clearance zones.
Disagree
APS understands that itâ€™s possible to have an annual plan and not implement it. However, we feel that the document itself would be easier to follow if it was re-organized so that the requirement to have the plan is kept together with the requirement to implement it.
APS has a comment to NERC on picking the standard drafting team. FAC-003 is a vegetation management standard not an engineering standard. The team members should have been chosen based on managing the vegetation program not because they were engineers. Any standard that is developed should not contain advisory-type languageâ€"it should be declarative in tone. For example, in R1.4, the ending clause that begins â€œâ€¦and may include actionsâ€¦â€□ should be removed because it is advisory in nature. The suggested actions are not even the responsibility of the vegetation management program. APS supports the development of this white paper as a way to help ensure consistent interpretation of the standard. Perhaps the lack of such a paper in the first version of the standard contributed to the varying interpretations by the auditors. The utilities understand however that this document is not a legal document and is not binding.
Group
Southern Company
Roman Carter
Southern Company Transmission
Disagree
The initial FAC-003-1 drafting team had a particular reason for not using Bulk Electric System for fear of it being widely recognized to characterize the entire networked transmission system. This reason was to limit possible confusion with the applicability of the Standard. The Bulk Electric System definition includes all lines of the grid operated at 100 kV and above. This term also does not necessarily include lines of any voltage class that are radial and directly serving load. Use of this term in lieu of â€œelectric transmission systemsâ€□ has the potential to cause additional confusion to the industry.
Disagree
The use of the Reliability Coordinator as the entity for identifying sub-200 kV lines is inconsistent with the approach used in other NERC standards, such as PRC-023. Other NERC standards utilize the Planning Coordinator or the RRO as the entity. We feel the Planning Coordinator would be the appropriate entity for identifying sub-200 kV lines covered by FAC-003-2.

Agree
Agree
Agree
Agree

The standard requirement, as written, requires the "immediate notification" of the operator. This standard requirement could be interpreted to mandate that this notification take place prior to any other action. There could be times that this communication would take up valuable time needed to relieve the immediate threat. The requirement should be modified to list examples of appropriate actions that could be taken. The Transmisison Owner should be allowed the flexibility of developing a communication process that ensures timely notification of a threat and the proper channels of communication that will be utilized in making the notifcation. The present wording in the standard alone suggests the individual observing the threat in the field is directly responsible for communicating with the Transmission Operator while the whitepaper tends to be more flexible. The Transmission Owner may wish to have the vegetation contractor notify the Transmisison Owner's forester who in turn will notify the Transmission Operator. While the whitepaper does an adequate job describing acceptable responses, the standard does not. It is recommend the standard, VSL, and RSAW better explain what is an acceptable response to the TOP. The requirement then goes on to address specific actions the operator "may" take in response to the notification. The imminent threat processs should be limited to the steps taken to notify the Transmission Operator in a timely manner. FAC-003 is not the appropriate place to address Transmission Operator decisions resulting from notification of a threat to the system.
Agree
Agree
Agree
Disagree
As written, R2 requires activation of the imminent threat process when the Critical Clearance Zone (CCZ) is "approached" by vegetation. The term "approach" is vague and open to interpretation. Since vegetation is dynamic in nature, it is constantly "approaching" any pre-defined zone. There could also be many examples given of encroachments into the theoretical CCZ that would neither threaten the transmission line conductor nor cause a reduction in the capacity of the transmission line. This concept would be better suited to be a â€œtrigger pointâ€☐ that, if found, would be incentive for the Transmission Owner to take immeidate action or ensure future action occurs on schedule. This action may be as urgent as implementation of the immediate threat procedure or as non-urgent as making sure that the upcoming maintenance on that line is scheduled appropriately. We are concerned this revision of FAC-003 continues to take a zero tolerance approach to compliance, which is contrary to the philosophy utilized in other NERC standards. A state of non-compliance should not exist simply because vegetation encroached within a pre-defined zone by a fractional inch, but only when an event, such as a sustained outage, occurs due to the Transmssion Owner's failure to maintain adequate clearance between conductors and vegetation.
Agree
Agree
Agree

Disagree
The Critical Clearance Zone is a concept that adequately describes the salient functionality a Transmission Owner must consider when determining acceptable clearances. However, the practicality of a requirement that forbids even one encroachment in the Critical Clearance Zone presents a problem for not only the field personnel doing the vegetation work, but also the Regional Entity that must enforce the requirement. This zone changes not only from one span to another, it also changes at each location along each span. The reality is that the difference in encroaching into the zone and not encroaching into the zone is a matter of a fractional inch. In order to prove non-compliance or to defend compliance at a particular site, all vegetation work would have to be postponed for survey accuracy equipment and appropriately trained personnel to be brought to the site, measurements and calculation to be made and consequently a determination rendered. This hardly seems worthwhile when the vegetation could simply be cut, the threat removed and the vegetation work could continue on down the transmission line. As stated in a previous comment, there could be many examples given of encroachments into this theoretical zone that would neither threaten the transmission line conductor nor cause a reduction in the capacity of the transmission line. This concept would be better suited to be a â€œtrigger pointâ€☐ that, if found, would be incentive for the Transmission Owner to either take immediate action or ensure future activities are appropriately scheduled and implemented. This action may be as urgent as implementation of the immediate threat procedure or as non-urgent as making sure that the upcoming maintenance on that line is scheduled appropriately. If a sustained outage occurs due to an encroachment, the outage should be the compliance measure.
Agree
Disagree
While we agree in principle, we feel Requirement R8 as written is â€œopen endedâ€☐ and could be interpreted to be in conflict with the â€œActive Rights of Wayâ€☐ concept. Clarifying the intent for the annual plan to focus on the Active Rights of Way will prevent incorrect interpretations. We suggest that the Requirement be reworded to read: Each Transmission Owner shall implement its annual work plan for vegetation management within the Active Right of Way to accomplish the purpose of this standard within the extent of its easements and or legal rights.
We would like to re-emphasize our concern over the zero tolerance philosophy of FAC-003-1 which is continued in this proposed revision. FAC-003 has been singled out as the only zero tolerance NERC standard. Compliance should not be based on the encroachment of vegetation into a theoretical, pre-defined zone, but on the occurrence of a sustained outage, as stated in the document's Purpose Statement. We agree with the philosophy utilized in other NERC standards where a clearly discernible compliaince event signals a review of the Transmission Owner's plans, policies, and procedures to determine the effectiveness of the entity's programs and spirt toward complaince. Applicability Section 4.2 describes the Facilities pertinent to this Standard. Recommendation is to restructure the sentence by relocating the parenthetical phrase: Transmission lines operated at 200kV or higher, and transmission lines operated below 200kV designated by the Reliability Coordinator as being subject to this standard (â€œapplicable linesâ€☐) including but not limited to those that cross lands owned by federal, state, provincial, public, private, or tribal entities. Requirement R3 Recommend rephrasing to say: Each Transmission Owner shall conduct vegetation inspections of all applicable lines in accordance with the frequency specified in its transmission vegetation management program. Requirement 10 The standard does not mention whether or not the results of this specific assessment methodology are supposed to be compiled and maintained. The resulting information could be labeled as sensitive and possibly critical since the loss would place the grid at an unacceptable risk of instability, separation, or cascading failures. If the resulting information becomes auditable (subject to discovery and posting) then precautions must be taken that are comparible to those designed to preserve the integrity of critical assets or critical cyber assets. We would like to express our sincere appreciation and thanks the drafting team for their efforts.
Individual
Patrick Brown
PJM Interconnection
Disagree
The RC or PC should not play a role in the vegetation management standard. All TOs need to ensure

they have a vegetation program to avoid unnecessary tripping of transmission lines, at any voltage levels and regardless of their impacts on the BES. Identification of critical facilities is not a part of this standard; it belongs to other standards that deal with SOL/IROL calculations, SPS, protection and critical infrastructure protection. R9 and R10 should be removed from the standard.
the current version of this standard, FAC-003-1, kept the subject of vegetation outside of the Rights of Way in the standard. Why are outside of Rights of Way vegetation issues not mentioned in FAC-003-2, or some responsibility for looking for outside of Rights of Way imminent threats or issues requiring corrective action plans not addressed?
Individual
William T. Rees
Baltimore Gas & Electric Company
Agree
Agree
The documented method to assess the reliability significance of sub-200 kV lines referenced in R10 should be put out for comment by the Reliability Coordinator to the regulated entities and FERC/NERC before it is finalized.
Disagree
I agree with the simplification of the language, but I am uncomfortable with the definition of Active Right-of-Way (R/W). The definition in FAC-003-2 and the examples used in the white paper continue to leave room for interpretation, particularly with respect to the example where only one circuit is installed on a double circuit tower. Moreover, there may be circumstances where the Active R/W is relatively narrow and the utility has an Inactive R/W or otherwise owns land adjacent to the Active R/W that can be maintained to protect the facilities from grow-ins. Consequently, consideration should be given to require utilities to protect lines from grow-ins into the CCZ regardless of whether or not the R/W is Active or Inactive as long as the utility has the legal ability to do the necessary work.
Agree
Agree
Disagree
See response to question no. 17.
Agree
This requirement references Danger trees which according to ANSI A-300, Part 7 is any tree that could fall on the conductor. Should this more appropriately be changed to Hazard tree which is a

structurally unsound tree? It might be helpful if an imminent threat were defined, e.g trees that are presently encroaching in or near the CCZ, or trees that by virtue of their hazardous condition appear to be likely to fall into or near the CCZ in the near future. (or just leave the explanation to the White Paper)
Agree
Agree
While I may agree with the removal of this requirement strictly for reasons of simplification and self-determination, the current requirement forced utilities to structure their TVMP to develop safeguards to keep trees from encroaching into the Clearance 2 envelope. The proposed change will leave the clearance issue beyond the CCZ unaddressed. Responsible utilities will take the appropriate measures and other utilities will not.
Agree
Similar to the response to no. 9, the end result is what counts and each utility will be responsible and accountable for their actions. Qualifications unlike clearance requirements, are far-removed from results and can easily be left unaddressed in the new std.
Agree
Again, each utility is responsible and accountable for it's actions. The Gallet clearances are a much better approximation of a true spark gap than the present requirement. Without a clearance one requirement, the closer tolerance produced by the Gallet equation will leave little room for error when a line is at or approaching it's max. engineered sag. When vegetation gets in the new CCZ (if adopted), it will be likely that an outage will be imminent. With the present clearance 1 and clearance 2 requirements, there is more of a buffer for encroaching vegetation.
Disagree
As noted in 11 above, the Gallet equation would appear to be a much closer approximation of the actual spark gap/flashover distance. It seems as though the new std. is making the protective zone around the conductors smaller by replacing the Clearance 2 requirement with the CCZ, while at the same time eliminating any other type of consideration for how much clearance needs to be achieved while trimming. All things being equal, if the only demarcation for when vegetation is a threat to the lines is the clearance 2 or CCZ areas, it would make sense to have this area be larger rather than smaller. Accordingly, I would recommend that the Clearance 2 value continue to be used instead of the Gallet equation-created CCZ.
I have no expertise to respond to this question.
Disagree
If frequency of inspections are required to be specified, it is implied that the inspections will follow. I suggest that R3 be eliminated and R1.2 be reworded to say: "Vegetation inspections shall occur at least once per year, or more frequently as dictated by local and environmental factors. Specify the frequency of when vegetation inspections will occur."
Disagree
One concern with the proposed wording is that the verbiage seems to provide a loophole that will count any fallen tree, or tree with the potential to fall from inside or outside of the R/W (that doesn't meet the criteria in footnotes 4 & 5) that passes or could pass through the CCZ, and that may or may not cause an outage, would qualify as a violation in the std. There is no other language that I can detect in the std. that counters this point. Determination of whether or not a fallen tree, or tree with the potential to fall would qualify would be predicated upon height measurements of the fallen or standing tree(s) relative to the CCZ at max. engineered sag. An alternative wording suggestion is: "Each Transmission Owner shall prevent encroachment within the Critical Clearance Zone of it's applicable lines associated with trees that meet the criteria for grow-ins from on or off the Active right-of-way. Fall-ins from inside or outside of the active right-of-way are not applicable to this sub-requirement." If the occurrence is a violation, reporting of the incident will be an ethical issue and rely on the honesty of the inspector or whomever finds the problem. If it's not a violation, it will be more likely that the incident will be reported and can be treated as "Near Miss' reports are with respect to safety incidents - they provide valuable input to help forestall future more serious incidents. Consequently, I recommend that no violation occur as long as the 'Imminent Threat Procedure' is implemented. Further, if there is no violation associated with Imminent Threat Procedure

implementation, I would suggest that falling or standing trees orginating from within the active right-of-way that encroached or could encroach in the CCZ be added to the requirement to enhance the 'Near Miss' datapool.
Agree
Disagree
As in question no. 14 above for R1.2, it would seem to make more sense to combine R1.3 & R8 as follows: "Require development and implementation of an annual plan thatâ€¦."
The Applicability Section of the Reliability Standards (4.2 Facilities) defines the Transmission Lines (Applicable Lines) that must comply to the reliability standard. This section should clearly state that the scope is limited to the facilities that are Bulk Electric System facilities consistent with the Bulk Electric System definition as defined by the Regional Entity. Regarding M5, M6, M7: The intention of these paragraphs is unclear to me as written. At first glance, it appeared that the paragraphs were asking for a negative to be proven, e.g. prove that you didn't have any tree-related outages. Anther possible meaning is that utilities have to justify the cause of any outage that may occur. As such, the burden of proof is on the TO to provide evidence that an outage was not caused by trees. If an outage were to occur but the TO could not find any evidence of the cause, the wording in these paragraphs suggests that by default, the outages will be classified as tree-related. If these paragraphs are intended to assign an outage cause to an outage that has already occurred, then perhaps they could be reworded to say something to the effect of: "TO shall provide results of investigation into all transmission outagesâ€¦â€¦" If these paragraphs are not intended to assign an outage cause to an outage that already occurred, but to provide a mechanism to report outage performance that is currently covered in M3 and M4 in FAC-003-1, then perhaps they could be reworded to say something to the effect of: "TO shall provide documentation of tree-related outage performance on a quarterly basis. Investigation results for unknown outages shall also be provided on a quarterly basis." Or as one last suggestion, the wording could simply be: " The TO has evidence that there was a Sustained Tree-related Outageâ€¦. Regarding the Tech. Reference, I thought that overall it was helpful and will be valuable to help provide guidance for TVMP development and implementation. The area that covers the Active/Inactive R/W should be more clearly explained and illustrated, particularly with respect to the towers with space for another circuit on one side of the structures.
Individual
Greg Rowland
Duke Energy Corporation
Disagree
Duke disagrees with changing "electric transmission systems" to "Bulk Electric System" because this creates the potential for confusion or indiscriminate expansion of the scope of applicability to 100kV facilities which may not have an impact on network system reliability. Using "Bulk Electric System" confuses the applicability of the standard. Duke believes that Section 4.2 has the specificity to clearly designate any applicable lines. Thus, the term "electric transmission systems" is appropriate.
Disagree
Duke believes that the Planning Coordinator is the appropriate entity to identify any sub-200 kV facilities that this standard should apply to. Of note is the time frame â€“ once a sub-200kV line is designated, then the TO has 12 months before the line is subject to the standard. This coincides with the longer term view of the Planning Coordinator.
Agree
Agree
This is a good change from a compliance perspective; the documentation requirements can now be assigned lower VRFs than the implementation requirements.
Agree
Agree
Disagree

Duke believes that Transmission Owners should have a Vegetation Imminent Threat Procedure, and "Vegetation Imminent Threat" should be a defined term, defined as: "Vegetation observed in the field encroaching upon a conductor within a distance that is twice the Gallet clearance distances referenced in Table I of the draft standard FAC-003-2." In this case, the threat would require an immediate response and would include communication to the Transmission Operator. From there, the actions that the operator decides to take will be dependent on the incident and system conditions. We do not need to be prescriptive with this requirement but rather allow the Transmission Operator and appropriate field personnel the flexibility to make the right decisions to safely, promptly and appropriately remove the vegetation threat. From a Transmission Owner's perspective, many situations can constitute an imminent threat but this approach will clearly define a "Vegetation Imminent Threat" as it relates to the Purpose of this standard. See our related comment on #11 below.
Agree
Agree
Agree
Disagree
No. Duke believes that the CCZ is a good theoretical concept to aid industy in understanding the overall movement of conductors, but it is an impractical concept for field application. Due to the variability in the size of the CCZ as you move along a conductor, as well as changes from span to span or even line to line due to design parameters, loading or weather-related issues, the CCZ concept should not be tied to an imminent threat procedure. Vegetation approaching the CCZ does not constitute an imminent threat. It may be years before this vegetation ever gets to a proximity distance from the conductor to be within a "spark-over" distance as defined by the Gallet equations. Requirement R2 should support the purpose of this standard by requiring implementation of the Vegetation Imminent Threat Procedure when the Transmission Owner has visual, field knowledge that vegetation is encroaching upon a conductor within some specific distance that is a multiple of the Gallet distances referenced in Table I of FAC-003-2 (to be conservative we suggest two times the Gallet distances). Failure to implement the Vegetation Imminent Threat Procedure in such instances would be a violation of R2. As R2 is currently stated, a Transmission Owner cannot comply with R2 unless the imminent threat procedure is continuously being implemented, because vegetation that is growing is always approaching the CCZ. "Approaching the CCZ" cannot be the trigger for implementation of the Vegetation Imminent threat Procedure. Instead, the trigger should be an encroachment within an observed distance from vegetation to conductor that is twice the Gallet distances in Table I. Requirement R2 could be reworded as follows: â€œEach Transmission Owner shall implement its Vegetation Imminent Threat Procedure when the Transmission Owner has knowledge, obtained through normal operating practices or notification from others, that vegetation is encroaching upon a conductor within a distance that is twice the Gallet clearance distances referenced in Table I." Using a multiple of the Gallet distances provides a safety factor. Assessing a violation for failure to appropriately implement the Vegetation Imminent Threat Procedure or for a sustained vegetation-related outage incents the proper behavior.
Agree
Agree
Agree
Disagree
The second bulleted alternative above is the best approach, but Duke believes it should be improved by changing the imminent threat trigger from "encroachment of the CCZ" to "encroachment within some observed, field distance that is a multiple of the Gallet distances referenced in Table I". We have recommended changes to accomplish this in Requirement R2 (see our response to Question #11 above), and R4 should simply be deleted. While the CCZ is valuable to understanding the movement

of conductors, it cannot be readily applied in the field. This field application challenge is noted in the Technical Reference Document (pages 29 & 30). The way R4 is currently stated, the Transmission Owner would be in violation of R4 for any CCZ encroachment not due to natural disasters or human or animal activity. This would include a tree falling from outside the right of way corridor that passes through the theoretical CCZ. Furthermore, Transmission Owners would be required to self-certify compliance with R4. The technological requirements for accurately certifying compliance would be impossible to administer. Clearly the approach of assessing violations for CCZ encroachment is unworkable. Likewise, the third alternative listed above is untenable. The tiered approach could have a mitigating effect on violations, but it would require the same inspection effort and postponement of vegetation management that makes the first alternative unworkable. Both the first and third alternatives would require very significant additional expenditures for surveys and documentation in an impossible attempt to certify compliance - money that would be better spent controlling vegetation.
Agree
Agree
Duke agrees with the requirement to implement the annual work plan, but recommends striking the words "within the extent of its easement and/or legal rights". The emphasis for this requirement is to execute the annual work plan. The white paper already speaks to the point that it is a best practice for utilities to exercise their legal rights. If we agree that the goal is to prevent outages, then we can simply end this requirement with "accomplish the purpose of the standard". Each TO will be accountable to manage compliance with this standard.
FAC-003-1 lacks clarity that is essential for understanding what is necessary for compliance. The proposed FAC-003-2 needs to be simplified to aid with field implementation and compliance interpretation. Currently, it does not provide the clarity and simplification needed by Transmission Owners and regulatory bodies to enhance reliability.

IRC Standards Review Committee
Charles Yeung
Southwest Power Pool
Disagree
We do not see the role of an RC or PC in a vegetation management standard. All TOs need to ensure they have a vegetation program to avoid unnecessary tripping of transmission lines, at any voltage levels and regardless of their impacts on the BES. Identification of critical facilities is not a part of this standard; it belongs to other standards that deal with SOL/IROL calculations, SPS, protection and critical infrastructure protection. R9 and R10 should be removed from the standard.

Group
E.ON U.S.
Brent Ingebrigtson
E.ON U.S.
Disagree
The definition of the Bulk Electric System generally does not include radial transmission lines directly serving load and, in addition, includes all lines operated at 100 kV and above. Use of the term Bulk Electric System will cause unnessesary confusion to the industry concerning applicability of this standard. Therefore, we recommend the continued use of the undefined term "electric transmission systems."
Agree
Agree
Agree
Agree
Disagree
The Requirement as written is too prescriptive and is open to interpretation, from an audit perspective, with use of the term â€œimmediateâ€☐ communication and a partial list of activities. Many conditions or threats, requiring immediate removal, would not require communcation with the Transmission Operator, who is not an applicable entity for this standard. We suggest that R1.4 be deleted. Since this is a "zero tolerance" standard any Transmission Owner will remove any discovered threats to prevent outages. If R1.4 is not deleted, we believe that imminent threats should be a defined term. The definition should be as follows: â€œImminent Threat: A vegetation condition which, if not addressed, will place a transmission line at a significant risk of a Sustained Outage.â€☐
Agree
Agree
Agree
Disagree
E.ON U.S. suggests that R2 be deleted. Since this is a "zero tolerance" standard any Transmission Owner will remove any discovered threats to prevent outages. While we agree that the implementation of an imminent threat procedure may be a valid concept, visualization of the Critical Clearance Zone and determining an approaching encroachment is a practice in application of theoretical conductor locations in real time.
Agree
Agree
Agree
Disagree
The concept of the Critical Clearance Zone is useful as a mental model to visualize required vegetation management work. While this is a good conceptual tool to drive consistent terminology and proper vegetation management practices, it remains theoretical in nature and impractical to measure on a

span by span basis. The complexity of determining an encroachment into the Critical Clearance Zone is overly burdensome due to the need for survey accuracy measurements and engineering evaluations. In addition, this complexity leads to questions about the ability to audit this requirement. These complexities introduce reliability and audit issues when encroachments into this conceptual area are defined as violations. We believe the Sustained Outage, as defined by other measures in this standard, should be the non-compliance measure. We suggest that the Critical Clearance Zone concept be kept in the technical white paper and that all references to the Critical Clearance Zone be removed from the body of the standard.
Agree
Disagree
E.ON U.S. believes that the Requirement, as written, is â€œopen endedâ€□ and could be interpreted to be in conflict with the "Active Rights of Way" concept. Clarifying the intent for the annual plan to focus on the Active Rights of Way will prevent incorrect interpretations. We suggest that the Requirement be reworded to read: â€œEach Transmission Owner shall implement its annual work plan for vegetation management within the Active Right of Way to accomplish the purpose of this standard within the extent of its easements and or legal rights.â€□
Individual
Michael Pakeltis
CenterPoint Energy
Agree
Agree
Disagree
The term "Active Transmission Line Right-of-way" is not defined in sufficient detail in the Definition of Terms Used in the Standard section to know how to apply the Requirements. The term causes a circular reference problem with the term "Critical Clearance Zone" that refers to the "limits of the Active Transmission Line Right-of-way" which has no specific definition as to its limits within the proposed revised Standard. There is an attempt to differentiate between the "Total R.O.W." and the "Active R.O.W." portion by using the phrase "occupied by active transmission facilities", but no specific limits of such occupation are included within the definition. Are "active transmission facilities" only the physical energized conductors as-is, where-is? Does "occupied" include the conductor vertical and horizontal movement envelope and any horizontal and vertical electrical clearance as well? Does the term "Active Transmission Line Right-of-way" refer to the legal limits of the right-of-way? The new R8 includes the phrase "within the extent of its easement and/or legal rights" which seems to support that definition. The phrase "a strip of land" seems to refer to a metes and bounds description, but how is that relevant when no specific land space is defined, such as with a railroad occupation or Corp of Engineer's permit? On page 16 of the Technical Reference, there is a reference to the Bramble and Byrnes wire-border zone technique. The wire zone is defined in the Technical Reference as "the section of a utility transmission right-of-way directly under the wires and extending outward about 10 feet on each side". Are the limits of the "Active Transmission Line Right-of-way" intended to be equivalent to the Bramble and Byrnes wire zone, or is the Transmission Owner to use its discretion to define the limits? The examples in the Technical Reference document do not define the limits of the "active transmission facilities" either. The "Active R.O.W." limit in Figure 1 and Figure 3 is arbitrary. Figure 2 is supposed to display an edge zone for vegetation to exist, which implies an "Inactive R.O.W" portion, but no such zone is defined. Figure 1 also has trees shown inside the "Total R.O.W." and within the "Inactive R.O.W." that are tall enough and close enough to be within falling distance of the active transmisssion line which seems averse to R7 for vegetation falling into a conductor when the Transmission Owner likely has legal rights to remove them if they are within the "Total R.O.W." and are within falling distance. The interpretation of M7 will be difficult in this case without a specific method to define the "Active R.O.W." portion of the Total R.O.W. We recommend deleting the confusing terms "Active Transmisssion Line Right-of-way and "Critical Clearance Zone" and returning to the prior Clearance 2 Requirement with the newly specified minimum clearances from Table I of

Attachment 1 as an alternative approach should the definition of minimum vegetation clearance distances remain integral to the Standard.
Disagree
Additional revisions are needed to clarify the requirements. For instance, R1.3 refers to "the objectives" of the TVMP, which are no longer a required element and are not specified in M1.3. Reference to "the objectives" should be deleted. The last sentence of R1.3 should read: "It shall use the methodologies outlined in the transmission vegetation management program." R1.4 requires a process for a response to an "imminent threat of a vegetation related Sustained Outage", but R2 refers to implementing an "imminent threat procedure" to "prevent an encroachment of the Critical Clearance Zone". The requirement and the implementation should both refer to an "imminent threat of a vegetation related Sustained Outage".
Disagree
The Standard and the Technical Reference provide no specific justification for defining a 1-year inspection frequency and is abritrary. The requirement itself does not take into account "local and environmental factors". Since the type of inspection is not specified within the Standard, a frequency of at least once per calendar year is currently workable for CenterPoint Energy, but it may not necessarily be appropriate for Transmission Owners with sparsely vegetated service territories. The Technical Reference for R1.2 should state, "the Transmission Owner is given discretion as to the inspection method", and "that while the inspection frequency is specified, it is not the intent of the Standard that all vegetation be maintained on the same frequency". For example, CenterPoint Energy currently utilizes a 5-year ground-based inspection cycle coupled with a 5-year cycle for vegetation maintenance, and performs a supplemental annual aerial inspection.
Agree
See comments to Q4 above as well.
Agree
Disagree
Since there is no longer a reference to defined clearances in the Standard, it is unclear under what specific "constrained" conditions R1.5 applies. R1.5 does not have a sister requirement for implementation within the Standard which implies it has a diminished value. R1.5 and M1.5 should be deleted as a requirement and measure, but should be footnoted as best practice as was ANSI A300 in R1.1.
Agree
Designation of Clearance 1 is not required to meet the purpose of the Standard.
Agree
Designation of Personnel Qualifications are not required to meet the purpose of the Standard.
Agree
We agree with replacing IEEE 516 standard distances with the Gallet equation standard distances. However, the term "Critical Clearance Zone" refers to the "limits of the Active Transmission Line Right-of-way" which has no specific definition as to its limits within the proposed revised Standard. (See comments to Q3 above.) R2 should be reworded to coordinate with R1.4. (See comments to Q4 above.)
Agree
Agree
Agree
Disagree
It is not reasonable to expect Transmission Owners to devote resources, both human and financial, to prove that vegetation never encroached into the Critical Clearance Zone, anytime-anywhere. R4 and M4 should be deleted. R2 and M2 are sufficient in ensuring a level of reliability equal to or better than FAC-003-1 with some minor wording changes to adopt similar wording of the alternative to R4 that

was considered by the drafting team that includes "immediate implementation of the imminent threat procedure" for imminent threats of a vegetation related Sustained Outage in lieu of a nebulous "encroachment of the Critical Clearance Zone". According to the Technical Reference, it is "nearly impossible to field correlate and accurately 'superimpose' the Critical Clearance Zone around the conductor". It not likely that the Transmission Owner will know when the Critical Clearance Zone is approached through field observation. The previous Clearance 2 provided for a specific radial clearance from the conductor that was much easier to observe. (See comments to Q3 above.)
Agree
We agree with the exemptions; however, R6 and R7 refer to an "Active Transmission Line Right-of-way" which is not defined as to its limits, so M6 and M7 cannot be determined by definition. See comments to Q3 above relating to the definitions and the examples in the Technical Reference.
Agree
R8 requires implementation of the annual work plan "within the extent of its [the Transmission Owner's] easement and/or legal rights." All measures and compliance should be determined on this basis as well. This concept should also be carried through the definitions for "Active Transmission Line Right-of-way" and "Critical Clearance Zone", or for any definition of clearances should the Standard continue to utilize such terms.
The proposed FAC-003-2 has gone FAR beyond what was contemplated by the Commission in FERC Order 693 and equates to a total re-writing of the Standard for no apparent reason. The Commission's determination dealt with the following areas: (1) applicability; (2) inspection cycles; and (3) minimum clearances on National Forest Service lands. For instance in Paragraph 729, the Commission states, â€œAs proposed in the NOPR, the Commission approves Reliability Standard FAC-003-1 with no proposed modification on the issue of clearances. The Commission reaffirms its interpretation that FAC-003-1 requires sufficient clearances to prevent outages due to vegetation management practices under all applicable conditionsâ€¦.â€□ Rewriting the minimum clearances introduced a new set of confusing definitions, and further burdens the Transmission Owners with new documentation requirements with little if any benefit when compared to the Clearance 2 concept in the existing Standard. A preferred approach would have been to incorporate the following few items into the existing Standard: (1) the RC versus the RRO; (2) the designation of a specific inspection frequency; (3) the Gallet equation; and (4) the applicability to National Forest Service lands. We agree that the removal of requirements for quarterly reporting of outages, Clearance 1, and personnel qualifications reduces the burden on the Transmission Owners and does not affect the purpose of the standard to prevent vegetation outages. The Standard could meet its purpose and be streamlined by considering the following changes: 1. Delete the new terms and definitions for "Active Transmission Line Right-of-way" and "Critical Clearance Zone" and revert back to a Clearance 2 requirement while replacing the IEEE 516 standard distances with the Gallet equation standard distances. 2. Delete R2, M2, R4 and M4 which refer to the "Critical Clearance Zone" and rely on R5, M5, R6, M6, R7, and M7 which refer to the prevention of Sustained Outages. 3. Delete R1.5 and M1.5 as a requirement and measure, but footnote the "interim corrective action process" as a best practice as was ANSI A300 in R1.1.

Transmission Reliability Program
Agree
Agree
Disagree
R1: BPA understands that version 2 clearly states that the Critical Clearance Zone does not extend beyond the Active Transmission Right of Way. The Technical reference provides examples of active and inactive portions of corridors. BPA feels this list of examples is not exhaustive and therefore the technical reference language should be changed to read, "Examples of active and inactive portions of corridors include, BUT MAY NOT BE LIMITED TO:" Also, since it is clearly stated on page 2 of the Standard, that the Critical Clearance Zone shall not extend beyond the limits of the Active

Transmission Line Right of Way, and that these limits are not specifically defined because they may vary by circumstance, the definition of Active Transmission Line Right of Way on Page 2 of the Standard should include a statement that the actual physical limits of each Active Right of Way will be determined by the Transmission Owner. R1.1: BPA recommends retaining the version 1 language of "objectives, practices, approved procedures, and work specifications" as it is more instructive in what is expectied of a TMVP then the version 2 replacement language of "methodologies."
Agree
Agree
It would be helpful to clarify what is expected in regards to what constitutes an inspection. This could be done in the technical reference. Some Transmission Operators inspect vegetation as part of line patrol that focuses on more than just the condition of vegetation along the Right of Way. It should be clear that the Transmission Owner, though required to complete a inspection frequency of at least once per calendar year, has the ability to implement the type of inspection it deems necessary. Also the frequency of once per calendar year may create some unintended reporting difficulties if Transmission Owners currently track progress and completion of inspections using a differenct convention than calendar year, e.g., fiscal year or other period. It may be helpful to change the wording of R1.2 from "at least once per calendar year" to "once in a twelve month period."
Agree
Agree
BPA agrees with 1.4, with the following change. The ending phrase: "and may include actions such as a temporary reduction in line Rating, switching lines out of service, or other actions" should be eliminated. Not only does BPA feel it is inappropriate to use advisory-type rather than declarative language in a Standard, BPA feels it is also questionable to give examples of imminent response actions that are often not within the direct capability of a vegetation program to enact. Eliminating the reference to these possible actions leaves it up to the Transmission Operator to decide what the eminent threat response is.
Agree
Disagree
BPA opposes removal of Clearance 1. Clearance 1 provides a regulatory justification for a Transmission Owner to apply and extend proactive vegetation threat prevention programs on its rights of way easements across municipal, state, tribal, other federal and private properties. In many cases, without the regulatory leverage of a Clearance 1 requirement, Transmission Owners would be limited to maintaining less effective and higher risk vegetation management practices where it has legal restrictions, then it presently can implement under the present version of FAC 003-01. BPA recommends that Clearance 1 be placed back into the document , but as a Measure and not a Requirement.
Agree
Agree
BPA agrees with R2, but refer to comments submitted regarding R4 (please see our response to Question #15) for related recommendations to R2.
Agree
Agree
Agree
Disagree
R4 states that the Transmission Owner is in violation of the Standard if the Critical Clearance Zone is encroached upon. The CCZ, as defined by the Standard, changes along the transmission line from the

insulator to mid-span, depending on loading, actual operating temperature, wind and ice loading, maximum design rating and operating load, etc. Also, the tandem, Measure M4, requires that the Tramsission Owner has evidence demonstrating that there has been no vegetation encoachments in the CCZ along its transmission system. In order to meet the letter of the Standard, that is to provide evidence that no encroachments in the CCZ have occurred under all manner of these fluid environmental and operating conditions, the Transmission Owner would have to employ the highest level of modeling technology available, which would seem to be LiDAR technology. The standard should not be written in such a manner so that it requires, by all intent and purpose, a Transmission Owner to acquire a particular technology. BPA recommends that the Alternative represented by "the second bullet" above, be used rather than R4 in its present state, or that R.4. be simply dropped and R1.4 modified to state that the imminent threat procedures include immediate removal of encroachments into the Critical Clearance Zone. Also, the term "immediate" implies instantaneous response. The use of another term is recommended, such as "as immediate as human health and safety considerations allow, in order to prevent the possibility of flashover".
Agree
Agree
There is a typographical error / omission in the Technical Reference on Page 36, which states, "R6. Each Transmission Owner shall prevent Sustained Outages of applicable lines due to the blowing together of vegetation and a conductor with (sic) Active Transmission Line Right of Way) operatiing within design blow-out conditions) with the following exception: . . . " I believe the intent is for the statement to read "due to the blowing together of vegetation and a conductor WITHIN Active Transmission Line Right of WAY". This change is needed to make the technical reference consistent with R6. as it appears in the Standard, the definition of Active Transmission Line Right of Way on Page 5 of the Technical Reference, as well as the terminology used on Page 37 in describing Fall-into outages. This needs correction.

Public Service Electric and Gas Company
Jeffrey C. Mueller
Public Service Electric and Gas Company
Disagree
An additional clarifying exception in the footnotes to R4 consisting of a tree that is located off of the transmission owner's right of way falling into the CCZ should be added to the encroachment exceptions. Transmission owners should not be found in violation of the standard for falling vegetation located off of the TO's property.

These comments were prepared by Richard Wolowicz, Manager Vegetation Management, on behalf of Public Service Electric and Gas Company ("PSE&G"). PSE&G also joins with and supports the comments filed by the Edison Electric Institute (EEI) in this matter.
Individual
Ed Davis
Entergy Services
Disagree
Entergy disagrees with changing â€œelectric transmission systemsâ€□ to â€œBulk Electric System.â€□ Historically, the definition of the Bulk Electric System has included all lines operated at voltages 100 kV and greater. The above change in terminology will add ambiguity to which lines this standard is applicable. Entergy is concerned about the potential for this ambiguity leading to the expansion of the applicability of the standard to include lines below 200kv.
Agree
The applicability of this standard should state that it is not applicable to insulated transmission lines, such as underground lines.
Agree
Agree
Agree
Agree
Disagree
1. The requirement should state that each Transmission Owner will be responsible for creating and maintaining a Vegetation Imminent Threat Process. This process will clearly define how the Transmission Owner defines a vegetation imminent threat. 2. The requirement needs to state that only vegetation conditions identified, to the Transmission Owner, by regular field inspections, including aerial inspections, and other internal and external verifiable reports of vegetation imminent threats will be managed through this process. 3. If the standard requires a process to mitigate potential immediate threats to the system, the term â€œvegetation imminent threatâ€□ must be defined. This definition must not delineate the precise steps that are required to be taken to allow experts as many options as necessary to address each vegetation condition specifically. 4. The list of possible mitigating actions should be removed from the standard since it is not an all inclusive list. Listing these actions in the standard may imply that the entity must do one or all of the actions to be in compliance. The entity must have sufficient latitude to evaluate each possible vegetation condition and apply the most appropriate mitigation steps, up to and including the removal of the identified vegetation.
Agree
Agree
Agree
Disagree
: 1. Entergy suggests that the requirement for activation of the vegetation imminent threat process should not be tied to the Critical Clearance Zone and that the each entity should define the activation of their vegetation imminent threat process. Tying the activation of the imminent threat process to the Critical Clearance Zone is limited in that this criterion does not address the possibilities of vegetation falling into the line or Critical Clearance Zone. 2. In the sentence â€œCritical Clearance Zone approached by vegetationâ€□ â€“ the use of â€œapproachedâ€□ is subjective and not specifically quantifiable. Effective, uniform activation of the imminent threat process will require objective measurement criteria. 3. The standard needs to include a clear statement to the effect that

when the Transmission Operator is notified of a potential vegetation problem, obtained by normal operations and inspections, the entity will activate the Vegetation Imminent Threat Process. 4) This requirement, as stated, is redundant. The requirements for maintaining the Critical Clearance Zones and / or avoiding vegetation outages, and the associated Violation Risk Factors and Violation Severity Levels, already reinforce the desired behavior of the entity to identify and mitigate any potential issues before the possibility of vegetation causing an outage.
Agree
Agree
Agree
Disagree
1. Entergy believes that outages caused by vegetation are the most reasonable and objective measures for a violation which is not consistent with the proposed R4. See additional comments in section 16 related to R5, 6, and 7. 2. If R4 remains, Entergy proposes that the most reasonable approach to this requirement is a variation of the second bulleted option. This variation would include wording clarifying that only known encroachments of the Critical Clearance Zone would be considered violations. Entergy is willing to include failures to enact the imminent threat process (which is really a violation of R2) and also known vegetation inside the Critical Clearance Zone. This variation should continue to include the exceptions for natural disaster and human activities. 3. Determining objective, quantifiable encroachments into the Critical Clearance Zone is very challenging in field operations because such determination may require a degree of accuracy only obtainable using survey equipment or other sophisticated, costly measuring devices. 4. Entergy is concerned about the challenges of uniform auditability due to noted uncertainties and the statement of absolute criteria that have to be shown in the negative. If the first bullet option is approved for R4, Entergy suggests the sentence â€œEvidence will be required to prove that no encroachments of the Critical Clearance Zone have occurred anywhere at the any time during the annual compliance periodâ€□ be deleted. It is very difficult in regulatory terms to attest that no vegetation has ever crossed the Critical Clearance Zone during the time period being reviewed given the wide range of potential conditions that may not have been detected or even been detectable unless the conditions afforded direct observation. Too many assumptions would have to be made for an entity to self certify to this requirement. If R4 is implemented as stated, those assumptions need to be stated and clarified. 5. If any version of R4 is approved, Entergy suggests that the standard include an exception for trees falling from off the right of way and encroaching the Critical Clearance Zone. For example, a tree that falls from off the right of way. During the fall towards the conductor, the tree could possibly break the Critical Clearance Zone without causing an outage or even a threat of an outage yet still be a violation of the proposed standard. 6. If the second bulleted item is approved, it should be altered to read â€œa violation would have occurred only if no vegetation imminent threat process was initiated.â€□ 7. Entergy does not feel the third bulleted item is adequately defined to use as a requirement in the standard at this time. 8. Conditions for blow-out, in the development of the Critical Clearance Zone, need to be defined in the standard. Their inclusions, in the white paper only, are not appropriate, as well.
Disagree
1. If a version of R4 that states an encroachment to the Critical Clearance Zone is a violation, Entergy disagrees with the need for R5, R6, and R7 because it is redundant to R4. An outage cause by vegetation: a) growing into the line b) blowing into the line and c) falling into the conductor would require the vegetation to break the Critical Clearance Zone. If these requirements stay in the standard, an outage of the above nature would mean the entity violated two requirements, R4 and R5, R6, or R7. 2. Entergy is amenable to keeping R5, 6, and 7 if R4 is removed from the standard. 3. If approved, we suggest that R5, 6, and 7 not apply to trees from off the right of way.
Agree
Entergy would like to note that requirements R1.3 and R8 are administrative requirements that add marginal value to the reliability of the Transmission System. Since entities are required to have flexible annual plans, deviations from the annual plan only need to be documented and these requirements will be met. Entergy utilizes annual plans as a good practice but sees limited value with the inclusion in this standard.

Entergy requests that the proposed FAC-003-2 revision continue work on clarifying the above mentioned â€œDisagreeâ€☐ items and appreciates the consideration of the above comments in the development of the standard. A clear understanding of all standard requirements by the industry is needed to make certain field implementation is achieved and that ultimately we improve system reliability.
Individual
Anita Lee
Alberta Electric System Operator
Disagree
The AESO believes that the inspection schedule should consider local and environmental factors that may impact the anticipated growth rate of vegetation. In many of the areas in Alberta, due to cold climate and arid conditions, we have slow vegetation growth rates. The requirement for minimum annual inspection is not necessary. We recommend the inspection schedule be determined by the Tranmisssion Owner and documented in its vegetation management plan.
The AESO is also a signatory to the joint ISO/RTO Council Standards Review Committee comments which reflect our comments to the other questions in the Comment Form.

Agree
The Inactive Right of Way, by definition, should include a strip of trees on each side of the of the right of way that was purchased, but not cleared at the time of construction. This could be a narrow strip ten feet on each side that is intended for future hazard tree removal.
Agree
Agree
Agree
Although we agree with R1.3, we suggest it be broken up into subrequirements to allow for better

clarity to the reader as well as aid in the development of violation severity levels when developed. We suggest the following: R1.3. Require an annual plan that includes the following as a minimum: (Note: Adjustments to the plan within the year are permissible) R1.3.1. It shall identify the applicable lines to be maintained and associated work to be performed during the year. R1.3.2. Is shall be flexible to adjust to changing conditions and to findings from vegetation inspections. R1.3.3. It shall take into consideration permitting and scheduling requirements from landowners or regulatory authorities. R1.3.4. It shall support the objectives of the transmission vegetation management program and use the methodologies outlined in the transmission vegetation management program.
Agree
The safety of the personnel required to remove a tree or vegetation on or near an energized conductor must be considered when implementing the imminent threat procedure. Although this is a reliability standard, the safety of the personnel may be one "trigger" to implement the imminent threat procedure. That being said, the workers on site, in their judgement, are not able to remove the vegetation safely then the imminent threat procedure would be implemented. See comments for CCZ.
Agree
We agree with the concept of a corrective action plan. However, it is not clear what flexibility the TO is afforded in making adjustments to the work plan that may carry over from one calender year to the next. Legal issues with property owners or other factors may prevent the utility from carrying out the work plan as scheduled. Also, we question the use of the term "constrained". It should be clear as to what constitutes appropriate or valid constraints.
Agree
Agree
Disagree
The CCZ is not equal to Clearance 2 in FAC-003-1. Per requirement R4, any encroachment into the CCZ is a violation of the standard even if an outage does not occur. This is too strict because it refers to a "0" tolerance even for encroachments that do not affect reliability. This can be an extremely costly standard to comply with that may or may not improve reliability. The CCZ distance is a difficult to determine from one moment to the next based upon the description and calculations outlined. The conditions on the right of way are dynamic and ever changing. It would be more proactive for the TO to focus on implementing the TVMP rather than expending time and money trying to determine if the CCZ has been violated. A better approach would be to establish a minimum clearance at all times rather than to monitor encroachment to a theoretical CCZ.
Agree
Agree
Agree
Disagree
Providing evidence to prove that there were no encroachments of the CCZ is difficult at best. An occurrence of an encroachment does not necessarily translate to an outage. The CCZ is dynamic and difficult to measure exactly from span to span and day to day and is dependent on environmental and line conditions. The costs to comply with this requirement as written are difficult to justify considering that reliability may not be improved at all. FirstEnergy believes that the first alternative above should be used and is a more logical approach from both a reliability and compliance standpoint. Furthermore, since the first alternative is already covered by the currently proposed wording of R2, the only changes needed to the standard are to remove the proposed R4 and M4 and re-number the requirements.
Agree
Agree

FirstEnergy agrees with the intent of R8, but the standard should be clarified by removal of the word "easement". As written the standard is open to interpretation between "easement" and active right of way. It is important to have the term "legal rights" remain in the standard. The TO should be held accountable to fully enforce the legal rights outlined in maintaining the active right of way. This will lead to a more reliable transmission system.
FE provides these additional comments for consideration: 1. Regarding the Applicable Facilities - Section 4.2.2 would be more appropriately placed under Sec. 5 "Effective Dates" since it deals with the timeframe the TO has to implement its TVMP on sub-200 kV lines. - Section 4.2.3 - We suggest removing this section. First energy does not agree that this standard should dictate the amount of time a TO has to obtain compliance with this standard for newly acquired transmission lines. It should be the responsibility of every organization to "self-report" its compliance issues and planned mitigation plans for all standards when they acquire new lines or facilities. If the SDT believes this should be explicitly stated, then it should recommend to NERC that explicit language be placed in the NERC Rules of Procedure. No other standards set timetables for newly acquired facilities and this standard should be no exception. 2. Regarding R1.1, this subrequirement requires the TO to specify the methodologies it uses to control vegetation. It should be clear that not all of these methodologies are required to be deployed in every situation (as explained in the white paper pg.12). We suggest rewording the requirement as follows: "R1.1. Specify the methodologies that the Transmission Owner may use to control vegetation." 3. R1.5 requires a process for "interim corrective action" be specified in the TVMP. However, the standard does not explicitly specify that this corrective action be implemented when the TO is constrained from performing vegetation maintenance as planned. 4. As written, in addition to the responsible RC, R9 may imply that this requirement is also the responsibility of the TO(s) and neighboring RC(s) due to the use of the term "jointly". Also, R9 should require the RC submit the list of designated lines below 200 kV to the TO(s) and neighboring RC(s) within a reasonable time-frame after its completion. We suggest rewording and addition of subrequirements to R9 as follows: R9. Each Reliability Coordinator, in consultation with its Transmission Owner(s) and neighboring Reliability Coordinator(s), shall prepare and keep current a list of designated applicable lines that are operated below 200kV, if any, which are subject to this standard. R9.1. The RC shall submit the list to the impacted TO(s) within 30 calendar days of completion and/or revision. R9.2. The RC shall submit the list to its neighboring RC(s) within 30 calendar days of completion and/or revision. Lastly, measure M9 will need to add sub-measures for the proposed additions above. 5. Requirement R10 should require that the RC ONLY uses the assumptions detailed in R10.1 and R10.2 to designate a line as significant. Also, R10.1. should reference the IROL methodology standard FAC-011 since it directly ties into this requirement. Also, in R10.2, "grid" should be replaced with "BES" and the term "failures" is not necessary. We suggest re-wording R10, R10.1 and R10.2 as follows: R10. Each Reliability Coordinator shall document its method for assessing the reliability significance of sub-200kV lines and shall be based only on the following: R10.1 Transmission lines whose loss would result in the exceedance of an Interconnection Reliability Operating Limit (IROL) as determined by standard FAC-011. R10.2 Transmission lines whose loss would place the BES at an unacceptable risk of instability, separation, or cascading.

Pepco Holdings, Inc
Agree
Agree
FERC Order 693 essentially has the RC replacing the RRO.
Agree
Agree
Disagree
While an annual inspection is reasonable and appropriate for all but very low precipitation areas, In Order 693, the Commission directs the ERO to develop compliance audit procedures, using relevant industry experts, which would identify appropriate inspection cycles based on local factors. The SDT

does not seem to have thaken the local factors into account. FERC also does not want to leave this up to the Transmission Owners. While the standards being developed are moving many things to the RC, PHI sees that as the only way to have someone other than the TO determine an inspection cycle that would consider local factors.
Agree
Disagree
While an imminent threat procedure is prudent and reasonable, it does not need to consider a Critical Clearance Zone as addressed in our comments on other questions. In fact, one can quickly provide examples of imminent threats when the threat is not even on the right of way. The TO should simply have an imminent threat procedure to address identified imminent or potential imminent threats.
Agree
Agree
Agree
Disagree
R5, R6 and R7 make this requirement redundant and unnecessary - it should be deleted. It is largely unenforceable and does not make the standard clear, specific and regulatorily enforceable. Further, PHI believes the concept of enforcing no encroachment into the Critical Clearance Zone is a flawed approach.
Agree
Agree
Agree
Disagree
As discussed in our response to Q11, the concept of encroachment into the Critical Clearance Zone is flawed. It is enforceable almost exclusively through self reports. R5, R6 and R7 provide all incentives for the TO to follow its inspection and maintenance plans, and R2, if properly written to remove references to the Critical Clearance Zone provides additional incentives. R4 is not needed and should be deleted. PHI is puzzled where this concept came from. Nowhere in Order 693 is this concept discussed.
Agree
There is no need for three separate requirements if the incident is a Sustained Outage, but there is nothing inherently wrong with the three requirements.
Disagree
THE SDT has introduced the term Active Transmission Line Right of Way. R8 should use this term to avoid any misinterpretation.
Individual
Virginia Cook and Kim Wheeler
JEA
Disagree
We disagree with this change as it may cause confusion on the applicability of the standard as the BES is generally 100kV and above, but this standard generally applies to 200kV and above.
Agree
Disagree

The standard should EITHER require an entity to have and follow a program OR hold an entity to performance standards, but not both. Requiring a procedure in conjunction with performance requirements incents the entity to write procedures that meet only the minimum requirements of the standard, as they will be audited and held accountable for what is documented and performance against that. If performance requirements are in place without the concurrent requirement for a procedure, then the entity is incented to develop procedures that meet best practices in order to assure that they will meet or beat the performance standards, because in this scenario, such procedures do not expose the entity to additional compliance risk while enhancing reliability.
Disagree
See comment from #3.
Agree
Although there are probably few areas where this is appropriate, the entity should be able to reduce the required number of inspections with RC approval if they are able to demonstrate that vegetation conditions surrounding transmission lines does not warrant inspections at that frequency.
Disagree
See comment from #3.
Agree
It is appropriate to require procedures to respond to "emergency" condidtions, however Imminent Vegetation Threat should be a defined term.
Agree
Agree
Agree
Disagree
The use of Gallet equations is not practical either for field use or for demonstrating compliance.
Agree
Agree
Disagree
See comment from #3.
Disagree
As written, demonstration of compliance may not be feasible and would certainly be prohibitively expensive, consuming resources better spent managing vegetation. In general, putting entities in the position of proving something didn't occur is exptremely difficult and burdensome, without really aiding reliability. If the incident was significant, the region would know about it, and investigations can be pursued, if warranted. The first alternative requiring implementation of the imminent threat procedure is a better choice.
Agree
Disagree
See comment from #3.
M5, 6 and 7 ask the entity to prove the negative. This type of evidence is problematic, and may result in nothing better than the entity making an attestation that the event did not occur, thus this measure is not useful. With well over 100,000 miles of transmission covered by this standard, even six-sigma performance would result in vegetation related issues. It is unreasonable to expect zero-tolerance for vegetation events and unneccessary for the industry (and customers) to expend resources to attempt to meet this level of compliance when the transmission system is planned and operated to handle any single contingency, which means that a vegetation contact should not, in isolation, cause a major problem to the bulk power system. This standard needs work to make it

clear, unambiguous, feasible and enforceable.
Individual
Dan Rochester
Independent Electricity System Operator
Agree
Disagree
The IESO does not see a role for an RC or PC in a vegetation management standard. All TOs need to ensure they have a vegetation program to avoid unnecessary tripping of transmission lines, particularly those that impact the BES. We are of the view that identification of critical facilities is not a part of this standard; it belongs to other standards that deal with SOL/IROL calculations, SPS, protection and critical infrastructure protection. R9 and R10 should therefore be removed from the standard.
Agree
Agree
Agree
Agree
Agree
Agree
Agree
Agree
Agree
Agree

Karen Powell
Salt River Project
Agree

Agree
Disagree
R1.1 states "Specify the methodologies that the Transmission Owner uses to control vegtation". The word "methodologies" does not adequately replace "objectives, practices, approved procedures, and work specifications". Recommend to keep the original wording.
Disagree
Although we agree that it is important to identify both aspects of the program for "prepare/documentation" and "implementation", we do not agree that this needs to be documented in separate requirements. It makes the standard longer than necessary and creates redundancy. The document would be easier to follow if the two elements were kept together in the same requirement. In addition, it is not defined what is "VRFs". We understand that this was detailed in a previous draft document as "Violation Risk Factor". This needs to be defined and clarified in order to provide comment back.
Agree
The Transmission owner needs the ability to define what an inspection is in the context of their utility operation. Inspections may not constitute a dedicated, comprehensive vegetation management inspection, but could often be part of a routine line patrol, where linemen or engineers look for vegetation concerns in addition to undertaking maintenance work. Clarification of that would be helpful, suggest that could be documented in the Technical Reference document.
Disagree
The document would be easier to follow if the two elements were kept together in the same requirement (similar to comments stated in Comment #4 above). It makes the standard longer than necessary and creates redundancy. Also, under the new wording in R1, the TVMP no longer has a requirement to include objectives. However, there is a phrase in R1.3 to "support the objectivesâ€¦and methodologiesâ€¦outlined in the...program". To be consistent with R1.3, it is recommended that R1.1 be reworded to specify the methodologies and objectives that the Transmission Owner uses to control vegetation.
Disagree
Agree with R1.4, however with the suggested change: Remove the language "â€¦and may include actions such as a temporary reduction in line Rating, switching lines out of service, or other actions.". Any stardard should not contain advisory-type language, it should be declarative in tone. The suggested actions are not the responsibility of the vegetation management program.
Agree
Disagree
Recommend adding it back to the document, however, only if it is changed to become a measurement (M) rather than a requirement (R). Leaving it in as a measurement provides justification and leverage for operational clearances when dealing with landowners. Without Clearance 1 landowners may only allow vegetation clearance just at the Critical Clearance Zone at all times, which is not a feasible, cost-effective, or responsible way for utilities to manage vegetation clearance.
Agree
Agree
Although we agree that using the Gallet equation is more definitive than using IEEE 516, we still question from an engineering prespective as to how and why this method was chosen. It is stated in the Technical Reference paper that the Gallet Equation is a well known method of computing the required strike distance for proper insulation coordination. It is our understanding it's purpose is for designing towers, to define the "tower window" or opening inside of a tower under normal conditions. Because this is not a method designed specifically for vegetation management, was there any physical testing involved in choosing this approach, such as testing in both wet and dry conditions? We would recommend additional information to clarify this method to use for vegetation management. See additional comments in Comment #18 below. In addition, we feel this clause makes R4 redundant, as per our comments under Comment #15 below.

Agree
As commented in Comment #11 above, although we agree that using the Gallet equation is more definitive than using IEEE 516, we still question from an engineering prespective as to how and why this method was chosen. It is stated in the Technical Reference paper that the Gallet Equation is a well known method of computing the required strike distance for proper insulation coordination. It is our understanding it's purpose is for designing towers, to define the "tower window" or opening inside of a tower under normal conditions. Because this is not a method design specifically for vegetation management, was there any physical testing involved in choosing this approach, such as testing in both wet and dry conditions? We would recommend additional information to clarify this method to use for vegetation management. See additional comments in Comment #18 below.
Agree
As commented in Comments #11 & #12 above, although we agree that using the Gallet equation is more definitive than using IEEE 516, we still question from an engineering prespective as to how and why this method was chosen. It is stated in the Technical Reference paper that the Gallet Equation is a well known method of computing the required strike distance for proper insulation coordination. It is our understanding it's purpose is for designing towers, to define the "tower window" or opening inside of a tower under normal conditions. Because this is not a method design specifically for vegetation management, was there any physical testing involved in choosing this approach, such as testing in both wet and dry conditions? We would recommend additional information to clarify this method to use for vegetation management. See additional comments in Comment #18 below.
Disagree
The document would be easier to follow if the two elements would be kept together in the same requirement (similar to comments stated in Comments #4 & #6 above). It makes the standard longer than necessary and creates redundancy.
Disagree
Disagree with R4 as it is written. The new requirement in R4 stipulates that the Transmission Owner is in violation if an encroachment of the Critical Clearance Zone occurs at any time. However, the Critical Clearance Zone changes with each foot of the transmission line from the insulator to the mid-span, depending on loading, actual operating temperature, wind loading, ice loading, maximum design rating, maximum operating load, and so on. See additional comments in Comment #18 below. Furthermore, Measure M4 requires that the Transmission Owner has evidence demonstrating there were no vegetation encroachments into the Critical Clearance Zone. To provide evidence demonstrating there were no vegetation encroachments into the Critical Clearance Zone would be an extremely onerous task and an expensive requirement for the utilities. We strongly support changing this to the 1st alternative written in Comment #15 "One alternative to R4 required immediate removal of the vegetation or immediate implementation of the immenent threat procedure upon discovery of a possible encroachment of the Critical Clearance Zone, thereby proactively preventing an outage. A violation would have occurred only if the immenent threat process was not successfully implemented." This alternative is essentially the same as R2, therefore, we recommend removing R4 from the standard entirely.
Disagree
Recommend that the requirement under R7 be changed from "shall prevent sustained outages" to "shall minimize sustained outages due to vegetation falling into a conductor". We understand that the word "minimize" was present in earlier drafts of the document. We are concerned about the requirement to prevent sustained outages from vegetation falling into the conductor from within the active transmission ROW. It is operationally almost impossible to know precisely where the edge of the ROW is in all situations under all conditions. This could lead to an incident where a utility is charged unreasonably - for example, for an outage from a tree that was one foot within the active ROW line. We should not be held liable when reasonable due diligence is practiced. Furthermore, it is not economically feasible for utilities to survey every ROW to determine precise clearance zones.
Disagree
The document would be easier to follow if the two elements would be kept together in the same requirement (similar to comments in #4, #6, & #14 above). It makes the standard longer than necessary and creates redundancy.
We question the method used in determining the clearance distances for Vegetation near Transmission Lines. First is the use of the Gallet Equation. Although the Gallet Equation is more

definitive than using IEEE 516 as identified in the current standard, we have questions from an engineering prespective as to how and why this method was chosen for vegetation management. It is stated in the Technical Reference paper that the Gallet Equation is a well known method of computing the required strike distance for proper insulation coordination. It is our understanding it's purpose is for designing towers, to define the "tower window" or opening inside of a tower under normal conditions. Because this is not a method designed specifically for vegetation management, what is the basis for applying this to vegetation management? Was there, or could there be testing done? We would find it definitive to substantiate the calculated equation assertions with test data from actual energized flashover distances to vegetation. The testing ought to include dry and misting conditions at 200+ kilovolt levels on a sampling of fresh cut common vegetation types. Reputable EHV testing facilities where such tests can be performed exist within the United States and Canada. Is there additional information to clarify why this method was used to help establish clearance distances for vegetation near transmission lines? Second, it is expected that each utility needs to define their "Critical Clearance Zone". It is outlined in the Technical Reference document how complicated it is to define this clearance area. As the conductor moves throughout its "flight path", the minimum clearance shell surrounding the conductor moves along with it. The shape and size of the Critical Clearance Zone around the conductors is irregular and will change depending on where a conductor segment is located within the span. At mid-span, where the potential for conductor movement is the greatest due to sag and wind deflection, the corresponding Critical Clearance Zone is also the largest and most irregular. With the size, shape, and area of the Critical Clearance Zone dramatically changing as one progresses along a span, identifying the precise location and boundary of the Critical Clearance Zone around the conductor in the field becomes very problematic. There are many variables that are involved at any point along a line and at any given time (loading, operating temperature, wind, maximum design rating, maximum operating loading and so on). Therefore, even if the exact size and shape of the Critical Clearance Zone is known, it becomes nearly impossible to field correlate and accurately "superimpose" the Critical Clearance Zone" around the conductor. Therefore, it seems unreasonable to expect each utility to develop and implement a defensible and auditable clearance zone. We strongly support the development of the Technical Reference document. This would have been helpful if it was available for the first version, as it will help both utilities and auditors. We recommend that this be included in the revised version and subsequent future revisions. Please note that as FAC-003-2 goes through additionals revisions prior to finalization, the Technical Reference document needs to be revised to reflect the final revisions prior to implementation.

Northeast Utilities
Agree
Agree with the term "bulk electric system." Disagree with the wording of the Purpose Statement; The Purpose statement reads "To improve the reliability of the bulk electric system by preventing vegetation related outages that could lead to Cascading." One vegetation-caused outage does not in and of itself cause Cascading. Cascading will only result due to a combination of events - either multiple vegetation outages during the same time or an outage coupled with equipment malfunction or operational errors. The document seems to be internally inconsistent in this regard. The Techincal Reference for FAC-003-2 notes that outages due to trees falling from outside the right-of-way or other outage causes on a critical facility would not constitute a possible cascading effect. If one occurance of these types of outages would not constitute a cascading potential then one must wonder why an outage from a tree contact within the right-of-way is considered a possible cascading event? Suggest rewording the statement to exclude the comment about Cascading and use "by preventing vegetation related outages on critical transmission facilities."
Agree
One question: Will the Reliability Coordinators use consistent criteria for listing sub 200-kV facilities to be included under FAC-003-2? The purpose of FAC-003 is to ensure inter-regional reliability and to focus on the reliable operation of these lines. By leaving the decision up to the individual Reliability Coordinators - there is the potential for local differences in determining which sub-200-kV facilities may be critical. This could result in some transmission owners having to include certain facilities under the requirements of FAC-003-2 where in other regions of the country - similar facilities may not be included by the Reliability Coordinator. Although there have been criteria established to guide the Reliability Coordinators in the detemination of sub-200-KV facilities for inclusion under FAC-003-2 - is

this sufficient to ensure uniformity throughout the US? Perhaps some involvement at the Regional Entity level at least, is warranted.
Agree
With respect to "active transmisison line ROW" the examples provided in the Technical Reference document for FAC-003-2 show that any areas of the easement or fee-owned right-of-way not cleared in accordance with company approved design standards will not be considered "active transmission line ROW". Any vegetation contacts resulting from trees that fail in these non-cleared sections ("corridor edge zones") would not constitute a violation of FAC-003-2. The definition of the "active transmission line right-of-way" states that this does not include areas of the easement or fee-owned property that is unused or inactive and intended for other facilities. Does this imply that areas not cleared and not intended for other facilities are part of the active right-of-way? If a company had constructed new lines and allowed for a buffer strip of the easement that was not cleared, but is also not intended for new facilities, and trees are allowed to remain in this strip - that an outage from contact with a tree falling into the lines from this buffer would constitute a violation of R7 as a tree falling from within the active right-of-way? Does this imply that trees in these buffer strips must be removed? This will constitute a very costly and problematic position that will result in extreme adverse public opposition to the required clearing. It is suggested that the clearing limits of any right-way comply with some established standards or codes. A utility should not be allowed to eliminate a large number of vegetation violations by simply decreasing the size or width of the active right-of-way. However, this may also need to be flexible when new lines are constructed when easement widths are limited due to local or state requirements.
Agree
Agree
Agree
Disagree
Agree with the need to have and implement when necessary an imminent threat procedure. Disagree with the need to implement the imminent threat procedure merely because a CCZ is being approached, as required by R2. Is there a desired distance from the CCZ where this procedure must be implemented, since all vegetation within a right-of-way will "approach" the CCZ as it grows? How will time of year and operating conditions be factored in, which may change the requirements to perform control during periods of low temperature or low load? It would not be necessary to perform all the requirements of an imminent threat procedure when there is adequate clearance to schedule the work without jeopardizing the reliability of the system. For example, in mid winter a line is 8 feet from a tree - there is little chance of the line reacing maximum sag at that time of year and the present condition does not constitute an imminent threat at that time. Also, disagree with the requirement for the imminent threat procedure to include actions that could be taken by the TOP (reduction in line rating, switching). The requirement should be limited to notifications to the TOP, since decisions on what specific system operating actions to take are beyond the responsibility of the TO. The decision on what actions to take needs to be performed either by the TOP, or by the TOP in conjunction with the TO.
Agree
Agree
Agree
Agree
Agree
Agree

Agree
Disagree
First - the determination of the CCZ is highly problematic in the field. Second - it is impossible for any utility to certify that no encroachments have occurred at any time unless a utility has completely removed all potentially interferring vegetation on all areas of their transmission system. If the standard is to clearcut and maintain a tree free right of way, the standard should say so. To determine if vegetation may have violated the CCZ the inspector must know at the time of the inspection the ambient temperature, the wind speed, the loading of the line and the actual distances between the vegetation and conductors. Then, the information must be compared to possible extreme operating levels of the line under all conditions to know if the vegetation may violate the CCZ. As stated - it is improbable that this could accurately be performed in the field as the data changes within each segment of a span's length. The first alternative provides the most effective means of addressing encroachment of the CCZ - having an encroachment is not a violation - knowing there is an encroachment and not correcting the problem would be a violation. Implementing the imminent threat procedure and correcting the problem is a more effective approach. Having a zero tolerance for encroachments of the CCZ under all situations and operating conditions would sub-optimize the use of resources. No actual event may have occurred on the system, yet the utilities will be in violation just for a possible or potential problem that even under extreme operating conditions may not actually occur. It would be best if the violations were limited to "known encroachments" (not "possible encroachments") such as would occur if a line were to trip due to vegetation contact, or if there is evidence of any burns. If no action was taken on known encroachments to correct the problem (such as implementation of the imminent threat procedure) then a violation will have occurred. It is doubtful that any utility will be able to certify that at no time has vegetation encroached into the CCZ. Utilities will have to spend an untold amount of resources to verify that there have not been any encroachments during a compliance period - instead of using these resources more effectively in taking proactive measures to manage and control encroaching vegetation. As written, any encroachment into the CCZ is considered a violation of FAC-003-2 (R4). There are exceptions provided for encroachments due to natural disasters and human or animal activity. There is no exception for encroachments due to the failure of a tree(s) outside of the active transmission line ROW. Based on R4, a trip and reclose of a transmission line (no outage) is a violation even if the tree is outside of the active right-of-way; whereas per R6 and R7, a line outage would not be a violation if the tree was outside of the active right-of-way. As written - this is not clear - there should be exceptions to allow for trees falling into the CCZ (and into the active transmission line right-of-way) from outside the limits of the active transmission line right-of-way. Also - how are violations of the CCZ requirement to be reported - there is no provision for the reporting process and requirements (specifics on the type of violation). Will this be addressed in the Compliance Section yet to be added?
Agree
Agree that contacts resulting in sustained outages due to vegetation from within the active transmission line right-of-way should constitute a violation of the Standard. However, this Standard is written for a zero tolerance of any vegetation caused outages or encroachment into the CCZ. One vegetation-caused outage or one CCZ encroachment may not result in a potential Cascading effect. Agree with the use of different violation risk factors (VRF's) and violation severity levels (VSL's) for each of the three outage classes. Also - how are outage violations to be reported - there is no provision in the revision for the reporting process and requirements (specifics on the type of violation). Will this be addressed in the Compliance Section yet to be added? Suggest in both R6 and R7, move the phrase "within an Active Transmission Line Right of Way" to immediately follow "vegetation".
Agree
In section 4.2.2. the time period for bringing sub 200-kV lines into compliance with the standard states a 12 month period following the designation of the lower voltage lines by the Reliability Coordinator. This can present problems if the RC designates the lines during the course of a plan year, because budgets may not have been established or funded for the additional work. It is suggested that the time period be revised to state, "by the end of the following calendar or budget

year after the designation of lower voltage lines", allowing for a full calendar/budget year that can be planned and budgeted to bring lines into compliance. There is concern over the use of the CCZ and making this the "bright line" where encroachment at any time under any conditions is a violation of the standard. The CCZ is a very detailed and calculated zone. It is improbable that an accurate determination of the CCZ could be made in the field. Mere encroachment should not constitute a violation. If the encorachment can be determined and corrected once found - this should be an acceptable practice. It is reasonable for utilities to spend the time, money and manpower to actively manage rights-of-way, and dealing with encroachment issues which can be identified. Many potential encroachments will not be identifiable unless one can accurately identify the CCZ in all cases in all areas at all times. Also, there is some concern over how the requirements are set up for violations of the CCZ and for sustained outages. A sustained outage due to vegetation within the active transmission right-of-way is a violation under R.5, R.6 and R.7. It is also possible that the outage is a violation of the CCZ under R.4. The standard implies that a utility could be assessed multiple violations of the standard for one outage with multiple penalties. Is this the desired intent? Finally, version 1 had clear requirements on what was to be reported, when the reports were required, and who was to submit reports. Is it intended that the standard rely soley on self-reports? Version 2 makes no mention of what is to be reported when a violation occurs, or of any other reports. Is reporting going to be left up to the Regional Entity to establish?

Agree
Disagree
HQT believe that the Planning Coordinator (PC) should be the entity responsible to determine the elements part of the BPS submitted to this Standard, and in fact for all other Standards. Those elements should be determined by an impact based methodology, as used in NPCC, with no voltage limitation and no fixed voltage treshold level as imposed in Applicability 4.2.
Disagree
While we agree with the suggested changes for the terms proposed , we believe that the TVMP should be focused on removal of incompatible vegetation from the Active Right of Way. R1.1 could read:Specify the methodologies that the Transmission Owner uses to control vegetation and demonstrate that the removal of non-compatible vegetation is a focus within the plan. Incompatible vegetation should be defined as any vegetation which has the potential to grow tall enough to jeopardize the integrity of an applicable transmission line by growing into the CCZ or falling into the CCZ. This would provide clear guidance to all stakeholders, support long term vegetation management philosophies, and complement methods such as IVM where incompatible vegetation is completely removed, and compatible vegetation is encouraged to proliferate, thereby helping to control incompatible vegetation in an environmentally positive manner.
Agree
Disagree
The frequency and need for inspection is based on a number of factors that include: type of vegetation on a right of way, rainfall during any given year, climate (very slow growth in nordic area), when the last removal of vegetation was done, etc. HQT believes R1.2 is overly prescriptive when a «at least once a year» becomes mandatory; these terms should be removed from the Standard.
Disagree
R1.2 and R1.3 specify calendar year. The individual entities should define the 12 month period for their programs.
Disagree
While we strongly agree that an imminent threat procedure should be required in the TVMP, we disagree with some specific wording in R1.4. R1.4 requires immediate communication of an imminent threat to the Transmission Operator, which we would normally agree with. R2 however requires that the imminent threat procedure be implemented when the Critical Clearance Zone (CCZ) is approached

by vegetation. "Approached" is not defined as a specific distance, so this part of the requirement is left up to the individual's interpretation. In cases where the CCZ is approached by vegetation no threat to the system is possible if the vegetation is removed before it actually grows into the CCZ. In many cases the vegetation can be removed without taking clearance outages because the CCZ is large, and the conductor and vegetation are still relatively far apart. In such cases there is no need to notify the Transmission Operator, although there is a need to remove the vegetation immediately. We recognize that the opposite is also true, and that in some cases it will be necessary to notify the Transmission Operator because a clearance outage or line de-rating may be required to remove the vegetation. We therefore suggest a simple change to the wording of the second sentence of R1.4. Change "â€¦. specify actions which shall include immediate communication of the threat to the Transmission Operator, and may include actions such as a temporary reduction in line Rating, switching lines out of service, or other actions" to "... specify actions which may include immediate communication of the threat to the Transmission Operator, a temporary reduction in line Rating, switching lines out of service, or other actions". This change will address the issue which is described above and will allow each Transmission Operator to develop an imminent threat procedure that best fits their system. It should also be noted that many Transmission Operators have imminent threat procedures in place to address all imminent threats to their transmission system, not just threats due to vegetation. It makes sense for Transmission Owners to have only one imminent threat process, therefore the flexibility that can be achieved in the context of this standard would be helpful.
Agree
Agree
We agree but believe that the TVMP should target removal of all incompatible vegetation on the Active Right of Way as described in the response to question 3.
Agree
Agree
Agree
Agree
Agree
Disagree
The purpose of the standard is "To improve the reliability of the Bulk Electric System by preventing vegetation related outages that could lead to Cascading". We believe that R4 is not the most effective way to achieve this purpose because it does not provide incentive for Transmission Owners to take advantage of modern technology, such as aerial laser survey (ALS) using Light Detection and Ranging technology (LIDAR), that is capable of accurately identifying vegetation which is approaching the CCZ or has encroached into it. In fact R4 provides an incentive not to utilize this technology because Transmission Owners who identify encroachments would be in violation of R4 for each identified encroachment. On the other hand, Transmission Owners who choose to be less proactive often would not identify such encroachments because the CCZ and encroachments of it are generally not easy to determine without taking precise measurements. Unless the line is heavily loaded or the vegetation is significantly overgrown, encroachments of the CCZ would not be readily noticed. In most cases these Transmission Owners would simply remove or cut back incompatible vegetation without taking measurements. The threat to the line would have been eliminated with no encroachment having been identified. R4 presents a dilemma for Transmission Owners that are considering making the significant investment in ALS technology. While the technology would allow them to identify any potential grow-in or fall-in conditions, it would also expose them to the risk of identifying violations of R4, that would otherwise not have been identified. Violation Risk Factors (VRFs), Violation Severity Levels (VSLs), and Time Horizons are not included in this Draft, but after making a significant investment in ALS, Transmission Owners could be faced with significant additional cost in terms of NERC penalties. In addition, even if the penalties were relatively low they would be exposing themselves to violations

that less proactive Transmission Owners would not be exposed to. In our view R4 as written would, in some cases, have the opposite effect of what is intended because the business case for using ALS is more difficult to make. This will result in less use of ALS and other emerging technology that is likely to be developed. This would result in fewer problems being identified, a small percentage of which will not be discovered until they result in a line trip. Still we believe that the concept of the CCZ is a good one and recommend that R4 be changed so that Transmission Owners are provided with an incentive to invest in the best technology available in order to ensure the highest level of reliability. The opportunity exists to develop the standard in a manner that encourages the industry to take advantage of new technology and manage vegetation in a very proactive way. We recommend that R4 be changed as follows: Modify R4 to require Transmission Owners to immediately implement the imminent threat process defined in R1.4 when they identify instances where the CCZ is approached or encroached upon. Failure to do so would be a violation of R4. Eliminate encroachment of the CCZ as a violation of R4. This would eliminate R2 and incorporate implementation of the imminent threat process into R4. Require Transmission Owners to report to the Regional Entity on a quartely basis any instances where the imminent threat process was implemented due to an encroachment of the CCZ. This would add a reporting requirement for Transmission Operators. Require Transmission Owners to report to the Regional Entity on a quarterly basis any instances where either a momentary or sustained outage was caused by grow-ins, Active Transmission Line Right of Way blow-ins, or Active Transmission Line Right-of-Way fall-ins. This would add three additional reporting requirements for Transmission Operators. Require Regional Entities to perform additional audits of Transmission Owners that exceed metrics for violations of the CCZ . The metrics would be established in this Standard based upon 100 circuit miles of applicable lines. This would add an additional requirement for Regional Entites. This concept would result in a more rigorous standard than FAC-003-01 because of the additional reporting and auditing requirements. It would drive proactive behavior throughout the industry and provide a significant incentive for Transmisison Owners to invest in new technology such as ALS that is capable of accurately identifying vegetation that has approached or encroached upon the CCZ. We believe that this change would result in the identification of more incipient vegetation-related problems and fewer vegetation-related outages as soon as it was implemented and would best support the purpose of the Standard.
Disagree
HQT request clarification if violations of R5, R6, and R7 result in outages that must be reported. A further exception would be a sustained outage where the conductor has moved outside the critical clearance zone. This could occur under conditions of heavy icing, operating outside the line rating or excessive wind.
Agree
HQT recommends that the Standard Drafting Team review the compliance and reporting requirements for consistency and adequacy. Aplicability 4.2.3 contradict first part of Applicability 4.2.1 and that of former Applicability 4.3

MRO NERC Standards Review Subcommittee
Joseph Knight
GRE
Disagree
The standard specifically calls out that 200kV and higher are applicable to FAC-003. Changing to BES would imply all lines 100kV and above would be applicable.
Disagree
The MRO disagrees that the RC is appropriately positioned to identify and designate any sub-200kV lines that should be subject to this standard. The MRO believes that the lines below 200kV should include only those that are currently classified as Interconnection Reliability Operating Limit (IROL) lines which are already defined and listed for registered entities. As such R9 and R10 should be eliminated from these standards along with the RC in the applicability section.
Agree
The MRO agrees but requests further clarification on the definition of the term "Active" in Active Transmission Line R.O.W. For example: A utility has a 150 foot easement for a 230kV line and currently manages 80 feet. First; is it the intent of the standard that the utility manage the entire 150 foot easement? Second; is the entire easement considered the Active Transmission Line R.O.W?
Agree
The MRO believes that clarity was improved by separating documentation and implementation. The MRO suggests that moving the requirement for implementationt so that it immediately follows the requirement for documentation will further enhance clarity.
Agree
The MRO suggests rewording the requirement to remove ".. and environmental" . The MRO believes

that local factors includes environmental.
Agree
The MRO suggests removing the words "during the year" from sentence 1 and removing the words "within the year" in sentence 3. The MRO believes that having it only within the plan year is too restrictive.
Agree
The MRO agrees and believes that it is very important for the applicable entities to posses a Imminent Threat Procedure. The MRO also believes that the term "Imminent Threat" is subjective an should be defined.
Agree
The MRO believes that the term "interim" should be removed from R1.5. The term Interim is subjective.
Agree
The MRO agrees and fully supports the removal of Clearance 1. The MRO believes that the Gallet equation is a more effective way of determining the required clearances.
Agree
Agree
The MRO agrees and believes that the Gallet equation yeilds a less subjective measurement. The MRO believes R2 should be modified to be more definitive. The imminent threat procedure should be implemented when vegetation â€œentersâ€☐ the critical clear zone. Fines and violations for approaching the zone is not measurable or enforceable. The MRO believes that "approached" is subjective and not enforceable and should be removed from the requirement.
Agree
Agree
Agree
Disagree
The MRO believes R4 should be eliminated as vegetation contacts are covered in R5 and R6. A violation should only occur with a vegetation contact. Assessing a violation and fine for a potential reduction in system reliability is not correct. Actual contacts that trip a transmission element have some measurable impact on system reliability even if it is slight.
Agree
Agree
The MRO both Agrees and Disagrees. The MRO agrees with the separation between having an annual plan and implementing it. However, the MRO suggests removing all the words after vegetation manangement.

Midwest ISO
Disagree
By definition Bulk Electric System includes most facilities 100 to 200 kV. The previous version of this standard appropriately restricted the applicability of the standard to these facilities by requiring the Regional Reliability Organization to identify only those facilities that are critical in this voltage class. This new version of the standards attempts to limit the 100-200 kV class applicability by having the RC identify the critical facilities. We believe to have one requirement of the standard say that it applies to all the BES and then another requirement to limit the application only confuses the applicability and recommend leaving the term "electric transmission systems" in the definition.
Disagree
We do not believe that the RC is the appropriate entity to identify those facilities sub-200 kV facilities that this standard should apply to. Vegetation management is not performed in the operating horizon. Rather it is performed in the planning and operations planning horizons. The RC should not be distracted from focusing on the operating horizon by this task. We believe what the standard is essentially requiring is identifying critical facilities. There are other similar requirements such as PRC-023-1 R3 that appear to require the determination of critical facilities even though the term critical facilities is not defined. We believe this represents broader issue that requires NERC to define critical facilities. Failure to do so could result in the inefficient identification of multiple lists of critical facilities for specific requirements that may ultimately be challenged in due process.
Agree
Agree
This is a good change from a compliance perspective; the documentation requirements can now be assigned lower VRFs than the implementation requirements.
Agree
Agree
Disagree
Transmission Owners should have a Vegetation Imminent Threat Procedure, and "Vegetation Imminent Threat" should be a defined term, defined as: "Vegetation observed in the field encroaching upon a conductor within a distance that is twice the Gallet clearance distances referenced in Table I of the draft standard FAC-003-2." In this case, the threat would require an immediate response and would include communication to the Transmission Operator. From there, the actions that the operator decides to take will be dependent on the incident and system conditions. We do not need to be prescriptive with this requirement but rather allow the Transmission Operator and appropriate field personnel the flexibility to make the right decisions to safely, promptly and appropriately remove the vegetation threat. From a Transmission Owner's perspective, many situations can constitute an imminent threat but this approach will clearly define a "Vegetation Imminent Threat" as it relates to the Purpose of this standard. See our related comment on #11 below.

he CCZ is a good theoretical concept to aid industy in understanding the overall movement of conductors, but it is an impractical concept for field application. Due to the variability in the size of the CCZ as you move along a conductor, as well as changes from span to span or even line to line

due to design parameters, loading or weather-related issues, the CCZ concept should not be tied to an imminent threat procedure. Vegetation approaching the CCZ does not constitute an imminent threat. It may be months to years before this vegetation ever gets to a proximity distance from the conductor to be within a "spark-over" distance as defined by the Gallet equations. Requirement R2 should support the purpose of this standard by requiring implementation of the Vegetation Imminent Threat Procedure when the Transmission Owner has visual, field knowledge that vegetation is encroaching upon a conductor within some specific distance that is a multiple of the Gallet distances referenced in Table I of FAC-003-2 (to be conservative we suggest two to three times the Gallet distances). Failure to implement the Vegetation Imminent Threat Procedure in such instances would be a violation of R2. As R2 is currently stated, a Transmission Owner cannot comply with R2 unless the imminent threat procedure is continuously being implemented, because vegetation that is growing is always approaching the CCZ. "Approaching the CCZ" cannot be the trigger for implementation of the Vegetation Imminent threat Procedure. Instead, the trigger should be an encroachment within some observed field distance. Requirement R2 could be reworded as follows: â€œEach Transmission Owner shall implement its Vegetation Imminent Threat Procedure when the Transmission Owner has knowledge, obtained through normal operating practices or notification from others, that vegetation is encroaching upon a conductor within a distance that is twice the Gallet clearance distances referenced in Table I." Using a multiple of the Gallet distances provides a safety factor. Assessing a violation for failure to appropriately implement the Vegetation Imminent Threat Procedure or for a sustained vegetation-related outage incents the proper behavior.
Agree
Agree
Agree

The second bulleted alternative above is the best approach, but it should be improved by changing the imminent threat trigger from "encroachment of the CCZ" to "encroachment within some observed, field distance that is a multiple of the Gallet distances referenced in Table I". We have recommended changes to accomplish this in Requirement R2 (see our response to Question #11 above), and R4 should simply be deleted. While the CCZ is valuable to understanding the movement of conductors, it cannot be readily applied in the field. This field application challenge is noted in the Technical Reference Document (pages 29 & 30). The way R4 is currently stated, the Transmission Owner would be in violation of R4 for any CCZ encroachment not due to natural disasters or human or animal activity. This would include a tree falling from outside the right of way corridor that passes through the theoretical CCZ. Furthermore, Transmission Owners would be required to self-certify compliance with R4, and we don't think there's any way to do that. Clearly the approach of assessing violations for CCZ encroachment is unworkable. Likewise, the third alternative listed above is untenable. The tiered approach could have a mitigating effect on violations, but it would require the same inspection effort and postponement of vegetation management that makes the first alternative unworkable. Both the first and third alternatives would require very significant additional expenditures for surveys and documentation in an impossible attempt to certify compliance - money that would be better spent controlling vegetation.
Agree
Agree
We recommend striking the words "within the extent of its easement and/or legal rights". The emphasis for this requirement is to execute the annual work plan. The white paper already speaks to the point that it is a best practice for utilities to exercise their legal rights. By tagging the words on to the requirement, we are adding unnecessary compliance validation to this requirement for both industry and the regulators. By the way this is written, it could be interpreted different ways. If we agree that the goal is to prevent outages, then we can simply end this requirement with "accomplish the purpose of the standard". Each TO would be accountable to manage compliance with this standard and public relations in their service area.

FAC-003-1 lacks clarity that is essential for understanding what is necessary for compliance. The proposed FAC-003-2 needs to be simplified to aid with field implementation and compliance interpretation. Currently, it does not provide the clarity and simplification needed by Transmission Owners and regulatory bodies to enhance reliability.
Group
SERC Compliance Staff
John Wolfmeyer
SERC Reliability Corp
Disagree
The definition of the Bulk Electric System generally includes all lines operated at 100 kV and above and may exclude radial lines to load only. The standard is applicable to lines operated at greater than 200 kV regardless of their function. SERC staff does not believe that it is the intent of the standard to address lines operated at less than 200 kV unless they are deemed to be critical to the operation of the BES nor do we believe it is the intent to exclude radials to load only from the applicability. Use of the term Bulk Electric System will cause unnecessary confusion to the industry concerning applicability of this standard. Therefore, we recommend the continued use of the undefined term "electric transmission systems."
Agree
Agree
Agree
Agree
Agree
Disagree
SERC staff agrees with the concept of an imminent threat procedure, but disagrees with this requirement in its current form. The use of the word "immediate" is ambiguous. There are many conditions or threats that may require immediate removal, but would not require communication with the Transmission Operator and may require communication with another entity. SERC staff suggests that the proper communication paths be outlined by the Transmission Owner. Imminent threats should be a defined term, however SERC staff has not developed an objective, unambiguous definition.
Agree
Agree
Agree
Disagree
SERC staff agrees that the implementation of an imminent threat procedure may be a valid concept; however visualization of the Critical Clearance Zone and determining an approaching encroachment will be difficult from a practical matter. There also needs to be definition of what is meant by "approaching" if this is used. While it may be a technically sound approach to designate the clearance zone to be tied to the conductor movement envelope as found in the NESC, this results in a banana-shaped zone that is difficult to substantiate in the field by entity and compliance personnel. It may be better, and more reasonable to define a constant zone around a conductor that would be the same throughout the span. The clearance zone should not include the limitation that the zone cannot extend outside the active right of way.
Disagree

While the actual sparkover distance may be more correctly calculated using the Gallet equations, SERC staff believes it is a less conservative approach to the goal of preventing vegetation related outages. If the concept of the CCZ will remain in the standard, we suggest that the tables based on the Gallet equations be removed from the standard and be kept in the technical white paper solely to assist in developing a common understanding of the theory behind the establishment of a CCZ. However, the CCZ will continue to be a very difficult, if not impossible, aspect of the standard to implement from the perspective of practical application and compliance enforcement.
Agree
Agree
Disagree
The concept of the Critical Clearance Zone is useful as a mental model to visualize required vegetation management work. While this is a good conceptual tool to drive consistent terminology and proper vegetation management practices, it is impractical to measure on a span by span basis. The complexity of determining an encroachment into the Critical Clearance Zone is overly burdensome due to the need for survey accuracy measurements and engineering evaluations. While it may be a technically sound approach to designate the clearance zone to be tied to the conductor movement envelope as found in the NESC, this results in a banana-shaped zone that is difficult to substantiate in the field by entity and compliance personnel. We suggest that the Critical Clearance Zone concept be kept in the technical white paper and that all references to the Critical Clearance Zone be removed from the body of the standard.
Agree
Agree
Vegetation management practices should be extended areas outside of the active rights-of-way (ROW) to the extent necessary to prevent vegetation-related outages. This should include the identification and removal of trees that could impact transmission line operation similar to the practice of identifying danger trees off of the ROW. The requirement as written could serve to reward those entities that, for whatever reason, have insufficient right-of-way widths. From a practical perspective, it should not be necessary to perform clear cutting of non-active ROW, but Entities should be held responsible for any outages that occur due to contact with vegetation within their legal rights to control.
SERC staff continues to find the Applicability section of the standard to be confusing and contentious. While we recognize it is the intent this section to make the standard applicable t all entities that own transmission lines that operate at greater than 200 kV, this section should not be written to be applicable to transmission lines. Only registered entities can be held accountable for compliance with the standards. SERC staff believes the applicability should be rewritten to include Transmission Owners, Distribution Providers, and Generation Owners that own transmission lines with the characteristics defined in Section 4.2. This would eliminate the need to make register, for example, a Distribution Provider that own a 230 kV line that serves load as a Transmission Owner and make them subject to the requirements of FAC-001 and FAC-002. SERC Staff also suggest the applicability could be handled as it is in PRC-005-1 where the applicability is qualified as 'distribution provider that owns...' and 'generator owner that owns...' or in a similar manner that captures the appropriate subgroup but does not include unintended entities. SERC Staff believes a flashover between vegetation and overhead ungrounded supply conductors that occurs, whether or not the flashover results in a Sustained Outage, is clear evidence of an unallowable encroachment of vegetation into the space that should be avoided and thus should be identified as evidence of a violation of the standard. SERC staff has also found that excluding outages resulting from "earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Ownerâ€¦" results in inconsistencies in reporting because of the inconsistency of the Transmission Owners' definitions of same. If such exceptions are to be allowed, a consistent method of determining the acceptability of those exemptions should be pursued.

Consideration of Comments on 1st Draft FAC-003-2 Vegetation Management SDT — Project 2007-07

The Vegetation Management Standard Drafting Team (VM SDT) thanks all commenters who submitted comments on the 1st draft of FAC-003-2 — Transmission Vegetation Management Program standard. This standard was posted for a 30-day public comment period from October 27, 2008 through November 25, 2008. Stakeholders were asked to provide feedback on the standard through a special Standard Comment Form. There were more than 60 sets of comments, including comments from more than 100 different people from over 60 companies representing each of the 10 Industry Segments as shown in the table on the following pages.

http://www.nerc.com/filez/standards/Vegetation-Management_Project_2007-7.html

Key differences between first posting and second posting of proposed FAC-003 -2 include:

- Replaced the CCZ concept found in R4 with a practical field measurement to address commenter's concerns.
- Eliminated the CCZ as the trigger of imminent threat in R2 to address commenter's concerns.
- Added a sub part to the TVMP (1.6) in order to address commenter's concerns regarding the elimination of Clearance 1. This change requires that the TO account for anticipated conductor movement.
- Developed VRF's and VSL's consistent with the NERC Drafting Team Guidelines.
- Created a second grow-in outage requirement to allow for different VRF levels based on the actual criticality of the line.

There were 3 strong minority views not resolved:

- Some commenters disagreed with the "zero tolerance" nature of the existing in-force standard.
- Some commenters disagreed with a minimum Vegetation Inspection frequency of one year.
- Some commenters want to retain Clearance 1 that is in the existing in-force standard.

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Gerry Adamski, at 609-452-8060 or at gerry.adamski@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

1. In the Purpose Statement the term "electric transmission systems" was changed to Bulk Electric System, and the Purpose statement was shortened by moving the various explanatory objectives to other locations in the revised Standard. Do you agree with the purpose statement? If not, please explain.

Summary Consideration: The SDT revised the purpose statement based on industry comments. The SDT returned to "electric transmission system" based on the comments that indicated confusion with the use of "BES". The SDT also inserted the word "those" in front of the phrase "vegetation-related outages" to clarify that not all vegetation-related outages lead to cascading. The revised purpose statement now reads:

Purpose: To improve the reliability of the electric transmission system by preventing those vegetation related outages that could lead to Cascading.

Organization	Agree?	Question 1 Comment
Associated Electric Cooperative Inc.	Disagree	The definition of Bulk Electric System includes most transmission lines operated at 100 kv and above. While Section A.4.2.1 limits the applicability of FAC-003-2 to 200 kv and higher transmission lines, the use of the term Bulk Electric System could cause unnecessary confusion. Associated Electric Cooperative Inc recommends the continued use of the term "electric transmission systems."
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by "BES" and has revised the purpose statement to delete BES and return to electric transmission system.		
SERC Vegetation Management Subcommittee (VMS)	Disagree	The definition of the Bulk Electric System generally does not include radial transmission lines directly serving load and, in addition, includes all lines operated at 100 kV and above. Use of the term Bulk Electric System will cause unnecessary confusion to the industry concerning applicability of this standard. Therefore, we recommend the continued use of the undefined term "electric transmission systems."
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by "BES" and has revised the purpose statement to delete BES and return to electric transmission system.		
Progress Energy Florida	Disagree	The intent of the revision of the standard was to bring clarity to the standard. Referring to the BES in the purpose creates confusion as to the applicability of the standard. Therefore, Progress Energy recommends the continued use of the term "electric transmission systems."
Response: The SDT thanks you for your comment Based on the comments received, the SDT understands there may be confusion caused by "BES"		

Organization	Agree?	Question 1 Comment
and has revised the purpose statement to delete BES and return to electric transmission system.		
Kansas City Power & Light	Disagree	The definition of the bulk electric system does not match the scope of the systems covered by the vegetation management standard. If the term bulk electric system is used , it should exclude the areas not covered by the standard.
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by “BES” and has revised the purpose statement to delete BES and return to electric transmission system.		
Western Area Power Administration, Rocky Mountain Region	Disagree	Use of the general term Bulk Electrical System creates unintentional confusion regarding the applicability of this standard to lines operated at 200 kV or higher and designated lines operated below 200 kV.
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by “BES” and has revised the purpose statement to delete BES and return to electric transmission system.		
Progress Energy Carolinas	Disagree	The intent of the revision of the standard was to bring clarity to the standard. Referring to the BES in the purpose creates confusion as to the applicability of the standard. Therefore, Progress Energy recommends the continued use of the term "electric transmission systems."
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by “BES” and has revised the purpose statement to delete BES and return to electric transmission system.		
SERC OC Standards Review Group	Disagree	The following comments are supplied by the SERC OC Standards Review Group (OCSRG): The definition of the Bulk Electric System generally does not include radial transmission lines directly serving load. The current standard covers all 200 kV and above transmission lines along with those lower voltage lines designated by the RRO while the BES includes all lines 100 kV and above. Use of the term Bulk Electric System will cause unnecessary confusion to the industry concerning applicability of this standard. Therefore, the SERC OCSRG recommends the continued use of the undefined term "electric transmission systems."
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by “BES” and has revised the purpose statement to delete BES and return to electric transmission system.		
Florida Power & Light	Disagree	The Purpose Statement of any regulation or standard should be completely consistent with the body of regulation or standard. Here the use of Bulk Electric System (which is defined as 100 kV and above) is inconsistent with the language of the Standard that states this Standard applies to 200 kV and above. One of the primary purposes of re-

Organization	Agree?	Question 1 Comment
		drafting a Reliability Standard is to clear up any previous confusion -- here the Purpose Statement instead of adding to clarity, adds an unnecessary element of confusion. Thus, the Purpose Statement should be re-written to state 200 Kv and above.
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by "BES". Rather than create a new class of BES (>200kv), the SDT revised the purpose statement to delete BES and return to electric transmission system.		
Southern Company	Disagree	The initial FAC-003-1 drafting team had a particular reason for not using Bulk Electric System for fear of it being widely recognized to characterize the entire networked transmission system. This reason was to limit possible confusion with the applicability of the Standard. The Bulk Electric System definition includes all lines of the grid operated at 100 kV and above. This term also does not necessarily include lines of any voltage class that are radial and directly serving load. Use of this term in lieu of "electric transmission systems" has the potential to cause additional confusion to the industry.
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by "BES" and has revised the purpose statement to delete BES and return to electric transmission system.		
E.ON U.S.	Disagree	The definition of the Bulk Electric System generally does not include radial transmission lines directly serving load and, in addition, includes all lines operated at 100 kV and above. Use of the term Bulk Electric System will cause unnecessary confusion to the industry concerning applicability of this standard. Therefore, we recommend the continued use of the undefined term "electric transmission systems."
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by "BES" and has revised the purpose statement to delete BES and return to electric transmission system.		
MRO NERC Standards Review Subcommittee	Disagree	The standard specifically calls out that 200kV and higher are applicable to FAC-003. Changing to BES would imply all lines 100kV and above would be applicable.
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by "BES" and has revised the purpose statement to delete BES and return to electric transmission system.		
Midwest ISO Stakeholders Standards Collaborators	Disagree	By definition Bulk Electric System includes most facilities 100 to 200 kV. The previous version of this standard appropriately restricted the applicability of the standard to these facilities by requiring the Regional Reliability Organization to identify only those facilities that are critical in this voltage class. This new version of the standards attempts to limit the 100-200 kV class applicability by having the RC identify the critical facilities. We believe to have one requirement of the standard say that it applies to all the BES and then another requirement to limit the

Organization	Agree?	Question 1 Comment
		application only confuses the applicability and recommend leaving the term "electric transmission systems" in the definition.
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by "BES" and has revised the purpose statement to delete BES and return to electric transmission system.		
SERC Compliance Staff	Disagree	The definition of the Bulk Electric System generally includes all lines operated at 100 kV and above and may exclude radial lines to load only. The standard is applicable to lines operated at greater than 200 kV regardless of their function. SERC staff does not believe that it is the intent of the standard to address lines operated at less than 200 kV unless they are deemed to be critical to the operation of the BES nor do we believe it is the intent to exclude radials to load only from the applicability. Use of the term Bulk Electric System will cause unnecessary confusion to the industry concerning applicability of this standard. Therefore, we recommend the continued use of the undefined term "electric transmission systems."
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by "BES" and has revised the purpose statement to delete BES and return to electric transmission system.		
ITC HOLDINGS	Disagree	ITC does not agree with the new purpose statement. The NERC Glossary of terms states that the BES ?.generally operated at voltages of 100kV or higher and the Applicability in Section 4 clearly states the standard is intended to apply to all line voltages of 200kV and above and those lines designated by the Reliability Coordinator (4.2.1) as being subjected to this standard. Using the term Bulk Electric System (BES) clearly sends a confusing message and should be eliminated. Thus the term of "electric transmission system" is appropriate for the standard
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by "BES" and has revised the purpose statement to delete BES and return to electric transmission system.		
Tennessee Valley Authority	Disagree	TVA feels the use of the term Bulk Electric System will cause unnecessary confusion to the industry concerning applicability of this standard. TVA recommends the continued use of the undefined term "electric transmission systems. TVA recommends changing the phrase "by preventing vegetation-related outages that could lead to Cascading" to "by preventing those vegetation-related outages that could lead to Cascading", this removes the improper inference that each vegetation-related outage leads to Cascading
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by "BES" and has revised the purpose statement to delete BES and return to electric transmission system. Additionally, at your suggestion and that of others, the SDT has added the qualifying word "those" to define that the standard should address interconnection reliability and security.		

Organization	Agree?	Question 1 Comment
Central Maine Power Company	Disagree	Central Maine Power suggests that a definition be provided for Bulk Power.
Response: The SDT is uncertain of the need to define Bulk Power.		
American Electric Power (AEP)	Disagree	American Electric Power ("AEP") does not agree with this purpose statement. First, it is clear from the Applicability (in Section 4) that the standard applies only to certain lines, not to the entire Bulk Electric System (BES). Reference to the BES in the Purpose statement tends to muddy the water, potentially leading to an assumption that the Standard indeed applies to the entire BES. AEP suggests that the term BES used herein be replaced with "electric transmission system" or "transmission grid". Second, the phrase "by preventing vegetation-related outages that could lead to Cascading" should be changed to "by preventing those vegetation-related outages that could lead to Cascading", to remove any suggestion that all vegetation-related outages could lead to Cascading.
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by “BES” and has revised the purpose statement to delete BES and return to electric transmission system. Additionally, at your suggestion and that of others, the SDT has added the qualifying word “those” to define that the standard should address interconnection reliability and security.		
Tampa Electric Company	Disagree	NERC glossary of terms defines the Bulk Electric System as "the electrical generation resources, transmission lines, interconnections with neighboring systems, and associated equipment, generally operated at voltages of 100 kV or higher." This, at a minimum, could lead to confusion over what impacts the reliability of the Grid by potentially including facilities less than 200 kV.
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by “BES” and has revised the purpose statement to delete BES and return to electric transmission system.		
Orange and Rockland Utilities Inc.	Disagree	The use of the term "Bulk Electric System" (BES) could lead to confusion. In most regions BES includes lines with operating voltages equal to or greater than 100kV. The Standard is intended to apply to all lines with operating voltages equal to or greater than 200kV, and only those sub-200kV lines which are designated by the Reliability Coordinator (paragraph 4.2.1). Use of the words "electric transmission systems" rather than BES would eliminate this potential source of confusion.
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by “BES” and has revised the purpose statement to delete BES and return to electric transmission system.		
American Transmission	Disagree	ATC disagrees with changing the term "electric transmission systems" to "Bulk Electric System". This standard applies to 200 kV and higher transmission lines not all BES facilities. Suggested Purpose statement: To maintain

Organization	Agree?	Question 1 Comment
Company		the reliability of the electric transmission system by requiring entities to have and implement a transmission vegetation management plan.
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by "BES" and has revised the purpose statement to delete BES and return to electric transmission system. We also appreciate your suggested purpose statement but based on others' comments to be more specific about the reliability need for this standard we modified the purpose statement as seen in the Summary Consideration above.		
Ameren	Disagree	By definition, the capitalized term, Bulk Electric System, is defined to include most facilities 100 kV and above. The previous version of this standard appropriately restricted the applicability of the standard to those facilities operating above 200kV and any additional facilities identified by the Regional Reliability Organization as critical. This new version of the standards attempts to limit the 100-200 kV class applicability by having the RC identify the critical facilities. We believe the change creates unnecessary and undesirable confusion in that one requirement of the standard says that it applies to all the BES and then another requirement limits the application. Leaving the term "electric transmission systems" in the definition is preferable to that proposed.
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by "BES" and has revised the purpose statement to delete BES and return to electric transmission system.		
Nebraska Public Power District	Disagree	NPPD disagrees with the change to bulk electric system, because it creates confusion on the applicability. This standard only applies to certain lines and not the entire (bulk) system.
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by "BES" and has revised the purpose statement to delete BES and return to electric transmission system.		
Manitoba Hydro	Disagree	Manitoba Hydro disagrees with changing "electric transmission systems" to "Bulk Electric System" because BES applies to facilities 100kV and above which may not have an impact on system reliability.
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by "BES" and has revised the purpose statement to delete BES and return to electric transmission system.		
Consumers Energy Company	Disagree	Consumers Energy disagrees with changing the current "electric transmission systems" to "bulk electric system". This change will create confusion and can lead to a discrepancy concerning lines operating below 200kV that may be included in the "bulk electric system" but are otherwise excluded from this standard.
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by "BES"		

Organization	Agree?	Question 1 Comment
and has revised the purpose statement to delete BES and return to electric transmission system.		
National Grid	Disagree	Use of the term Bulk Electric System will cause unnecessary confusion to the industry concerning applicability of this Standard.
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by "BES" and has revised the purpose statement to delete BES and return to electric transmission system.		
Edison Electric Institute	Disagree	The purpose of the standard should be revised to state 'To maintain minimum clearances sufficient to avoid any vegetation-related Sustained Outages for all applicable conditions.' This is the identical wording taken from Order No. 693, Paragraph 731.
Response: The SDT appreciates your comments to use the exact wording in the FERC Order for the purpose statement. However, the SDT believes strongly that the interconnected system reliability which FERC should be protecting is better defined by the second posting statement. For instance, there are 200 kV circuits which serve only local load. Outages to these circuits from vegetation are no different than from other causes. The issue for this standard should be the prevention of vegetation outages that will threaten the interconnection.		
Consolidated Edison Company of New York (CECONY)	Disagree	The phrase "Bulk Electric System" (BES) is somewhat misleading. BES includes transmission voltages greater than 100kV but this Standard addresses transmission lines with operating voltages at or above 200kV and only those lines below 200kV designated by the Reliability Coordinator. Use of the phrase "electric transmission circuits" or something similar rather than BES would reduce confusion.
Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by "BES" and has revised the purpose statement to delete BES and return to electric transmission system.		
Arizona Public Service Company	Disagree	APS suggest the following change; To improve the reliability of the Bulk Electric System by preventing vegetation related outages. This is a reliability standard APS would suggest removing "that could lead to widespread cascading failures" from the purpose statement.
Response: The SDT thanks you for your comment. However, the SDT believes strongly that the interconnected system reliability which FERC should be protecting is better defined by the second posting statement. For instance, there are 200 kV circuits which serve only local load. Outages to these circuits from vegetation are no different than from other causes. The issue for this standard should be the prevention of vegetation outages that will threaten the interconnection.		
Duke Energy Corporation	Disagree	Duke disagrees with changing "electric transmission systems" to "Bulk Electric System" because this creates the potential for confusion or indiscriminate expansion of the scope of applicability to 100kV facilities which may not

<table>
<tr><th>Organization</th><th>Agree?</th><th>Question 1 Comment</th></tr>
<tr><td></td><td></td><td>have an impact on network system reliability. Using "Bulk Electric System" confuses the applicability of the standard. Duke believes that Section 4.2 has the specificity to clearly designate any applicable lines. Thus, the term "electric transmission systems" is appropriate.</td></tr>
<tr><td colspan="3">Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by “BES” and has revised the purpose statement to delete BES and return to electric transmission system.</td></tr>
<tr><td>Entergy Services</td><td>Disagree</td><td>Entergy disagrees with changing “electric transmission systems” to “Bulk Electric System.” Historically, the definition of the Bulk Electric System has included all lines operated at voltages 100 kV and greater. The above change in terminology will add ambiguity to which lines this standard is applicable. Entergy is concerned about the potential for this ambiguity leading to the expansion of the applicability of the standard to include lines below 200kv.</td></tr>
<tr><td colspan="3">Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by “BES” and has revised the purpose statement to delete BES and return to electric transmission system.</td></tr>
<tr><td>JEA</td><td>Disagree</td><td>We disagree with this change as it may cause confusion on the applicability of the standard as the BES is generally 100kV and above, but this standard generally applies to 200kV and above.</td></tr>
<tr><td colspan="3">Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by “BES” and has revised the purpose statement to delete BES and return to electric transmission system.</td></tr>
<tr><td>Great River Energy</td><td>Disagree</td><td>The standard specifically calls out that 200kV and higher are applicable to FAC-003. Changing to BES would imply all lines 100kV and above would be applicable</td></tr>
<tr><td colspan="3">Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by “BES” and has revised the purpose statement to delete BES and return to electric transmission system.</td></tr>
<tr><td>Western Area Power Administration, Upper Great Plains Region</td><td>Agree</td><td>Western (UGPR) agrees with the objective of using the FERC/NERC defined term "Bulk Electric System", but believe that the FERC/NERC definition includes lines above 100 kV. It needs to be clearly understood that use of the generic term in the Purpose section does not supersede the specific definitions (greater than 200 kV, etc.) contained in the Facilities section.</td></tr>
<tr><td colspan="3">Response: The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by “BES” and has revised the purpose statement to delete BES and return to electric transmission system based on a overwhelming industry preference for the latter.</td></tr>
</table>

Organization	Agree?	Question 1 Comment
Platte River Power Authority	Agree	The use of the approved terminology, Bulk Electric System, from the NERC Glossary of Terms is better than the undefined term electric transmission systems.
Response The SDT thanks you for your comment. Based on the comments received, the SDT understands there may be confusion caused by “BES” and has revised the purpose statement to delete BES and return to electric transmission system based on a overwhelming industry preference for the latter.		
Northeast Utilities	Agree	Agree with the term "bulk electric system. "Disagree with the wording of the Purpose Statement; The Purpose statement reads "To improve the reliability of the bulk electric system by preventing vegetation related outages that could lead to Cascading." One vegetation-caused outage does not in and of itself cause Cascading. Cascading will only result due to a combination of events - either multiple vegetation outages during the same time or an outage coupled with equipment malfunction or operational errors. The document seems to be internally inconsistent in this regard. The Technical Reference for FAC-003-2 notes that outages due to trees falling from outside the right-of-way or other outage causes on a critical facility would not constitute a possible cascading effect. If one occurrence of these types of outages would not constitute a cascading potential then one must wonder why an outage from a tree contact within the right-of-way is considered a possible cascading event? Suggest rewording the statement to exclude the comment about Cascading and use "by preventing vegetation related outages on critical transmission facilities."
Response: The SDT thanks you for your comment. The SDT acknowledges that a single vegetation-related outage will not, in the absence of other contributing factors cause a cascading collapse of the electric grid. The intent of the standard is to prevent those vegetation-related outages that could contribute to a cascading event. Therefore based on your comment, and others’, the SDT added “those” to further refine the intent.		
Southern California Edison Company	Agree	Q1: SCE agrees in part with the proposed revisions to the purpose statement. However, we believe the phrase "vegetation related outages" is unnecessarily vague. Based on the content of certain requirements in Version 2, the intent of this standard is and should be to prevent sustained outages due to vegetation-to-line contacts. SCE respectfully suggests the purpose statement (A3) be revised to read: "To improve the reliability of the Bulk Electric System by preventing vegetation-to-line contacts that could lead to Cascading?
Response: The SDT thanks you for your comment. The SDT focuses this standard on preventing vegetation-related Sustained Outages rather than vegetation to line contacts as you recommend because not all contacts result in Sustained Outages.		
BCTC	Agree	Yes, we agree.
Western Utility Arborists	Agree	Yes, we agree.

Hydro-Quebec Transenergie (HQT)	Agree	
Buckeye Power, Inc.	Agree	
Response: The SDT thank you for your participation. The SDT made revisions to the purpose statement in response to industry comment. In order to avoid confusion the SDT replace “BES” with “electric transmission system” and inserted the word “those” in front of the phrase “vegetation-related outages”.		

2. The Reliability Coordinator was chosen as the proper entity to identify sub-200kV transmission lines to be subject to this standard (see applicability, R9, and R10). Do you agree with this choice? If not, please explain.

Summary Consideration: A majority of the commenters agreed with the selection of Reliability Coordinator to designate sub-200 kV transmission lines to which this standard applies. However several dissenters recommended the Planning Coordinator (PC) as a more appropriate choice. The stakeholders' main reason for preferring the PC is the longer time horizon that the PC normally considers in the performance of its function. Typically an RC considers the real time to months ahead operating time horizons. A PC typically takes into account a planning horizon extending out several years. An example cited by some stakeholders is the assignment to the PC for identifying applicable lines in NERC Standard PRC-023 R3 – Transmission Relay Loadability.

Upon consideration of the sound rationale for replacement of RC with PC, the SDT changed Requirement R10 and R11 as well as the applicability section 4.2 to reflect this.

Some commenters suggested that facilities critical to the derivation of an IROL should be the only criterion for selection of lines subject to this standard. The Independent System Operator - Regional Transmission Owner Council (ISO/RTO Council) and individual ISOs offered that all transmission lines of the BES are applicable under this standard regardless of voltage class or impact on the BES. However the ISO/RTO Council believes that there are other standards that determine critical facilities. The SDT agreed that including facilities critical to the derivation of an IROL would be a technically acceptable threshold to determine applicability of sub-200 kV lines, but concluded that there are other thresholds that define circuits important to the reliability of the Bulk Electric System (e.g., the WECC region's Major Transfer Paths). The SDT wishes to allow the application of other criteria in addition to IROL to support to the greatest extent possible the reliability of the BES.

Several commenters recommended the inclusion of a dispute resolution process and coordination between Transmission Owner/RC in this standard to ensure agreement and consistency across regions. The SDT believes that the language in Requirement R10 which specifies "consultation" **OR CONSENSUS** between the Planning Coordinator and its member Transmission Owners, would minimize the need for a dispute resolution process. Additionally, other Standards in which the PC determines important circuits to the reliability of the BES include no such mechanism.

Requirements R9 and R10 (now R10 and R11) were changed as follows:

R9. Each Planning Coordinator shall prepare and review annually, a list lines that are operated below 200kV, if any, which are subject to this standard. . Each Planning Coordinator shall consult with its Transmission Owner(s) and neighboring Planning Coordinators to obtain input to develop the list.

Formatted: Indent: Left: 0", Pattern: Clear (Custom Color(RGB(211,220,233)))

Deleted: Reliability

Deleted: in consultation with its Transmission Owner(s) and neighboring Reliability Coordinator(s) shall jointly prepare and keep current

Deleted: of designated applicable

Formatted: Indent: Left: 0", Pattern: Clear (Custom Color(RGB(211,220,233)))

R10. Each Planning Coordinator shall develop and document its method for assessing the reliability significance of sub-200kV lines whose loss would place the grid at an unacceptable risk of instability, separation, or cascading failures.

Deleted: Reliability

Deleted: considering all of the following:¶
R10.1 Transmission lines whose loss would result in the exceedance of an Interconnection Reliability Operating Limit (IROL)¶
R10.2 Transmission lines

Organization	Agree?	Question 2 Comment
SERC Vegetation Management Subcommittee (VMS)		The SERC Vegetation Management Subcommittee (VMS) abstains on this question. However, we believe that this comment form should provide an option to abstain in addition to the options to agree/disagree.
Response: Thank you for your comment. The SDT does not believe this issue can be addressed by this team. However it is appropriate to raise this limitation with the NERC staff.		
American Transmission Company	Disagree	Requirements 9 and 10 should be deleted and replaced with the following language. Proposed Language The Transmission Owner shall include those transmission lines below 200 kV that that are associated with an established IROL. (This language could either be uses as a requirement or inserted into the Applicability section.) Our statement provides a clear decision on which lower voltage lines have to be included in an entities transmission vegetation management program.
Response: Thank you for your comments. The SDT replaced RC with PC in Requirements R9 and R10 (now R10 and R11)as well as the applicability section 4.2. The SDT believes that further guidance is needed to ensure all regions have evaluated and developed a list of sub 200kV lines that are subject to this standard. The FERC indicated that not all regions produced such lists and directed the ERO, using this stakeholder process, to develop a mechanism to provide the list. The proposed R10 continues to require consultation between the PC and Transmission Owner as well as neighboring PCs. In R10, the SDT believes that the PC has the requisite expertise and planning horizon perspective to designate sub 200kV lines to comply with this standard. Limiting the choice of lines to solely IROL lines may not achieve the purpose of this standard. The SDT intends in R10 that the PC employ a technically sound criterion when designating transmission lines to be subject to this standard which includes IROL calculations.		
Associated Electric Cooperative Inc.	Disagree	Associated Electric Cooperative Inc does not believe the Reliability Coordinator (RC) is the appropriate entity to determine whether or not selected sub-200 kv transmission lines should be subject to this standard. The planning horizon for the RC is typically much shorter than the time needed to incorporate a sub-200 kv transmission line into a vegetation management program. Associated recommends Planning Coordinator be designated as the applicable functional entity and be substituted wherever Reliability Coordinator appears in the Standard.
Response: Thank you for your comment. The SDT agrees and has replaced RC with PC in Requirements R9 and R10 (now R10 and R11) as well as the applicability section 4.2.		
Santee Cooper	Disagree	The RC should not define applicable lines that are operated below 200 kV. PRC023 requires the Planning Coordinator to define transmission lines operated at 100 kV to 200 kV that are considered critical to the reliability of

Organization	Agree?	Question 2 Comment
		the Bulk Electric System. Multiple lists will lead to confusion among electric utilities.
Response: Thank you for your comments. Several commenters offered sound rationale for replacement of RC with PC including a reference to NERC Standard PRC-023 Relay Loadability. The SDT agreed with the rationale and changed Requirements R9 and R10 (now R10 and R11) as well as the applicability section 4.2 to reflect this.		
Southern Company	Disagree	The use of the Reliability Coordinator as the entity for identifying sub-200 kV lines is inconsistent with the approach used in other NERC standards, such as PRC-023. Other NERC standards utilize the Planning Coordinator or the RRO as the entity. We feel the Planning Coordinator would be the appropriate entity for identifying sub-200 kV lines covered by FAC-003-2.
Response: Thank you for your comments. Several commenters offered sound rationale for replacement of RC with PC including a reference to NERC Standard PRC-023 Relay Loadability. The SDT agreed with the rationale and changed Requirements R9 and R10 (now R10 and R11) as well as the applicability section 4.2 to reflect this.		
SERC OC Standards Review Group	Disagree	The SERC OCSRG does not believe that the RC is the appropriate entity to identify sub-200 kV transmissions to be subject to this standard. Vegetation Management programs are longer than the normal operating horizons of RCs. We believe that the proper function to identify sub-200 kV transmission lines subject to this standard is the Planning Coordinator. This must be consistent with PRC-023, Requirement 3. We also recommend that a process be established for dispute resolution. NERC should develop a comprehensive approach to the determination of "critical" facilities rather than pushing a piecemeal approach as evidenced by this standard and PRC-023, among others.
Response: Thank you for your comments. Several commenters offered sound rationale for replacement of RC with PC including a reference to NERC Standard PRC-023 Relay Loadability. The SDT agreed with the rationale and changed Requirements R9 and R10 (now R10 and R11) as well as the applicability section 4.2 to reflect this. In regard to dispute resolution process, the SDT believes that the requirement for consultation implies cooperation and collaboration between entities and a dispute resolution process is not currently needed. **In regard to a comprehensive approach to identify/determine "critical" facilities, the SDT agrees in concept but has some reservations. The reservations are based upon doubt that "one size can fit all" for every context of every standard. A critical facility for one situation may not be a critical facility for another. For example, the PRC standard seeks to identify facilities that may need to carry very heavy contingent flows to stop a cascade. This FAC-003 standard seeks to identify facilities for which their OUTAGE (due to vegetation) would create reliability concerns for the BES.**		
IRC Standards Review Committee	Disagree	We do not see the role of an RC or PC in a vegetation management standard. All Transmission Owners need to ensure they have a vegetation program to avoid unnecessary tripping of transmission lines, at any voltage levels and regardless of their impacts on the BES. Identification of critical facilities is not a part of this standard; it belongs to other standards that deal with SOL/IROL calculations, SPS, protection and critical infrastructure protection. R10 and

Organization	Agree?	Question 2 Comment
		R11 should be removed from the standard.
Response: Thank you for your comments. The SDT does not agree with removal of R10 and R11. The SDT does not believe the burden of compliance for low voltage circuits with little or no impact on the BES is reasonable for electricity consumers to bear. FERC has acknowledged the same and given guidance for this standard's applicability which provides that a distinction exists in sub-200 kV facilities. The SDT sought to develop a reasonable mechanism that balances these concerns when we drafted R9 and R10 (now R10 and R11). The SDT agrees with respect to use of the label "critical". This standard does not intend to classify facilities as critical, that is left to CIP-002.		
Independent Electricity System Operator	Disagree	The IESO does not see a role for an RC or PC in a vegetation management standard. All Transmission Owners need to ensure they have a vegetation program to avoid unnecessary tripping of transmission lines, particularly those that impact the BES. We are of the view that identification of critical facilities is not a part of this standard; it belongs to other standards that deal with SOL/IROL calculations, SPS, protection and critical infrastructure protection. R10 and R11 should therefore be removed from the standard.
Response: Thank you for your comments. The SDT does not agree with removal of R10 and R11. The SDT does not believe the burden of compliance for low voltage circuits with little or no impact on the BES is reasonable for electricity consumers to bear. FERC has acknowledged the same and given guidance for this standards' applicability which provides that a distinction exists in sub-200 kV facilities. The SDT sought to develop a reasonable mechanism that balances these concerns when we drafted R9 and R10 (now R10 and R11). The SDT agrees with respect to use of the label "critical". This standard does not intend to classify facilities as critical, that is left to CIP-002.		
Hydro-Quebec Transenergie (HQT)	Disagree	HQT believe that the Planning Coordinator (PC) should be the entity responsible to determine the elements part of the BPS submitted to this Standard, and in fact for all other Standards. Those elements should be determined by an impact based methodology, as used in NPCC, with no voltage limitation and no fixed voltage threshold level as imposed in Applicability 4.2.
Response: Thank you for your comments. Several commenters offered sound rationale for replacement of RC with PC. The SDT agreed with the rationale and changed Requirement R9 and R10 (now R10 and R11) as well as the applicability section 4.2 to reflect this. The SDT believes each PC can determine the appropriate threshold to assure the reliability of the BES and does not believe it necessary to instruct PCs in this regard in this Standard.		
MRO NERC Standards Review Subcommittee	Disagree	The MRO disagrees that the RC is appropriately positioned to identify and designate any sub-200kV lines that should be subject to this standard. The MRO believes that the lines below 200kV should include only those that are currently classified as Interconnection Reliability Operating Limit (IROL) lines which are already defined and listed for registered entities. As such R10 and R11 should be eliminated from these standards along with the RC in the applicability section.
Response: Thank you for your comments. The SDT agrees that the RC is not appropriately positioned and replaced the RC with the PC. The SDT believes		

Organization	Agree?	Question 2 Comment
that further guidance is needed to ensure all regions have evaluated and developed a list of sub 200kV lines that are subject to this standard. FERC indicated that not all regions produced such lists and directed the ERO, using this stakeholder process, to develop a mechanism to provide the list. The proposed R10 continues to require consultation between the PC and Transmission Owner as well as neighboring PCs. In R10, the SDT believes that the PC has the requisite expertise and planning horizon perspective to designate sub 200kV lines to comply with this standard. Limiting the choice of lines to solely those included in the derivation of an IROL may not achieve the purpose of this standard. The SDT intends in R10 that the PC employ a technically sound criterion when designating transmission lines to be subject to this standard, which could include those included in the derivation of IROL calculations.		
Midwest ISO Stakeholders Standards Collaborators	Disagree	We do not believe that the RC is the appropriate entity to identify those facilities sub-200 kV facilities that this standard should apply to. Vegetation management is not performed in the operating horizon. Rather it is performed in the planning and operations planning horizons. The RC should not be distracted from focusing on the operating horizon by this task. We believe what the standard is essentially requiring is identifying critical facilities. There are other similar requirements such as PRC-023-1 R3 that appear to require the determination of critical facilities even though the term critical facilities is not defined. We believe this represents broader issue that requires NERC to define critical facilities. Failure to do so could result in the inefficient identification of multiple lists of critical facilities for specific requirements that may ultimately be challenged in due process.
Response: Thank you for your comments. Several commenters offered sound rationale for replacement of RC with PC including a reference to NERC Standard PRC-023 Relay Loadability. The SDT agreed with the rationale and changed Requirements R9 and R10 (now R10 and R11) as well as the applicability section 4.2 to reflect this. Your comment on time horizon further supports this change. **In regard to a comprehensive approach to identify/determine circuits, the SDT agrees in concept but has some reservations. The reservations are based upon doubt that "one size can fit all" for every context of every standard. A critical facility for one situation may not be a critical facility for another. For example, the PRC standard seeks to identify facilities that may need to carry very heavy contingent flows to stop a cascade. This FAC-003 standard seeks to identify facilities for which their OUTAGE (due to vegetation) would create reliability concerns for the BES.**		
Ameren	Disagree	While the RC would seemingly have the wide area view to make the assignment appropriate, the standard is really trying to determine the entity who can assess the risk to the BES of a vegetation-related outage. The management of that risk is in the venue of the Transmission Planner who, in the long term, designs the system and, in the Operating Horizon, establishes the parameters of operation that will lead to reliability. Certainly, the RC is preferable to the RE (RRO). However, the TP is preferable to the RC.
Response: Thank you for your comments. Several commenters offered sound rationale for replacement of RC with PC including a reference to NERC Standard PRC-023 Relay Loadability. The SDT agreed with the rationale and changed Requirements R9 and R10 (now R10 and R11) as well as the applicability section 4.2 to reflect this. The PC performs its function over a similarly long term time horizon as the Transmission Planner but would be better positioned as a result of the PC's wider area view.		

Organization	Agree?	Question 2 Comment
Manitoba Hydro	Disagree	Manitoba Hydro disagrees that the RC is appropriately positioned to identify and designate any sub-200kV lines that should be subject to this standard. Lines below 200kV should include only those that are currently classified as Interconnection Reliability Operating Limit (IROL) lines which are already defined and listed for registered entities. As such R10 and R11 should be eliminated from this standards along with the RC in the applicability section.
Response: Thank you for your comments. The SDT agrees that the RC is not appropriately positioned and replaced the RC with the PC in the revised draft proposed Standard. **The SDT agrees that lines included in the derivation of an IROL should be included in the PC's list; there are other lines that have importance to the reliability of the BES, e.g. the WECC Major Transfer Paths. The PC is well qualified for this differentiation task and may choose to develop thresholds which match the needs of its region. Therefore, the SDT respectfully disagrees that the only sub-200 kV circuits for which this standard should apply are those stated by MH.**		
WECC	Disagree	WECC believes the Regional Entity should remain the proper entity to identify sub-200kV transmission lines subject to this standard. The Regional Entity is in the best position to work with Transmission Owners (Transmission Owners) and Reliability Coordinators across the interconnection to determine critical sub-200kV transmission lines.
Response: Thank you for your comments. Several commenters offered sound rationale for replacement of RC with PC. The SDT agreed with the rationale and changed Requirements R9 and R10 (now R10 and R11) as well as the applicability section 4.2 to reflect this.		
PJM Interconnection	Disagree	The RC or PC should not play a role in the vegetation management standard. All Transmission Owners need to ensure they have a vegetation program to avoid unnecessary tripping of transmission lines, at any voltage levels and regardless of their impacts on the BES. Identification of critical facilities is not a part of this standard; it belongs to other standards that deal with SOL/IROL calculations, SPS, protection and critical infrastructure protection. R10 and R11 should be removed from the standard.
Response: Thank you for your comments. The SDT does not agree with removal of R10 and R11. The SDT does not believe the burden of compliance for low voltage circuits with little or no impact on the BES is reasonable for electricity consumers to bear. FERC has acknowledged the same and given guidance for this standards' applicability which provides that a distinction exists in sub-200 kV facilities. The SDT sought to develop a reasonable mechanism that balances these concerns when we drafted R10 and R11. The SDT agrees with respect to use of the label "critical". This standard does not intend to classify facilities as critical, that is left to CIP-002		
National Grid	Disagree	No opinion.
Response: Thank you for your participation.		

Organization	Agree?	Question 2 Comment
Duke Energy Corporation	Disagree	Duke believes that the Planning Coordinator is the appropriate entity to identify any sub-200 kV facilities that this standard should apply to. Of note is the time frame once a sub-200kV line is designated, then the Transmission Owner has 12 months before the line is subject to the standard. This coincides with the longer term view of the Planning Coordinator.
Response: Thank you for your comment. Several commenters offered sound rationale for replacement of RC with PC. The SDT agreed with the rationale and changed Requirements R9 and R10 (now R10 and R11) as well as the applicability section 4.2 to reflect this.		
Great River Energy	Disagree	GRE disagrees that the RC is appropriately positioned to identify and designate any sub-200kV lines that should be subject to this standard. GRE believes that the lines below 200kV should include only those that are currently classified as Interconnection Reliability Operating Limit (IROL) lines which are already defined and listed for registered entities. As such R10 and R11 should be eliminated from this standards along with the RC in the applicability section.
Response: Thank you for your comments. The SDT agrees that the RC is not appropriately positioned and replaced the RC with the PC in the draft proposed Standard. **The SDT agrees that lines included in the derivation of an IROL should be included in the PC's list, there are other lines that have importance to the reliability of the BES, e.g. the WECC Major Transfer Paths. The PC is well qualified for this differentiation task and may choose to develop thresholds which match the needs of its region. Therefore, the SDT respectfully disagrees that the only sub-200 kV circuits for which this standard should apply are those stated by GRE.**		
WECC Reliability Coordination	Agree	This would be a new function in WECC RC; we are not currently staffed to perform this function.
Response: Thank you for your comment. The SDT replaced RC with PC in Requirements R9 and R10 (now R10 and R11) as well as the applicability section 4.2.		
Western Area Power Administration, Upper Great Plains Region	Agree	Western's (UGPR) agreement is contingent upon maintaining the requirements for consulting with Transmission Owners and neighboring Reliability Coordinator(s) and documenting the method for assessing the reliability significance of each included line as contained in R10 and R11.
Response: Thank you for your comment. The SDT replaced RC with PC in Requirements R9 and R10 (now R10 and R11) as well as the applicability section 4.2. The proposed R10 continues to require consultation between the PC and Transmission Owner as well as neighboring PCs.		
Progress Energy Florida	Agree	While Progress Energy agrees that the RC is the appropriate entity, the drafting team should consider including a dispute resolution requirement for those instances when the Transmission Owner and the Reliability Coordinator disagree as to which lines below 200 kV should be included.

Organization	Agree?	Question 2 Comment
Response: Thank you for your comment. Several commenters offered sound rationale for replacement of RC with PC. The SDT agreed with the rationale and changed Requirements R9 and R10 (now R10 and R11) as well as the applicability section 4.2 to reflect this. In regard to dispute resolution process, the SDT believes that the requirement for consultation implies cooperation and collaboration between entities and a dispute resolution process is not currently needed.		
Kansas City Power & Light	Agree	I agree with the qualification that the Reliability Coordinator identify sub-200kv facilities in consultation with its Transmission Owner(s) and neighboring Reliability Coordinator(s).
Response: Thank you for your comment. The SDT replaced RC with PC in Requirements R9 and R10 (now R10 and R11) as well as the applicability section 4.2. The proposed R10 continues to require consultation between the PC and Transmission Owner as well as neighboring PCs.		
Progress Energy Carolinas	Agree	While Progress Energy agrees that the RC is the appropriate entity, the drafting team should consider including a dispute resolution requirement for those instances when the Transmission Owner and the Reliability Coordinator disagree as to which lines below 200 kV should be included.
Response: Thank you for your comment. Several commenters offered sound rationale for replacement of RC with PC. The SDT agreed with the rationale and changed Requirements R9 and R10 (now R10 and R11) as well as the applicability section 4.2 to reflect this. In regard to dispute resolution process, the SDT believes that the requirement for consultation implies cooperation and collaboration between entities and a dispute resolution process is not currently needed.		
Southern California Edison Company	Agree	Q2: No comments.
Response: Thank you for your participation.		
Western Utility Arborists	Agree	Yes, we agree.
Response: Thank you for your comment. Please see the summary consideration – based on stakeholder comments, the SDT changed the applicability in Requirements R9 and R10 (now R10 and R11) from the Reliability Coordinator to the Planning Coordinator.		
ITC HOLDINGS	Agree	ITC agrees that the Reliability Coordinator is the appropriate entity to identify and designate any sub - 200kV lines deemed applicable to the standard with the concurrence of the Transmission Owner.
Response: Thank you for your comment. Based on other stakeholder comments, the SDT replaced RC with PC in Requirements R9 and R10 (now R10 and R11) as well as the applicability section 4.2. The proposed R10 continues to require consultation between the PC and Transmission Owner as well as		

Organization	Agree?	Question 2 Comment
neighboring PCs.		
Tennessee Valley Authority	Agree	TVA agrees with Comment question 2
Response: Thank you for your comment. Based on other stakeholder comments, the SDT replaced RC with PC in Requirements R9 and R10 (now R10 and R11) as well as the applicability section 4.2. The proposed R10 continues to require consultation between the PC and Transmission Owner as well as neighboring PCs.		
American Electric Power (AEP)	Agree	AEP concurs with the drafting team that the Reliability Coordinator is the appropriate entity for identifying sub-200kV lines (if any) that would be subject to the Standard.
Response: Thank you for your comment. Based on other stakeholder comments, the SDT replaced RC with PC in Requirements R9 and R10 (now R10 and R11) as well as the applicability section 4.2.		
Platte River Power Authority	Agree	The Reliability Coordinator is better able to identify lines under 200 kv that would exceed an Interconnection Reliability Operating Limit (IROL), cause instability, uncontrolled separation, or cascading outages resulting from a vegetation related outage than the Regional Entity.
Response: Thank you for your comment. Based on other stakeholder comments, the SDT replaced RC with PC in Requirements R9 and R10 (now R10 and R11) as well as the applicability section 4.2.		
Nebraska Public Power District	Agree	NPPD agrees that the Reliability Coordinator is the correct body for identification of any sub 200kV lines that would be subject to this standard.
Response: Thank you for your comment. Based on other stakeholder comments, the SDT replaced RC with PC in Requirements R9 and R10 (now R10 and R11) as well as the applicability section 4.2.		
Consolidated Edison Company of New York (CECONY)	Agree	CECONY agrees provided that R10 remains the same as is currently written. This states that the Reliability Coordinator, in consultation with the Transmission Owner, shall jointly prepare and keep current, a list of designated applicable lines.
Response: Thank you for your comment. Based on other stakeholder comments, the SDT replaced RC with PC in Requirements R9 and R10 (now R10 and R11) as well as the applicability section 4.2. The proposed R10 continues to require consultation between the PC and Transmission Owner as well as neighboring PCs.		

Organization	Agree?	Question 2 Comment
Northeast Utilities	Agree	One question: Will the Reliability Coordinators use consistent criteria for listing sub 200-kV facilities to be included under FAC-003-2? The purpose of FAC-003 is to ensure inter-regional reliability and to focus on the reliable operation of these lines. By leaving the decision up to the individual Reliability Coordinators - there is the potential for local differences in determining which sub-200-kV facilities may be critical. This could result in some transmission owners having to include certain facilities under the requirements of FAC-003-2 where in other regions of the country - similar facilities may not be included by the Reliability Coordinator. Although there have been criteria established to guide the Reliability Coordinators in the determination of sub-200-KV facilities for inclusion under FAC-003-2 - is this sufficient to ensure uniformity throughout the US? Perhaps some involvement at the Regional Entity level at least, is warranted.
Response: Thank you for your comments. The SDT agrees with the points you raise regarding inter-regional reliability. This is addressed in part by the requirement R10 where consultation with neighboring entities is specified. We feel that the requirement R10 ensures that inter-regional coordination is addressed. **In addition several commenters offered sound rationale for replacement of RC with PC. The SDT agreed with the rationale and changed Requirements R9 and R10 (now R10 and R11) as well as the applicability section 4.2 to reflect this.**		
Baltimore Gas & Electric Company	Agree	The documented method to assess the reliability significance of sub-200 kV lines referenced in R10 should be put out for comment by the Reliability Coordinator to the regulated entities and FERC/NERC before it is finalized.
Response: Thank you for your comment. Several commenters offered sound rationale for replacement of RC with PC. The SDT agreed with the rationale and changed Requirements R9 and R10 (now R10 and R11) as well as the applicability section 4.2 to reflect this.		
Entergy Services	Agree	The applicability of this standard should state that it is not applicable to insulated transmission lines, such as underground lines.
Response: Thank you for your comment. The SDT believes that the general term "transmission line" along with the associated tables and terminology sufficiently eliminates any misconception or misdirected thought that this standard applies to underground conductors or other conductors that are insulated in a manner that would prevent their flashover to trees.		
Pepco Holdings, Inc	Agree	FERC Order 693 essentially has the RC replacing the RRO.
Response: Thank you for your comment. Several commenters offered sound rationale for replacement of RC with PC. The SDT agreed with the rationale and changed Requirements R9 and R10 (now R10 and R11) as well as the applicability section 4.2 to reflect this.		
BCTC	Agree	Yes, we agree.

3. In R1 the proposed standard replaces "prepare, and keep current" with "have", replaces the list of terms, "objectives, practices, approved procedures, and work specifications," with "designed to control vegetation", defines the "active transmission line ROW", and specifies that the transmission vegetation management program applies to that area. Do you agree with R1? If not, please explain.

Summary Consideration:

Regarding the use of "have", some commenters requested that the original wording should remain. However, the SDT and some other commenters note that proving whether something is "current" is an opportunity for compliance ambiguity and unintended discrimination. Therefore, the SDT continues to use "have" in the second draft.

A few commenters raised the issue concerning Critical Clearance Zone in this question and that has been addressed with the substantive changes which have been made to the second draft standard.

While some commenters prefer the list of terms, the SDT chose the term "methods" as a more global, all encompassing term that allows transmission owners flexibility in developing their Transmission Vegetation Management Program. The SDT agrees the list of terms is helpful. However, when listed in a Requirement there is an expectation that all such terms must be included and evidence produced to show compliance. The list of terms can be included in the technical reference to assist Transmission Owners.

Finally, many commenters wanted more specificity in the reference material to describe the "Active Transmission Line Right-of-Way". The SDT has provided additional clarification in the technical reference document.

The revised R1 is shown below:

R1. Each Transmission Owner shall have a documented transmission vegetation management program that describes how it conducts work on its Active Transmission Line Rights of Way to prevent Sustained Outages due to vegetation, considering all possible locations the conductor may occupy under the effects of sag and sway throughout its operating range under rated conditions. The transmission vegetation management program shall:

1.1. Specify the methods that the Transmission Owner may use to control vegetation.

1.2. Specify a Vegetation Inspection frequency of at least once per calendar year that takes into account local[3] and environmental factors.

1.3. Require an annual plan. An annual work plan shall:

1.3.1 Identify the applicable lines to be maintained

1.3.2 Identify the work to be performed

1.3.3 Be flexible to adjust to changing conditions and to findings from Vegetation Inspections. Adjustments to the plan within the year are permissible.

1.3.4 Take into consideration permitting and scheduling requirements from landowners or regulatory authorities.

1.4. Require a process or procedure for response to an imminent threat of a vegetation related Sustained Outage. The process or procedure shall specify actions which shall include immediate communication of the threat to the responsible control center.

1.5. Specify an interim corrective action process for use when the Transmission Owner is constrained from performing vegetation maintenance as planned.

1.6 Specify the maintenance strategies used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that Table 1 clearances in Attachment 1 are never violated. The maintenance strategies shall consider the sag and sway of the conductor throughout its operating range under rated conditions.

Organization	Agree?	Question 3 Comment
Bonneville Power Administration	Disagree	R1: BPA understands that version 2 clearly states that the Critical Clearance Zone does not extend beyond the Active Transmission Right of Way. The Technical reference provides examples of active and inactive portions o corridors. BPA feels this list of examples is not exhaustive and therefore the technical reference language shou be changed to read, "Examples of active and inactive portions of corridors include, BUT MAY NOT BE LIMITED Transmission Owner:" Also, since it is clearly stated on page 2 of the Standard, that the Critical Clearance Zone shall not extend beyond the limits of the Active Transmission Line Right of Way, and that these limits are not specifically defined because they may vary by circumstance, the definition of Active Transmission Line Right of Way on Page 2 of the Standard should include a statement that the actual physical limits of each Active Right of Way will be determined by the Transmission Owner. R1.1: BPA recommends retaining the version 1 language of "objectives, practices, approved procedures, and work specifications" as it is more instructive in what is expected of a TMVP then the version 2 replacement language of "methodologies."
Response: Thank you for your comment. The issues concerning Critical Clearance Zone have been addressed by changes which have been made to		

Organization	Agree?	Question 3 Comment
the draft standard. The definition and use of the term "Critical Clearance Zone" have both been removed from the revised standard. **The SDT chose, for the revised standard, the term "methods" as a more global, all encompassing term that allows transmission owners flexibility in developing their Transmission Vegetation Management Program. ANSI A300 has been referenced as a best management practice by reference as a footnote to R1.1.**		
Associated Electric Cooperative Inc.	Disagree	Associated Electric Cooperative Inc agrees with the changes described in Question 3 except for the definition of Active Transmission Line Right of Way. Associated suggests the term be revised to "Active Right-of-Way" for consistency with the present Glossary term "Right-of-Way" and that the definition of Active Right-of-Way be revised to explicitly permit the Transmission Owner to solely determine the appropriate width. A suggested definition is "Active Right-of-Way: The portion of Right-of-Way utilized for active transmission facilities. The width of the Active Right-of-Way, as determined by the Transmission Owner, shall be consistent with the Transmission Owner's normal standards and practices and shall be consistent with good utility practice for other transmission lines of similar voltage and configuration. Inactive or unused portions of the Right-of-Way, intended for future transmission lines or other facilities, may be excluded from the Active Right-of-Way."
Response: Thank you for your comment. While there is logic in your proposal to simply modify Rights-of-Way with "Active", previous commenters wanted to include "Transmission" to clearly eliminate the case of rights-of-way that include lower voltage facilities.		
NPCC	Disagree	While we agree with the suggested changes, we believe that the Transmission Vegetation Management Program should be focused on removal of incompatible vegetation from the Active Right of Way. We recommend using the following phrase in R1: "designed to remove incompatible vegetation on its Active Transmission Lines' Rights 0f Way" instead of "designed to control vegetation on its Active Transmission Lines' Rights of Way ". Incompatible vegetation should be defined as any vegetation which has the potential to grow tall enough to jeopardize the integrity of an applicable transmission line by growing into the Critical Clearance Zone or falling into the Critical Clearance Zone. This would provide clear guidance to all stakeholders, support long term vegetation management philosophies, and complement methods such as IVM where incompatible vegetation is completely removed, and compatible vegetation is encouraged to proliferate, thereby helping to control incompatible vegetation in an environmentally positive manner. Removal of incompatible vegetation is superior to pruning, topping, and trimming in terms of short and long term reliability of the Bulk Electric System. This language would also serve to align NERC and FERC with Transmission Owners who attempt achieve the highest degree of reliability by exercising their full easement rights in cases where strong opposition from landowners and public officials is encountered. If such language is adopted it should apply to R1 and the Transmission Vegetation Management Program. It should be made clear in the technical reference document that removal, rather than pruning of incompatible vegetation is the philosophy that must be incorporated into the Transmission Vegetation Management Program. It

Organization	Agree?	Question 3 Comment
		must be clearly explained that Transmission Owners have the flexibility to perform removals gradually over several treatment cycles in sensitive areas as long as pruning is performed as an interim measure to ensure that Critical Clearance Zone encroachments and on-Right of Way fall overs do not occur. It must also be made clear that the presence of incompatible vegetation on the Right of Way will always occur and does not in itself constitute a violation of the Standard.
Response: Thank you for your comment. The SDT has addressed removal of incompatible vegetation as a best management practice by referencing ANSI A300 as a footnote to Requirement R1. It is noted that A300 is not a requirement of the standard, only a best management practice. We will address your other comments in the technical reference paper for industry guidance.		
Baltimore Gas & Electric Company	Disagree	I agree with the simplification of the language, but I am uncomfortable with the definition of Active Right-of-Way (R/W). The definition in FAC-003-2 and the examples used in the white paper continue to leave room for interpretation, particularly with respect to the example where only one circuit is installed on a double circuit tower. Moreover, there may be circumstances where the Active R/W is relatively narrow and the utility has an Inactive R/W or otherwise owns land adjacent to the Active R/W that can be maintained to protect the facilities from grow-ins. Consequently, consideration should be given to require utilities to protect lines from grow-ins into the Critical Clearance Zone regardless of whether or not the R/W is Active or Inactive as long as the utility has the legal ability to do the necessary work.
Response: Thank you for your comment. The Standard clearly addresses that all grow-ins are considered to be within the active right-of-way, regardless of whether or not the tree is rooted within the active right-of-way. The Standard requires that such vegetation be managed as described in the Transmission Owner's Transmission Vegetation Management Program. Additionally, the SDT has revised the drawings and guidance in the technical reference paper to eliminate the confusion you and others detected.		
Northern Indiana Public Service Company	Disagree	Use of the term "have" is a notable and unnecessary weakening versus the terms "prepare and keep current". One of the key lessons learned from past vegetation related outages and subsequent investigations and reports is that successful UVM programs must continually adapt to changing circumstances which means practices and procedures must be kept current. Why weaken this expectation in the standard? Also, I disagree with the elimination from the revised standard the present requirement R1 that all Transmission Vegetation Management Programs include certain essential components (objectives, practices, approved procedures & work specifications). Why make changes that imply Transmission Vegetation Management Program's without these key components are acceptable?
Response: Thank you for your comment. The SDT believes that the term "have" is appropriate. While sympathetic to your perception about the terms, in order to "have" a Transmission Vegetation Management Program it had to have been prepared. Latency of the plan, like all plans required by NERC standards, can easily be addressed in compliance without creating the task of proving "current" if it is included in the Requirement. The SDT chose, for the revised standard, the term "methods" as a more global, all encompassing term that allows transmission owners flexibility in developing their		

Organization	Agree?	Question 3 Comment
Transmission Vegetation Management Program. ANSI A300 has been referenced as a best management practice by reference as a footnote to R1.1.		
Xcel Energy	Disagree	We propose adding the following language to the end of the definition for "Active Transmission Line Right of Way": OR OTHER PURPOSES, REGARDLESS OF THE PREMISES DIMENSIONS IN ANY EASEMENT, LICENSE AGREEMENT OR OTHER LAND RIGHT DOCUMENT.
Response: Thank you for your comment. The SDT believes that the definition of “active transmission line right-of-way” is appropriate for meeting the objectives of the Standard. This topic will be covered in the technical reference document which will be issued with the next draft of the Standard.		
Hydro One Networks Inc.	Disagree	We agree in changing the text as proposed only if R1 is expanded as suggested below. The standard as written is primarily, if not exclusively focused on outage prevention through one means, to keep vegetation out of the Critical Clearance Zone. The burden to accomplish this is placed on the Transmission Owner/Operator as it should be. The first section highlights that a program is required, but does not provide a requirement above this simplistic view, and from our perspective the Measures do not introduce any further rigour. This simplistic approach, in our opinion, does not adequately address the reliability risks associated with the various methodologies of managing vegetation. The White Paper notes removal is superior to pruning in ensuring tree conflicts do not occur. The White Paper includes elements of vegetation management risks, but the revised standard for the most part excludes this issue. One could argue that the audits and fines will manage reliability risks, but we are not convinced that this will do so in a consistent and adequate manner. There are numerous clearance risk factors associated with managing vegetation on rights of way. Some of these are: accurate measurement of conductor sag, accurate measurement of vegetation, vegetation growth rate, conductor sway, tree movement. If one looks at Table 1, the Clearance Distances are to the nearest cm or 1/100 of a foot. This makes one wonder, how realistic are the expectations laid out in the standard? To manage the risks around the Critical Clearance Zone the Standard requires each Transmission Owner to work with these precise numbers and build in a margin of safety to manage the situation. Will each Transmission Owner use identical criteria to trigger work? This doubtful, so this leads one to believe that the standard has not been designed to produce consistent results, which in our opinion is the case. So one has varied field conditions that are difficult to nail down, precise clearance requirements to the nearest 1/100? and the likelihood of inconsistent margins of safety. We realize that the audit process will help to assess these situations, but it may not be enough to achieve a somewhat uniform risk profile across the transmission systems. Other standards that we are familiar with include a margin of safety such as added clearance above the absolute minimum recognizing that it may not be practical to work to such precise measures. Examples of standards that use this approach to ensure consistent and reliable results include OHSA and the Canadian Standards Association. We are not advocating that this standard follows an identical approach, but do want to highlight that the standard may fall short in the area of managing vegetation management risks which in turn have a direct impact on reliability. Considering the above, it is suggested that the aspect of managing vegetation reliability risks be added to the White Paper to allow Transmission Owners to develop somewhat consistent criteria. Further on the topic of managing risk. We believe that reliability risks are

Organization	Agree?	Question 3 Comment
		directly related to the amount of incompatible vegetation on a right of way that is approaching the Critical Clearance Zone. Incompatible vegetation would be vegetation that has the potential to grow into the Critical Clearance Zone at full growth. We suggest that risks could be reduced significantly by including direction in the standard concerning the management of incompatible vegetation. This would drive a greater degree of consistency among Transmission Owners and would reduce the amount of vegetation on rights of way that have the potential to cause flashover. In addition, this would reinforce the reliability risks associated with vegetation, not just from a clearance perspective but also from a volume perspective, and would provide a more comprehensive view for the public and interest groups. In order to respond to what we consider a shortcoming of the proposed standard, our suggestion would be to expand R1.1 similar to the following: Specify the methodologies that the Transmission Owner uses to control vegetation and demonstrate that the removal of non-compatible vegetation is a focus within the plan. It is recognized that reliability risks increase appreciably with an increase in incompatible vegetation on an active right of way, and the Transmission Owner is required to remove incompatible vegetation at a point no later in time when it poses a threat to the reliability of the transmission line. Exceptions include vegetation used for designated visual screens, trees of a historic significance, vegetation to control erosion, agreements made at the time of environmental approval for construction,???etc.
Response: Thank you for your comments. The SDT revised the standard so that it no longer references the “Critical Clearance Zone.” The SDT chose, in the revised standard, to use the term “methods” as a more global, all encompassing term that allows transmission owners flexibility in developing their Transmission Vegetation Management Program. ANSI A300 has been referenced as a best management practice by reference as a footnote to R1.1. Moreover, we believe the Standard as subsequently revised provides flexibility for Transmission Owners to develop their own vegetation management programs. But we are sensitive to the issues you raised and have tried to define through the subsections in R1 that specific elements are necessary.		
CenterPoint Energy	Disagree	The term "Active Transmission Line Right-of-way" is not defined in sufficient detail in the Definition of Terms Used in the Standard section to know how to apply the Requirements. The term causes a circular reference problem with the term "Critical Clearance Zone" that refers to the "limits of the Active Transmission Line Right-of-way" which has no specific definition as to its limits within the proposed revised Standard. There is an attempt to differentiate between the "Total R.O.W." and the "Active R.O.W." portion by using the phrase "occupied by active transmission facilities", but no specific limits of such occupation are included within the definition. Are "active transmission facilities" only the physical energized conductors as-is, where-is? Does "occupied" include the conductor vertical and horizontal movement envelope and any horizontal and vertical electrical clearance as well? Does the term "Active Transmission Line Right-of-way" refer to the legal limits of the right-of-way? The new R9 includes the phrase "within the extent of its easement and/or legal rights" which seems to support that definition. The phrase "a strip of land" seems to refer to a metes and bounds description, but how is that relevant when no specific land space is defined, such as with a railroad occupation or Corp of Engineer's permit? On page 16 of the Technical Reference, there is a reference to the Bramble and Byrnes wire-border zone technique. The wire zone

Organization	Agree?	Question 3 Comment
		is defined in the Technical Reference as "the section of a utility transmission right-of-way directly under the wires and extending outward about 10 feet on each side". Are the limits of the "Active Transmission Line Right-of-way" intended to be equivalent to the Bramble and Byrnes wire zone, or is the Transmission Owner to use its discretion to define the limits? The examples in the Technical Reference document do not define the limits of the "active transmission facilities" either. The "Active R.O.W." limit in Figure 1 and Figure 3 is arbitrary. Figure 2 is supposed to display an edge zone for vegetation to exist, which implies an "Inactive R.O.W" portion, but no such zone is defined. Figure 1 also has trees shown inside the "Total R.O.W." and within the "Inactive R.O.W." that are tall enough and close enough to be within falling distance of the active transmission line which seems averse to R7 for vegetation falling into a conductor when the Transmission Owner likely has legal rights to remove them if they are within the "Total R.O.W." and are within falling distance. The interpretation of M7 will be difficult in this case without a specific method to define the "Active R.O.W." portion of the Total R.O.W. We recommend deleting the confusing terms "Active Transmission Line Right-of-way and "Critical Clearance Zone" and returning to the prior Clearance 2 Requirement with the newly specified minimum clearances from Table I of Attachment 1 as an alternative approach should the definition of minimum vegetation clearance distances remain integral to the Standard.
Response: Thank you for your comments. The Critical Clearance Zone concept has been removed from the latest draft of the Standard. While the SDT believes that the definition of "active transmission line right-of-way" in the Standard is appropriate, this concept will be further reviewed by the SDT in the context of the technical reference and your comments. And we agree that a further explanation is required to eliminate questions like the ones you raised. The new examples in the technical reference should eliminate that ambiguity.		
JEA	Disagree	The standard should EITHER require an entity to have and follow a program OR hold an entity to performance standards, but not both. Requiring a procedure in conjunction with performance requirements incents the entity to write procedures that meet only the minimum requirements of the standard, as they will be audited and held accountable for what is documented and performance against that. If performance requirements are in place without the concurrent requirement for a procedure, then the entity is incented to develop procedures that meet best practices in order to assure that they will meet or beat the performance standards, because in this scenario, such procedures do not expose the entity to additional compliance risk while enhancing reliability.
Response: Thank you for your comment. The Standard provides the framework for Transmission Owners to develop and implement an effective transmission vegetation management program in support of the main reliability objective: preventing sustained outages of transmission lines that could lead to cascading. During the drafting process, many members of the drafting team asserted that several of the requirements are merely facilitative in nature and would be unnecessary if sustained outages are successfully prevented. Because this standard is relatively new compared to standards that were developed from operating policies that had been followed for decades, there is a sense that the benefits of "defense in depth" (keeping the facilitating requirements) may be warranted until entities have more experience with mandatory vegetation management.		

Organization	Agree?	Question 3 Comment
Salt River Project	Disagree	R1.1 states "Specify the methodologies that the Transmission Owner uses to control vegetation". The word "methodologies" does not adequately replace "objectives, practices, approved procedures, and work specifications". Recommend to keep the original wording.
Response: Thank you for your comments. The SDT chose "methods" in R1 part 1.1 to provide flexibility for Transmission Owners to develop their own vegetation management programs. ANSI A300 has been referenced as a best management practice in a footnote to 1.1. The Technical Reference Document provides examples of the variations in methods that are necessary due to the wide diversity of vegetation across North America.		
Hydro-Quebec Transenergie (HQT)	Disagree	While we agree with the suggested changes for the terms proposed , we believe that the Transmission Vegetation Management Program should be focused on removal of incompatible vegetation from the Active Right of Way.R1.1 could read: Specify the methodologies that the Transmission Owner uses to control vegetation and demonstrate that the removal of non-compatible vegetation is a focus within the plan. Incompatible vegetation should be defined as any vegetation which has the potential to grow tall enough to jeopardize the integrity of an applicable transmission line by growing into the Critical Clearance Zone or falling into the Critical Clearance Zone . This would provide clear guidance to all stakeholders, support long term vegetation management philosophies, and complement methods such as IVM where incompatible vegetation is completely removed, and compatible vegetation is encouraged to proliferate, thereby helping to control incompatible vegetation in an environmentally positive manner.
Response: Thank you for your comments. The SDT has re-written this Requirement to address your concerns in a manner that allows transmission owners flexibility in developing their Transmission Vegetation Management Program. ANSI A300 has been referenced as a best management practice by reference as a footnote to R1.1. Moreover, we believe the Standard as subsequently revised provides flexibility for Transmission Owners to develop their own vegetation management programs.		
Western Area Power Administration, Upper Great Plains Region	Agree	A question that has surfaced during discussions within the industry is "Can the Transmission Owner designate an active R/W width that is less than the easement width even with a single-circuit line with no R/W set aside for vegetation buffer or future development?" OR, does the easement width equate to "Active T-Line ROW" under the situation described above.
Response: Thank you for your comment. The intent of the Standard is that such rights-of-way as identified in your response are considered as "active transmission rights-of-way" in general for their full width. The definition of "active transmission line right-of-way" was developed to recognize that in some cases additional ROW width was secured to allow for buffers and future expansion. This is further described in the technical reference document.		
Western Utility Arborists	Agree	Yes, we agree, subject to the qualification about "active" rights-of-way under Comment #16. Under R1.1, it says "Specify the methodologies that the Transmission Owner uses to control vegetation." The single word "methodologies" does not adequately replace "objectives, practices, approved procedures, and work

Organization	Agree?	Question 3 Comment
		specifications." The Western Utilities recommends keeping the original wording. We would also like to point out that the original intent of the standard was to ensure that utilities had a complete vegetation management program. The new standard is evolving towards an outage control program, and no longer encourages programs or behaviors that would ensure the causes of outages are prevented long before they become a problem. The standard now redirects efforts to avoiding outages instead of managing vegetation.
Response: Thank you for your comments. The SDT has re-written this Requirement to address your concerns in a manner that allows transmission owners flexibility in developing their Transmission Vegetation Management Program. ANSI A300 has been referenced as a best management practice by reference as a footnote to R1.1. Moreover, we believe the Standard as subsequently revised provides flexibility for Transmission Owners to develop their own vegetation management programs. The SDT believes that the latest draft includes Requirements that dictate appropriate behavior in controlling vegetation but also added a strong statement that outages, that could have been prevented, are inconsistent with interconnection reliability and should be violations.		
Southern California Edison Company	Agree	Q3: No Comments.
Response: Thank you for your response.		
FirstEnergy	Agree	The Inactive Right of Way, by definition, should include a strip of trees on each side of the of the right of way that was purchased, but not cleared at the time of construction. This could be a narrow strip ten feet on each side that is intended for future hazard tree removal.
Response: Thank you for your comment. The definition of "Active Transmission Line Right-of-Way" has been modified in the current draft of the Standard. The SDT believes that the definition of "Active Transmission Line Right-of-Way" as currently defined is appropriate. The definition was developed to recognize that in some cases additional ROW width was secured to allow for buffers and future expansion. This is further described in the technical reference document. However, the SDT does not agree that a categorical "set aside" which is not active but can be is appropriate for all Transmission Owners. Rather, some Transmission Owners may want to manage the entire rights-of-way. But flexibility is permitted within the current draft.		
MRO NERC Standards Review Subcommittee	Agree	The MRO agrees but requests further clarification on the definition of the term "Active" in Active Transmission Line R.O.W. For example: A utility has a 150 foot easement for a 230kV line and currently manages 80 feet. First; is it the intent of the standard that the utility manage the entire 150 foot easement? Second; is the entire easement considered the Active Transmission Line R.O.W?
Response: Thank you for your comment. The Transmission Owner is responsible for determining the Active ROW width based upon the definition of "active transmission line right-of-way" included in the Standard. The scenario presented in your comment does not provide enough information for the		

Organization	Agree?	Question 3 Comment
SDT to provide a definitive answer. The definition of "Active Transmission Line Right-of-Way" has been changed in the most current draft. In addition a technical reference document with a more detailed explanation of this topic will be issued with the next draft. These documents should provide clarity. The definition was developed to recognize that in some cases additional ROW width was secured to allow for buffers and future expansion. This is further described in the technical reference document. However, the SDT does not agree that a categorical "set aside" which is not active but can be is appropriate for all Transmission Owners. Rather, some Transmission Owners may want to manage the entire rights-of-way. But flexibility is permitted within the current draft.		
ITC HOLDINGS	Agree	The standard doesn't actually explain or define the Active Transmission Line Right of Way.
Response: Thank you for your comment. A definition of "Active Transmission Line ROW" is included in the Standard. This definition has been modified in the most current draft of the Standard. The technical reference will provide further clarity.		
Tennessee Valley Authority	Agree	TVA agrees with Comment Question 3
Response: Thank you for your comment.		
American Electric Power (AEP)	Agree	While Requirement R1 does not actually define "Active Transmission Line Right of Way" (it is defined on page 2 of the Standard), AEP concurs with R1, except as noted below for R1.4.
Response: Thank you for your comment.		
Platte River Power Authority	Agree	The list of terms, "objectives, practices, approved procedures and work specifications," from version 1 provides more clarity that the one word "methodology" and should both be replaced. The newly defined term "active transmission line ROW" provides clarity to the portion of the ROW requiring vegetation management and is a valuable addition to the standard.
Response: Thank you for your comment. The SDT revised R1.1 to allow transmission owners the necessary flexibility in developing their Transmission Vegetation Management Program. ANSI A300 has been referenced as a best management practice by reference as a footnote to R1.1.		
American Transmission Company	Agree	We agree with the idea but the term "active transmission facilities" needs additional clarity. This clarity could be accomplished with a footnote. Proposed Footnote: A transmission facility that contains a transmission line to which FAC-003 is applicable. The proposed footnote aids in the identification of applicable transmission facilities.
Response: Thank you for your comment. Applicable lines are defined in Section 4 of the Standard.		

Organization	Agree?	Question 3 Comment
USDA Forest Service, Southwestern Region, Regional Office for AZ and NM	Agree	My disagreement with R1
Response: Thank you for your comment; however the SDT does not understand your comment.		
National Grid	Agree	Defining "Active Transmission Line Right-of-Way" solves the Right-of-Way definition problem within the SAR.
Response: Thank you for your comment.		
NV Energy (fka Sierra Pacific / Nevada Power Co.)	Agree	Yes, we agree, subject to the qualification about “active” rights-of-way under Comment #16. We would also like to point out that the original intent of the standard was to ensure that utilities had a complete vegetation management program. The new standard is evolving towards an outage control program, and no longer encourages programs or behaviors that would ensure the causes of outages are prevented long before they become a problem. Instead, it redirects efforts to avoiding outages instead of managing vegetation. If this is now the preferred approach, the term Transmission Vegetation Management Program is no longer valid and should perhaps be changed to the Transmission Vegetation Outage Prevention Program. Under R1.1, it says “Specify the methodologies that the Transmission Owner uses to control vegetation.” The single word “methodologies” does not adequately replace “objectives, practices, approved procedures, and work specifications.” We recommend that the SDT retain the original wording.
Response: Thank you for your comments. The SDT revised R1.1 to allow transmission owners the necessary flexibility in developing their Transmission Vegetation Management Program. ANSI A300 has been referenced as a best management practice by reference as a footnote to R1.1. The SDT believes that the latest draft includes Requirements that dictate appropriate behavior in controlling vegetation but also added a strong statement that outages, that could have been prevented, are inconsistent with interconnection reliability and should be violations.		
San Diego Gas & Electric	Agree	Yes, we agree, subject to the qualification about "active" rights of way under comment 16. Under R1.1 it says "Specify the methodologies that the Transmission Owner uses to control vegetation." The single word "methodologies" does not adequately replace "objectives, practices, approved procedures, and work specifications." We recommend keeping the original wording.
Response: Thank you for your comment. The SDT revised R1.1 to allow transmission owners the necessary flexibility in developing their Transmission Vegetation Management Program. ANSI A300 has been referenced as a best management practice by reference as a footnote to R1.1.		
Northeast Utilities	Agree	With respect to "active transmission line ROW" the examples provided in the Technical Reference document for FAC-003-2 show that any areas of the easement or fee-owned right-of-way not cleared in accordance with

Organization	Agree?	Question 3 Comment
		company approved design standards will not be considered "active transmission line ROW". Any vegetation contacts resulting from trees that fail in these non-cleared sections ("corridor edge zones") would not constitute a violation of FAC-003-2.The definition of the "active transmission line right-of-way" states that this does not include areas of the easement or fee-owned property that is unused or inactive and intended for other facilities. Does this imply that areas not cleared and not intended for other facilities are part of the active right-of-way? If a company had constructed new lines and allowed for a buffer strip of the easement that was not cleared, but is also not intended for new facilities, and trees are allowed to remain in this strip - that an outage from contact with a tree falling into the lines from this buffer would constitute a violation of R7 as a tree falling from within the active right-of-way? Does this imply that trees in these buffer strips must be removed? This will constitute a very costly and problematic position that will result in extreme adverse public opposition to the required clearing. It is suggested that the clearing limits of any right-way comply with some established standards or codes. A utility should not be allowed to eliminate a large number of vegetation violations by simply decreasing the size or width of the active right-of-way. However, this may also need to be flexible when new lines are constructed when easement widths are limited due to local or state requirements.
Response: Thank you for your comments. The definition of "Active Transmission Line Right-of-Way" has been modified in the current draft of the Standard. The SDT believes that the definition of "Active Transmission Line Right-of-Way" as currently defined is appropriate. The definition was developed to recognize that in some cases additional ROW width was secured to allow for buffers and future expansion. This is further described in the technical reference document. The new section in the technical reference attempts to address these issues.		
Buckeye Power, Inc.	Agree	OK with R1. However, the active transmission line right of way seems to be a reduction in ROW width which would likely decrease reliability during the one moment when we need it most.
Response: Thank you for your comment. The "active transmission line right-of-way" definition has been developed to address rights-of-way obtained for future facilities. It is not intended to diminish the Transmission Owners' responsibility to manage vegetation on a right-of-way which was acquired solely for the purpose of the subject line and is necessary for the reliable operation of the line.		
Great River Energy	Agree	GRE agrees but requests further clarification on the definition of the term "Active" in Active Transmission Line R.O.W. For example: A utility has a 150 foot easement for a 230kV line and currently manages 80 feet. First; is it the intent of the standard that the utility manage the entire 150 foot easement? Second; is the entire easement considered the Active Transmission Line R.O.W?
Response: Thank you for your comment. The Transmission Owner is responsible for determining the Active ROW width based upon the definition of "active transmission line right-of-way" included in the Standard. The scenario presented in your comment does not provide enough information for the SDT to provide a definitive answer. The definition of "Active Transmission Line Right-of-Way" has been changed in the most current draft. In addition a technical reference document with a more detailed explanation of this topic will be issued with the next draft. These documents should provide clarity.		

Organization	Agree?	Question 3 Comment
BCTC	Agree	Yes, we agree, subject to the qualification about "active" rights-of-way under Comment #16. We would also like to point out that the original intent of the standard was to ensure that utilities had a complete vegetation management program. The new standard is evolving towards an outage control program, and no longer encourages programs or behaviours that would ensure the causes of outages are prevented long before they become a problem. Instead, it redirects efforts to avoiding outages instead of managing vegetation. If this is now the preferred approach, the term Transmission Vegetation Management Program is no longer valid and should perhaps be changed to the Transmission Vegetation Outage Prevention Program. Under R1.1, it says "Specify the methodologies that the Transmission Owner uses to control vegetation." The single word "methodologies" does not adequately replace "objectives, practices, approved procedures, and work specifications." BCTC recommends keeping the original wording.
Thank you for your comments. The SDT revised R1.1 to allow transmission owners the necessary flexibility in developing their Transmission Vegetation Management Program. ANSI A300 has been referenced as a best management practice by reference as a footnote to R1.1. The SDT believes that the latest draft includes Requirements that dictate appropriate behavior in controlling vegetation but also added a strong statement that outages, that could have been prevented, are inconsistent with interconnection reliability and should be violations.

4. Documentation and implementation of the transmission vegetation management program which were previously combined in Requirement R1 are now separated in order to apply appropriate VRFs and time horizons. The implementation of some elements has been moved into standalone requirements such as inspection cycles (R3) and annual plan implementation (R9). Do you agree with these revisions and separation? If not, please explain.

Summary Consideration: Most respondents were in favor of separating the documentation from the implementation. A minority of the respondents wanted to keep the two together. The SAR directed the team to bring the standard into conformance with the latest version of the Sanctions Guidelines. Retention of documentation to demonstrate compliance is now addressed, in most cases, solely in the "Data Retention" section of standards and does not need to be covered in requirements. If an entity does not retain data and there is no impact to reliability, then the retention of that data, if needed to demonstrate compliance, is covered under the Data Retention section.

Some respondents advocated modifying the order or sequence of the standard's requirements. The SDT has considered various sequence options and offers a re-sequencing proposal as Question #12 in the second Comment Form.

Organization	Agree?	Question 4 Comment
BCTC		Although it's important to have these two separate aspects – documentation and implementation – separating them spatially in the document itself makes the standard longer than necessary and creates redundancy. It seems obvious that if you prepare elements of the Transmission Vegetation Management Program, they also need to be implemented. The document would be easier to follow if the two elements were kept together.
Response: The SDT thanks you for your comments. The SDT determined that the requirements to document and implement are distinctly different activities and therefore separated them. Having separate requirements allows for assignment of VRF's and VSL's that more closely reflect their respective characteristics. The SDT has considered various sequence options and offers a re-sequencing proposal as Question #12 in the second Comment Form.		
Western Utility Arborists		Although it's important to have these two separate aspects "documentation and implementation "separating them spatially in the document itself makes the standard longer than necessary and creates redundancy. It seems obvious that if you prepare elements of the Transmission Vegetation Management Program, they also need to be implemented. The document would be easier to follow if the two elements were kept together.
Response: The SDT thanks you for your comments. The SDT determined that the requirements to document and implement are distinctly different activities and therefore separated them. The SDT have considered various sequence options and offer a re-sequencing proposal as Question #12 in the second		

Organization	Agree?	Question 4 Comment
Comment Form.		
Progress Energy Florida	Disagree	The sub-requirements should be moved up to requirement level if the team desires to have different VRFs and VSLs.
Response: The SDT thanks you for your comments. The Standards drafting team has dropped the sub requirement designations and the sub parts are simply listed as part of R1.		
Progress Energy Carolinas	Disagree	The sub-requirements should be moved up to requirement level if the team desires to have different VRFs and VSLs.
Response: The SDT thanks you for your comments. The Standards drafting team has dropped the sub requirement designations and the sub parts are simply listed as part of R1.		
Southern California Edison Company	Disagree	Q4: SCE does not agree with separating the documentation and implementation aspects of the Transmission Vegetation Management Program into separate requirements R3 and R9 (respectively). SCE believes that proposed R3 and corresponding M3 should be eliminated and replaced with a modified version of proposed R9. SCE respectfully suggests that proposed R9 be revised to read: "Each Transmission Owner shall implement and follow its Vegetation Management Program to the extent allowed by existing easement and/or legal rights."
Response: The SDT thanks you for your comments. The team believes that conducting inspections is independently important and therefore should be addressed in a separate requirement. The SDT debated the issue of whether to include "Each Transmission Owner shall implement and follow its Vegetation Management Program to the extent allowed by existing easement and/or legal rights". The final consensus of the SDT was to exclude the requirement because having the legal rights do not imply one is obligated to exercise those rights to their fullest extent. The SDT did not want to give that impression.		
NV Energy (fka Sierra Pacific / Nevada Power Co.)	Disagree	Although it’s important to have these two separate aspects “ documentation and implementation “ separating them spatially in the document itself makes the standard longer than necessary and creates redundancy. It seems obvious that if you prepare elements of the Transmission Vegetation Management Program, they also need to be implemented. The document would be easier to follow if the two elements were kept together.
Response: The SDT thanks you for your comments. The SDT determined that the requirements to document and implement are distinctly different activities and therefore separated them. Having separate requirements allows for assignment of VRF’s and VSL’s that more closely reflect their respective characteristics. The SDT have considered various sequence options and offer a re-sequencing proposal as Question #12 in the second Comment Form.		

Organization	Agree?	Question 4 Comment
San Diego Gas & Electric	Disagree	The document would be easier to follow if kept together. Separation of the recommendations and implementation will make this a redundant process, because both will say the same thing.
Response: The SDT thanks you for your comments. The SDT determined that the requirements to document and implement are distinctly different activities and therefore separated them. Having separate requirements allows for assignment of VRF's and VSL's that more closely reflect their respective characteristics. The SDT considered other sequence options and offer a re-sequencing proposal as Question #12 in the second Comment Form.		
JEA	Disagree	See comment from #3.
Response: The SDT thanks you for your comments. See response to Q #3.		
Salt River Project	Disagree	Although we agree that it is important to identify both aspects of the program for "prepare/documentation" and "implementation", we do not agree that this needs to be documented in separate requirements. It makes the standard longer than necessary and creates redundancy. The document would be easier to follow if the two elements were kept together in the same requirement. In addition, it is not defined what is "VRFs". We understand that this was detailed in a previous draft document as "Violation Risk Factor". This needs to be defined and clarified in order to provide comment back.
Response: The SDT thanks you for your comments. The SDT determined that the requirements to document and implement are separate and require different levels of VRF's and VSL's. The team refers you to the *Sanction Guidelines of North American Electric Reliability Corporation* to explain the use of VRF's and VSL's.		
CenterPoint Energy	Disagree	Additional revisions are needed to clarify the requirements. For instance, R1.3 refers to "the objectives" of the Transmission Vegetation Management Program, which are no longer a required element and are not specified in M1.3. Reference to "the objectives" should be deleted. The last sentence of R1.3 should read: "It shall use the methodologies outlined in the transmission vegetation management program."R1.4 requires a process for a response to an "imminent threat of a vegetation related Sustained Outage", but R2 refers to implementing an "imminent threat procedure" to "prevent an encroachment of the Critical Clearance Zone". The requirement and the implementation should both refer to an "imminent threat of a vegetation related Sustained Outage".
Response: The SDT thanks you for your comments. The team is posting a revised standard and R1 identifies the required elements of the Transmission Vegetation Management Program. The sub requirements have been changed to elements that roll up into R1 and an additional element has been added to cover methods used to control vegetation – the word, "objectives" is not used in the revised standard.		
MRO NERC Standards Review	Agree	The MRO believes that clarity was improved by separating documentation and implementation. The MRO

Organization	Agree?	Question 4 Comment
Subcommittee		suggests that moving the requirement for implementation so that it immediately follows the requirement for documentation will further enhance clarity.
Response: The SDT thanks you for your comments. The SDT has considered various sequence options and offers a re-sequencing proposal as Question #12 in the second Comment Form.		
Midwest ISO Stakeholders Standards Collaborators	Agree	This is a good change from a compliance perspective; the documentation requirements can now be assigned lower VRFs than the implementation requirements.
Response: The SDT thanks you for your comments.		
Tennessee Valley Authority	Agree	TVA agrees with Comment Question 4
Response: The SDT thanks you for your comments.		
Exelon	Agree	Refer to footnotes in R1.1 and 1.2. Are applicable entities to be held accountable to ANSI A300 (footnote 2) and for providing documentation to support analysis that "local factors" were accounted for (footnote 3)? These footnotes should be requirements or they should be removed and included in a Reference Document not subject to compliance audit.
Response: The SDT thanks you for your comments. Please note the phrase in the current version of footnote 2," while not a requirement of this standard." A300 is a recommended best practice and not a requirement. Footnotes may be used to provide explanatory information.		
American Electric Power (AEP)	Agree	AEP agrees with these changes from Version 1.
Response: The SDT thanks you for your comments.		
Platte River Power Authority	Agree	The separation allows lower sanctions and penalties to be assessed for weak documentation and higher sanctions and penalties to be assessed for weak inspection programs and weak vegetation management. However, the standard would be easier to follow if the two elements were kept together in the document.
Response: The SDT thanks you for your comments. The SDT determined that the requirements to document and implement are separate and require different levels of VRF's and VSL's. The SDT has considered various sequence options and offers a re-sequencing proposal as Question #12 in the second Comment Form.		
City of Tallahassee	Agree	See Question 6 and 17.

Organization	Agree?	Question 4 Comment
Response: The SDT thanks you for your comments. See the responses to Questions 6 and 17.		
Northern Indiana Public Service Company	Agree	I agree with the separation and re-ordering of documentation and implementation requirements into two distinct groups. This is a welcome improvement to the standard.
Response: The SDT thanks you for your comments. The SDT has considered various sequence options and offers a re-sequencing proposal as Question #12 in the second Comment Form.		
National Grid	Agree	These revisions and separation make it easier to match requirements and measures.
Response: The SDT thanks you for your comments.		
Ameren	Agree	This is a good change from a compliance perspective; the documentation requirements can now be assigned lower VRFs than the implementation requirements
Response: The SDT thanks you for your comments.		
Duke Energy Corporation	Agree	This is a good change from a compliance perspective; the documentation requirements can now be assigned lower VRFs than the implementation requirements.
Response: The SDT thanks you for your comments		
Great River Energy	Agree	GRE believes that clarity was improved by separating documentation and implementation. GRE suggests that moving the requirement for implementation so that it immediately follows the requirement for documentation will further enhance clarity
Response: The SDT thanks you for your comments. The SDT has considered various sequence options and offers a re-sequencing proposal as Question #12 in the second Comment Form.		
Associated Electric Cooperative Inc.	Agree

5. In R1.2 the Transmission Owner is required to have an inspection frequency of at least once per calendar year. Do you agree with R1.2? If not, please explain.

Summary Consideration: The majority of the respondents were in favor of the one year frequency. Most of the minority commenters wanted to leave the decision with the Transmission Owner. Since vegetation inspections can be included in overhead maintenance inspections, the SDT did not consider the annual inspection requirement to be burdensome. Several commenters asked for a definition of "inspection" and the SDT is proposing the following modification to an existing NERC Glossary definition of "Vegetation Inspection:"

Vegetation Inspection: The systematic examination of vegetation conditions on an Active Transmission Line Right of Way. This inspection may be combined with a general line inspection. The inspection includes the documentation of any vegetation that may pose a threat to reliability prior to the next planned inspection or maintenance work, considering the current location of the conductor and other possible locations of the conductor due to sag and sway for rated conditions.

Organization	Agree?	Question 5 Comment
BCTC		Clarification is required on exactly what an inspection is, which should perhaps be outlined in the white paper. At BCTC although all lines are currently inspected at least once every year the thoroughness of the inspection will vary with the local conditions. Some areas with limited vegetation management issues only require a patrol from the air and are often inspected as part of a routine line patrol, where the lineman looks for vegetation concerns in addition to undertaking maintenance work. Other areas require a detailed ground inspection. BCTC needs some assurance that this inspection will not constitute a dedicated, comprehensive vegetation management inspection of the entire operating system. . Therefore, BCTC needs the ability within the Transmission Vegetation Management Program to define what an inspection is in the context of our utility operations.
Response: The SDT thanks you for your comments. The consensus of the SDT is that inspection of any operating transmission line should be done annually to cover both engineering and vegetation situations. Vegetation inspections can be included in overhead maintenance inspections. The SDT revised the NERC glossary term Vegetation Inspection to allow it to be combined with other line inspections.		
Western Utility Arborists		Clarification is required on exactly what an inspection is, which should perhaps be outlined in the white paper. There are areas where inspections are not necessary at all, such as lines over a parking lot, or in a remote desert area. The Western Utilities need some assurance that this inspection will not constitute a dedicated, comprehensive vegetation management inspection. Inspections are currently often part of a routine line patrol, where the lineman looks for

Organization	Agree?	Question 5 Comment
		vegetation concerns in addition to undertaking maintenance work. Therefore, the Transmission Owner needs the ability within their Transmission Vegetation Management Program to define what an inspection is in the context of their utility operations.
Response: The SDT thanks you for your comments. The consensus of the SDT is that inspection of any operating transmission line should be done annually to cover both engineering and vegetation situations. Vegetation inspections can be included in overhead maintenance inspections. The SDT revised the NERC glossary term Vegetation Inspection to allow it to be combined with other line inspections.		
Associated Electric Cooperative Inc.	Disagree	While Associated Electric Cooperative Inc agrees with this requirement in general, there may be areas (e.g. highly arid terrain, open water, etc.) where an annual interval is unnecessary and adds little or nothing to reliability.
Response: The SDT thanks you for your comments. The consensus of the SDT is that inspection of any operating transmission line should be done annually to cover both engineering and vegetation situations. Vegetation inspections can be included in overhead maintenance inspections.		
NPCC	Disagree	There were differing opinions within the group. Those entities with extensive overhead transmission felt the once a year requirement was overly prescriptive and would not improve reliability, others were in agreement with the "at least once per calendar year" requirement.
Response: The SDT thanks you for your comments. The consensus of the SDT is that annual inspections add to the reliability of the system.		
Tennessee Valley Authority	Disagree	TVA suggests that R1.2 be changed by adding "except in cases where lines or significant sections of lines are over terrain which is void of vegetation(such as bodies of deep water)or over terrain void of any vegetation that can grow to a mature height that could threaten the conductors, then longer cycles will be acceptable". This would avoid unnecessary expenses in such cases.
Response: The SDT thanks you for your comments. The consensus of the SDT is that inspection of any operating transmission line should be done annually to cover both engineering and vegetation situations. Vegetation inspections can be included in overhead maintenance inspections.		
Western Area Power Administration, Rocky Mountain Region	Disagree	Some areas such as highly developed urban areas, deserts, or grassland prairie may not be conducive to tall vegetation growth and require frequent (annual) inspection.
Response: The SDT thanks you for your comments. The consensus of the SDT is that inspection of any operating transmission line should be done annually to cover both engineering and vegetation situations. Vegetation inspections can be included in overhead maintenance inspections.		

Organization	Agree?	Question 5 Comment
Southern California Edison Company	Disagree	Q5: SCE does not agree with imposing a one-size-fits-all inspection frequency of ?at least once per calendar year? upon all U.S. Transmission Owners. The associated technical paper presents no credible evidence or statistical corroboration to support the proposed inspection frequency. Until such time as a thorough industry study or similar evidence is presented that demonstrates the proposed inspection frequency is cost effective and will enhance system reliability, Transmission Owners should be allowed to establish their own inspection frequency rate. Regarding the enforcement of a non-standardized inspection frequency, should a Transmission Owner incur a vegetation-to-line contact that results in a Sustained Outage, upon review of the investigation results, the responsible Reliability Coordinator and/or NERC could then impose a more stringent inspection frequency requirement upon the infracting Transmission Owner. The imposition of more stringent inspection frequencies could be applied on a temporary or permanent basis, depending on the severity of the outage, but lacking a demonstrated need, good performing Transmission Owners should be allowed to establish their own inspection frequencies based upon their individual needs and operating conditions. SCE respectfully suggests R1.2 be revised to read: "Specify a vegetation inspection frequency that takes into account local and environmental factors."
Response: The SDT thanks you for your comments. The consensus of the SDT is that inspection of any operating transmission line should be done annually to cover both engineering and vegetation situations. Vegetation inspections can be included in overhead maintenance inspections.		
SERC OC Standards Review Group	Disagree	While the SERC OCSRG agrees with this requirement in general, there may be areas (e.g., desert terrain) where an annual interval would be unnecessary and not cost effective.
Response: The SDT thanks you for your comments. The consensus of the SDT is that inspection of any operating transmission line should be done annually to cover both engineering and vegetation situations. Vegetation inspections can be included in overhead maintenance inspections.		
City of Tallahassee	Disagree	While TAL's specific conditions and current process would meet this requirement, I can envision where some conditions may not require an annual inspection. These might include desert conditions, crop fields, over water, etc. To dictate a specific one-year requirement could be burdensome to some utilities with no improvement to the reliability of the BES.
Response: The SDT thanks you for your comments. The consensus of the SDT is that inspection of any operating transmission line should be done annually to cover both engineering and vegetation situations. Vegetation inspections can be included in overhead maintenance inspections.		
Xcel Energy	Disagree	Add a note of exception to the requirement for inspections on those lines that do not have vegetation management issues (e.g. lines that traverse desert areas only).
Response: The SDT thanks you for your comments. The consensus of the SDT is that inspection of any operating transmission line should be done		

Organization	Agree?	Question 5 Comment
annually to cover both engineering and vegetation situations. Vegetation inspections can be included in overhead maintenance inspections.		
USDA Forest Service, Southwestern Region, Regional Office for AZ and NM	Disagree	It would seem also that the T.O. should be expected to react to circumstances that create the need for a more frequent inspection cycle such as conditions that cause widespread vegetation mortality such as drought and/or beetle infestations.
Response: The SDT thanks you for your comments. The standard does restrict the number of inspections and does require the Transmission Owner to examine the local and environmental conditions that might require a greater frequency.		
Consumers Energy Company	Disagree	FERC required NERC in Order 693 to develop appropriate inspection cycles based on local factors. Potential annual tree growth varies considerably within the geography of the United States and FAC-003-1 recognized this factor and left it up to the utility to determine the most appropriate inspection cycle for their system. This was in lieu of having proper data readily available to determine inspection cycles for various areas that could be incorporated into the standard. FAC-003-2 greatly decreases the minimum separation distance between conductors and vegetation. Table 1 shows the minimum distance at sea level for a 345 kV line a 3.12 feet. This is considerably less than the potential annual growth rate of many tree species in many areas of the United States. Therefore, the annual inspection cycle would not be acceptable to identify tree growth that can violate the minimum distance before it occurs. Consumers Energy strongly believes that using the Gallet formula to determine the minimum clearance between conductors and vegetation will decrease the reliability of the system compared to the minimum clearance requirements in FAC-003-1.
Response: The SDT thanks you for your comments. The consensus of the SDT is that the frequency of inspection does not drive the minimum clearance the Transmission Owner operates from. The SDT would expect the minimum clearance to be driven by growth rate and maintenance frequency.		
National Grid	Disagree	R1.2, M1.2 and M1.3 in the Standard all refer to calendar year. National Grid objects to inspections being based on a calendar year. Transmission Owners should be able to define their own "year". (See Question No. 18.)
Response: The SDT thanks you for your comments. By using “once per calendar year” the standard does not confine the inspection to a specific date. This improves flexibility in the inspection schedule.		
Hydro One Networks Inc.	Disagree	Clarification is required on the requirements. The frequency and need for inspection is based on a number of factors that include: type of vegetation on a right of way, change in growing conditions and the Transmission Owner’s clearance standards (i.e., if the clearance standards are well above the Critical Clearance then the risk to reliability may be very low, so why inspect for vegetation clearances on an annual basis?) This being the case, clarification is needed on inspection requirements relative to the overall approach used to manage vegetation clearances. For example, Hydro One conducts routine line inspections on an annual basis and identifies clearance issues. Would this

Organization	Agree?	Question 5 Comment
		meet the requirements of the standard?
Response: The SDT thanks you for your comments. Yes. The SDT added a definition for Vegetation Inspection to the standard.		
NV Energy (fka Sierra Pacific / Nevada Power Co.)	Disagree	Clarification is required on exactly what an inspection is, which should perhaps be outlined in the white paper. There are areas where inspections are not necessary at all, such as lines over a parking lot, or in a remote desert area. We need some assurance that this inspection will not constitute a dedicated, comprehensive vegetation management inspection. Inspections are currently often part of a routine line patrol, where the lineman looks for vegetation concerns in addition to undertaking maintenance work. Therefore, the Transmission Owner needs the ability within their Transmission Vegetation Management Program to define what an inspection is in the context of their utility operations.
Response: The SDT thanks you for your comments. The SDT added a definition for Vegetation Inspection to the standard.		
CenterPoint Energy	Disagree	The Standard and the Technical Reference provide no specific justification for defining a 1-year inspection frequency and is arbitrary. The requirement itself does not take into account "local and environmental factors". Since the type of inspection is not specified within the Standard, a frequency of at least once per calendar year is currently workable for CenterPoint Energy, but it may not necessarily be appropriate for Transmission Owners with sparsely vegetated service territories. The Technical Reference for R1.2 should state, "the Transmission Owner is given discretion as to the inspection method", and "that while the inspection frequency is specified, it is not the intent of the Standard that all vegetation be maintained on the same frequency". For example, CenterPoint Energy currently utilizes a 5-year ground-based inspection cycle coupled with a 5-year cycle for vegetation maintenance, and performs a supplemental annual aerial inspection.
Response: The SDT thanks you for your comments. The consensus of the SDT is that inspection of any operating transmission line should be done annually to cover both engineering and vegetation situations and this is explained in the Technical Reference. Vegetation inspections can be included in overhead maintenance inspections. The SDT added a definition for Vegetation Inspection to the standard which would work provided you do your annual flight.		
Alberta Electric System Operator	Disagree	The AESO believes that the inspection schedule should consider local and environmental factors that may impact the anticipated growth rate of vegetation. In many of the areas in Alberta, due to cold climate and arid conditions, we have slow vegetation growth rates. The requirement for minimum annual inspection is not necessary. We recommend the inspection schedule be determined by the Transmission Owner and documented in its vegetation management plan.
Response: The SDT thanks you for your comments. The consensus of the SDT is that inspection of any operating transmission line should be done at		

Organization	Agree?	Question 5 Comment
least annually to cover both engineering and vegetation situations. A more frequent cycle may specified by the Transmission Owner to account for local conditions. Slow growth rates, arid conditions etc. which may render an annual frequency unnecessary for Vegetation Inspections can be included in overhead maintenance inspections.		
Pepco Holdings, Inc	Disagree	While an annual inspection is reasonable and appropriate for all but very low precipitation areas, In Order 693, the Commission directs the ERO to develop compliance audit procedures, using relevant industry experts, which would identify appropriate inspection cycles based on local factors. The SDT does not seem to have taken the local factors into account. FERC also does not want to leave this up to the Transmission Owners. While the standards being developed are moving many things to the RC, PHI sees that as the only way to have someone other than the Transmission Owner determine an inspection cycle that would consider local factors.
Response: The SDT thanks you for your comments. The consensus of the SDT is that inspection of any operating transmission line should be done at least annually to cover both engineering and vegetation situations. A more frequent cycle may specified by the Transmission Owner to account for local conditions. Slow growth rates, arid conditions etc. which may render an annual frequency unnecessary for Vegetation Inspections can be included in overhead maintenance inspections.		
Hydro-Quebec Transenergie (HQT)	Disagree	The frequency and need for inspection is based on a number of factors that include: type of vegetation on a right of way, rainfall during any given year, climate (very slow growth in nordic area), when the last removal of vegetation was done, etc. HQT believes R1.2 is overly prescriptive when a “at least once a year” becomes mandatory; these terms should be removed from the Standard.
Response: The SDT thanks you for your comments. The consensus of the SDT is that inspection of any operating transmission line should be done at least annually to cover both engineering and vegetation situations. A more frequent cycle may specified by the Transmission Owner to account for local conditions. Slow growth rates, arid conditions etc. which may render an annual frequency unnecessary for Vegetation Inspections can be included in overhead maintenance inspections.		
Bonneville Power Administration	Agree	It would be helpful to clarify what is expected in regards to what constitutes an inspection. This could be done in the technical reference. Some Transmission Operators inspect vegetation as part of line patrol that focuses on more than just the condition of vegetation along the Right of Way. It should be clear that the Transmission Owner, though required to complete a inspection frequency of at least once per calendar year, has the ability to implement the type of inspection it deems necessary. Also the frequency of once per calendar year may create some unintended reporting difficulties if Transmission Owners currently track progress and completion of inspections using a different convention than calendar year, e.g., fiscal year or other period. It may be helpful to change the wording of R1.2 from "at least once per calendar year" to "once in a twelve month period."
Response: The SDT thanks you for your comments. The consensus of the SDT is that inspection of any operating transmission line should be done		

Organization	Agree?	Question 5 Comment
annually to cover both engineering and vegetation situations. Vegetation inspections can be included in overhead maintenance inspections.		
MRO NERC Standards Review Subcommittee	Agree	The MRO suggests rewording the requirement to remove ". and environmental" . The MRO believes that local factors includes environmental.
Response: The SDT thanks you for your comments. The SDT considers local conditions to account for design and operating situation and environmental includes both the normal expected environmental conditions and changes from the norm such as drought major storms, fire etc.		
SERC Vegetation Management Subcommittee (VMS)	Agree	While the SERC VMS agrees in general, there may be areas (i.e. desert terrain) where an annual interval would be unnecessary and not cost effective.
Response: The SDT thanks you for your comments. The consensus of the SDT is that annual inspections add to the reliability of the system.		
American Electric Power (AEP)	Agree	AEP agrees with this change.
Response: The SDT thanks you for your comments.		
Platte River Power Authority	Agree	The inspection frequency is reasonable.
Response: The SDT thanks you for your comments.		
American Transmission Company	Agree	We agree with a minimum inspection frequency, but believe that the additional verbiage "? that takes into account local and environmental factors" should be deleted. The additional verbiage does not provide greater reliability only more documentation. Proposed Language: Specify a vegetation inspection frequency of at least once per calendar year.
Response: The SDT thanks you for your comments. The consensus of the SDT is that local and environmental factors might demand a greater frequency than once per calendar year and vegetation inspections can be included in overhead maintenance.		
Arizona Public Service Company	Agree	Clarification is required on exactly what an inspection is, which should perhaps be outlined in the white paper. There are areas where inspections are not necessary at all, such as lines over a parking lot, or in a remote desert area. APS needs some assurance that this inspection will not constitute a dedicated, comprehensive vegetation management inspection. Inspections are currently often part of a routine line patrol, where the forester or lineman looks for vegetation concerns in addition to undertaking maintenance work. Therefore, the Transmission Owner needs the

Organization	Agree?	Question 5 Comment
		ability within their Transmission Vegetation Management Program to define what an inspection is in the context of their utility operations.
Response: The SDT thanks you for your comments. The SDT added a definition for Vegetation Inspection to the standard.		
Pacific Gas & Electric Co.	Agree	This requirement is appropriate to ensure adequate inspection frequencies, however, a clear definition of "inspection" should be contained in either the standard or white paper.
Response: The SDT thanks you for your comments. The SDT added a definition for Vegetation Inspection to the standard.		
JEA	Agree	Although there are probably few areas where this is appropriate, the entity should be able to reduce the required number of inspections with RC approval if they are able to demonstrate that vegetation conditions surrounding transmission lines does not warrant inspections at that frequency.
Response: The SDT thanks you for your comments. The consensus of the SDT is that inspection of any operating transmission line should be done annually to cover both engineering and vegetation situations. Vegetation inspections can be included in overhead maintenance inspections.		
Salt River Project	Agree	The Transmission owner needs the ability to define what an inspection is in the context of their utility operation. Inspections may not constitute a dedicated, comprehensive vegetation management inspection, but could often be part of a routine line patrol, where linemen or engineers look for vegetation concerns in addition to undertaking maintenance work. Clarification of that would be helpful, suggest that could be documented in the Technical Reference document.
Response: The SDT thanks you for your comments. The SDT added a definition for Vegetation Inspection to the standard.		
Great River Energy	Agree	GRE suggests rewording the requirement to remove ". and environmental" . GRE believes that local factors takes into account environmental.
Response: The SDT thanks you for your comments. The SDT considers local conditions to account for design and operating situation and environmental includes both the normal expected environmental conditions and changes from the norm such as drought major storms, fire etc.		
San Diego Gas & Electric	Agree	The term "inspection" needs to be better defined, as well as the term "calendar year."

6. **In R1.3 the Standard requires that transmission vegetation management program specify an Annual Plan and specifies parameters for the plan. Implementation of the Annual Plan is separated and placed in R9. Do you agree with R1.3 and the separation of the implementation from the specification of the Annual Plan? If not, please explain.**

Summary Consideration: The majority of the respondents are in favor of the changes. There was a minority of the respondents that made a valid point that elements in the annual plan were lost in the posting. The SDT determined that the requirement to document and implement are separate and require different levels of VRF's and VSL's. The SDT chose a compromise wording to accommodate those points.

Organization	Agree?	Question 6 Comment
BCTC		The document would benefit from keeping the two requirements together, since they relate to the same topic. Under the new wording in R1, the Transmission Vegetation Management Program no longer has a requirement to include objectives. However, there is a phrase in R1.3 to "support the objectives…and methodologies…outlined in the…program." To be consistent with R1.3, BCTC recommends that R1.1 be reworded to specify the methodologies and objectives that the Transmission Owner uses to control vegetation.
Response: The SDT thanks you for your comments. However, the SDT determined that the requirements to document and implement should be separate and require different levels of Violation Risk Factors and Violation Severity Levels. Thus, the SDT respectfully does not adopt your suggestion to keep the two requirements together. The SDT also disagrees with returning "objectives" to R1. We do, however, agree that there exists a small dichotomy since "objectives" are no longer stated in R1 while being referenced in part 1.3. Subsequently the SDT has removed this wording from part 1.3. Further, the SDT has revised R1 to require the Transmission Owner to specifically describe how it will conduct work to comply with the Standard in lieu of requiring the Transmission Owner to only identify general objectives.		
Western Utility Arborists		The document would benefit from keeping the two requirements together, since they relate to the same topic. Under the new wording in R1, the Transmission Vegetation Management Program no longer has a requirement to include objectives. However, there is a phrase in R1.3 to "support the objectives" and methodologies "outlined in the "program." To be consistent with R1.3, the Western Utilities recommends that R1.1 be reworded to specify the methodologies and objectives that the Transmission Owner uses to control vegetation.
Response: The SDT thanks you for your comments. However, the SDT determined that the requirements to document and implement should be separate and require different levels of Violation Risk Factors and Violation Severity Levels. Thus, the SDT respectfully does not adopt your suggestion to keep the two requirements together. The SDT also disagrees with returning "objectives" to R1. We do, however, agree that there exists a small dichotomy since "objectives" are no longer stated in R1 while being referenced in part 1.3. Subsequently the SDT has removed this wording from part 1.3. Further, the SDT has revised R1 to require the Transmission Owner to specifically describe how it will conduct work to comply with the		

Organization	Agree?	Question 6 Comment
Standard in lieu of requiring the Transmission Owner to only identify general objectives.		
NPCC	Disagree	R1.2 and R1.3 should specifically state calendar year, and the Annual Plan and inspection follow the same calendar year timing.
Response: The SDT thanks you for your comments. The SDT points out that these two parts, R1.2 and R1.3, refer to different aspects of the Transmission Vegetation Management Program. Further, to assist in clarity, the SDT has revised part 1.3 and in doing so has removed the phrase "during the year" since it added no value to the requirement. The SDT does not agree with your suggestion to base the annual plan on a calendar year and feels that the Transmission Owner should retain the flexibility to determine the time period for - Requirement R1 clearly limits the scope of the TVMP to work on the entity's Active Transmission Line Rights of Way - and the "annual work plan" is one element of the overall TVMP annual plan.		
City of Tallahassee	Disagree	While I can agree with a separate requirement (R9) to implement the plan developed in R1.3, they need to both have the flexibility desired in R1.3. I do not see that flexibility in R9. See response to question 17.
Response: The SDT thanks you for your comments. R9 is the implementation of 1.3 which is flexible. The flexibility of 1.3 carries through to R9.		
Northern Indiana Public Service Company	Disagree	I disagree with the elimination of the present requirement R2 (last sentence) that requires a Transmission Owner to have proper quality control (QC) systems and procedures in place to document & track planned UVM work so as to verify it was completed properly to work specifications. The need for this requirement was demonstrated as recently as last year when a grow-in outage occurred at BG&E due to a contractor trimming the wrong tree at the wrong location, a situation that could have been prevented with effective QC.
Response: The SDT thanks you for your comments. The consensus of the SDT is that in order to implement the plan the Transmission Owner must complete its work plan to its standards. The level of QC is within the Transmission Owner's purview.		
USDA Forest Service, Southwestern Region, Regional Office for AZ and NM	Disagree	I think that the Transmission Owner should be able to specify the effective period of the plan whether it is one year or ten years. Arizona utilities are starting to think in terms of multi-year corridor management plans. A one year planning period could be specified as the minimum planning period.
Response: The SDT thanks you for your comments. The SDT agrees that long term plans can be of value and can be done within the standard. The standard is trying to insure the immediate reliability work is budgeted and completed.		
NV Energy (fka Sierra Pacific / Nevada Power Co.)	Disagree	The document would benefit from keeping the two requirements together, since they relate to the same topic. Under the new wording in R1, the Transmission Vegetation Management Program no longer has a requirement to include objectives. However, there is a phrase in R1.3 to "support the objectives" and methodologies" outlined in the "program." To be consistent with R1.3, we recommend that R1.1 be reworded to specify the methodologies and

Organization	Agree?	Question 6 Comment
		objectives that the Transmission Owner uses to control vegetation.
Response: The SDT thanks you for your comments. However, the SDT determined that the requirements to document and implement should be separate and require different levels of Violation Risk Factors and Violation Severity Levels. Thus, the SDT respectfully does not adopt your suggestion to keep the two requirements together. The SDT also disagrees with returning "objectives" to R1. We do, however, agree that there exists a small dichotomy since "objectives" are no longer stated in R1 while being referenced in part 1.3. Subsequently the SDT has removed this wording from part 1.3. Further, the SDT has revised R1 to require the Transmission Owner to specifically describe how it will conduct work to comply with the Standard in lieu of requiring the Transmission Owner to only identify general objectives.		
Arizona Public Service Company	Disagree	The document would benefit from keeping the two requirements together, since they relate to the same topic. Under the new wording in R1, the Transmission Vegetation Management Program no longer has a requirement to include objectives. However, there is a phrase in R1.3 to "support the objectives" and methodologies "outlined in the "program." To be consistent with R1.3, APS recommends that R1.1 be reworded to specify the methodologies and objectives that the Transmission Owner uses to control vegetation.
Response: The SDT thanks you for your comments. However, the SDT determined that the requirements to document and implement should be separate and require different levels of Violation Risk Factors and Violation Severity Levels. Thus, the SDT respectfully does not adopt your suggestion to keep the two requirements together. The SDT also disagrees with returning "objectives" to R1. We do, however, agree that there exists a small dichotomy since "objectives" are no longer stated in R1 while being referenced in part 1.3. Subsequently the SDT has removed this wording from part 1.3. Further, the SDT has revised R1 to require the Transmission Owner to specifically describe how it will conduct work to comply with the Standard in lieu of requiring the Transmission Owner to only identify general objectives.		
Baltimore Gas & Electric Company	Disagree	See response to question no. 17.
Response: The SDT thanks you for your comments. See response to comments on #17.		
JEA	Disagree	See comment from #3.
Response: The SDT thanks you for your comments. See response to comments on #3.		
Salt River Project	Disagree	The document would be easier to follow if the two elements were kept together in the same requirement (similar to comments stated in Comment #4 above). It makes the standard longer than necessary and creates redundancy. Also, under the new wording in R1, the Transmission Vegetation Management Program no longer has a requirement to include objectives. However, there is a phrase in R1.3 to "support the objectives" and methodologies "outlined in the..program". To be consistent with R1.3, it is recommended that R1.1 be reworded to

<table>

<tr><td>Hydro-Quebec Transenergie (HQT)</td><td>Disagree</td><td>R1.2 and R1.3 specify calendar year. The individual entities should define the 12 month period for their programs.</td></tr>
<tr><td colspan="3">Response: The SDT thanks you for your comments. The annual work plan may be for a calendar year or for a fiscal year.</td></tr>
<tr><td>Western Area Power Administration, Upper Great Plains Region</td><td>Agree</td><td>The description of the annual plan now appears to require a detailed plan for each line. Under FAC-003-1, Western (UGPR) identified higher priority vegetation during aerial inspection and handled those expediciously. We then addressed a percentage of the lower priority trees based upon a number of agency defined factors (vegetation priority, ground conditions, resource availability, etc). The less rigid annual plan allowed us the freedom to cut the lower priority trees that made the best sense to cut. We are concerned that the additional rigidity will create a ever-changing annual plan because we may have to adjust dozens of lines based on inspections. We question whether it is prudent to occupy finite resources in continually modifying the annual plan when the real benefits accrue from actually performing the vegetation management activities.</td></tr>
<tr><td colspan="3">Response: The SDT thanks you for your comments. The SDT intent is for the Transmission Owner’s Transmission Vegetation Management Program to be developed based on the unique requirements of each Transmission Owner’s system. For example, where the Transmission Owner has a heavily forested or geographically large territory the annual plan may address many transmission lines on a cyclic basis along with additional items found on the vegetation inspections. On the other hand, where the Transmission Owner has a very sparsely forested territory, or a small number of transmission line miles, the Transmission Vegetation Management Program may necessitate an annual plan that only addresses items found on the vegetation inspections. Therefore, the specificity of the annual plan is subject to the discretion of the Transmission Owner. We agree that only the appropriate amount of resources should be applied to the execution and management of the annual plan, provided the overall Transmission Vegetation Management Program is effective.</td></tr>
<tr><td>Progress Energy Florida</td><td>Agree</td><td>Annual Plan should be a defined term in the standard. Without a definition, the term may be interpreted differently by industry and the regulator. The drafting team should raise the prominence of annual plan and define the attributes of an annual plan.</td></tr>
</table>

Organization	Agree?	Question 6 Comment
Response: The SDT thanks you for your comments. The SDT did attempt to address this concern by breaking the annual plan into 4 separate sub-requirements. We feel this may help limit the range of subjective interpretations of this requirement.		
Progress Energy Carolinas	Agree	Annual Plan should be a defined term in the standard. Without a definition, the term may be interpreted differently by industry and the regulator. The drafting team should raise the prominence of annual plan and define the attributes of an annual plan.
Response: The SDT thanks you for your comments. The SDT did attempt to address this concern by breaking the annual plan into 4 separate sub-requirements. We feel this may help limit the range of subjective interpretations of this requirement.		
Southern California Edison Company	Agree	Q6: SCE agrees in part. Proposal R1.3, requiring Transmission Owners to establish an annual maintenance plan is generally acceptable. However, SCE disagrees with including peripheral information in R1.3 and the institution of a separate implementation requirement (R9). Further, we note that some portions of FAC-003-1 (R2) appear to have been transplanted into proposed R1.3 and that the word “shall” has been replaced with the word “should”. SCE believes that inserting the word “shall” into statements that are clearly advisory in nature does not necessarily create enforceable requirements. As proposed, an enforcement auditor might incorrectly determine that the new “requirement” statements in proposed R1.3, describing the need for “flexibility”, “consideration of permitting and scheduling requirements”, and self-determined “methodologies” is a comprehensive list of items for the maintenance plan. Because this list of program elements is not complete, SCE recommends all text following the opening sentence be removed from R1.3 and inserted into the supporting technical paper. SCE respectfully suggests that R1.3 be revised to read: "Specifies a plan that identifies the applicable lines to be maintained and associated work to be performed."
Response: The SDT thanks you for your comments. The consensus of the SDT is the components of an annual work plan must be part of the requirement to ensure that all plans are adequate. Major changes that could affect reliability must be made.		
FirstEnergy	Agree	Although we agree with R1.3, we suggest it be broken up into subrequirements to allow for better clarity to the reader as well as aid in the development of violation severity levels when developed. We suggest the following:R1.3. Require an annual plan that includes the following as a minimum: (Note: Adjustments to the plan within the year are permissible) R1.3.1. It shall identify the applicable lines to be maintained and associated work to be performed during the year. R1.3.2. Is shall be flexible to adjust to changing conditions and to findings from vegetation inspections. R1.3.3. It shall take into consideration permitting and scheduling requirements from landowners or regulatory authorities. R1.3.4. It shall support the objectives of the transmission vegetation management program and use the methodologies outlined in the transmission vegetation management program.

Organization	Agree?	Question 6 Comment
Response: The SDT thanks you for your comments. Requirement R1.3 has been subdivided for clarity in proposed version 2.		
MRO NERC Standards Review Subcommittee	Agree	The MRO suggests removing the words "during the year" from sentence 1 and removing the words "within the year" in sentence 3. The MRO believes that having it only within the plan year is too restrictive.
Response: The SDT thanks you for your comments. By definition an annual plan covers a one year period. This one year period, at the discretion of the Transmission Owner, may or may not be constrained to a calendar year. However, in an effort to make the requirement more concise, the SDT did remove the words "during the year" from the requirement but retained the words "within the year" in the requirement.		
Tennessee Valley Authority	Agree	TVA agrees with Comment Question 6 and proposes that the Annual Plan be a defined term.
Response: The SDT thanks you for your comments. The SDT did attempt to address this concern by breaking the annual plan into 4 separate sub-requirements. We feel this may help limit the range of subjective interpretations of this requirement.		
American Electric Power (AEP)	Agree	AEP agrees with these changes.
Response: The SDT thanks you for your comments.		
Platte River Power Authority	Agree	Under the new working in R1., the Transmission Vegetation Management Program no longer has a requirement to include objectives. However, there is a phrase in R1.3. to "support the objectives.. and methodologies outlined in the Transmission Vegetation Management Program". R1.3. should be consistent with the wording in R1.
Response: The SDT thanks you for your comments. The SDT has made changes to address this concern and the word, "objectives" is no longer used in the revised standard.		
American Transmission Company	Agree	ATC agrees with separating the implementation Requirements from the Annual Plan Requirements.
Response: The SDT thanks you for your comments.		
Manitoba Hydro	Agree	Agree with the separation - but suggest that the time horizon of one year be removed as some changes may push the work beyond the current planning year.
Response: The SDT thanks you for your comments. By definition an annual plan covers a one year period. This one year period, at the discretion of		

Organization	Agree?	Question 6 Comment
the Transmission Owner, may or may not be constrained to a calendar year. If findings during the year from Vegetation Inspections justify changes to the plan, such adjustments are allowed as long as they occur within the planning year, not after the fact.		
San Diego Gas & Electric	Agree	To be consistent with R1.3, we recommend that R1.1 be reworded to specify the methodologies and objectives that the Transmission Owner uses to control vegetation.
Response: The SDT thanks you for your comments. The SDT has made changes to address this concern.		
CenterPoint Energy	Agree	See comments to Q4 above as well.
Response: The SDT thanks you for your comments. See response to comments on Q4.		
Great River Energy	Agree	GRE suggests removing the words "during the year" from sentence 1 and removing the words "within the year" in sentence 3. GRE believes that having it only within the plan year is too restrictive.
Response: The SDT thanks you for your comments. By definition an annual plan covers a one year period. This one year period, at the discretion of the Transmission Owner, may or may not be constrained to a calendar year. However, in an effort to make the requirement more concise, the SDT did remove the words "during the year" from the requirement but retained the words "within the year" in the requirement.

7. In R1.4 the Standard requires the Transmission Owner to have an Imminent Threat Procedure and specifies elements to be in that procedure. Do you agree with R1.4? If not, please explain.

Summary Consideration: Approximately half of the comments received were critical of the lack of a definition for imminent threat. The SDT prefers to allow the verbiage "an imminent threat of a vegetation-related Sustained Outage" to stand without further definition.

About the same number of commenters objected to the "prescriptive" list of other actions for the Transmission Operator, and that language has been removed from R1.4.

R1.4 Require a process or procedure for response to imminent threats of a vegetation related Sustained Outage. The process or procedure shall specify actions which shall include immediate communication of the threat to the responsible control center.

Deleted: Transmission Operator

Deleted: , and may include actions such as a temporary reduction in line Rating, switching lines out of service, or other actions.

Commenters also expressed a desire to set the procedure for specific internal needs and the SDT modified the language to give that latitude to the Transmission Owner when developing its Imminent Threat procedure.

Some comments referred to parts of the standard not asked about in this question and the SDT directed the commenters to review the changes in R1, R2 and R4.

Organization	Agree?	Question 7 Comment
Associated Electric Cooperative Inc.	Disagree	The language in R1.4, requiring notification of the Transmission Operator, is inconsistent with the Applicability in Section A.4.1.1 which designates the Transmission Owner as the responsible entity.
Response: Thank you for your comment. The main purpose of requirement R1.4 is to enhance the responsible operator's situational awareness of the power system's status. Therefore, the salient requirement of this procedure is notification of the responsible operator of any potential threat to the power system. This requirement does not mandate any action of the responsible operator and thus, this entity would not need to be listed in the Applicability section. Please also note that the wording in R1.4 has been altered to change the "Transmission Operator" to the "responsible control center", to better identify the appropriate responsible party.		
NPCC	Disagree	While we strongly agree that an imminent threat procedure should be required in the Transmission Vegetation Management Program, we disagree with some specific wording in R1.4. R1.4 requires immediate communication of an imminent threat to the Transmission Operator, which we would normally agree with. R2 however requires that the imminent threat procedure be implemented when the Critical Clearance Zone (Critical Clearance Zone) is approached by vegetation. "Approached" is not defined as a specific distance, so this part of the requirement is left up to the individual's interpretation. In cases where the Critical Clearance Zone is

Organization	Agree?	Question 7 Comment
		approached by vegetation no threat to the system is possible if the vegetation is removed before it actually grows into the Critical Clearance Zone . In many cases the vegetation can be removed without taking clearance outages because the Critical Clearance Zone is large, and the conductor and vegetation are still relatively far apart. In such cases there is no need to notify the Transmission Operator, although there is a need to remove the vegetation immediately. We recognize that the opposite is also true, and that in some cases it will be necessary to notify the Transmission Operator because a clearance outage or line de-rating may be required to remove the vegetation. We therefore suggest a simple change to the wording of the second sentence of R1.4. Change "?. specify actions which shall include immediate communication of the threat to the Transmission Operator, and may include actions such as a temporary reduction in line Rating, switching lines out of service, or other actions" to ".. specify actions which may include immediate communication of the threat to the Transmission Operator, a temporary reduction in line Rating, switching lines out of service, or other actions". This change will address the issue which is described above and will allow each Transmission Operator to develop an imminent threat procedure that best fits their system. It should also be noted that many Transmission Operators have imminent threat procedures in place to address all imminent threats to their transmission system, not just threats due to vegetation. It makes sense for Transmission Owners to have only one imminent threat process, therefore the flexibility that can be achieved in the context of this standard would be helpful.
Response: Thank you for your comment. We agree with your comments concerning the Critical Clearance Zone and the elusiveness of the term "approach". Subsequently, the Critical Clearance Zone methodology has been removed from the Standard. The SDT also agrees that the main purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of the power system's status. Please also note that the wording has been altered to change the "Transmission Operator" to the "responsible control center" to better identify the appropriate responsible party. The SDT maintains that the salient requirement of this procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to develop an imminent threat procedure that best fits its system.		
SERC Vegetation Management Subcommittee (VMS)	Disagree	The Requirement as written is too prescriptive and is open to interpretation, from an audit perspective, with use of the term "immediate" communication and a partial list of activities. Many conditions or threats, requiring immediate removal, would not require communication with the Transmission Operator, who is not an applicable entity for this standard. The SERC VMS recommends that R1.4 be deleted. Since this is a "zero tolerance" standard any Transmission Owner will remove any discovered threats to prevent outages. If R1.4 is not deleted, the SERC VMS believes that imminent threats should be a defined term. The definition should be as follows: ?Imminent Threat: A vegetation condition which, if not addressed, will place a transmission line at a significant risk of a Sustained Outage.?
Response: Thank you for your comment. We agree that an imminent threat can exist in many different forms. Part of your concern has been addressed by the removal of the term "immediate". However, the SDT does not agree with removing the imminent threat requirement. The main purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of reliability dangers to the power system. Please note that the requirement wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to		

Organization	Agree?	Question 7 Comment
better identify the appropriate party. The salient requirement of the imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to develop an imminent threat procedure that best fits its system.		
Progress Energy Florida	Disagree	Progress Energy agrees with the need for a Transmission Owner to have an Imminent Threat Procedure and that the Transmission Operator should be immediately notified of imminent threats but only when it is appropriate as defined by the Transmission Owner's imminent threat procedure. We disagree with the requirement to immediately communicate with the Transmission Operator whenever the Critical Clearance Zone is approached. Not every scenario is an issue that requires action by the Transmission Operator: It is possible that the Critical Clearance Zone is being approached by vegetation at the lowest point of the Critical Clearance Zone whereas the conductor may be at its highest point in the Critical Clearance Zone (potentially 30 feet away from the vegetation) -- This typical situation does not merit notification to the Transmission Operator (which is required by FAC-003-2 as currently written).
Response: Thank you for your comment. We agree with your comments concerning the Critical Clearance Zone methodology. Subsequently, the Critical Clearance Zone methodology has been removed from the Standard. The SDT also agrees that the main purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of reliability dangers to the power system. Please also note that the requirement wording has been altered to change the "Transmission Operator" to the "responsible control center". The SDT feels this better identifies the appropriate party. The SDT maintains that the salient requirement of R1.4 is notifying the responsible operator of any imminent threat to the power system.		
Progress Energy Carolinas	Disagree	Progress Energy agrees with the need for a Transmission Owner to have an Imminent Threat Procedure and that the Transmission Operator should be immediately notified of imminent threats but only when it is appropriate as defined by the Transmission Owner's imminent threat procedure. We disagree with the requirement to immediately communicate with the Transmission Operator whenever the Critical Clearance Zone is approached. Not every scenario is an issue that requires action by the Transmission Operator: It is possible that the Critical Clearance Zone is being approached by vegetation at the lowest point of the Critical Clearance Zone whereas the conductor may be at its highest point in the Critical Clearance Zone (potentially 30 feet away from the vegetation) -- This typical situation does not merit notification to the Transmission Operator (which is required by FAC-003-2 as currently written).
Response: Thank you for your comment. We agree with your comments concerning the Critical Clearance Zone methodology. Subsequently, the Critical Clearance Zone methodology has been removed from the Standard. The SDT maintains that the salient requirement of R1.4 is notifying the responsible operator of any imminent threat to the power		

Organization	Agree?	Question 7 Comment
system.		
SERC OC Standards Review Group	Disagree	The Requirement as written is too prescriptive and is open to interpretation from an audit perspective with use of the term “immediate” communication and a partial list of activities. Due to limitations of communication capabilities in the field, "immediate" may not be practical. While the White Paper provides insight into what is acceptable communications to the Transmission Operator, the standard is less prescriptive in describing what is an acceptable communication path to the Transmission Operator. We recommend better descriptions in VSLs, measures and the Reliability Standard Audit Worksheet as to what is acceptable. Many conditions or threats, requiring immediate removal, would not require communication with the Transmission Operator, who is not an applicable entity for this standard. The SERC OCSRG recommends that R1.4 be deleted. Since this is a "zero tolerance" standard any Transmission Owner will remove any discovered threats to prevent outages. If R1.4 is not deleted, the SERC OCSRG believes that imminent threats should be a defined term. The definition should be as follows: “Imminent Threat: A vegetation condition which, if not addressed, will place a transmission line at an immediate risk of a Sustained Outage.”
Response: Thank you for your comment. Part of your concern has been addressed by the removal of the term “immediate”. However, the SDT does not agree with removing the imminent threat requirement. The main purpose of the imminent threat requirement is to enhance the responsible control center’s situational awareness of reliability dangers to the power system. Please note that this requirement’s wording has also been altered to change the designation “Transmission Operator” to the “responsible control center” to better identify the appropriate party. The salient requirement of the imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to develop an imminent threat procedure that best fits its system and field communication capabilities. The SDT also feels that it is important for the aspects of the imminent threat procedure and the triggers be defined by the Transmission Owner. The Violation Severity Levels for this requirement are now binary and self explanatory. The SDT is prepared to provide input in the revision of RSAWs, but under current practice, RSAWs are not developed by standard drafting teams.		
Florida Power & Light	Disagree	The definition of Imminent Threat procedure should be included in the Standard. As FERC has stated with regard to the definition of sabotage, the industry should come up with a standard definition and it should not vary from company-to-company. FPL further disagrees with defining Imminent Threat only in a white paper as proposed by some. The Standard should not refer to other reference documents, especially when it is to add clarity and should define the Imminent Threat procedure as well as its requirements within the body of the Standard.
Response: Thank you for your comment. The SDT disagrees with your comments. We feel that the Transmission Owner should have the flexibility to not only develop the imminent threat procedure but also define the triggers needed for its particular system. The main purpose of the imminent threat requirement is to enhance the responsible control center’s situational awareness of reliability dangers to the power system. The notification requirement is a mandatory requirement for all Transmission Owners. Please note that this requirement’s wording has also been altered to change the designation “Transmission Operator” to the “responsible control center” to better identify the appropriate party. Beyond this, it is left to the		

Organization	Agree?	Question 7 Comment
Transmission Owner to develop all other imminent threat procedure components.		
Southern Company	Disagree	The standard requirement, as written, requires the "immediate notification" of the operator. This standard requirement could be interpreted to mandate that this notification take place prior to any other action. There could be times that this communication would take up valuable time needed to relieve the immediate threat. The requirement should be modified to list examples of appropriate actions that could be taken. The Transmisison Owner should be allowed the flexibility of developing a communication process that ensures timely notification of a threat and the proper channels of communication that will be utilized in making the notification. The present wording in the standard alone suggests the individual observing the threat in the field is directly responsible for communicating with the Transmission Operator while the whitepaper tends to be more flexible. The Transmission Owner may wish to have the vegetation contractor notify the Transmisison Owner's forester who in turn will notify the Transmission Operator. While the whitepaper does an adequate job describing acceptable responses, the standard does not. It is recommend the standard, VSL, and Reliability Standard Audit Worksheet better explain what is an acceptable response to the Transmission OwnerP. The requirement then goes on to address specific actions the operator "may" take in response to the notification. The imminent threat processes should be limited to the steps taken to notify the Transmission Operator in a timely manner. FAC-003 is not the appropriate place to address Transmission Operator decisions resulting from notification of a threat to the system.
Response: Thank you for your comment. Part of your concern has been addressed by the removal of the term “immediate”. We agree that the main purpose of this requirement is to enhance the responsible control center’s situational awareness of reliability dangers to the power system. Further, please note that the requirement wording has also been altered to change the designation “Transmission Operator” to the “responsible control center” to better identify the appropriate party. Beyond this, it is left to the Transmission Owner to develop an imminent threat procedure that best fits its system and field communication capabilities. The Violation Severity Levels for this requirement are now binary and self explanatory. The SDT is prepared to provide input in the revision of RSAWs, but under current practice, RSAWs are not developed by standard drafting teams.		
E.ON U.S.	Disagree	The Requirement as written is too prescriptive and is open to interpretation, from an audit perspective, with use of the term “immediate” communication and a partial list of activities. Many conditions or threats, requiring immediate removal, would not require communication with the Transmission Operator, who is not an applicable entity for this standard. We suggest that R1.4 be deleted. Since this is a "zero tolerance" standard any Transmission Owner will remove any discovered threats to prevent outages. If R1.4 is not deleted, we believe that imminent threats should be a defined term. The definition should be as follows: “Imminent Threat: A vegetation condition which, if not addressed, will place a transmission line at a significant risk of a Sustained Outage.”
Response: Thank you for your comment. We agree that an imminent threat can exist in many different forms. Part of your concern has been addressed by the removal of the term “immediate”. However, the SDT does not agree with removing the imminent threat requirement. The main		

Organization	Agree?	Question 7 Comment
purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of reliability dangers to the power system. Please note that the requirement wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to better identify the appropriate party. The salient requirement of this procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to develop an imminent threat procedure that best fits its system.		
Midwest ISO Stakeholders Standards Collaborators	Disagree	Transmission Owners should have a Vegetation Imminent Threat Procedure, and "Vegetation Imminent Threat" should be a defined term, defined as: "Vegetation observed in the field encroaching upon a conductor within a distance that is twice the Gallet clearance distances referenced in Table I of the draft standard FAC-003-2." In this case, the threat would require an immediate response and would include communication to the Transmission Operator. From there, the actions that the operator decides to take will be dependent on the incident and system conditions. We do not need to be prescriptive with this requirement but rather allow the Transmission Operator and appropriate field personnel the flexibility to make the right decisions to safely, promptly and appropriately remove the vegetation threat. From a Transmission Owner's perspective, many situations can constitute an imminent threat but this approach will clearly define a "Vegetation Imminent Threat" as it relates to the Purpose of this standard. See our related comment on #11 below.
Response: Thank you for your comment. We agree that many situations can constitute an imminent threat. While we do not agree that an imminent threat should be defined in the Standard, we do agree that the Transmission Owner should have the flexibility to develop an imminent threat procedure that allows the appropriate decisions to address the vegetation threat. This requirement allows the Transmission Owner to develop an imminent threat procedure that best fits its system. The main purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of reliability dangers to the power system. Please note that the requirement's wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to better identify the appropriate party. The SDT feels this is a better approach than to have a rigid definition of an imminent threat procedure.		
SERC Compliance Staff	Disagree	SERC staff agrees with the concept of an imminent threat procedure, but disagrees with this requirement in its current form. The use of the word "immediate" is ambiguous. There are many conditions or threats that may require immediate removal, but would not require communication with the Transmission Operator and may require communication with another entity. SERC staff suggests that the proper communication paths be outlined by the Transmission Owner. Imminent threats should be a defined term, however SERC staff has not developed an objective, unambiguous definition.
Response: Thank you for your comment. Part of your concern has been addressed by the removal of the term "immediate". We agree that the main purpose of the imminent threat requirement is the timely communication of a threat to the responsible operator. Therefore, the requirement wording has been altered to change the designation "Transmission Operator" to the "responsible control center". The main purpose of this requirement is to enhance the responsible control center's situational awareness of reliability dangers to the power system. While we do agree that the Transmission Owner should outline the proper communication paths, we do not agree that an imminent threat should be defined in the Standard. The SDT feels the		

Organization	Agree?	Question 7 Comment
Transmission Owner should have the flexibility to develop an imminent threat procedure that best fits its system.		
ITC HOLDINGS	Disagree	Agree & Disagree with the question: Agree with the need to have an Imminent Threat Procedure and upon discovery of an IT, the Transmission Operations (Transmission Owner) should be notified. We Disagree however, with the requirement as written as its too prescriptive and is open to interpretation, from an audit perspective, with use of the term “immediate” communication and a partial list of activities that the Transmission Owner may consider. Decisions on what specific system operating actions that could be taken are beyond the responsibility of the vegetation management personnel. Disagree with the need to implement the imminent threat procedure merely because a Critical Clearance Zone is being approached. It is possible that the Critical Clearance Zone is being approached by vegetation at the lowest point of the Critical Clearance Zone where the conductor may be at its highest point in the Critical Clearance Zone , (potentially 20 or 30 feet from vegetation) and wouldn’t necessitate notification to the Transmission Owner. Is there a desired distance from the Critical Clearance Zone where this procedure must be implemented since all vegetation within a Right-of-Way will approach the Critical Clearance Zone as it grows? R1.4 should be changed to ?Require a process for response to vegetation related imminent threat to applicable lines and not the Critical Clearance Zone
Response: Thank you for your comment. We agree with your comments concerning the Critical Clearance Zone and the elusiveness of the terms “approach” and “immediate”. Subsequently, the Critical Clearance Zone methodology has been removed from the Standard. Also, the term “immediate” has been removed. The main purpose of the imminent threat requirement is to enhance the responsible control center’s situational awareness of the power system’s status. Please also note that the wording has been altered to change the “Transmission Operator” to the “responsible control center” to better identify the appropriate responsible party. The SDT maintains that the salient requirement of the imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to develop an imminent threat procedure that best fits its system.		
Tennessee Valley Authority	Disagree	TVA recommends that R1.4 and R2 both be removed from this Standard. This is a "zero tolerance" Standard with significant penalties for outage violations. These penalty conditions are the necessary and sufficient conditions for the Transmission Owner to immediately react to any discovered threats to prevent potential outages.
Response: Thank you for your comments. While the drafting team does agree that the penalties for the “zero tolerance” aspect of the Standard certainly provide a strong incentive, we still feel that a requirement for an imminent threat procedure should be included in the Standard. The main purpose of the imminent threat requirement is to enhance the responsible control center’s situational awareness of reliability dangers to the power system. Please note that this requirement’s wording has been altered to change the designation “Transmission Operator” to the “responsible control center” to better identify the appropriate party. The salient part of this procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, the Transmission Owner should develop all other components of the imminent threat procedure to best fit its system.		

Organization	Agree?	Question 7 Comment
American Electric Power (AEP)	Disagree	AEP agrees with the need for a Transmission Owner to have an Imminent Threat Procedure and that the Transmission Operator should be immediately notified of imminent threats. However, AEP disagrees with the requirement that the Transmission Operator be notified merely because the Cricitical Clearance Zone (Critical Clearance Zone) has been approached. It is possible that the Critical Clearance Zone is encroached by vegetation at the lowest point of the Critical Clearance Zone whereas the conductor may be at its highest point in the Critical Clearance Zone (potentially 20 or 30 feet away from the vegetation). This situation does not merit notification to the Transmission Operator. Please also refer to our comments regarding Critical Clearance Zone in AEP's responses to Questions 15 and 18.
Response: Thank you for your comment. We agree with your comments concerning the Critical Clearance Zone and the elusiveness of the term “approach”. Subsequently, the Critical Clearance Zone methodology has been removed from the Standard. The SDT feels that the main purpose of the imminent threat requirement is to enhance the responsible control center’s situational awareness of the power system’s status. Please also note that the wording has been altered to change the “Transmission Operator” to the “responsible control center” to better identify the appropriate responsible party. The SDT maintains that the salient requirement of this procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to develop an imminent threat procedure that best fits its system.		
Tampa Electric Company	Disagree	TECO aggres with the need for the Imminent Threat Procedure. However, the use of the new Critical Clearance Zone could create a "fill in the blank" standard. We need to lock these clearances down as an industry so as to define what is an imminent threat and what the Critical Clearance Zone is in terms of specific distances.
Response: Thank you for your comments. The SDT agrees with your concern of having a standard with “fill in the blank” requirements. We have made some major changes to this requirement due to the overwhelming response from industry that the imminent threat requirement was needed but should not be overly prescriptive. The main purpose of the imminent threat requirement is to enhance the responsible control center’s situational awareness of reliability dangers to the power system. Please note that the requirement wording has also been altered to change the designation “Transmission Operator” to the “responsible control center” to better identify the appropriate party. The salient part of the imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. **Using the Critical Clearance Zone as an undefined “trigger” for implementing the imminent threat process has been removed from the Standard. The Critical Clearance Zone methodology has been deleted from the Standard.**		
Orange and Rockland Utilities Inc.	Disagree	While we agree that the imminent threat procedure should be included in the Transmission Vegetation Management Program, the requirement is overly prescriptive and should be revised to allow Transmission Owners flexibility to develop imminent threat procedures which best fit their systems and protocols. We recommend that R1.4 be reworded as follows: "Require a process or procedure for response to vegetation-related imminent threats to applicable lines. The imminent threat procedure shall require action to eliminate vegetation-related imminent threats, and shall be implemented upon discovery of such conditions". In addition, the definition of "Imminent Threat" should be defined. We suggest the following: "A condition which places a

<table>
<tr><th>Organization</th><th>Agree?</th><th>Question 7 Comment</th></tr>
<tr><td></td><td></td><td>transmission line at significant risk of an outage in the very near term". An example of a vegetation-related imminent threat would be an uprooted tree leaning precariously toward a conductor which is certain to make contact with the conductor as the tree falls. Many Transmission Operators have imminent threat procedures in place to address all imminent threats to their transmission systems, not just imminent threats due to vegetation. In many cases it would make sense for Transmission Owners to have one imminent threat process that covers all imminent threat conditions. The flexibility being recommended would facilitate this.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment. The SDT agrees that the requirement was overly prescriptive. The requirement has been revised to focus on the main purpose of the imminent threat requirement; which is to enhance the responsible control center's situational awareness of reliability dangers to the power system. Please note that this requirement's wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to better identify the appropriate party. The salient part of this procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to determine the follow up activities and procedures that best fit its systems and protocols; thereby providing for the flexibility that you have suggested. Along with this line of reasoning, we do not agree that an imminent threat should be defined in the Standard. Again, the SDT feels that the Transmission Owner should have the flexibility to define what constitutes an imminent threat to its individual power system. This flexibility also allows the Transmission Owner to have one imminent threat process in place to cover all imminent threats to its transmission systems, not just imminent threats due to vegetation as you have noted.</td></tr>
<tr><td>American Transmission Company</td><td>Disagree</td><td>We agree that entities should have a Vegetation Imminent Threat Procedure, but that the term should be defined. Also see related comments to Question #11.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment. We have made some major changes to this requirement due to the overwhelming response from industry that the imminent threat requirement was needed, as long as it was not an overly prescriptive requirement. We do not agree that an imminent threat should be defined in the Standard. The main purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of reliability dangers to the power system. Please note that the requirement wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to better identify the appropriate party. The salient requirement of an imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to determine the follow up activities and procedures that best fit its system. The SDT feels this is a better approach than to have a rigid definition of an imminent threat procedure.</td></tr>
<tr><td>Nebraska Public Power District</td><td>Disagree</td><td>NPPD agrees that a Transmission Owner should have an imminent threat procedure and the Transmission Owner be immediately notified of any threats. NPPD disagrees with prescribing what needs to be done as a result of the threat. This is condition based and staff can make the right decision as to what corrective actions are necessary.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment. The SDT agrees that prescribing what needs to be done as a result of the threat should not be included as part of the Standard requirement. This language has been removed from the text as you have suggested. The SDT also agrees that the main purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of reliability dangers to the power system.</td></tr>
</table>

Organization	Agree?	Question 7 Comment
Please note that this requirement's wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to better identify the appropriate party. The salient requirement of an imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to determine the follow up activities and procedures that best fit its system.		
Consumers Energy Company	Disagree	Consumers Energy believes that each Transmission Owner/Operator should have a Vegetation Imminent Threat Procedure. We disagree with this requirement because "vegetation imminent threat" is not defined in the standard. As interpreted, the "vegetation imminent threat" is only what is needed to avoid violating the Gallet formula minimum distance which would allow vegetation approaching close to 3 feet of separation on 345 kV conductors. At this distance, removal of the tree cannot occur without removing the line from service per OSHA rules. Therefore, the tree can "cause" an outage but be acceptable under this standard. Consumers Energy believes that vegetation must be maintained so that extraordinary measures needed to remove the vegetation threat do not have to occur in order to complete the work. Thus, the minimum distance to "trigger" an imminent threat must be greater than the OSHA minimum working distance and therefore the Gallet formula does not provide the protection that FERC demands. During high load periods options a system operator may have to mitigate the vegetation threat may not be available; you may not be able to remove the line from service, derate the line, etc., so the operator must "hope" to get through the high load period without the vegetation causing a outage. Allowing vegetation to approach the Gallet formula distance is unacceptable and severely decreases the reliability of the system.
Response: Thank you for your comment. The SDT does not agree that a vegetation imminent threat should be defined in the Standard. The Critical Clearance Zone methodology has been removed from the Standard. We feel that the Transmission Owner should have the flexibility to not only develop the imminent threat procedure but also define the triggers needed for its particular system. The main purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of reliability dangers to the power system. The notification requirement is a mandatory requirement for all Transmission Owners. Please note that this requirement's wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to better identify the appropriate party. The SDT maintains that the salient requirement of an imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to determine the follow up activities and procedures that best fit its system. Aside from the negative economic and operational impacts associated with unscheduled facility outages, failures by the Transmission Owner to effectively execute follow up activities and procedures will most likely lead to a violation(s) of other requirements related to Minimum Vegetation Clearance Distance (MVCD) encroachment or sustained outages.		
Ameren	Disagree	Transmission Owners should have a Vegetation Imminent Threat Procedure, and "Vegetation Imminent Threat" should be a defined term, defined as: "Vegetation observed in the field encroaching upon a conductor within a distance defined in the Vegetation Management plan." In this case, the threat would require an immediate response and would include communication to the Transmission Operator. From there, the actions that the operator decides to take will be dependent on the incident and system conditions. We do not need to be

<table>
<tr><th>Organization</th><th>Agree?</th><th>Question 7 Comment</th></tr>
<tr><td></td><td></td><td>prescriptive with this requirement but rather allow the Transmission Operator and appropriate field personnel the flexibility to make the right decisions to safely, promptly and appropriately remove the vegetation threat. From a Transmission Owner's perspective, many situations can constitute an imminent threat but this approach will clearly define a "Vegetation Imminent Threat" as it relates to the Purpose of this standard. While a definition of "Vegetation Imminent Threat - Vegetation observed in the field encroaching upon a conductor within a distance that is twice the Gallet clearance distances referenced in Table I of the draft standard FAC-003-2" would be acceptable and far superior to that which is proposed, it will still be difficult for field personnel to identify, at each foot of a transmission circuit, wherein twice the Gallet distance would be found. See comment on #11 below.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment. We agree with your assessment that the Standard needs an imminent threat requirement, but as it was written, the requirement was overly prescriptive. As a result, and because much of the industry agreed with you, we have made some major changes to this requirement. The main purpose of the imminent threat requirement is to enhance the responsible control center’s situational awareness of reliability dangers to the power system. Please note that the requirement wording has also been altered to change the designation “Transmission Operator” to the “responsible control center” to better identify the appropriate party. The salient requirement of an imminent threat procedure is notification of the responsible operator of any imminent threat to the power system.

We further agree that many situations can constitute an imminent threat, distance from the vegetation to the conductor being only one of such situations, so the references to the Critical Clearance Zone methodology as a defined “trigger” for implementing the imminent threat process has been removed from the Standard. For that matter, the Critical Clearance Zone methodology has been deleted from the Standard. While we do not agree that an imminent threat should be defined in the Standard, we do agree that the Transmission Owner should have the flexibility to develop an imminent threat procedure that allows the appropriate decisions to address the vegetation threat. The requirement, as it has been reworded, allows the Transmission Owner to develop an imminent threat procedure that best fits its system. The SDT feels this is a better approach than to have a rigid definition of an imminent threat procedure.</td></tr>
<tr><td>Consolidated Edison Company of New York (CECONY)</td><td>Disagree</td><td>CECONY currently has procedures that mandate response to imminent threats. The Standard should be made more general and not identify the specific actions that shall be taken in the procedure. The second sentence of R1.4 should be deleted and the first sentence should read, 'Require a process or procedure to respond to vegetation-related imminent threats." This adds the necessary flexibility that utilities require and avoids additional redundant processes or procedures from being developed.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment. The SDT agrees that the requirement should be more general and has revised the requirement to focus on the main purpose of the imminent threat requirement; which is, to enhance the responsible control center’s situational awareness of reliability dangers to the power system. Please note that this requirement’s wording has also been altered to change the designation “Transmission Operator” to the “responsible control center” to better identify the appropriate party. The salient requirement of an imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Organization	Agree?	Question 7 Comment
Duke Energy Corporation	Disagree	Duke believes that Transmission Owners should have a Vegetation Imminent Threat Procedure, and "Vegetation Imminent Threat" should be a defined term, defined as: "Vegetation observed in the field encroaching upon a conductor within a distance that is twice the Gallet clearance distances referenced in Table I of the draft standard FAC-003-2." In this case, the threat would require an immediate response and would include communication to the Transmission Operator. From there, the actions that the operator decides to take will be dependent on the incident and system conditions. We do not need to be prescriptive with this requirement but rather allow the Transmission Operator and appropriate field personnel the flexibility to make the right decisions to safely, promptly and appropriately remove the vegetation threat. From a Transmission Owner's perspective, many situations can constitute an imminent threat but this approach will clearly define a "Vegetation Imminent Threat" as it relates to the Purpose of this standard. See our related comment on #11 below.
Response: Thank you for your comment. While we do not agree that an imminent threat should be defined in the Standard, we do agree with your assessment that the Standard needs an imminent threat requirement, but as it was written, the requirement was overly prescriptive. As a result, and because much of the industry agreed with you, we have made some major changes to this requirement. The Critical Clearance Zone methodology has been deleted from the Standard. The main purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of reliability dangers to the power system. Please note that the requirement wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to better identify the appropriate party. The salient requirement of an imminent threat procedure is notification of the responsible operator of any potential threat to the power system. Beyond this, it is left to the Transmission Owner to determine the "triggers", follow up activities, and procedures that best fit its system; thereby providing for the flexibility that you have suggested. The SDT feels this is a better approach than to have a rigid definition of an imminent threat procedure.		
Entergy Services	Disagree	1. The requirement should state that each Transmission Owner will be responsible for creating and maintaining a Vegetation Imminent Threat Process. This process will clearly define how the Transmission Owner defines a vegetation imminent threat. 2. The requirement needs to state that only vegetation conditions identified, to the Transmission Owner, by regular field inspections, including aerial inspections, and other internal and external verifiable reports of vegetation imminent threats will be managed through this process. 3. If the standard requires a process to mitigate potential immediate threats to the system, the term ?vegetation imminent threat? must be defined. This definition must not delineate the precise steps that are required to be taken to allow experts as many options as necessary to address each vegetation condition specifically. 4. The list of possible mitigating actions should be removed from the standard since it is not an all inclusive list. Listing these actions in the standard may imply that the entity must do one or all of the actions to be in compliance. The entity must have sufficient latitude to evaluate each possible vegetation condition and apply the most appropriate mitigation steps, up to and including the removal of the identified vegetation.

Organization	Agree?	Question 7 Comment
Response: Thank you for your comments. **1. The SDT prefers to allow the verbiage "an imminent threat of a vegetation-related Sustained Outage" to stand without further definition. The SDT agrees that the Standard needs an imminent threat requirement. However, as it was written for the initial posting, the requirement was overly prescriptive. As a result, and because much of the industry agreed with you, the SDT has made some changes to this requirement. The main purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of reliability dangers to the power system. Please note that the requirement wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to permit communication with the relevant entity for the Transmission Owner. The salient requirement of an imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to determine the "triggers", follow up activities, and procedures that best fit its system, thereby providing for the flexibility that you have suggested. The SDT feels this is a better approach than to have a rigid definition of an imminent threat procedure.** **2. See response 1 above.** **3. See response 1 above.** **4. See response 1 above.**		
Salt River Project	Disagree	Agree with R1.4, however with the suggested change: Remove the language "?and may include actions such as a temporary reduction in line Rating, switching lines out of service, or other actions.". Any standard should not contain advisory-type language, it should be declarative in tone. The suggested actions are not the responsibility of the vegetation management program.
Response: Thank you for your comment. The advisory type language has been removed from the requirement as you have suggested. The SDT also agrees that these "advisory" actions could fall outside the responsibility of some utilities' Transmission Vegetation Management Program. The main purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of reliability dangers to the power system. Please note that this requirement's wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to better identify the appropriate party. The salient requirement of an imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to determine the follow up activities and procedures that best fit its situation.		
Northeast Utilities	Disagree	Agree with the need to have and implement when necessary an imminent threat procedure. Disagree with the need to implement the imminent threat procedure merely because a Critical Clearance Zone is being approached, as required by R2. Is there a desired distance from the Critical Clearance Zone where this procedure must be implemented, since all vegetation within a right-of-way will "approach" the Critical Clearance Zone as it grows? How will time of year and operating conditions be factored in, which may change the requirements to perform control during periods of low temperature or low load? It would not be necessary to perform all the requirements of an imminent threat procedure when there is adequate clearance to schedule the

Organization	Agree?	Question 7 Comment
		work without jeopardizing the reliability of the system. For example, in mid winter a line is 8 feet from a tree - there is little chance of the line reacing maximum sag at that time of year and the present condition does not constitute an imminent threat at that time. Also, disagree with the requirement for the imminent threat procedure to include actions that could be taken by the Transmission OwnerP (reduction in line rating, switching). The requirement should be limited to notifications to the Transmission OwnerP, since decisions on what specific system operating actions to take are beyond the responsibility of the Transmission Owner. The decision on what actions to take needs to be performed either by the Transmission OwnerP, or by the Transmission OwnerP in conjunction with the Transmission Owner.
Response: Thank you for your comments. We agree with your comments concerning the Critical Clearance Zone and the elusiveness of the term "approach". Subsequently, the Critical Clearance Zone methodology as it refers to the imminent threat process has been removed from the Standard. The SDT also agrees that the main purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of the power system's status. . Please also note that the wording has been altered to change the "Transmission Operator" to the "responsible control center" to better identify the appropriate responsible party. The salient requirement of an imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to develop an imminent threat procedure that best fits its system, and allows the Transmission Owner to make appropriate decisions on follow up actions.		
Hydro-Quebec Transenergie (HQT)	Disagree	While we strongly agree that an imminent threat procedure should be required in the Transmission Vegetation Management Program, we disagree with some specific wording in R1.4. R1.4 requires immediate communication of an imminent threat to the Transmission Operator, which we would normally agree with. R2 however requires that the imminent threat procedure be implemented when the Critical Clearance Zone (Critical Clearance Zone) is approached by vegetation. "Approached" is not defined as a specific distance, so this part of the requirement is left up to the individual's interpretation. In cases where the Critical Clearance Zone is approached by vegetation no threat to the system is possible if the vegetation is removed before it actually grows into the Critical Clearance Zone . In many cases the vegetation can be removed without taking clearance outages because the Critical Clearance Zone is large, and the conductor and vegetation are still relatively far apart. In such cases there is no need to notify the Transmission Operator, although there is a need to remove the vegetation immediately. We recognize that the opposite is also true, and that in some cases it will be necessary to notify the Transmission Operator because a clearance outage or line de-rating may be required to remove the vegetation. We therefore suggest a simple change to the wording of the second sentence of R1.4. Change "?. specify actions which shall include immediate communication of the threat to the Transmission Operator, and may include actions such as a temporary reduction in line Rating, switching lines out of service, or other actions" to ".. specify actions which may include immediate communication of the threat to the Transmission Operator, a temporary reduction in line Rating, switching lines out of service, or other actions". This change will address the issue which is described above and will allow each Transmission Operator to develop an imminent threat procedure that best fits their system. It should also be noted that many Transmission Operators have imminent threat procedures in place to address all imminent threats to their transmission system,

Organization	Agree?	Question 7 Comment
		not just threats due to vegetation. It makes sense for Transmission Owners to have only one imminent threat process; therefore the flexibility that can be achieved in the context of this standard would be helpful.
Response: Thank you for your comments. We agree with your comments concerning the Critical Clearance Zone and the elusiveness of the term “approach”. Subsequently, the Critical Clearance Zone methodology has been removed from the Standard. The SDT feels that the main purpose of the imminent threat requirement is to enhance the responsible control center’s situational awareness of the power system’s status. The wording about other follow up actions that could be taken has been removed from the requirement. Please also note that the wording has been altered to change the “Transmission Operator” to the “responsible control center” to better identify the appropriate responsible party. The SDT maintains that the salient requirement of an imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to develop an imminent threat procedure that best fits its system.		
Pepco Holdings, Inc	Disagree	While an imminent threat procedure is prudent and reasonable, it does not need to consider a Critical Clearance Zone as addressed in our comments on other questions. In fact, one can quickly provide examples of imminent threats when the threat is not even on the right of way. The Transmission Owner should simply have an imminent threat procedure to address identified imminent or potential imminent threats.
Response: Thank you for your comment. We agree with your comments concerning the Critical Clearance Zone methodology. Subsequently, the Critical Clearance Zone methodology has been removed from the Standard. The SDT feels that the main purpose of the imminent threat requirement is to enhance the responsible control center’s situational awareness of the power system’s status. Please also note that the requirement wording has been altered to change the “Transmission Operator” to the “responsible control center” to better identify the appropriate responsible party. The SDT maintains that the salient requirement of an imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, the SDT agrees that it should be left to the Transmission Owner to develop an imminent threat procedure that best fits its system.		
Southern California Edison Company	Agree	Q7: SCE agrees in part with the content of R1.4 because of its similarity to existing requirement R1.5 in FAC-003-1. However, we disagree with the drafter’s inclusion of peripheral information following the first sentence. We also note that the second sentence of proposed R1.4 includes both a requirement and a recommendation. SCE believes this and similar recommendations are best suited for the supporting technical paper. SCE respectfully suggests that R1.4 be revised to read: "Specify a process or procedure for communicating an impending vegetation-to-line contact that may result in a sustained outage and the appropriate response measures.”
Response: Thank you for your comment. The SDT feels that the main purpose of the imminent threat requirement is to enhance the responsible control center’s situational awareness of the power system’s status. We agree with your suggestions to exclude some of the peripheral language included in this requirement. Thus, the SDT has removed references to the Critical Clearance Zone, the word “immediate”, and the wording referring to other actions that may be taken by the responsible operator. Please also note that the wording has been altered to change the “Transmission		

Organization	Agree?	Question 7 Comment
Operator" to the "responsible control center" to better identify the appropriate responsible party.		
Western Utility Arborists	Agree	We agree with 1.4, with the following qualification: Any standard that is developed should not contain advisory-type language" it should be declarative in tone. For example, in R1.4, the ending clause that begins "and may include actions" should be removed because it is advisory in nature. The suggested actions are not even the responsibility of the vegetation management program.
Response: Thank you for your comments. The advisory type language has been removed from the requirement as you have suggested. The SDT also agrees that these "advisory" actions could fall outside the responsibility of some utilities' Transmission Vegetation Management Program. The main purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of reliability dangers to the power system. Please note that this requirement's wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to better identify the appropriate party. The salient requirement of an imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to determine the follow up activities and procedures that best fit its situation.		
Bonneville Power Administration	Agree	BPA agrees with 1.4, with the following change. The ending phrase: "and may include actions such as a temporary reduction in line Rating, switching lines out of service, or other actions" should be eliminated. Not only does BPA feel it is inappropriate to use advisory-type rather than declarative language in a Standard, BPA feels it is also questionable to give examples of imminent response actions that are often not within the direct capability of a vegetation program to enact. Eliminating the reference to these possible actions leaves it up to the Transmission Operator to decide what the eminent threat response is.
Response: Thank you for your comment. The advisory type language has been removed from the requirement as you have suggested. The SDT also agrees that these "advisory" actions could fall outside the direct capability of some utilities' Transmission Vegetation Management Program. The main purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of reliability dangers to the power system. Please note that this requirement's wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to better identify the appropriate party. The salient requirement of an imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to determine the follow up activities and procedures that best fit its situation.		
FirstEnergy	Agree	The safety of the personnel required to remove a tree or vegetation on or near an energized conductor must be considered when implementing the imminent threat procedure. Although this is a reliability standard, the safety of the personnel may be one "trigger" to implement the imminent threat procedure. That being said, the workers on site, in their judgment, are not able to remove the vegetation safely then the imminent threat procedure would be implemented. See comments for Critical Clearance Zone .
Response: Thank you for your comment. The SDT also believes human safety must be major consideration in this requirement. The Transmission		

Organization	Agree?	Question 7 Comment
Owner may include in its Imminent Threat procedure appropriate considerations for personnel safety as a trigger. The main purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of reliability dangers to the power system. The SDT made major changes to make the requirement less prescriptive. Also, the wording has been altered to change the designation "Transmission Operator" to the "responsible control center" to better identify the appropriate party. The salient requirement of an imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to determine the follow up activities and procedures that best fit its situation. The Critical Clearance Zone methodology has been removed from the Standard.		
MRO NERC Standards Review Subcommittee	Agree	The MRO agrees and believes that it is very important for the applicable entities to posses a Imminent Threat Procedure. The MRO also believes that the term "Imminent Threat" is subjective an should be defined.
Response: Thank you for your comment. We have made some major changes to this requirement due to the overwhelming response from industry that the imminent threat requirement was needed, as long as it was not an overly prescriptive requirement. We do not agree that an imminent threat should be defined in the Standard. The main purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of reliability dangers to the power system. Please note that the requirement wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to better identify the appropriate party. The salient requirement of an imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to determine the follow up activities and procedures that best fit its system. The SDT feels this is a better approach than to have a rigid definition of an imminent threat procedure.		
Western Area Power Administration, Rocky Mountain Region	Agree	The Technical Reference document could be expanded to explain that a well rounded Imminent Threat Procedure should contain many mitigation alternatives to appropriately address a wide range of field situations, including a "no immediate field action is required" option. For example, further investigation of a potential imminent threat situation may reveal that the situation has been erroneously reported or incorrectly measured and therefore no immediate vegetation removal actions are required. A utility's Imminent Threat Procedure may also address situations beyond just vegetation related incidents.
Response: Thank you for your comment. The SDT agrees that many situations can constitute an imminent threat beyond just vegetation related incidents. The requirement has been rewritten to focus on the main purpose of the imminent threat requirement; which is to enhance the responsible control center's situational awareness of reliability dangers to the power system. Please note that this requirement's wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to better identify the appropriate party. The salient requirement of an imminent threat procedure is notification of the responsible operator of any potential threat to the power system. Beyond this, it is left to the Transmission Owner to determine the follow up activities and procedures that best fit the wide range of field situations that are possible to encounter.		
Platte River Power Authority	Agree	Imminent threat is not a defined term in the NERC Glossary of Terms so it could be construed as a fill-in-the-blank requirement by FERC as each Transmission Owner could define Imminent Threat differently. Imminent threat should be defined or the requirement should be reworded to define what types of situations would require a procedure. Also, the language, "and may include actions such as a temporary reduction in line rating, switching

Organization	Agree?	Question 7 Comment
		lines out of service, or other actions" should be removed from the standard but could be included in the imminent threat procedure or definition.
Response: The SDT has made some major changes to this requirement due to the overwhelming response from industry that the imminent threat requirement was needed, as long as it was not an overly prescriptive requirement. For instance, we agree that the wording referring to other follow up actions that may be taken by the operator is too prescriptive and has been removed from this requirement. **The main purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of reliability dangers to the power system. Please note that the requirement wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to better identify the appropriate party. The SDT feels this is a better approach than to have a rigid definition of an imminent threat procedure. The salient requirement of an imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to determine the follow up activities and procedures that best fit the wide range of field situations that are possible to encounter.**		
USDA Forest Service, Southwestern Region, Regional Office for AZ and NM	Agree	The USFS would be expecting the Transmission Owner to be documenting the imminent threat procedures in an operating plan or corridor management plan that would be approved by the designated USFS decision maker. If such procedures are documented in the Transmission Owner's Transmission Vegetation Management Program and are compatible with USFS resource management direction, then the imminent threat procedures could be incorporated in the agency-approved operating plan by reference. If the Transmission Owner disputes any restrictions that are placed by the USFS on the imminent threat procedures, the USFS has an administrative appeals process which the Transmission Owner can use, but those procedures can be time-consuming and probably would not be perceived by the Transmission Owner as being neutral for negotiation purposes. It might help if a third federal party like NERC could help resolve disputes between the Transmission Owner and the USFS on the imminent threat procedures. Although the USFS would object to unreasonable intrusion of NERC into normal USFS land management prerogatives, imminent threat procedures would seem to be a topic for which NERC should take a very strong position, especially with a standard that identifies minimum vegetation clearances as related to prevention of arcing potential, or in other words, vegetation that should be considered hazardous and in immediate need of treatment.
Response: Thank you for your comments. The SDT developed this standard to apply to Transmission Owners in support of bulk electric system reliability. While there may be similar areas of regulation between the purview of NERC and the USFS, this standard is not intended to be incompatible with any USFS resource management direction. That being said, any NERC standard approved by the FERC does not need to be incorporated into "the agency-approved operating plan". In regard to the suggestion that NERC assist in resolving disputes between USFS and Transmission Owners, this would be beyond the scope of NERC. **The SDT suggests that USFS and affected Transmission Owners review language in permits and change that language to allow perpetual ingress and egress and vegetation maintenance without case-by-case application and review. Such a change would prevent current problems where it takes**		

Organization	Agree?	Question 7 Comment
upwards of one year before vegetation maintenance is allowed to proceed. **The SDT has made some major changes to this requirement due to the overwhelming response from industry that the imminent threat requirement was needed, as long as it was not an overly prescriptive requirement. For instance, we agree that the wording referring to other follow up actions that may be taken by the operator is too prescriptive and has been removed from this requirement.** **The main purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of reliability dangers to the power system. Please note that the requirement wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to better identify the appropriate party. The SDT feels this is a better approach than to have a rigid definition of an imminent threat procedure. The salient requirement of an imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to determine the follow up activities and procedures that best fit the wide range of field situations that are possible to encounter.**		
Manitoba Hydro	Agree	Suggest removing, "and may include actions such as a temporary reduction in line rating, switching lines out of service, or other actions", as this is outside the scope of a vegetation management program.
Response: Thank you for your comment. The language you mention has been removed from the requirement as you have suggested. The SDT agrees that these actions could fall outside the scope of some utilities' Transmission Vegetation Management Program. The main purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of reliability dangers to the power system. Please note that this requirement's wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to better identify the appropriate party. The salient requirement of an imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to determine the follow up activities and procedures that best fit its situation.		
Pacific Gas & Electric Co.	Agree	PG&E agrees an imminent threat procedure is a critical component of the standard and should be contained in the Transmission Vegetation Management Program. See additional comments for Q11.
Response: Thank you for your comment. See the responses to comments on Q11.		
NV Energy (fka Sierra Pacific / Nevada Power Co.)	Agree	We agree with 1.4, with the following qualification: Any standard that is developed should not contain advisory-type language? it should be declarative in tone. For example, in R1.4, the ending clause that begins "and may include actions" should be removed because it is advisory in nature. The suggested actions are not even applicable under the scope of a vegetation management program.
Response: Thank you for your comment. The advisory type language has been removed from the requirement as you have suggested. The SDT also agrees that these "advisory" actions could fall outside the scope of some utilities' Transmission Vegetation Management Program. The main purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of reliability dangers to the power system.		

Organization	Agree?	Question 7 Comment
Please note that this requirement's wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to better identify the appropriate party. The salient requirement of an imminent threat procedure is notification of the responsible operator of any potential threat to the power system. Beyond this, it is left to the Transmission Owner to determine the follow up activities and procedures that best fit its situation		
San Diego Gas & Electric	Agree	We recommend that any advisory language be removed, and replaced with a declaration to the utilities.
Response: Thank you for your comment. The advisory type language has been removed from the requirement as you have suggested, The remaining declaratory language addresses the main purpose of the imminent threat requirement which is to enhance the responsible control center's situational awareness of reliability dangers to the power system. Please note that this requirement's wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to better identify the appropriate party. The salient requirement of an imminent threat procedure is notification of the responsible operator of any potential threat to the power system. Beyond this, it is left to the Transmission Owner to determine the follow up activities and procedures that best fit its situation		
WECC	Agree	But for clarity, "Imminent Threat Procedure" should be replaced with "Vegetation Imminent Threat Procedure".
Response: Thank you for your comment. The SDT believes that the context is sufficiently clear.		
Arizona Public Service Company	Agree	APS agrees with 1.4, with the following qualification: Any standard that is developed should not contain advisory-type language? it should be declarative in tone. For example, in R1.4, the ending clause that begins "and may include actions" should be removed because it is advisory in nature. The suggested actions are not even the responsibility of the vegetation management program.
Response: Thank you for your comment. The advisory type language has been removed from the requirement as you have suggested. The SDT also agrees that these "advisory" actions could fall outside the responsibility of some utilities' Transmission Vegetation Management Program. The main purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of reliability dangers to the power system. Please note that this requirement's wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to better identify the appropriate party. The salient requirement of an imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to determine the follow up activities and procedures that best fit its situation.		
Baltimore Gas & Electric Company	Agree	This requirement references Danger trees which according to ANSI A-300, Part 7 is any tree that could fall on the conductor. Should this more appropriately be changed to Hazard tree which is a structurally unsound tree? It might be helpful if an imminent threat were defined, e.g. trees that are presently encroaching in or near the Critical Clearance Zone , or trees that by virtue of their hazardous condition appear to be likely to fall into or near the Critical Clearance Zone in the near future. (or just leave the explanation to the White Paper)

Organization	Agree?	Question 7 Comment
Response: Thank you for your comment. We agree with most of your comments and have made some major changes to this requirement due to the overwhelming response from industry that the imminent threat requirement was needed, as long as it was not an overly prescriptive requirement. Many situations can constitute an imminent threat, "danger" or "hazard" trees being only one of those situations. Further, due to the undefined "triggers" associated with the Critical Clearance Zone methodology, this approach has been removed from the Standard. **The main purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of reliability dangers to the power system. Please note that this requirement's wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to better identify the appropriate party. The salient requirement of an imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to determine the "triggers", follow up activities, and procedures that best fit its situation. The SDT feels this is a better approach than to have a rigid definition of an imminent threat.**		
JEA	Agree	It is appropriate to require procedures to respond to "emergency" conditions; however Imminent Vegetation Threat should be a defined term.
Response: Thank you for your comment. The SDT prefers to allow the verbiage "an imminent threat of a vegetation-related Sustained Outage" to stand without further definition.		
BCTC	Agree	We agree with 1.4, with the following qualification: Any standard that is developed should not contain advisory-type language—it should be declarative in tone. For example, in R1.4, the ending clause that begins "…and may include actions…" should be removed because it is advisory in nature. The suggested actions are not even the responsibility of the vegetation management program.
Response: Thank you for your comment. The advisory type language has been removed from the requirement as you have suggested. The SDT also agrees that these "advisory" actions could fall outside the responsibility of some utilities' Transmission Vegetation Management Program. The main purpose of the imminent threat requirement is to enhance the responsible control center's situational awareness of reliability dangers to the power system. Please note that this requirement's wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to better identify the appropriate party. The salient requirement of an imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to determine the follow up activities and procedures that best fit its situation.		
Great River Energy	Agree	GRE agrees and believes that it is very important for the applicable entities to posses an Imminent Threat Procedure. GRE recommends that the Imminent Threat procedure be renamed "Vegetation Imminent Threat Procedure" so as to clearly identify the procedure in the event that a company has imminent threat procedures for more than one situation.
Response: Thank you for your comment. We agree that many situations can constitute an imminent threat; however, the SDT did not rename the		

Organization	Agree?	Question 7 Comment
overall procedure as you have suggested. It is acceptable to have the imminent threat procedure for this standard included in a larger corporate procedure or set of procedures that address a wider array of threats. Instead the requirement has been rewritten to focus on the main purpose of the imminent threat requirement; which is to enhance the responsible control center's situational awareness of reliability dangers to the power system. Please note that this requirement's wording has also been altered to change the designation "Transmission Operator" to the "responsible control center" to better identify the appropriate party. The salient requirement of an imminent threat procedure is notification of the responsible operator of any imminent threat to the power system. Beyond this, it is left to the Transmission Owner to determine the follow up activities and procedures that best fit its situation. The SDT feels that this approach allows the Transmission Owner the flexibility to have imminent threat procedures for more than one situation which remain outside the specific requirements of the vegetation Standards.

Hydro One Networks Inc.	Agree	
Edison Electric Institute	Agree	
CenterPoint Energy	Agree	
Buckeye Power, Inc.	Agree	

8. Requirement 1 section R1.5 replaces Version 1 sub-requirement R1.4. This section is now referred to as interim corrective action process. This process addresses situations where vegetation maintenance activities cannot be performed as planned. The term corrective action plan is used in lieu of mitigation plan to avoid confusion with other uses in NERC of "mitigation plan". Do you agree with R1.5? If not, please explain.

Summary Consideration: Many of the stakeholders asked about the use of the word "interim" in R1.5 and what a constraint is. The SDT explains that 1.3 of the version 2 standard is intended to allow Transmission Owners to adjust the annual work plan to reflect such changes as a long term fix. Part 1.5 is intended to address an interim constraint such as customer refusals, governmental agency imposed restrictions, etc. To help clarify, the SDT added the word "temporarily" to the language noted in requirement R1.5. The SDT also added a new requirement R1.6 to address long term strategies.

1.5 Specify an interim corrective action process for use when the Transmission Owner is temporarily constrained from performing vegetation maintenance as planned.

1.6 Specify the maintenance strategies used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that Table 1 clearances in Attachment 1 are never violated. The maintenance strategies shall consider the sag and sway of the conductor throughout its operating range under rated conditions.

Organization	Agree?	Question 8 Comment
Western Area Power Administration, Rocky Mountain Region		The specifics of a "plan" as required by R1.4 in version 1 of the Standards has been replaced with the generalities of a "process" required by R1.5 in version 2 of the Standards. At the time of an audit, the adequacy of a general process is harder to measure than the adequacy of the specific mitigation measures that were previously required by R1.4 in version 1 of the Standards. It is unclear what an auditor will be looking for to determine compliance with R1.5 - will the auditor be looking for generalities or specifics? Further, if a utility has documented their interim corrective action process, but it is not followed, is this a violation of the Standards?
Response: Thank you for your comments. The SDT intended to require a documented process for Transmission Owners to develop plans which address instances such as customer refusals, government agency imposed constraints, etc. It is not intended solely for situations where initial desired clearances could not be achieved (as in requirement R1.4 of version 1 of FAC-003). The measure for Interim Corrective Action requires it be included in the Transmission Vegetation Management Program and failure to do so would be a violation.		
City of Tallahassee	Disagree	The use of the term "interim corrective action" implies that a permanent solution or return to the original plan must be pursued. I would change this to "alternate maintenance" process to prevent non-compliance if the Transmission Owner is constrained and has reached an agreement with the land owner that works to maintain

Organization	Agree?	Question 8 Comment
		the reliability of the line.
Response: Thank you for your comment. Requirement R1, Part 1.5 requires the Transmission Owner to specify a process in its Transmission Vegetation Management Program that the Transmission Owner may use when vegetation maintenance work is temporarily constrained. Constraints may include temporary situations such as caused by customer refusals, governmental agency imposed restrictions, etc. If a Transmission Owner reaches an agreement for "alternate maintenance" in these situations, Requirement R1,Part 1.3.3 allows for adjustment of the annual work plan. Alternative maintenance actions as suggested are now addressed in new Requirement R1,Part 1.6 as noted above in the consideration of comments to address long term maintenance strategies to ensure Table 1 clearance distances are never violated.		
Northern Indiana Public Service Company	Disagree	The existing R1.4 is focused on identifying where vegetation clearance objectives cannot be met at the time UVM work is performed due to restrictions outside of the Transmission Owner's immediate control. The proposed revised standard is focused on situations where work scheduled in the annual plan cannot be performed as planned for any reason. Can a constraint on planned work be internal such as budget related? Why bother with a corrective process for constrained planned work if the work not completed as planned poses no risk of causing an outage? I strongly believe that the sole focus of this provision must specifically address individual locations where, due to restrictions outside of the Transmission Owner owner's control, vegetation clearances specified in the Transmission Vegetation Management Program cannot be obtained. This section of the standard should be about trees being closer to conductors than they should be due to factors beyond the Transmission Owner's control, rather than whether or not planned work was performed.
Response: Thank you for your comments. Interim corrective actions are intended to address situations such as customer refusals, governmental agency imposed constraints, etc. Requirement R1, Part 1.3 requires that the annual work plan shall be documented and Requirement R1, Part 1.3.3 permits adjustments to the annual work plan. A Requirement R1, Part 1.6 was added to address long term maintenance strategies to ensure Table 1 clearance distances are never violated.		
Tampa Electric Company	Disagree	The phrasing above references a "corrective action plan". However, the standard as written is stated as an "interim corrective action process". These are not one and the same. Interim implies a truly temporary condition. As described on page 21 of the Technical reference, however, some of these operational issues may not be "interim".
Response: Thanks for your comments. The SDT agree that "interim" should have been included in the question. The Technical Reference document does not appear to be in conflict with this. To add clarity the SDT added the word temporarily to Requirement R1, Part 1.5 and long term strategies are addressed in new Requirement R1, Part 1.6 a to address long term maintenance strategies to ensure Table 1 clearance distances are never violated.		
Manitoba Hydro	Disagree	Agree with the change in terminology - but would suggest that wording clarify that this is not only for situations where the utility is unexpectedly prevented from implementing its annual plan - but also for areas where it is

Organization	Agree?	Question 8 Comment
		unable to implement its clearance requirements due to property rights limitations.
Response: Thank you for your comment. Requirement R1, Part 1.5 requires the Transmission Owner to specify a process in its Transmission Vegetation Management Program that the Transmission Owner may use when vegetation maintenance work is <u>temporarily</u> constrained. Constraints may include temporary situations such as caused by customer refusals, governmental agency imposed restrictions, etc. Requirement R1, Part 1.6 was added to address long term maintenance strategies to ensure Table 1 clearance distances are never violated.		
National Grid	Disagree	National Grid agrees replacing mitigation plan with corrective action process. However, National Grid questions the use of "interim" for a corrective action process in R1.5, and suggests striking "interim".
Response: Thank you for your comment. Requirement R1, Part 1.5 requires the Transmission Owner to specify a process in its Transmission Vegetation Management Program that the Transmission Owner may use when vegetation maintenance work is <u>temporarily</u> constrained. Constraints may include temporary situations such as caused by customer refusals, governmental agency imposed restrictions, etc. To add clarity the SDT added the word "temporarily" to Requirement R1, Part 1.5.		
CenterPoint Energy	Disagree	Since there is no longer a reference to defined clearances in the Standard, it is unclear under what specific "constrained" conditions R1.5 applies. R1.5 does not have a sister requirement for implementation within the Standard which implies it has a diminished value. R1.5 and M1.5 should be deleted as a requirement and measure, but should be footnoted as best practice as was ANSI A300 in R1.1.
Response: Thank you for your comments. The SDT intended to require a documented process for Transmission Owners to develop plans which address instances such as customer refusals, government agency imposed constraints, etc. It is not intended solely for situations where initial desired clearances could not be achieved (as in requirement R1.4 of version 1 of FAC-003). A new Requirement R1, Part1.6 was added to address long term maintenance strategies to ensure Table 1 clearance distances are never violated.		
American Transmission Company	Agree	ATC agrees with the concept but disagrees with the proposed language. ATC believes the term "interim" should be removed from R 1.5. In some cases, a corrective action can end up being a long term/normal fix. Proposed Language: Specify a corrective action process that will be used when established clearances or methodologies are altered.
Response: Requirement R1, Part 1.3 requires that the annual work plan shall be documented. Requirement R1, Part 1.3.3 permits adjustments to the annual work plan. A long term fix would be an adjustment to the annual work plan. In Requirement R1, Part 1.5, the SDT intended to require a documented process for Transmission Owners to develop plans which address instances such as customer refusals, government agency imposed constraints, etc. It is not intended solely for situations where initial desired clearances could not be achieved (as in requirement R1.4 of version 1 of FAC-003). To add clarity the SDT added the word "temporarily" to Requirement R1, Part 1.5. Long term strategies are addressed in new requirement R1.6 as noted above in the consideration of comments to address long term maintenance strategies to ensure Table 1 clearance distances are never		

Organization	Agree?	Question 8 Comment
violated.		
Southern California Edison Company	Agree	Q8: SCE agrees in part with the revisions to R1.5, including the proposed phrase "corrective action process". However, we do not believe it is necessary to include the term "Transmission Owner" in the sentence because the entire standard is clearly applicable to Transmission Owners. SCE respectfully suggests that proposed R1.5 be revised to read: "Specify an interim corrective action process for use when planned vegetation maintenance is deterred."
Response: Thank you for your comment. The SDT considered your suggested language and feels the language used in the draft standard is appropriate in order to maintain consistency with other parts of the standard.		
Western Utility Arborists	Agree	Yes, we agree.
Response: Thank you for your participation.		
FirstEnergy	Agree	We agree with the concept of a corrective action plan. However, it is not clear what flexibility the Transmission Owner is afforded in making adjustments to the work plan that may carry over from one calendar year to the next. Legal issues with property owners or other factors may prevent the utility from carrying out the work plan as scheduled. Also, we question the use of the term "constrained". It should be clear as to what constitutes appropriate or valid constraints.
Response: Thank you for your comments. Requirement R1, Part 1.3.3 permits adjustments to the annual work plan. As to your next concern, Requirement R1, Part 1.5 requires the Transmission Owner to specify a process in its Transmission Vegetation Management Program that the Transmission Owner may use when vegetation maintenance work is temporarily constrained. Constraints may include temporary situations such as caused by customer refusals, governmental agency imposed restrictions, etc. Refer to the Technical Reference document for additional information.		
MRO NERC Standards Review Subcommittee	Agree	The MRO believes that the term "interim" should be removed from R1.5. The term Interim is subjective.
Response: Thank you for your comment. The SDT uses “interim” to convey the temporary nature of these situations. To add clarity the SDT added the word “temporarily” to Requirement R1. Part 1.5 and a new Requirement R1, Part 1.6 was added to address long term maintenance strategies to ensure Table 1 clearance distances are never violated.		
Tennessee Valley Authority	Agree	TVA agrees with Comment Question 8
Response: Thank you for your participation.		

Organization	Agree?	Question 8 Comment
Platte River Power Authority	Agree	The term corrective action plan adds clarity.
Response: Thank you for your participation.		
USDA Forest Service, Southwestern Region, Regional Office for AZ and NM	Agree	In my opinion, problems between the Transmission Owner and the USFS over the Transmission Vegetation Management Program should be worked out before a Transmission Vegetation Management Program is ever finalized. A dispute resolution process outside the control of either party would be very helpful and would probably facilitate quicker solutions than if the Transmission Owner and the USFS are left to work out problems on their own. If a Transmission Vegetation Management Program is prepared in a vacuum, the problems may not come to light until some kind of outage actually occurs. It would be much better to flush any disagreements and deal with them before any outages actually occur.
Response: Thank you for your comment. We agree with the sentiment of collaboration and cooperation expressed. We are somewhat constrained by the types of entities that must be subject to this standard. The USFS, as a government agency, is not under the purview of the FERC and is not compelled to comply with this standard however well intended. The SDT would support a dispute resolution process that resolves potential disagreements consistent with the purpose of this standard.		
BCTC	Agree	Yes, we agree.
Response: Thank you for your participation.		
Great River Energy	Agree	GRE believes that the term "interim" should be removed from R1.5. The term Interim is subjective.
Response: Thank you for your comment. Requirement R1, Part 1.5 requires the Transmission Owner to specify a process in its Transmission Vegetation Management Program that the Transmission Owner may use when vegetation maintenance work is temporarily constrained. Constraints may include temporary situations such as caused by customer refusals, governmental agency imposed restrictions, etc. To add clarity the SDT added the word temporarily to Requirement R1, Part 1.5 and long term strategies are addressed in new Requirement R1, Part1.6 to address long term maintenance strategies to ensure Table 1 clearance distances are never violated.

9. Clearance 1 in Version 1 was a "fill-in-the-blank" requirement and was removed from the standard. Do you agree? If not, please explain.

Summary Consideration: Most of the industry comments are in favor of removing the "fill-in-the-blank" requirement. Some disagreed, citing the benefit of having perceived leverage that a Clearance 1 afforded them. The SDT points out that ANSI A300 remains a "best practice" referenced in the proposed standard and may be useful in dealing with public and private parties. In addition, the SDT added Requirement R1.6:

1.6 Specify the maintenance strategies used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that Table 1 clearances in Attachment 1 are never violated. The maintenance strategies shall consider the sag and sway of the conductor throughout its operating range under rated conditions.

The SDT believes that Clearance 1 may be unnecessarily restrictive in stipulating conductor-to-vegetation distances (as some commenters have done to comply) and therefore removed Clearance 1 in favor of Requirement R1, Part 1.6. which specifically allows for vegetation-to-ground distances to be used while at the same time accounting for the sag and sway of the conductor throughout its operating range under rated conditions.

Organization	Agree?	Question 9 Comment
Florida Power & Light		FPL neither agrees or disagrees with this removal but provides the following comment. FPL's experience regarding Clearance 1 is that it was an effective way of demonstrating a measurable requirement for compliance when dealing with public entities. The use of a corrective action process to mitigate instances where this clearance was not met before violations occurred is also very effective in promoting reliability and safety in the Standard.
Response: Thank you for your comment. The SDT team acknowledges the comment with regard to the usefulness of Clearance 1 in dealing with public entities and has attempted to retain that capability in Requirement R1, Part 1.6. Furthermore the use of a corrective action process is retained in this latest version but is renamed as an "interim correction action" in lieu of "Mitigation Plan" to avoid confusion with a Compliance Program term.		
Western Utility Arborists	Disagree	The Western Utilities do not agree with the removal of Clearance 1. We recommend adding it back to the document, but reworded and moved to include it as a measurement (M), rather than a requirement (R) under the new standard. Many utilities feel that Clearance 1 provides justification and leverage for operational clearances when dealing with organizations such as municipalities. Without Clearance 1, utilities could be mandated in specific situations to clear so that the vegetation is just beyond the Critical Clearance Zone at all times. This could result in pruning at six month intervals, which is not feasible or cost-effective.

Organization	Agree?	Question 9 Comment
Response: Thank you for your comment. The SDT notes that information contained in a Measure would not be mandatory nor enforceable and therefore has minimal usefulness as leverage. The SDT points out that ANSI A300 remains a "best practice" referenced in the proposed standard and may be useful in dealing with the public and private parties. The addition of Requirement R1, Part 1.6 allows for vegetation-to-ground working distances to be used while at the same time accounting for the sag and sway of the conductor throughout its operating range under rated conditions. The SDT believes this is superior to Clearance 1 as this gives Transmission Owners more flexibility in how they can achieve the reliability objective of Requirement R1.		
Bonneville Power Administration	Disagree	BPA opposes removal of Clearance 1. Clearance 1 provides a regulatory justification for a Transmission Owner to apply and extend proactive vegetation threat prevention programs on its rights of way easements across municipal, state, tribal, other federal and private properties. In many cases, without the regulatory leverage of a Clearance 1 requirement, Transmission Owners would be limited to maintaining less effective and higher risk vegetation management practices where it has legal restrictions, then it presently can implement under the present version of FAC 003-01. BPA recommends that Clearance 1 be placed back into the document, but as a Measure and not a Requirement.
Response: Thank you for your comment. The SDT notes that information contained in a Measure would not be mandatory nor enforceable and therefore has minimal usefulness as leverage. The SDT points out that ANSI A300 remains a "best practice" referenced in the proposed standard and may be useful in dealing with the public and private parties. The addition of Requirement R1, Part 1.6 allows for vegetation-to-ground working distances to be used while at the same time accounting for the sag and sway of the conductor throughout its operating range under rated conditions. The SDT believes this is superior to Clearance 1 as this gives Transmission Owners more flexibility in how they can achieve the reliability objective of Requirement R1.		
Exelon	Disagree	We do not understand the reference to "fill in the blank" requirement for clearance 1. As commonly understood, a "fill in the blank" standard /requirement is one that was assigned to the RRO. Clearance 1 in FAC-003-1 is a Transmission Owner requirement. The reference to a clearing zone should be retained, as each Transmission Owner will need to define this in their program so as to avoid encroachments into the Critical Clearance Zone .
Response: Thank you for your comment. The choice of a Clearance 1 distance is left to each Transmission Owner and as such is characterized as a fill-in-the blank style requirement. The SDT team believes each Transmission Owner is free to set any working distances it deems appropriate in order to accomplish its Transmission Vegetation Management Program objectives.		
Central Maine Power Company	Disagree	Central Maine Power Company disagrees with removal of clearance 1. The clearance 1 was included so that professional arborists could establish the clearance necessary for a transmission owner to reduce the risk of a tree caused power outage. The transmission owner should use ANSI- Standard A300, including PART 7, and other publications to develop best management practices which include clearances at time of maintenance. Clearance 1 provides leverage for Transmission Owners to achieve the clearances stated in their Transmission

Organization	Agree?	Question 9 Comment
		Vegetation Management Program.
Response: Thank you for your comment. The SDT notes that information contained in a Measure would not be mandatory nor enforceable and therefore has minimal usefulness as leverage. The SDT points out that ANSI A300 remains a "best practice" referenced in the proposed standard and may be useful in dealing with the public and private parties. The addition Requirement R1, Part 1.6 allows for vegetation-to-ground working distances to be used while at the same time accounting for the sag and sway of the conductor throughout its operating range under rated conditions. The SDT believes this is superior to Clearance 1 as this gives Transmission Owners more flexibility in how they can achieve the reliability objective of Requirement R1.		
USDA Forest Service, Southwestern Region, Regional Office for AZ and NM	Disagree	If it is possible for NERC to identify minimum clearance standards as related to arcing potential for hazardous vegetation, it would definitely help USFS field administrators to have some kind of hard and fast standards. If that kind of approach is not reasonable in light of the need to adjust standards for various load conditions and vegetation growth rates, then a prescribed formula for calculating minimum clearances would be the next best thing.
Response: Thank you for your comment. The SDT proposes the table of Minimum Vegetation Clearance Distances in this revised version of the standard in Requirement R4, which prohibits vegetation encroachment inside minimum vegetation clearance distances that are developed with Gallet equations for flashover (arcing).		
National Grid	Disagree	National Grid takes exception to the term "fill-in-the-blank". National Grid disagrees with the elimination of Clearance 1. The Clearance 1 requirement in FAC-003-1 was meant to allow a Transmission Owner to establish clearances to be achieved at the time of vegetation management work, and be sensitive to local and regional conditions. National Grid believes that Clearance 1 is needed for public education and safety reasons. Clearance 1 standards allow utilities to specify a cyclic programmatic approach, and gives the utility leverage with local and state regulators and the public to achieve significantly larger than minimal clearances.
Response: Thank you for your comment. The choice of a Clearance 1 distance is left to each Transmission Owner and as such is characterized as a fill-in-the blank style requirement. The SDT team believes each Transmission Owner is free to set any working distances it deems appropriate in order to accomplish its Transmission Vegetation Management Program objectives. The SDT points out that ANSI A300 remains a "best practice" referenced in the proposed standard and may continue to be useful in dealing with the public and private parties. The addition of Requirement R1, Part 1.6 allows for vegetation-to-ground working distances which can be larger than minimal clearances to be used while at the same time accounting for the sag and sway of the conductor throughout its operating range under rated conditions. The SDT believes this is superior to Clearance 1 as this gives Transmission Owners more flexibility in how they can achieve the reliability objective of Requirement R1.		

<table>
<tr><th>Organization</th><th>Agree?</th><th>Question 9 Comment</th></tr>
<tr><td>Platte River Power Authority</td><td>Disagree</td><td>Clearance 1 could be defined in the standard in tables developed using IEEE Standards for various voltages, line spans and altitudes. Clearance 1 provides justification and leverage for operational clearances when dealing with organizations such as municipalities. Without Clearance 1, utilities could be mandated in specific situations to clear so that the vegetation is just beyond the Critical Clearance Zone at all times. This could result in pruning at six month intervals, which is not feasible or cost-effective.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment. The SDT proposes the table of Minimum Vegetation Clearance Distances in this revised version of the standard in Requirement R4, which prohibits vegetation encroachment inside minimum vegetation clearance distances that are developed with Gallet equations for flashover (arcing). The SDT believes this is superior to Clearance 1 as this gives Transmission Owners more flexibility in how they can achieve the reliability objective of Requirement R1.</td></tr>
<tr><td>Northern Indiana Public Service Company</td><td>Disagree</td><td>I am strongly opposed to the removal of Clearance 1 from the standard. Being able to point to this provision has been invaluable to internal communications with upper management and external discussions with land owners and the public concerning UVM. In fact, other than the patrol/inspection requirements, no other provision in the standard has been as essential to preventing grow-in tree contacts than Clearance 1. It has forced Transmission Owner's across the country to re-claim overgrown ROW and re-commit to consistent UVM practices. We all know how easy it is for Transmission Owner's to get weak in the knees in the face of public opposition to proper and prudent UVM work even when it is clear what needs to be done. This dynamic is what led us to the 2003 blackout to begin with. I would like to see the drafting team consider expanding upon the existing model and create three clearances:

1. A clearance at the time work is performed,

2. An action threshold clearance which would trigger the Transmission Owner would take immediate action to clear encroaching vegetation posing an unacceptable outage risk, and

3. A no closer than clearance in which vegetation would never be allowed to encroach in order to prevent flashover.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment. The SDT team acknowledges the comment with regard to the usefulness of Clearance 1 to internal communications and in dealing with public entities and has attempted to retain that capability Requirement R1. Part 1.6. The addition of Requirement R1, Part 1.6 allows for vegetation-to-ground working distances to be used while at the same time accounting for the sag and sway of the conductor throughout its operating range under rated conditions. The SDT believes this is superior to Clearance 1 as this gives Transmission Owners more flexibility in how they can achieve the reliability objective of Requirement R1.</td></tr>
</table>

Organization	Agree?	Question 9 Comment
In regard to working distances or as you put it , each Transmission Owner continues to able to set any working distances it deems appropriate in order to accomplish its Transmission Vegetation Management Program objectives when complying with Requirement R1, Part 1.6. **With respect to your 3rd comment, the proposed version of the standard has Requirement R4, which prohibits vegetation encroachment inside Minimum Vegetation Clearance Distances that are developed with Gallet equations for flashover.**		
NV Energy (fka Sierra Pacific / Nevada Power Co.)	Disagree	We do not agree with the removal of Clearance 1. We recommend adding it back to the document, but reworded and moved to include it as a measurement (M), rather than a requirement (R) under the new standard. Many utilities feel that Clearance 1 provides justification and leverage for operational clearances when dealing with organizations such as municipalities. Without Clearance 1, utilities could be mandated in specific situations to clear so that the vegetation is just beyond the Critical Clearance Zone at all times. This could result in pruning at six month intervals, which is not feasible or cost-effective.
Response: Thank you for your comment. The SDT notes that information contained in a Measure would not be mandatory nor enforceable and therefore has minimal usefulness as leverage. The SDT points out that ANSI A300 remains a "Best Practice" referenced in the proposed standard and may be useful in dealing with the public and private parties. The addition of Requirement R1, Part 1.6 allows for vegetation-to-ground working distances to be used while at the same time accounting for the sag and sway of the conductor throughout its operating range under rated conditions. The SDT believes this is superior to Clearance 1 as this gives Transmission Owners more flexibility in how they can achieve the reliability objective of Requirement R1.		
San Diego Gas & Electric	Disagree	We do not agree with the removal of Clearance 1. We recommend that it be added back into the document, but reworded and moved so it be included as a measurement, rather than a requirement. Without Clearance 1, utilities could be mandated in specific situations to clear so that vegetation is just beyond the Critical Clearance Zone at all times, which is not feasible or cost effective.
Response: Thank you for your comment. The SDT notes that information contained in a Measure would not be mandatory nor enforceable and therefore has minimal usefulness as leverage. The SDT points out that ANSI A300 remains a "Best Practice" referenced in the proposed standard and may be useful in dealing with the public and private parties. The addition of Requirement R1, Paart 1.6 allows for vegetation-to-ground working distances to be used while at the same time accounting for the sag and sway of the conductor throughout its operating range under rated conditions. The SDT believes this is superior to Clearance 1 as this gives Transmission Owners more flexibility in how they can achieve the reliability objective of Requirement R1.		
Hydro One Networks Inc.	Disagree	We would agree only if the standard is revised to include the removal of incompatible vegetation as outlined in our response to question 3 above. If not, then added direction or requirements are needed to introduce the elements that combine (to a greater degree than exists under the revised standard) reliability and vegetation management. Clearance 1 accomplished this to some degree.

Organization	Agree?	Question 9 Comment
Response: Thank you for your comment. The SDT considered the insertion of the phrase “incompatible vegetation” however decided against it because incompatibility may be arguable and add to disagreement among interested parties. The SDT agrees with the commenter that all vegetation that is identified by the annual work plans and maintenance strategies should be targeted for removal. Each Transmission Owner is free to use any effective approach it deems appropriate in order to accomplish its Transmission Vegetation Management Program objectives. The proposed version of the standard has Requirement R4, which prohibits vegetation encroachment inside Minimum Vegetation Clearance Distances that are developed with Gallet equations for flashover.		
Arizona Public Service Company	Disagree	APS disagrees with removal of clearance one. Clearance one should be achieved at time of maintenance which is part of the vegetation program. This gives leverage with dealing with state and federal agencies, tribal and private landowners. This isn't a fill in the blank requirement, however it should be based on sound science in regards to vegetation management. A professional arborist/forester can determine the appropriate amount of vegetation that needs to be obtained at the time of maintenance. APS suggest the following language change for clearance 1. The Transmission Owner shall maintain ROW on Federal, State, Tribal and Private lands in accordance with ANSI-Standard A300 (Part 1)-2001 and (Part 7)-2006 in consultation with companion publication Best Management Practices: Integrated Vegetation Management, 2007. If all utilities followed this standard this would increase the reliability of the bulk electric system and reduce the risk of vegetation outages.
Response: Thank you for your comment. The SDT agrees that any requirement must be based on sound science and believes the Transmission Owner will continue to able to set any working distances it deems appropriate in order to accomplish its Transmission Vegetation Management Program objectives when complying with Requirement R1, Part 1.6. The stipulation that the Standard applies to Federal, State, Tribal and Private Lands is contained in the Applicability section. The SDT points out that ANSI A300 remains a “best practice” referenced in this standard and as such may be useful in dealing with state and federal agencies, tribal and private landowners, etc.		
BCTC	Disagree	BCTC do not agree with the removal of Clearance 1. We recommend adding it back to the document, but reworded and moved to include it as a measurement (M), rather than a requirement (R) under the new standard. Many utilities feel that Clearance 1 provides justification and leverage for operational clearances when dealing with organizations such as municipalities. Without Clearance 1, utilities could be mandated in specific situations to clear so that the vegetation is just beyond the Critical Clearance Zone at all times. This could result in pruning at six month intervals, which is not feasible or cost-effective.
Response: Thank you for your comment. The SDT notes that information contained in a Measure would not be mandatory nor enforceable and therefore has minimal usefulness as leverage. The SDT points out that ANSI A300 remains a ”best practice” referenced in the proposed standard and may be useful in dealing with the public and private parties. The addition of Requirement R1, Part 1.6 allows for vegetation-to-ground working distances to be used while at the same time accounting for the sag and sway of the conductor throughout its operating range under rated conditions. The SDT believes this is superior to Clearance 1 as this gives Transmission Owners more flexibility in how they can achieve the reliability objective of Requirement R1.		

Organization	Agree?	Question 9 Comment
Salt River Project	Disagree	Recommend adding it back to the document, however, only if it is changed to become a measurement (M) rather than a requirement (R). Leaving it in as a measurement provides justification and leverage for operational clearances when dealing with landowners. Without Clearance 1 landowners may only allow vegetation clearance just at the Critical Clearance Zone at all times, which is not a feasible, cost-effective, or responsible way for utilities to manage vegetation clearance.
Response: Thank you for your comment. The SDT notes that information contained in a Measure would not be mandatory nor enforceable and therefore has minimal usefulness as leverage. The SDT points out that ANSI A300 remains a "best practice" referenced in the proposed standard and may be useful in dealing with the public and private parties. The addition of Requirement R1, Part 1.6 allows for vegetation-to-ground working distances to be used while at the same time accounting for the sag and sway of the conductor throughout its operating range under rated conditions. The SDT believes this is superior to Clearance 1 as this gives Transmission Owners more flexibility in how they can achieve the reliability objective of Requirement R1.		
American Electric Power (AEP)	Agree	AEP agrees with the removal of Clearance 1 from the Standard.
Response: Thank you for your comment.		
NPCC	Agree	We agree but believe that the Transmission Vegetation Management Program should target removal of all incompatible vegetation on the Active Right of Way as described in the response to question 3.
Response: Thank you for your comment. The SDT agrees with the commenter that any vegetation located within the Active Transmission Line ROW should be targeted for removal using means and strategies described in its Transmission Vegetation Management Program.		
Western Area Power Administration, Upper Great Plains Region	Agree	While Western (UGPR) agrees with the removal of Clearance 1, we believe it is advantageous for Transmission Owners to have a "trigger distance" in order to have some additional time to plan and schedule vegetation work. The trigger distance is advantageous only if the Regulators do NOT interpret it to be an extended Critical Clearance Zone and do NOT enforce based on "trigger distance" instead of the Critical Clearance Zone .
Response: Thank you for your comment. The SDT team believes the addition of Requirement R1, Part 1.6 continues to allow each Transmission Owner to set any working distances it deems appropriate in order to accomplish the objectives with this Standard. This Requirement 1 Part 1.6 is superior to Clearance 1 as it gives Transmission Owners more flexibility in how they can achieve the reliability objective of Requirement R1.		
MRO NERC Standards Review Subcommittee	Agree	The MRO agrees and fully supports the removal of Clearance 1. The MRO believes that the Gallet equation is a more effective way of determining the required clearances.

Organization	Agree?	Question 9 Comment
Response: Thank you for your comment.		
Tennessee Valley Authority	Agree	TVA agrees with Comment Question 9
Response: Thank you for your comment.		
Orange and Rockland Utilities Inc.	Agree	We generally agree, however please see comments included in question 18.
Response: Thank you for your comment.		
Baltimore Gas & Electric Company	Agree	While I may agree with the removal of this requirement strictly for reasons of simplification and self-determination, the current requirement forced utilities to structure their Transmission Vegetation Management Program to develop safeguards to keep trees from encroaching into the Clearance 2 envelope. The proposed change will leave the clearance issue beyond the Critical Clearance Zone unaddressed. Responsible utilities will take the appropriate measures and other utilities will not.
Response: Thank you for your comment. Each Transmission Owner is free to use any effective approach it deems appropriate in order to accomplish its Transmission Vegetation Management Program objectives. The SDT believes there are significant disincentives against the behavior you warn about in the revised version.		
CenterPoint Energy	Agree	Designation of Clearance 1 is not required to meet the purpose of the Standard.
Response: Thank you for your comment.		
Hydro-Quebec Transenergie (HQT)	Agree	We agree but believe that the Transmission Vegetation Management Program should target removal of all incompatible vegetation on the Active Right of Way as described in the response to question 3.
Response: Thank you for your comment. The SDT agrees with the commenter that any vegetation that are located within the Active Transmission Line ROW should be targeted for removal using means and strategies described in its Transmission Vegetation Management Program.		
Great River Energy	Agree	GRE agrees and fully supports the removal of Clearance 1. GRE believes that the Gallet equation is a more effective way of determining the required clearances.
Response: Thank you for your comment.

10. Personnel Qualifications in R1.3 in Version 1 was a "fill-in-the-blank" requirement and was removed from Version 2 of the standard. Do you agree? If not please explain.

Summary Consideration: Most commenters agree with the deletion of R1.3 from the approved standard. The" fill in the blank" requirement that was included in version 1 allowed the Transmission Owner to set its own standard for personnel qualifications rather than require the same set of qualifications for personnel in all entities. The SDT recommended removing the requirement as it is not enforceable and recommended against replacing the "fill-in-the-blank" element with a continent-wide set of personnel qualifications. The SDT believes that any set of personnel qualifications enforced on a continent-wide basis would result in a set of "lowest common denominator" qualifications that would be too stringent for some entities, and too lax for others – with no apparent reliability benefit. Instead, the SDT recommended letting entities set their own internal personnel qualifications to best meet their own needs.

Organization	Agree?	Question 10 Comment
Central Maine Power Company	Disagree	Central Maine Power Company disagrees with the removal of the qualification statement. The individual responsible for this critical program must be qualified through experience, training, and education. The International Society of Arboriculture has a certification program that can help with guidelines for qualified arborists.
Response: The SDT thanks you for your response. Internal standards related to personnel qualifications, while not a requirement of the Standard, remain the internal responsibility of the Transmission Owner in the overall context of complying with the requirements of FAC-003-2.		
Northern Indiana Public Service Company	Disagree	If the standard continues to allow T.O.'s to design and implement their own TVMPs and expect them to use BMPs, ANSI A300, develop methods and practices, adapt schedules and plans to changing conditions, etc., then it is reasonable to expect that T.O. personnel responsible for the TVMP to be experts in the field of utility vegetation management with appropriate training, certifications, licenses and credentials. I do not agree with eliminating this requirement. Quite the opposite, I believe that the requirement needs to be more specific as to minimum qualifications key personnel must meet. There are more requirements & qualifications to drive a semi-truck than to design and implement a program (UVM) critical to the operation of the nation's electric grid. Does that make sense?
Response: The SDT thanks you for your response. Internal standards related to personnel qualifications, while not a requirement of the Standard, remain the internal responsibility of the Transmission Owner in the overall context of complying with the requirements of FAC-003-2.		
USDA Forest Service, Southwestern Region, Regional	Disagree	Perhaps standard M8 could be expanded or clarified to require the Transmission Owner to describe how employees, especially field supervisors, are trained to implement the plan and to prove that the training was

Organization	Agree?	Question 10 Comment
Office for AZ and NM		actually provided. Some problems have arisen in the USFS Southwestern Region because some Transmission Owners are not providing adequate supervision of field work.
Response: The SDT thanks you for your comment. The requirement that was dropped between the version 1 and version 2 spoke to the qualifications of development and implementation of the TVMP and not the adequacy of the field supervision. This does not relieve the TO from providing adequate field supervision.		
National Grid	Disagree	National Grid takes exception to the term “fill-in-the-blank”. National Grid would like Personnel Qualifications to remain in Standard FAC-003-2.
Response: The SDT thanks you for your response. Internal standards related to personnel qualifications, while not a requirement of the Standard, remain the internal responsibility of the Transmission Owner in the overall context of complying with the requirements of FAC-003-2.		
San Diego Gas & Electric	Disagree	We feel there must be appropriate knowledge to do the work, and that Transmission Owners must at least have internal standards related to personnel qualifications.
Response: The SDT thanks you for your response. Internal standards related to personnel qualifications, while not a requirement of the Standard, remain the internal responsibility of the Transmission Owner in the overall context of complying with the requirements of FAC-003-2.		
Arizona Public Service Company	Disagree	APS disagrees with the removal of personnel qualifications. The person responsible for vegetation management program should have experience and training in vegetation management and system operations. The International Society of Arboriculture has an ISA Certified Arborist and Utility Specialist certification. This requires the credential holder to have minimal qualifications before sitting for the certification and on going training to maintain the credential. The industry has already responded by providing the information as part of the current standard FAC-003-1. It makes no sense to remove personnel qualifications from the revision.
Response: The SDT thanks you for your response. Internal standards related to personnel qualifications, while not a requirement of the Standard, remain the internal responsibility of the Transmission Owner in the overall context of complying with the requirements of FAC-003-2.		
British Columbia Transmission Corp.	Disagree	BCTC does not agree with the elimination of this requirement. We feel strongly there must be appropriate knowledge to do the work, and that Transmission Owners must have internal standards related to personnel qualifications. We understand that several utilities would like this requirement removed because it created problems in the auditing process. It is unfortunate that this important requirement for an effective vegetation management program has been removed due misapplication of the intent during audits.
Response: The SDT thanks you for your response. Internal standards related to personnel qualifications, while not a requirement of the Standard,		

Organization	Agree?	Question 10 Comment
remain the internal responsibility of the Transmission Owner in the overall context of complying with the requirements of FAC-003-2.		
Central Maine Power Company	Disagree	Central Maine Power Company disagrees with the removal of the qualification statement. The individual responsible for this critical program must be qualified through experience, training, and education. The International Society of Arboriculture has a certification program that can help with guidelines for qualified arborists.
Response: The SDT thanks you for your response. While we agree that the International Society of Arboriculture certifications are credible qualifications for a large work force, these same programs may be too stringent and unnecessary for utilities only needing a very small work force. **It is unknown if certification by ISA or similar organizations has impacted reliability for any Transmission Owner.**		
Northern Indiana Public Service Company	Disagree	If the standard continues to allow T.O.'s to design and implement their own Transmission Vegetation Management Programs and expect them to use BMPs, ANSI A300, develop methods and practices, adapt schedules and plans to changing conditions, etc., then it is reasonable to expect that T.O. personnel responsible for the Transmission Vegetation Management Program to be experts in the field of utility vegetation management with appropriate training, certifications, licenses and credentials. I do not agree with eliminating this requirement. Quite the opposite, I believe that the requirement needs to be more specific as to minimum qualifications key personnel must meet. There are more requirements & qualifications to drive a semi-truck than to design and implement a program (UVM) critical to the operation of the nation's electric grid. Does that make sense?
Response: The SDT thanks you for your response. The SDT concurs that some Transmission Vegetation Management Programs are highly complex and would require highly trained arborists and vegetation management personnel to develop such programs. However, there are many programs that are substantially less complex and do not require that level of expertise. We feel that utilities with complex programs would by nature acquire appropriately trained personnel to implement their programs.		
USDA Forest Service, Southwestern Region, Regional Office for AZ and NM	Disagree	Perhaps standard M8 could be expanded or clarified to require the Transmission Owner to describe how employees, especially field supervisors, are trained to implement the plan and to prove that the training was actually provided. Some problems have arisen in the USFS Southwestern Region because some Transmission Owners are not providing adequate supervision of field work.
Response: The SDT thanks you for your comment. The requirement that was dropped between the version 1 and version 2 spoke to the qualifications of development and implementation of the Transmission Vegetation Management Program and not the adequacy of the field supervision.		
National Grid	Disagree	National Grid takes exception to the term "fill-in-the-blank". National Grid would like Personnel Qualifications

Organization	Agree?	Question 10 Comment
		to remain in Standard FAC-003-2.
Response: The SDT thanks you for your response. A" fill in the blank" requirement as stated in version 1 allowed the Transmission Owner to set its own standard and does not substantively add to the effectiveness of the Standard.		
British Columbia Transmission Corp.	Disagree	BCTC does not agree with the elimination of this requirement. We feel strongly there must be appropriate knowledge to do the work, and that Transmission Owners must have internal standards related to personnel qualifications. We understand that several utilities would like this requirement removed because it created problems in the auditing process. It is unfortunate that this important requirement for an effective vegetation management program has been removed due misapplication of the intent during audits.
Response: The SDT thanks you for your response. A" fill in the blank" requirement as stated in version 1 allowed the Transmission Owner to set its own standard and does not substantively add to the effectiveness of the Standard.		
Tennessee Valley Authority	Agree	TVA agrees with Comment Question 10
Response: The SDT thanks you for your response.		
Exelon	Agree	Agree but same comment as above, we do not understand the reference to "fill in the blank" requirement for R1.3. As commonly understood, a "fill in the blank" standard /requirement is one that was assigned to the RRO.
Response: The SDT thanks you for your response. A" fill in the blank" requirement as stated in version 1 allowed the TO to set its own standard as opposed to RRO. In either case the concept of a "fill in the blank requirement" does not substantively add to the effectiveness of the Standard.		
Tampa Electric Company	Agree	While we agree with the removal of "fill-in the blank" requirements, we recommend the inclusion of professional qualifications for staff involved in this Standard. Reading the 42 page technical reference and the attached comment form, all involved need to really understand the Standard as well as industry practices.
Response: The SDT thanks you for your response. Internal standards related to personnel qualifications, while not a requirement of the Standard, remain the internal responsibility of the Transmission Owner in the overall context of complying with the requirements of FAC-003-2.		
Baltimore Gas & Electric Company	Agree	Similar to the response to no. 9, the end result is what counts and each utility will be responsible and accountable for their actions. Qualifications unlike clearance requirements, are far-removed from results and can easily be left unaddressed in the new std.

Organization	Agree?	Question 10 Comment
Response: The SDT thanks you for your response.		
NV Energy (fka Sierra Pacific / Nevada Power Co.)	Agree	We are in agreement with the elimination of this requirement, but not without some qualifications. We feel strongly there must be appropriate knowledge to do the work, and that Transmission Owners must at least have internal standards related to personnel qualifications. It is unfortunate that this important requirement for an effective vegetation management program has been removed due to concerns with the auditing program.
Response: The SDT thanks you for your response. Internal standards related to personnel qualifications, while not a requirement of the Standard, remain the internal responsibility of the Transmission Owner in the overall context of complying with the requirements of FAC-003-2.		
CenterPoint Energy	Agree	Designation of Personnel Qualifications are not required to meet the purpose of the Standard.
Response: The SDT thanks you for your response.		
American Electric Power (AEP)	Agree	AEP agrees that the Standard should not stipulate or require personnel qualifications.
Response: The SDT thanks you for your response.		
Platte River Power Authority	Agree	The requirement should be removed because it is a “fill-in-the-blank” requirement. Defining the proper amount of personnel qualifications and training would be too prescriptive for utilities with small vegetation management programs and not prescriptive enough for utilities with large vegetation management programs.
Response: The SDT thanks you for your comments.		
Western Utility Arborists	Agree	The Western Utilities are in agreement with the elimination of this requirement. However, we feel strongly there must be appropriate knowledge to do the work, and that Transmission Owners must at least have internal standards related to personnel qualifications.
Response: The SDT thanks you for your response. Internal standards related to personnel qualifications, while not a requirement of the Standard, remain the internal responsibility of the Transmission Owner in the overall context of complying with the requirements of FAC-003-2.

11. The IEEE 516 standard distances were replaced with the Gallet equation distances. Clearance 2 was replaced by the Critical Clearance Zone. The Critical Clearance Zone is defined as the zone of all possible positions of the conductor at the line's designed operating ratings including wind factors. (Please refer to pages 22-32 in the Technical Reference Document on the Critical Clearance Zone for further background for this question.) The imminent threat procedure, R2, requires action to be taken to prevent an outage when the Critical Clearance Zone is approached. Do you agree with R2? If not please explain.

Summary Consideration: The majority of responders (61%) disagreed with the concept of the imminent threat procedure being associated with the Critical Clearance Zone (CCZ). The key concerns that commenters raised were associated with the Critical Clearance Zone and included the following:

- It is a good concept but is theoretical and difficult to administer in the field
- Respondents preferred a more defined distance that is real-time and measurable
- The word "approach" caused concern due to being vague and open to interpretation

Although there was no clear minority view, a number of respondents recommended eliminating R2 or R4 because of practical difficulties associated with the CCZ and their belief that R5, R6, and R7 were sufficient to achieve reliability

In response, the SDT modified R2 so that it does not use the CCZ to trigger the imminent threat procedure implementation. R2 now requires the Transmission Owner to implement its imminent threat procedure when it has knowledge of such a threat obtained through normal operating procedures. The SDT decided not to be prescriptive in the definition of a vegetation imminent threat. Rather, the Transmission Owner should have the flexibility of defining its own procedure per the TVMP. In addition R4 has been modified and now requires the Transmission Owner to prevent vegetation encroachment of the Minimum Vegetation Clearance Distances (MVCD) as observed in real time and eliminates the use of the CCZ for this purpose.

R2. Each Transmission Owner shall implement its imminent threat procedure when the Transmission Owner has actual knowledge of such a threat, obtained through normal operating practices.

Deleted: or notification from others, that the Critical Clearance Zone is approached by vegetation to prevent an encroachment of the Critical Clearance Zone.

Formatted: Indent: Left: 0", Pattern: Clear (Custom Color(RGB(211,220,233)))

Organization	Agree?	Question 11 Comment
BCTC		BCTC feels that changing to the Gallet equation will not have a large impact on its vegetation management operations, so we have no concerns. We agree with R2, but feel that this clause makes R4 redundant, as per our discussion under Comment # 15 below. We recommend the removal of R4 entirely from the standard.

Organization	Agree?	Question 11 Comment
Response: Thank you for your comment. The SDT has retained the use of Gallet equations in the proposed draft standard revision but has discontinued the use of the CCZ. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
Western Utility Arborists		The Western Utilities feel that changing to the Gallet equation will not have a large impact on its vegetation management operations, so we have no concerns. We agree with R2, but feel that this clause makes R4 redundant, as per our discussion under Comment # 15 below. We recommend the removal of R4 entirely from the standard.
Response: Thank you for your comment. The SDT has retained the use of Gallet equations in the proposed draft standard revision but has discontinued the use of the CCZ. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat upon discovery of such a threat. The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
Associated Electric Cooperative Inc.	Disagree	The phrase “Critical Clearance Zone is approached” in R2 is nebulous and probably unenforceable. The determination and visualization of the Critical Clearance Zone and approaching vegetation encroachment, under field conditions, is a practice in application of theoretical conductor locations in real time. Would the Transmission Owner be found in noncompliance if evidence showed vegetation had “approached” within 20 feet, 2 feet, 2 inches or some other arbitrary distance of the CCZ and the TO failed to implement its imminent threat procedure?
Response: Thank you for your comment. The SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
Western Area Power Administration, Upper Great Plains Region	Disagree	The CCZ as defined would very specifically outline a zone that needs to remain clear of vegetation to avoid a violation, but that specificity could be an overly burdensome concept to implement and/or monitor. Theoretically, there could be an infinite number of allowable vertical and horizontal (for outside phases) clearances depending on your location within each span. Theoretically, you may need to clear cut at mid-span (depending on retreatment intervals, growth rate, etc.) while allowing a 40 foot tree closer to the structure, along with everything in between depending on your location within the span. To fully comply with the CCZ as defined, each Transmission Owner would have to have a table of allowable vertical and horizontal clearances for every few feet on every available span length within each line section. Producing such tables

Organization	Agree?	Question 11 Comment
		would be a significant burden to each Transmission Owner, but without them, the Transmission Owner could not verify that vegetation had not encroached within the CCZ. In order to produce the tables outlined above, the Transmission Owner would need to identify what design parameter(s) are applicable for the "correct" CCZ? We remain concerned that weather conditions in excess of those parameters could lead to a vegetation contact/outage and proving that weather conditions were in excess of design criteria would be extremely difficult or impossible for all spans on a lengthy transmission line. It is not uncommon to have weather stations 50 or more miles away from points on our transmission system. In order to certify/verify compliance, the Transmission Owner would have to physically take their table to the field and verify vertical and horizontal clearances from the edge of the theoretical envelope (not the actual conductor position) for all vegetation within the span. This would be a time-consuming, burdensome, cumbersome process if Regulators are going to require specific evidence in order for the Transmission Owner to document their annual certification.
Response: Thank you for your comment. The SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat upon discovery of such a threat. The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
SERC Vegetation Management Subcommittee (VMS)	Disagree	The SERC VMS recommends that R2 be deleted. Since this is a "zero tolerance" standard any Transmission Owner will remove any discovered threats to prevent outages. While we agree that the implementation of an imminent threat procedure may be a valid concept, visualization of the Critical Clearance Zone (CCZ) and determining an approaching encroachment is a practice in application of theoretical conductor locations in real time.
Response: Thank you for your comment. The SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
Progress Energy Florida	Disagree	The Critical Clearance Zone as currently defined is too academic. Implementation of R2 would require field operations staff to determine the theoretical position of the line during inspections to decide whether to engage the imminent threat procedures. The academic/theoretical aspects of the Critical Clearance Zone definition are not practical or enforceable. The criteria for a violation needs to be limited to the position of the conductor in real time.
Response: Thank you for your comment. The SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat upon discovery of such a threat. The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		

Organization	Agree?	Question 11 Comment
Western Area Power Administration, Rocky Mountain Region	Disagree	As discussed in the Technical Reference document, the CCZ is a complicated theoretical envelope surrounding all rated operating positions of the conductor. Its dynamic shape is constantly changing and is contingent upon location within the span. Calculation of the size and shape of CCZ is based, in part, upon the design parameters of the transmission facility. However, as-built or long term maintenance conditions can often diverge from the original design requirements over time. Ground elevations can also change as a result of man made or natural causes from the original design elevations recorded on plan and profile engineering drawings. Consequently, precise field measurement of the as-built CCZ is extremely problematic and strategies that utilize the calculation of allowable right-of-way tree heights can be hindered by unrecorded deviations from the original design criteria. Allowable tree height strategies also become increasingly more difficult and impractical with increasing extremes in terrain. While the CCZ is a very important concept for an effective vegetation management program it is far to theoretical, dynamic, and impractical to field measure for use as a clear and precise boundary for regulatory purposes. In addition, the R2 requirement for action when the imprecise and theoretical CCZ boundary is "approached" by vegetation is an even more subjective and unmeasurable. The "rate of approach" is really the key issue of concern. The rate of vegetation approach is a function of many variables including species type and site specific growing conditions. For example, a Century Plant which can grow six inches a day is obviously a much greater concern than a Lodgepole Pine on a dry mountain top which grows only a few inches a year. As such, there is no practical way to define or measure for regulatory purposes those "approach" situations that legitimately require immediate action from those "approach" situations that do not. The wording and concepts of R2 are therefore to imprecise to be used as clear requirements for Standards compliance.
Response: Thank you for your comment. The SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat upon discovery of such a threat. The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
Progress Energy Carolinas	Disagree	The Critical Clearance Zone as currently defined is too academic. Implementation of R2 would require field operations staff to determine the theoretical position of the line during inspections to decide whether to engage the imminent threat procedures. The academic/theoretical aspects of the Critical Clearance Zone definition are not practical or enforceable. The criteria for a violation needs to be limited to the position of the conductor in real time.
Response: Thank you for your comment. The SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat upon discovery of such a threat. The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
SERC OC Standards Review	Disagree	The SERC OCSRG recommends that R2 be deleted. Since this is a "zero tolerance" standard any

Response: Thank you for your comment. The SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
Florida Power & Light	Disagree	FPL agrees that the Gallet equation is a better method to determine a Critical Clearance Zone. However, FPL does not agree with the application of the zone for several reasons outlined below. ? There are many environmental and engineering variables and assumptions included in the calculation of the Critical Clearance Zone. ? These assumptions are not clearly defined in the standard. ? Unless there is a significant intrusion into the Critical Clearance Zone, an engineer and surveyor would be necessary at all times to determine a violation. ? The success of this standard lies with a standard the field personnel can implement. When making actual trimming or removal decisions, the field personnel are not adequately skilled to do much more than make a rough guess at the Critical Clearance Zone. This standard must establish measurable and auditable parameters for field operations. ? In Requirement R2, determination of when to activate the Imminent Threat Procedure becomes unclear due to the difficulty in determining when the Critical Clearance Zone is encroached. ? As written, off ROW trees falling through the Critical Clearance Zone become a violation of Requirement R4. Unless an outage occurred, how would the utility determine that a violation occurred? In FAC 003-1 an outage of this nature is defined as Category 3 and is not a violation. Since fall-in tree interruptions have never been contributors to cascading events or blackouts they should not be a violation of a NERC standard. Consequently, as written, it is highly questionable whether this Standard is sufficiently specific and clear to be enforceable. The many questions and levels of confusion introduced with the application of the Critical Clearance Zone concept suggests that neither the industry nor NERC will ever know if compliance is met. Such a high level of ambiguity requires that the Critical Clearance Zone concept be revisited and most likely replaced with a measure that is workable for both the industry and NERC. To further this effort, FPL has outlined some alternative suggestions described in the answer to question 18.
Response: Thank you for your comment. The SDT has retained the use of Gallet equations in the proposed draft standard revision but has discontinued the use of the CCZ. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		

Organization	Agree?	Question 11 Comment
Southern Company	Disagree	As written, R2 requires activation of the imminent threat process when the Critical Clearance Zone (CCZ) is "approached" by vegetation. The term "approach" is vague and open to interpretation. Since vegetation is dynamic in nature, it is constantly "approaching" any pre-defined zone. There could also be many examples given of encroachments into the theoretical CCZ that would neither threaten the transmission line conductor nor cause a reduction in the capacity of the transmission line. This concept would be better suited to be a “trigger point” that, if found, would be incentive for the Transmission Owner to take immediate action or ensure future action occurs on schedule. This action may be as urgent as implementation of the immediate threat procedure or as non-urgent as making sure that the upcoming maintenance on that line is scheduled appropriately. We are concerned this revision of FAC-003 continues to take a zero tolerance approach to compliance, which is contrary to the philosophy utilized in other NERC standards. A state of non-compliance should not exist simply because vegetation encroached within a pre-defined zone by a fractional inch, but only when an event, such as a sustained outage, occurs due to the Transmission Owner's failure to maintain adequate clearance between conductors and vegetation.
Response: Thank you for your comment. The SDT has retained the use of Gallet equations in the proposed draft standard revision but has discontinued the use of the CCZ. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
E.ON U.S.	Disagree	E.ON U.S. suggests that R2 be deleted. Since this is a "zero tolerance" standard any Transmission Owner will remove any discovered threats to prevent outages. While we agree that the implementation of an imminent threat procedure may be a valid concept, visualization of the Critical Clearance Zone and determining an approaching encroachment is a practice in application of theoretical conductor locations in real time.
Response: Thank you for your comment. The SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
FirstEnergy	Disagree	The CCZ is not equal to Clearance 2 in FAC-003-1. Per requirement R4, any encroachment into the CCZ is a violation of the standard even if an outage does not occur. This is too strict because it refers to a "0" tolerance even for encroachments that do not affect reliability. This can be an extremely costly standard to comply with that may or may not improve reliability. The CCZ distance is a difficult to determine from one moment to the next based upon the description and calculations outlined. The conditions on the right of way are dynamic and ever changing. It would be more proactive for the TO to focus on implementing the TVMP rather than expending time and money trying to determine if the CCZ has been violated. A better approach

Organization	Agree?	Question 11 Comment
		would be to establish a minimum clearance at all times rather than to monitor encroachment to a theoretical CCZ.
Response: Thank you for your comment. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
Midwest ISO Stakeholders Standards Collaborators	Disagree	he CCZ is a good theoretical concept to aid industry in understanding the overall movement of conductors, but it is an impractical concept for field application. Due to the variability in the size of the CCZ as you move along a conductor, as well as changes from span to span or even line to line due to design parameters, loading or weather-related issues, the CCZ concept should not be tied to an imminent threat procedure. Vegetation approaching the CCZ does not constitute an imminent threat. It may be months to years before this vegetation ever gets to a proximity distance from the conductor to be within a "spark-over" distance as defined by the Gallet equations. Requirement R2 should support the purpose of this standard by requiring implementation of the Vegetation Imminent Threat Procedure when the Transmission Owner has visual, field knowledge that vegetation is encroaching upon a conductor within some specific distance that is a multiple of the Gallet distances referenced in Table I of FAC-003-2 (to be conservative we suggest two to three times the Gallet distances). Failure to implement the Vegetation Imminent Threat Procedure in such instances would be a violation of R2.As R2 is currently stated, a Transmission Owner cannot comply with R2 unless the imminent threat procedure is continuously being implemented, because vegetation that is growing is always approaching the CCZ. "Approaching the CCZ" cannot be the trigger for implementation of the Vegetation Imminent threat Procedure. Instead, the trigger should be an encroachment within some observed field distance. Requirement R2 could be reworded as follows: ?Each Transmission Owner shall implement its Vegetation Imminent Threat Procedure when the Transmission Owner has knowledge, obtained through normal operating practices or notification from others, that vegetation is encroaching upon a conductor within a distance that is twice the Gallet clearance distances referenced in Table I." Using a multiple of the Gallet distances provides a safety factor. Assessing a violation for failure to appropriately implement the Vegetation Imminent Threat Procedure or for a sustained vegetation-related outage incents the proper behavior.
Response: Thank you for your comment. The SDT has retained the use of Gallet equations in the proposed draft standard revision but has discontinued the use of the CCZ. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4. The proposed standard revision specifies the MVCD as a starting point and TOs may apply multiples at its own discretion in order to achieve its TVMP objectives and adhere to applicable safety standards.		

Organization	Agree?	Question 11 Comment
SERC Compliance Staff	Disagree	SERC staff agrees that the implementation of an imminent threat procedure may be a valid concept; however visualization of the Critical Clearance Zone and determining an approaching encroachment will be difficult from a practical matter. There also needs to be definition of what is meant by "approaching" if this is used. While it may be a technically sound approach to designate the clearance zone to be tied to the conductor movement envelope as found in the NESC, this results in a banana-shaped zone that is difficult to substantiate in the field by entity and compliance personnel. It may be better, and more reasonable to define a constant zone around a conductor that would be the same throughout the span. The clearance zone should not include the limitation that the zone cannot extend outside the active right of way.
Response: Thank you for your comment. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
ITC HOLDINGS	Disagree	Just because vegetation is approaching the CCZ doesn't represent an imminent threat and should not be set to an imminent threat procedure. Implementation of R2 would require field personnel to determine the speculative position of the line during inspections to decide whether to engage the imminent threat procedures. While we agree that an imminent threat procedure should be implemented to address vegetation related imminent threats as soon as they are identified, we believe that an approach of the CCZ should not be used to generate implementation. The term "approached" does not identify a specific distance, so it's not clear to what extend vegetation would have to approach the CCZ to require implementation of the imminent threat process. ITC agrees that the implementation of an imminent threat procedure may be a valid concept, but visualization of the CCZ and determining approaching vegetation is a practice in hypothetical conductor locations in real time. This may be a good imaginary concept in understanding conductor movement but it's impractical for field applications.
Response: Thank you for your comment. The SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
Tennessee Valley Authority	Disagree	TVA recommends that R2 be removed from this standard. Since this is a "zero tolerance" standard there is a very significant incentive for the Transmission Owner to inspect and plan maintenance to prevent potential outages. The Gallet Equations should be kept within the white paper solely for the TO to reference for developing maintenance and inspection cycles.
Response: Thank you for your comment. The SDT has retained the use of Gallet equations in the proposed draft standard revision but has		

Organization	Agree?	Question 11 Comment
discontinued the use of the CCZ. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
Exelon	Disagree	Comments: 1) In spite of the rigor associated with the Gallet equations, the definition of CCZ is imprecise as the Ratings to be used are not specified. In addition, Exelon is concerned that it will be difficult to determine the CCZ for each span under all possible operating conditions. Implementing an imminent threat procedure (R2) in combination with the CCZ may be unworkable under actual field conditions. 2) We are concerned that CCZ is only fully defined in the Technical Reference documentation and not in the standard itself. As stated in the NERC Standards Process Manual, Elements of a Reliability Standard, "Supporting documents to aid in the implementation of a standard may be referenced by the standard but are not part of the standard itself." There needs to be enough specificity as to the definition of CCZ in FAC-003-2 so that adequate documentation and evidence of compliance can be developed.
Response: Thank you for your comment. The SDT has retained the use of Gallet equations in the proposed draft standard revision but has discontinued the use of the CCZ. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
American Electric Power (AEP)	Disagree	AEP agrees with the need for a TO to have an Imminent Threat Procedure and that the Transmission Operator should be immediately notified of imminent threats. However, AEP disagrees with the requirement that the Transmission Operator be notified merely because the CCZ has been approached. Vegetation approaching the CCZ does not necessarily constitute an imminent threat. It is possible that the CCZ is encroached by vegetation at the lowest point of the CCZ whereas the conductor may be at its highest point in the CCZ (potentially 20 or 30 feet away from the vegetation). This situation does not merit notification to the Transmission Operator. Please also refer to our comments regarding CCZ in AEP's responses to Questions 15 and 18.
Response: Thank you for your comment. The SDT has retained the use of Gallet equations in the proposed draft standard revision but has discontinued the use of the CCZ. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		

Organization	Agree?	Question 11 Comment
Platte River Power Authority	Disagree	Changing to the Gallet equation will not have a large impact on vegetation management operations, keeping Clearance 1 and 2 with tables developed using IEEE Standards for various voltages, line spans and altitudes is preferable. Actions should be taken to prevent an outage when vegetation encroaches Clearance 2.
Response: Thank you for your comment. The SDT chose to use Gallet equations over IEEE primarily because Gallet is more appropriate for determining the probability of flashover. The IEEE standard was developed for human safety purposes.		
Northern Indiana Public Service Company	Disagree	While I agree with the argument that the Gallet equatiion is a better technical or scientific method than IEEE 516 for determining realistic conductor to tree flashover distances, I do not agree that the new proposed clearance tables serve any useful purpose as a vegetation clearance standard from an operational perspective. The FAC-003-2 Technical Reference itself points to this fact when it states, "even if the exact size and shape of the C.C.Z. is known, it becomes nearly impossible in the field to correlate and accurately superimpose the C.C.Z. around the conductor." The Tech. Ref. goes on to say that "it is anticipated that many T.O.s will establish a work trigger well outside the C.C.Z." I agree wholeheartedly with that concept and believe that the Gallet clearance tables should be used by TO's to develop the more important "work trigger" or "action threshold" clearances. This revision is overly focused on C.C.A.'s that have no practical operational application while being silent to the more critical to reliability issue of "work trigger/action threshold" clearances. This needs to be addressed if we hope to be successful at achieving the goal of zero preventable tree related outages.
Response: Thank you for your comment. The SDT has retained the use of Gallet equations in the proposed draft standard revision but has discontinued the use of the CCZ. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
Tampa Electric Company	Disagree	This is a good start. The Critical Clearance Zone (CCZ) is a very real and practical concept; however, it is not transferable to field conditions. This could result in a "fill in the blank" standard relative to what the Critical Clearance Zone will be in terms of distance. As I read this, it will be a sliding scale from insulator to mid span and back for each designated line voltage. The max wind speed to be used and other assumptions behind the determination of this zone may be as involved a Gallet's formula. This will lead to complications during operational inspection and verification of these clearances.
Response: Thank you for your comment. The SDT has retained the use of Gallet equations in the proposed draft standard revision but has discontinued the use of the CCZ. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission		

Organization	Agree?	Question 11 Comment
Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
Orange and Rockland Utilities Inc.	Disagree	While we agree that the imminent threat procedure should be implemented to address vegetation-related imminent threats as soon as they are identified, we believe that an "approach" of the CCZ should not be used to trigger implementation. The term "approached" does not identify a specific distance, so it is not clear to what extent vegetation would have to approach the CCZ in order to require implementation of the imminent threat process. This is left to the discretion of individual interpretation, is confusing to field personnel, and presents compliance and auditing problems. Imminent threats which are based on vegetation clearances should be identified based on specific clearances, not undefined approach distances. In practical field application the CCZ is an invisible area that changes shape and size along the length of the conductor. It is impossible to readily identify in the field without engineering calculations and precise measurements or the use of technology such as Aerial Laser Survey (ALS) using Light, Detection and Ranging (LIDAR) technology. Therefore under normal circumstances the location, size, and shape of the CCZ and vegetation encroachments of the CCZ can only be roughly estimated. Even with the use of ALS, which is relatively accurate, information is often not available for months after the survey flight. We believe that under normal circumstances imminent threats which are based on vegetation clearances should be identified in terms of specific distances from the conductor. While it is not possible for an inspector to readily identify a vegetation encroachment of the CCZ in the field, an inspector could more easily estimate a specified short distance between a conductor and vegetation in real time and initiate implementation of the imminent threat procedure based on that assessment. This assessment would be significantly more accurate than attempting to measure the distance between vegetation and the CCZ, which is not visible and constantly changes size and shape throughout the span. In cases where the Transmission Owner chooses to deploy ALS, the CCZ rather than the conductor could be used as the reference because in most cases the CCZ could be identified relative to approaching vegetation with a reliable degree of accuracy. Still a specific distance should be used to trigger implementation of the imminent threat procedure because of the issues previously raised with the use of the word "approached".
Response: Thank you for your comment. The SDT has retained the use of Gallet equations in the proposed draft standard revision but has discontinued the use of the CCZ. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
American Transmission Company	Disagree	ATC believes that the Critical Clearance Zone (CCZ) is a good theoretical concept to aid industry in understanding the overall movement of conductors, but it is an impractical concept for field application. Due to the variability in the size of the CCZ as you move along a conductor, as well as changes from span to span or

Organization	Agree?	Question 11 Comment
		even line to line due to design parameters, loading or weather-related issues, the CCZ concept should not be tied to an imminent threat procedure. Vegetation approaching the CCZ does not constitute an imminent threat. It may be months to years before this vegetation ever gets to a proximity distance from the conductor to be within a "spark-over" distance as defined by the Gallet equations. Requirement R2 should support the purpose of this standard by requiring implementation of the Vegetation Imminent Threat Procedure when the Transmission Owner has visual, field knowledge that vegetation is encroaching upon a conductor within some specific distance that is a multiple of the Gallet distances referenced in Table I of FAC-003-2 (to be conservative we suggest two to three times the Gallet distances). Failure to implement the Vegetation Imminent Threat Procedure in such instances would be a violation of R2.As R2 is currently written, a Transmission Owner cannot comply with R2 unless the imminent threat procedure is continuously being implemented or monitored, because vegetation that is growing is always approaching the CCZ. "Approaching the CCZ" cannot be the trigger for implementation of the Vegetation Imminent threat Procedure. Instead, the trigger should be an encroachment within some observed field distance. Requirement R2 could be rewritten as follows: ?Each Transmission Owner shall implement its Vegetation Imminent Threat Procedure when the Transmission Owner has knowledge, obtained through normal operating practices or notification from others, that vegetation is encroaching upon a conductor within a distance that is twice the Gallet clearance distances referenced in Table I." Using a multiple of the Gallet distances provides a safety factor. Assessing a violation for failure to appropriately implement the Vegetation Imminent Threat Procedure or for a sustained vegetation-related outage would promote the proper behavior.

In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
Nebraska Public Power District	Disagree	The CCZ is a good concept to explain the flight path of a conductor under all conditions but it would be impractical to use in the field. There are too many variables to consider and an encroachment does not constitute an immediate threat.
Response: Thank you for your comment. The SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
Manitoba Hydro	Disagree	The imminent threat process trigger should be well defined, and the vague "approaching" terminology needs to be changed. Imminent threat implies and that an elevated risk of contact exists. That is not the case if the vegetation is merely approaching the CCZ. The objective of the overall Vegetation Management program is to prevent an encroachment. The imminent threat procedure should be triggered by discovery of an encroachment into the CCZ. Even when an actual encroachment into the CCZ occurs - while the odds of an outage event have increased - the likelihood of a contact is still minimal, as other environmental factors still need to be in place (i.e. high temperature and/or high wind conditions).If this approach to an imminent threat process trigger, then the violation of this requirement implies a violation of R4, which prohibits the encroachment of the CCZ, and therefore either R2 or R4 could be removed, or they could be combined into one requirement.
Response: Thank you for your comment. The SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. The Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
Consumers Energy Company	Disagree	Absolutely disagree! The Gallet formula distances do not provide adequate protection of the system. The "Critical Clearance Zone" concept is not workable in the field. Every foot of every span would have a different

Organization	Agree?	Question 11 Comment
		CCZ that cannot be measured in the field without survey type equipment and knowledge of current line loadings. The clearance requirement needs to be uniform along the span for field crews to effectively achieve compliance. It appears that the drafting team hopes to minimize violations of vegetation violating FAC-003-1 Clearance 2 distances by decreasing the clearance distance between the conductor and vegetation using the Gallet formula. If NERC believes that FAC-003-1 Clearance 2 distances are too conservative, then the Gallet formula distance needs to be increased by some multiplier (2 or3) to achieve adequate safeguard for growing vegetation. Most trees in the United States in the size range that could exist beneath conductors achieve height growth of 3 feet or more annually. A tree in May may have adequate clearance per the proposed CCZ and in July violate that clearance causing an outage. Therefore, if the CCZ is to remain as is then the transmission owner/operator must have a defined imminent threat distance considerably greater than the CCZ and must be great enough that field personnel can safely remove the threat without de-energizing or de-rating the line.
Response: Thank you for your comment. The SDT has retained the use of Gallet equations in the proposed draft standard revision but has discontinued the use of the CCZ. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4. Pacific Gas & Electric Co.	Disagree	PG&E agrees the Gallet equation is superior to IEEE 516 and the imminent threat procedure is a critical component of the standard but disagrees that initiation of the procedure be based on such ambiguous language as "approaching the CCZ". Approaching could be any and all vegetation that is live and growing and CCZ is a theoretical calculation not a real time event. As written, the standard would require the TO to initiate an emergency action when such action may not be warranted or necessary to prevent an outage. PG&E recommends using a clearly defined and measureable threshold to determine when the imminent threat procedure must be initiated. A reasonable threshold would be 3 times the Gallet clearance distances referred to in Table 1 or when vegetation is threatening to fall into or otherwise impact a line.
Response: Thank you for your comment. The SDT has retained the use of Gallet equations in the proposed draft standard revision but has discontinued the use of the CCZ. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4. The proposed standard revision specifies the MVCD as a starting point and TOs may apply multiples at its own discretion in order to achieve its TVMP objectives.		

Organization	Agree?	Question 11 Comment
San Diego Gas & Electric	Disagree	We do not agree with replacing Clearance Zone 2 with the Critical Clearance Zone. We recommend the removal of R4 entirely from the standard.
Response: Thank you for your comment. The SDT has retained the use of Gallet equations in the proposed draft standard revision but has discontinued the use of the CCZ. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
Consolidated Edison Company of New York (CECONY)	Disagree	CECONY is in favor of using the Gallet equations as they provide a more realistic clearance distance for vegetation. We understand and agree that establishing a Critical Clearance Zone (CCZ) would provide the specific area that a conductor could possibly travel through during various field and weather conditions but we do not agree that this is the most practical approach. The main issue is that the wording '...the Critical Clearance Zone is approached by vegetation.....' is very vague and left open to wide interpretation which causes inconsistency and confusion throughout the industry. The CCZ changes throughout the length of each conductor in each span so a field inspector's job and an auditor's job become much more complicated when trying to confirm compliance when vegetation is present in the Actiove ROW. We feel that the time spent trying to measure and calculate the CCZ and then confirm compliance would be better spent initiating a response plan to safely remove the vegetation. The imminent threat procedure would only be implemented if vegetation encroaches beyond a specific distance from the conductor, not as it approaches the theoretical CCZ. Advanced technology would be required if a vegetation approach distance to the CCZ was to be calculated in the field. This is a very costly and time consuming requirement and does not efficiently meet the Standard's goal of ensuring reliability.
Response: Thank you for your comment. The SDT has retained the use of Gallet equations in the proposed draft standard revision but has discontinued the use of the CCZ. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
Duke Energy Corporation	Disagree	No. Duke believes that the CCZ is a good theoretical concept to aid industry in understanding the overall movement of conductors, but it is an impractical concept for field application. Due to the variability in the size of the CCZ as you move along a conductor, as well as changes from span to span or even line to line due to design parameters, loading or weather-related issues, the CCZ concept should not be tied to an imminent threat procedure. Vegetation approaching the CCZ does not constitute an imminent threat. It may be years before this vegetation ever gets to a proximity distance from the conductor to be within a "spark-over" distance

Organization	Agree?	Question 11 Comment
		as defined by the Gallet equations. Requirement R2 should support the purpose of this standard by requiring implementation of the Vegetation Imminent Threat Procedure when the Transmission Owner has visual, field knowledge that vegetation is encroaching upon a conductor within some specific distance that is a multiple of the Gallet distances referenced in Table I of FAC-003-2 (to be conservative we suggest two times the Gallet distances). Failure to implement the Vegetation Imminent Threat Procedure in such instances would be a violation of R2.As R2 is currently stated, a Transmission Owner cannot comply with R2 unless the imminent threat procedure is continuously being implemented, because vegetation that is growing is always approaching the CCZ. "Approaching the CCZ" cannot be the trigger for implementation of the Vegetation Imminent threat Procedure. Instead, the trigger should be an encroachment within an observed distance from vegetation to conductor that is twice the Gallet distances in Table I. Requirement R2 could be reworded as follows: ?Each Transmission Owner shall implement its Vegetation Imminent Threat Procedure when the Transmission Owner has knowledge, obtained through normal operating practices or notification from others, that vegetation is encroaching upon a conductor within a distance that is twice the Gallet clearance distances referenced in Table I." Using a multiple of the Gallet distances provides a safety factor. Assessing a violation for failure to appropriately implement the Vegetation Imminent Threat Procedure or for a sustained vegetation-related outage incents the proper behavior.
Response: Thank you for your comment. The SDT has retained the use of Gallet equations in the proposed draft standard revision but has discontinued the use of the CCZ. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4. **The proposed standard revision specifies the MVCD as a starting point and TOs may apply multiples at its own discretion in order to achieve its TVMP objectives and adhere to applicable safety standards.**		
Entergy Services	Disagree	: 1. Entergy suggests that the requirement for activation of the vegetation imminent threat process should not be tied to the Critical Clearance Zone and that the each entity should define the activation of their vegetation imminent threat process. Tying the activation of the imminent threat process to the Critical Clearance Zone is limited in that this criterion does not address the possibilities of vegetation falling into the line or Critical Clearance Zone. 2. In the sentence "Critical Clearance Zone approached by vegetation" the use of "approached" is subjective and not specifically quantifiable. Effective, uniform activation of the imminent threat process will require objective measurement criteria. 3. The standard needs to include a clear statement to the effect that when the Transmission Operator is notified of a potential vegetation problem, obtained by normal operations and inspections, the entity will

Organization	Agree?	Question 11 Comment
		activate the Vegetation Imminent Threat Process. 4) This requirement, as stated, is redundant. The requirements for maintaining the Critical Clearance Zones and / or avoiding vegetation outages, and the associated Violation Risk Factors and Violation Severity Levels, already reinforce the desired behavior of the entity to identify and mitigate any potential issues before the possibility of vegetation causing an outage.
Response: Thank you for your comment. **1) The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4. These changes may address your concerns.** **2) Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The word, "approached" is not used in the revised standard.** **3) Requirement R1 Part 1.4 specifies the TVMP have an Imminent Threat procedure that includes notification of the responsible control center.** **4) The SDT believes that having to implement an Imminent Threat procedure is proactive behavior and is in support of prevention of outages.**		
Pepco Holdings, Inc	Disagree	R5, R6 and R7 make this requirement redundant and unnecessary - it should be deleted. It is largely unenforceable and does not make the standard clear, specific and regulatory enforceable. Further, PHI believes the concept of enforcing no encroachment into the Critical Clearance Zone is a flawed approach.
Response: Thank you for your comment. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4. **The SDT believes that having to implement an Imminent Threat procedure is proactive behavior and is in support of prevention of outages.**		
JEA	Disagree	The use of Gallet equations is not practical either for field use or for demonstrating compliance.
Response: Thank you for your comment. The SDT chose to use Gallet equations over IEEE primarily because Gallet is more appropriate for determining the probability of flashover and the SDT believes holds distinct advantages for use in vegetation management applications. IEEE 516 is developed for human safety purposes.		
NV Energy (fka Sierra Pacific / Nevada Power Co.)	Agree	We feel that changing to the Gallet equation will not have a large impact on its vegetation management operations, so we have no concerns. We agree with R2, but feel that this clause makes R4 redundant, as per

Organization	Agree?	Question 11 Comment
		our discussion under Comment # 15 below. We recommend the removal of R4 entirely from the standard.
Response: Thank you for your comment. The SDT has retained the use of Gallet equations in the proposed draft standard revision but has discontinued the use of the CCZ. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
WECC	Agree	Yes but the wording is ambiguous. Vegetation under a transmission line is always "approaching" or growing towards the transmission line. Entities should define a specific distance greater than the Critical Clearance Zone when they are required to implement their Imminent Threat Procedures.
Response: Thank you for your comment. The proposed standard revision specifies a "Minimum Vegetation Clearance Distance" as a starting point and TOs may apply greater distances at their discretion in order to trigger implementation of the Imminent Threat procedure. The word, "approaching" is not used in the revised standard.		
Baltimore Gas & Electric Company	Agree	Again, each utility is responsible and accountable for it's actions. The Gallet clearances are a much better approximation of a true spark gap than the present requirement. Without a clearance one requirement, the closer tolerance produced by the Gallet equation will leave little room for error when a line is at or approaching it's max. engineered sag. When vegetation gets in the new CCZ (if adopted), it will be likely that an outage will be imminent. With the present clearance 1 and clearance 2 requirements, there is more of a buffer for encroaching vegetation.
Response: Thank you for your comment. The SDT has retained the use of Gallet equations in the proposed draft standard revision but has discontinued the use of the CCZ. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4. The proposed standard revision specifies the MVCD as a starting point and TOs may apply multiples at its own discretion in order to achieve its TVMP objectives and adhere to applicable safety standards.		
CenterPoint Energy	Agree	We agree with replacing IEEE 516 standard distances with the Gallet equation standard distances. However, the term "Critical Clearance Zone" refers to the "limits of the Active Transmission Line Right-of-way" which has no specific definition as to its limits within the proposed revised Standard. (See comments to Q3 above.) R2 should be reworded to coordinate with R1.4. (See comments to Q4 above.)

<table>
<tr><th>Organization</th><th>Agree?</th><th>Question 11 Comment</th></tr>
<tr><td colspan="3">Response: Thank you for your comments. Please see our responses to Questions 3 and 4 comments as well as the summary consideration for this question Based on stakeholder comments, the SDT made significant modifications to Requirement R2 and removed the concept of the CCZ.</td></tr>
<tr><td>Salt River Project</td><td>Agree</td><td>Although we agree that using the Gallet equation is more definitive than using IEEE 516, we still question from an engineering prespective as to how and why this method was chosen. It is stated in the Technical Reference paper that the Gallet Equation is a well known method of computing the required strike distance for proper insulation coordination. It is our understanding it's purpose is for designing towers, to define the "tower window" or opening inside of a tower under normal conditions. Because this is not a method designed specifically for vegetation management, was there any physical testing involved in choosing this approach, such as testing in both wet and dry conditions? We would recommend additional information to clarify this method to use for vegetation management. See additional comments in Comment #18 below. In addition, we feel this clause makes R4 redundant, as per our comments under Comment #15 below.</td></tr>
<tr><td colspan="3">Response: Thank you for your comment. The Gallet equations indeed are useful in tower design; however it is not exclusively for that purpose. The decision whether to use Gallet is not contingent upon testing and none were considered or conducted. No physical testing was utilized by the SDT; however, the Gallet Equation method and its explanation in the White Paper do have their basis in physical testing in both laboratory and field conditions. The Gallet Equation method is not solely applicable to tower structure design, but to any application requiring spark-over calculations. The SDT believes that the Gallet Equation method holds distinct advantages over the IEEE 516 method for use in vegetation management applications.</td></tr>
<tr><td>Southern California Edison Company</td><td>Agree</td><td>Q11: SCE agrees in part with proposed R2. The use of the Gallet equation and the replacement of the existing Clearance 2 requirement with the Critical Clearance Zone is acceptable. However, SCE strongly disagrees with establishing a separate requirement for implementing an imminent threat procedure should there be an encroachment of the Critical Clearance Zone because it forms the basis of an unnecessary zero-tolerance enforcement policy. Read in context with corresponding Measure 2, R2 appears to require Transmission Owners to prove that a Critical Clearance Zone encroachment did or did not occur and also prove that that an imminent threat procedure was or was not properly invoked. Although SCE agrees that CCZ encroachments should be addressed timely, we disagree with the notion and underlying assumption that a CCZ incursion will always lead to a flash-over or a vegetation-to-line contact. If the goal of FAC-003-2 is to prevent sustained outages (due to vegetation-to-line contacts) that could lead to Cascading, emphasizing “prevention” is understandable, however, enforcing prevention measures is an entirely different matter. Under the proposed requirements, a vegetation-to-line contact could conceivably represent two distinct violations of FAC-003-2. SCE believes this type of regulatory double jeopardy is patently unfair and forcing Transmission Owners to prove a CCZ encroachment did or did not occur is equally unfair and unenforceable. Because R1.4 adequately addresses the Transmission Owner’s responsibility regarding the implementation of an imminent threat procedure, SCE respectfully recommends that proposed R2 and corresponding M2 be removed from</td></tr>

Organization	Agree?	Question 11 Comment
		FAC-003-2.
Response: Thank you for your comment. The SDT has retained the use of Gallet equations in the proposed draft standard revision but has discontinued the use of the CCZ. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat upon discovery of such a threat. The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
Buckeye Power, Inc.	Agree	I agree with R2. I like the language changes, but decreasing the clearances will not improve reliability.
Response: Thank you for your comment. The SDT has retained the use of Gallet equations in the proposed draft standard revision but has discontinued the use of the CCZ. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
Great River Energy	Agree	GRE agrees and believes that the Gallet equation yields a less subjective measurement. GRE believes R2 should be modified to be more definitive. The imminent threat procedure should be implemented when vegetation “enters” the Critical Clearance Zone (CCZ). It is GRE's opinion that approaching the CCZ is subjective and as such very difficult to enforce.
Response: Thank you for your comment. The SDT has retained the use of Gallet equations in the proposed draft standard revision but has discontinued the use of the CCZ. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure. The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
USDA Forest Service, Southwestern Region, Regional Office for AZ and NM	Agree	Attachment 1 is very conservative. I think that the clearance distances shown on the attachment should be expanded to create, in effect, a standard that reflects maximum line loading and maximum line sag. I would also like to see some flexibility built into the process so that the Transmission Owner and the USFS could negotiate some consideration for vegetation growth rates. The end result would generate a standard that would give the Transmission Owner the security of knowing that vegetation would not grow into the potential arcing zone for some reasonable amount of time - some kind of entry cycle.
Response: Thank you for your comment. The SDT has retained the use of Gallet equations in the proposed draft standard revision but has discontinued the use of the CCZ. The SDT received a substantial number of negative comments on the matter of R2 and the CCZ. In response, the SDT		

Organization	Agree?	Question 11 Comment
modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Measure M2 requires that the entity have evidence showing dates and activities accomplished to meet the R2 implementation requirement. The SDT notes that the proposed standard revision does not preclude the USFS and the TO from negotiating consideration for vegetation growth rates and in fact it is a good idea.		
City of Tallahassee	Agree	As long as we do not have to have evidence of using the calculation! We should be able to use Table I as provided.
Response: Thank you for your comment. Please see the summary response. Many commenters disagreed with this requirement and it has been substantially modified.		
Bonneville Power Administration	Agree	BPA agrees with R2, but refer to comments submitted regarding R4 (please see our response to Question #15) for related recommendations to R2.
Response: Thank you for your comment. The SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.		
MRO NERC Standards Review Subcommittee	Agree	The MRO agrees and believes that the Gallet equation yields a less subjective measurement. The MRO believes R2 should be modified to be more definitive. The imminent threat procedure should be implemented when vegetation “enters” the critical clear zone. Fines and violations for approaching the zone is not measurable or enforceable. The MRO believes that "approached" is subjective and not enforceable and should be removed from the requirement.
Response: Thank you for your comment. The SDT modified R2 to remove the use of the CCZ to trigger Imminent Threat procedure implementation. Requirement R2 now requires the Transmission Owner to implement its imminent threat procedure upon discovery of such a threat. . The Critical Clearance Zone has been replaced with Minimum Vegetation Clearance Distance (MCVD) in R4.

12. The Standard Drafting Team revised the spark-over (also referred to as "flashover") distance thresholds utilizing technically-equivalent Gallet equations in lieu of IEEE 516 minimum air insulation distance (MAID) calculations that were used in FAC-003-1. The rationale is that the minimum air insulation distances in IEEE 516 were safety clearances developed under laboratory conditions and thus there exists concern these distances may be too conservative to apply to lines operating in actual field conditions. Do you agree with this? If not, please explain.

Summary Consideration: The majority of responders (90%) agreed with this change. The minority view favored the continued use of IEEE 516 and four responders advocating removing the tables from the standard.

After reviewing the industry comments, the SDT continues to support the merits of using the Gallet equations and maintaining the tables in the standard. IEEE 516 values are safety clearances developed under laboratory conditions and thus these distances are inappropriate for vegetation spark-over clearances associated with lines operating in actual field conditions. In addition, IEEE Standards are subject to change which the SDT did not desire to have the Vegetation Reliability associated with an IEEE Standard that may change without proper consideration of the impact to the Vegetation Reliability Standard.

By using the Gallet distances, the SDT feels this is a technically sound, independent value that represents a true spark-over threshold distance. One must remember this is a minimum distance and the new requirement of 1.6 specifies the Transmission Owner develop a maintenance strategy to ensure these clearances are never violated.

Organization	Question 12	Question 12 Comment
SERC Compliance Staff	Disagree	While the actual sparkover distance may be more correctly calculated using the Gallet equations, SERC staff believes it is a less conservative approach to the goal of preventing vegetation related outages. If the concept of the CCZ will remain in the standard, we suggest that the tables based on the Gallet equations be removed from the standard and be kept in the technical white paper solely to assist in developing a common understanding of the theory behind the establishment of a CCZ. However, the CCZ will continue to be a very difficult, if not impossible, aspect of the standard to implement from the perspective of practical application and compliance enforcement.
Response: The SDT thanks you for your response. The SDT feels that the tables are an important component and should be part of the standard. The supporting documentation for the derivation of the tables resides in the technical reference document. The revised standard does not use the concept of the CCZ.		
Tennessee Valley Authority	Disagree	TVA agrees with this concept however as stated in Comment Question 11 response, this should be an element of the White Paper and should not be in the Standard Requirement.

Organization	Question 12	Question 12 Comment
Response: The SDT thanks you for your response. The SDT feels that the tables are an important component and should be part of the standard. The supporting documentation for the derivation of the tables resides in the technical reference document.		
Exelon	Disagree	Comments: By using the Gallet equations, the draft standard appears to support reducing the clearance requirements as compared to IEEE 516. Given what we believe would be the difficulties in applying the clearances as developed using the Gallet equation method, we question if dropping the IEEE 516 guidance could have the unintended consequence of reducing reliability.
Response: The SDT thanks you for your response. The reduction in the clearance distances is due to applying smaller transient over-voltage factors and not due to using the Gallet equations. The SDT feels that using the reduced over-voltage factors is a more realistic approach than using the maximum factors in version 1. The Gallet equations are only one of the factors in developing clearances. The utility must also consider sag, sway, growth, environmental conditions and other factors when developing an effective TVMP.		
Northern Indiana Public Service Company	Disagree	If T.O.'s are serious about public safety and potential electrical hazards or are required to comply with NESC/IEEE safety standards, then the greater, more conservative clearance distances must apply. On an complex issue where the aerial distances between live conductors and trees are dynamic and changing, I would prefer to be on the side of caution and on the side of safety. Given the history of cascading blackouts due to preventable tree contacts, there is a need to be conservative with the standards. I don't see it being in the public interest to argue that established minimum air insulation distances are inappropriately restrictive when applied to UVM.
Response: The SDT thanks you for your response. The Gallet equations are only one of the factors in developing clearances. The utility must also consider sag, sway, growth, environmental conditions and other factors when developing an effective TVMP.		
Consumers Energy Company	Disagree	The Gallet distances severely lessen the reliability of the transmission system since there is not a define imminent threat distance and the Clearance 1 distances have been removed from this draft. The IEEE 516 distances provided a safety margin to allow for vegetation to grow and not be a reliability risk. A transmission owner/operator of a moderate size could not effectively inspect often enough during the growing season to protect lines from outages when trees are permitted to approach the Gallet formula distance and not be a violation. Such close distances would permit utility management to severely cut vegetation management budgets and allow trees to grow for 1-2 years beyond their scheduled maintenance cycle and not be in violation. But, 2-3 years after the budget cut, the field operation would be faced with an insurmountable amount of trees needing addressed and limited timeframes to complete the work. This is basically how the blackout occurred and this standard decreases the requirements to allow this to happen again.
Response: The SDT thanks you for your response. The Gallet equations are only one of the factors in developing clearances. The utility must also		

Organization	Question 12	Question 12 Comment
consider sag, sway, growth, environmental conditions and other factors when developing an effective TVMP.		
Baltimore Gas & Electric Company	Disagree	As noted in 11 above, the Gallet equation would appear to be a much closer approximation of the actual spark gap/flashover distance. It seems as though the new std. is making the protective zone around the conductors smaller by replacing the Clearance 2 requirement with the CCZ, while at the same time eliminating any other type of consideration for how much clearance needs to be achieved while trimming. All things being equal, if the only demarcation for when vegetation is a threat to the lines is the clearance 2 or CCZ areas, it would make sense to have this area be larger rather than smaller. Accordingly, I would recommend that the Clearance 2 value continue to be used instead of the Gallet equation-created CCZ.
Response: The SDT thanks you for your response. The Gallet equations are only one of the factors in developing clearances. The utility must also consider sag, sway, growth, environmental conditions and other factors when developing an effective TVMP. Note that the revised standard does not use the concept of the CCZ.		
SERC Vegetation Management Subcommittee (VMS)	Agree	Developing minimum sparkover distances in this standard is a superior approach for the stated reason in question 12. In addition, referring to tables and values in another standard is problematic if the referenced standard is revised and the tables are re-numbered or deleted altogether. We suggest that the tables based on the Gallet equations be removed from the standard and be kept in the technical white paper solely to assist in developing a common understanding of the threshold for taking actions.
Response: The SDT thanks you for your response. The SDT feels that the tables are an important component and should be part of the standard. The supporting documentation for the derivation of the tables resides in the technical reference document.		
SERC OC Standards Review Group	Agree	Developing minimum sparkover distances in this standard is a superior approach for the stated reason in question 12. In addition, referring to tables and values in another standard is problematic if the referenced standard is revised and the tables are re- numbered or deleted altogether. The SERC OOCSRG suggests that the tables based on the Gallet equations be removed from the standard and be kept in the technical white paper solely to assist in developing a common understanding of the threshold for taking actions.
Response: The SDT thanks you for your response. The SDT feels that the tables are an important component and should be part of the standard. The supporting documentation for the derivation of the tables resides in the technical reference document.		
Western Utility Arborists	Agree	The Western Utilities feel that changing this will not have a large impact on its vegetation management operations, so we have no concerns.
Response: The SDT thanks you for your response.		

Organization	Question 12	Question 12 Comment
American Electric Power (AEP)	Agree	AEP agrees that the Gallet Equation method is a reasonable and appropriate replacement for the IEEE 516 method.
Response: The SDT thanks you for your comments.		
Platte River Power Authority	Agree	Changing this will not have a large impact on vegetation management operations, so we have no concerns.
Response: the SDT thanks you for your comments.		
USDA Forest Service, Southwestern Region, Regional Office for AZ and NM	Agree	See comment for Question 11.
Response: The SDT thanks you for your response. The Gallet equations are only one of the factors in developing clearances. The utility must also consider sag, sway, growth, environmental conditions and other factors when developing an effective TVMP.		
NV Energy (fka Sierra Pacific / Nevada Power Co.)	Agree	We feel that changing this will not have a large impact on its vegetation management operations, so we have no concerns.
Response: The SDT thanks you for your comments.		
Salt River Project	Agree	As commented in Comment #11 above, although we agree that using the Gallet equation is more definitive than using IEEE 516, we still question from an engineering prespective as to how and why this method was chosen. It is stated in the Technical Reference paper that the Gallet Equation is a well known method of computing the required strike distance for proper insulation coordination. It is our understanding it's purpose is for designing towers, to define the "tower window" or opening inside of a tower under normal conditions. Because this is not a method design specifically for vegetation management, was there any physical testing involved in choosing this approach, such as testing in both wet and dry conditions? We would recommend additional information to clarify this method to use for vegetation management. See additional comments in Comment #18 below.
Response: The SDT thanks you for your response. The SDT searched for a method other than the laboratory condition based IEEE 516 method to determine minimum spark-over distances. The Gallet equations were derived for both wet and dry conditions and have been successfully used in many design applications. The SDT feels that using these equations to derive these minimum distances is a conservative approach. We also expect that the TO must also consider sag, sway, growth, environmental conditions and other factors when developing clearances for an effective TVMP.		

Organization	Question 12	Question 12 Comment
Buckeye Power, Inc.	Agree	I understand the reasoning for the change, but I do not see how decreasing clearances will increase reliability.
Response: The SDT thanks you for your response. The Gallet equations are only one of the factors in developing clearances. The utility must also consider sag, sway, growth, environmental conditions and other factors when developing an effective TVMP.		
British Columbia Transmission Corp	Agree	BCTC feels that changing this will not have a large impact on its vegetation management operations, so we have no concerns.

Formatted: Indent: Left: 0"

13. The Standard Drafting Team applied a transient overvoltage factor (T) of 1.4 and 2.0 for ac voltage classes of 345kV and above and sub-345kV facilities, respectively. Version 1, using the IEEE 516 method, assumes a maximum transient overvoltage value. The Standard Drafting Team asserts that in this application of steady-state flashovers and due to the design attributes of higher voltage systems, a lower T factor is applicable. Do you agree with this? If not, please explain.

Summary Consideration: The majority of responders (93%) agreed with this change. Two responders commented that they use a more conservative transient over-voltage factor in their design.

The SDT chose its transient over-voltage factors ("T") as being the most appropriate values for the industry as a whole. The majority of industry stakeholder comments supported this decision. It is permissible to use more conservative values if the Transmission Owner so desires.

Organization	Agree ?	Question 13 Comment
BCTC		BCTC feels that changing this will not have a large impact on its vegetation management operations, so we have no concerns.
Response: The SDT thanks you for your response.		
Tennessee Valley Authority	Disagree	TVA agrees with this concept however as stated in Comment Question 11 response, this should be an element of the White Paper and should not be in the Standard Requirement.
Response: The SDT thanks you and refers you to the response to Question 11.		
Exelon	Disagree	We disagree with the T factors that are proposed as our design is more conservative.
Response: The SDT thanks you and also acknowledges that various utilities may employ various T factors in their line designs. However, the SDT chose this value as the most appropriate value for the industry as a whole. Individual Transmission Owners are free to establish larger zones around the conductor than that established by the new MVCD. MVCD as currently drafted establishes a minimum value, not the only value.		
Manitoba Hydro	Disagree	Manitoba Hydro has historically designed the ROW clearance requirements based on an operating limitation of not switching during extreme wind conditions, therefore, beyond a wind pressure of 230 Pa, our design does not account for switching surge over voltages. We do however, agree with the use of overvoltage factors

Organization	Agree ?	Question 13 Comment
		as described above for wind conditions of less than 230 Pa.
Response: The SDT thanks you for your comments. Industry as a whole. Individual Transmisssion Owners are free to establish larger zones around the conductor than that established by the new MVCD. MVCD as currently drafted establishes a minimum value, not the only value.		
National Grid	Disagree	No opinion.
Response: The SDT thanks you for your comments. The SDT believes that it has chosen an approach that is the most appropriate method for the industry as a whole.		
SERC Vegetation Management Subcommittee (VMS)	Agree	See comments in #12 above.
Response: The SDT thanks you for your comments. See response to #12.		
SERC OC Standards Review Group	Agree	See comments in #12 above.
Response: The SDT thanks you for your comments. See response to #12.		
Salt River Project	Agree	As commented in Comments #11 & #12 above, although we agree that using the Gallet equation is more definitive than using IEEE 516, we still question from an engineering prespective as to how and why this method was chosen. It is stated in the Technical Reference paper that the Gallet Equation is a well known method of computing the required strike distance for proper insulation coordination. It is our understanding it's purpose is for designing towers, to define the "tower window" or opening inside of a tower under normal conditions. Because this is not a method design specifically for vegetation management, was there any physical testing involved in choosing this approach, such as testing in both wet and dry conditions? We would recommend additional information to clarify this method to use for vegetation management. See additional comments in Comment #18 below.
Response: The SDT thanks you for your comments. No physical testing was utilized by the SDT; however, the Gallet Equation method and its explanation in the White Paper do have their basis in physical testing in both laboratory and field conditions. The Gallet Equation method is not solely applicable to tower structure design, but to any application requiring spark-over calculations. The SDT believes that the Gallet Equation method holds distinct advantages over the IEEE 516 method for use in vegetation management applications.		
Western Utility Arborists	Agree	The Western Utilities feel that changing this will not have a large impact on its vegetation management

Organization	Agree ?	Question 13 Comment
		operations, so we have no concerns.
Response: The SDT thanks you for your comments.		
American Electric Power (AEP)	Agree	AEP agrees that the choice of transient overvoltage factors is sufficiently sound.
Response: The SDT thanks you for your comments.		
Platte River Power Authority	Agree	Changing this will not have a large impact on vegetation management operations, we have not concerns.
Response: The SDT thanks you for your comments.		
City of Tallahassee	Agree	As long as we do not have to have evidence of using the calculation! We should be able to use Table I as provided.
Response: The SDT thanks you for your comments.		
NV Energy (fka Sierra Pacific / Nevada Power Co.)	Agree	We feel that changing this will not have a large impact on its vegetation management operations, so we have no concerns.
Response: The SDT thanks you for your comments.

USDA Forest Service, Southwestern Region, Regional Office for AZ and NM		Don't know!

14. R3 has been added to clarify that conduction of inspections is a separate requirement from specifying the frequency that inspections will occur. Do you agree with R3? If not please explain.

Summary Consideration: The majority of commenters (85%) were in favor of the standard as written. There were minority comments that wanted a reformatting of the standard to put documentation and implementation side by side. Following the directives in FERC order 693 and the SAR to bring the standard in line with the Sanction Guidelines, the SDT created a separate requirement, R3 that explicitly requires inspections be conducted. This is to differentiate R3 from Requirement 1, Part 1.2. Addressing inspections separately allows for appropriate assignment of VRFs and VSLs.

Organization	Agree?	Question 14 Comment
BCTC		BCTC understands that it's possible to have a schedule and not implement it. However, we feel that the document itself would be easier to follow if it was re-organized so that the requirement to have the schedule is kept together with the requirement to implement it.
Response: The SDT thanks you for your comment. The SDT considered other sequence options and suggest a new sequence for the industry to comment upon. See related question in the second Comment Form.		
Western Utility Arborists		The Western Utilities understands that it's possible to have a schedule and not implement it. However, we feel that the document itself would be easier to follow if it was re-organized so that the requirement to have the schedule is kept together with the requirement to implement it.
Response: The SDT thanks you for your comment. The SDT considered other sequence options and suggest a new sequence for the industry to comment upon. See related question in the second Comment Form.		
Progress Energy Florida	Disagree	The standard has established a threshold of compliance. For consistency, compliance should be measured at the threshold not a Registered Entities program requirement.
Response: The SDT thanks you for your comments. R3 clarifies that the inspections in the TVMP are to be conducted. The TVMP defines a Transmission Operator's standards. The general application of NERC standards is that a Transmission Operator is to adhere to the standards it establishes.		
Progress Energy Carolinas	Disagree	The standard has established a threshold of compliance. For consistency, compliance should be measured at the threshold not a Registered Entities program requirement.

Organization	Agree?	Question 14 Comment
Operator's standards. The general application of NERC standards is that a Transmission Operator is to adhere to the standards it establishes.		
Southern California Edison Company	Disagree	Q14: SCE does not agree with the inclusion of proposed R3 and believes it should be replaced with a modified version of proposed R8.SCE respectfully suggests that proposed R8 be revised to read: "Each Transmission Owner shall implement and follow its Vegetation Management Program to the extent allowed by existing easement and/or legal rights."
Response: The SDT thanks you for your comments. Inspections are a key element of an effective TVMP. The SDT therefore decided to explicitly require that inspections be conducted in accordance with the Transmission Owners' requirements. In addition, addressing inspections separately allows for appropriate assignment of VRFs and VSLs.		
NV Energy (fka Sierra Pacific / Nevada Power Co.)	Disagree	We understand that it is possible to have a schedule and not implement it. However, we feel that the document itself would be easier to follow if it was re-organized so that the requirement to have the schedule is kept together with the requirement to implement it.
Response: The SDT thanks you for your comment. The SDT decided to explicitly require that inspections be conducted in accordance with the Transmission Owners' requirements. Addressing inspections separately allows for appropriate assignment of VRFs and VSLs.		
San Diego Gas & Electric	Disagree	The information should not be separated. It will be much easier to follow if the requirement to have the schedule is kept together with the requirement to implement it.
Response: The SDT thanks you for your comment. The SDT decided to explicitly require that inspections be conducted in accordance with the Transmission Owners' requirements. Addressing inspections separately allows for appropriate assignment of VRFs and VSLs.		
Edison Electric Institute	Disagree	Consistent with previous comments, NERC should respond to FERC Order No. 693 Paragraph 721 regarding compliance audit procedures to identify appropriate inspection cycles.
Response: The SDT thanks you for your comment. The SDT decided to explicitly require that inspections be conducted in accordance with the Transmission Owners' requirements. Your comment has been forwarded to NERC staff. The Reliability Standard Audit Worksheet is where the FERC Order is addressed with respect to compliance audit procedures to identify appropriate inspection cycles.		
Baltimore Gas & Electric Company	Disagree	If frequency of inspections are required to be specified, it is implied that the inspections will follow. I suggest that R3 be eliminated and R1.2 be reworded to say: "Vegetation inspections shall occur at least once per year, or more frequently as dictated by local and environmental factors. Specify the frequency of when vegetation inspections will occur."

Organization	Agree?	Question 14 Comment
Response: The SDT thanks you for your comment. The SDT decided to explicitly require that inspections be conducted in accordance with the Transmission Owners' requirements. Addressing inspections separately allows for appropriate assignment of VRFs and VSLs. The STD believes that the phrase "Specify a vegetation inspection frequency…" adequately requires the Transmission Operator to ". . . .specify the frequency…"		
JEA	Disagree	See comment from #3.
Response: The SDT thanks you for your comment. This was addressed in the response to question 3.		
Salt River Project	Disagree	The document would be easier to follow if the two elements would be kept together in the same requirement (similar to comments stated in Comments #4 & #6 above). It makes the standard longer than necessary and creates redundancy.
Response: The SDT thanks you for your comment. The SDT decided to explicitly require that inspections be conducted in accordance with the Transmission Owners' requirements. Addressing inspections separately allows for appropriate assignment of VRF and VSLs.		
Tennessee Valley Authority	Agree	TVA agrees with Comment Question 14
Response: The SDT thanks you for your comment.		
American Electric Power (AEP)	Agree	AEP agrees with this change.
Response: The SDT thanks you for your comment.		
Platte River Power Authority	Agree	The separation allows lower sanctions and penalties to be assessed for a weak schedule and higher sanctions and penalties to be assessed for not implementing schedules. However, we feel that the standard itself would be easier to follow if it was re-organized so that the requirement to have the schedule is kept together with the requirement to implement it.
Response: The SDT thanks you for your comment. The SDT decided to explicitly require that inspections be conducted in accordance with the Transmission Owners' requirements. Addressing inspections separately allows for appropriate assignment of VRFs and VSLs.		
Arizona Public Service Company	Agree	APS understands that it's possible to have a schedule and not implement it. However, we feel that the document itself would be easier to follow if it was re-organized so that the requirement to have the schedule is kept together with the requirement to implement it.

Organization	Agree?	Question 14 Comment

15. Several alternatives to R4 were considered by the drafting team. The drafting team explored these significantly different alternatives at length. They are outlined below to provide background to industry during this comment period. (Please refer to pages 22-32 in the Technical Reference Document on the Critical Clearance Zone for further background for this question.) Do you agree that R4 is written in the most effective way to achieve the purpose of the standard? If not, what do you propose as an alternative to R4 that would ensure a level of reliability equal to or better than FAC-003-1?

As written, R4, a new requirement, stipulates that the Transmission Owner is in violation if an encroachment of the Critical Clearance Zone occurs at any time. If vegetation enters the Critical Clearance Zone, a violation will have occurred, regardless of the actual proximity of the vegetation to the conductor at the time. Evidence will be required to prove that no encroachments of the Critical Clearance Zone have occurred anywhere at any time during the annual compliance period. This will require the time and effort to postpone vegetation maintenance to perform field investigations and document all possible encroachments.

One alternative to R4 required immediate removal of the vegetation or immediate implementation of the imminent threat procedure upon discovery of a possible encroachment of the Critical Clearance Zone, thereby proactively preventing an outage. A violation would have occurred only if the imminent threat process was not successfully implemented.

Another alternative was a tiered approach. This tiered approach involved a "per thousand mile" metric to determine when a violation had occurred and the severity of the violation. This metric was an attempt to equitably account for varying exposures that exist due to widely ranging system sizes.

Summary Consideration: Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The Critical Clearance Zone has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.

Ninety-four percent of the commenters disagreed with the proposed alternatives. The SDT classified the comments into 44 different concepts with many commenters weighing in on several concepts. For 37 commenters the dominant concept was "Measure M4 requires proof of no encroachments, i.e., "prove a negative", compliance certification is difficult." Below is a redlined version of R4. reflecting the changes that were made by the SDT.

R4. Each Transmission Owner shall prevent encroachment of vegetation into the Minimum Vegetation Clearance Distances ("MVCD") listed in Attachment 1 for its applicable lines as observed in real-time operating between no-load and their Rating with the following exceptions: *[Violation Risk Factor VRF= Medium][Time Horizon – Real Time]*

Deleted: ~~within~~

Deleted: ~~Critical~~

- Encroachment into the Minimum Vegetation Clearance Distances listed in Attachment 1 resulting from natural disasters.[2]
- Encroachment into the Minimum Vegetation Clearance Distances listed in Attachment 1 resulting from human or animal activity.[3]
- Brief encroachment into the Minimum Vegetation Clearance Distances listed in Attachment 1 resulting from falling vegetation.

The SDT further weighed the NERC interpretation of the vegetation management standard during FERC's consideration of proposed FAC-003-1: A vegetation-related transmission line outage as a result of vegetation that has grown into the pre-defined clearance zone is a violation of the standard. The Commission adopted that interpretation when it approved NERC's proposed reliability standards. It stated, "FAC-003-1 requires sufficient clearances to prevent outages due to vegetation management practices under all applicable conditions."4

In reviewing the comments and the FERC opinion the SDT considered 4 options:

- Re-word R4 and keep R4 the way it was originally intended (violation would only be if you had the outage) (Alternative B of Question 15**) {implies that R5, R6, & R7 are retained}
- Remove R2 and R4 from the standard. Keep the Critical Clearance Zone concept in the white paper.
- Remove R4 from the standard and revise R2 to have a "trigger distance" for implementation of the imminent threat process. Keep the Critical Clearance Zone concept in the white paper. Team would need to consider the true definition of an imminent threat.
- Return to the Clearance 2 concept. But define (somehow) that this is a "real time" violation only. Distance could be defined as the Gallet distance or a multiple of the Gallet distance.

The SDT made the following changes in line with bullet 4.

R4. Each Transmission Owner shall prevent encroachment of vegetation into the Minimum Vegetation Clearance Distances (MVCD) listed in FAC-003-2 - Attachment 1 for its applicable lines as observed in real-time operating between no-load and their Rating, with the following exceptions:

- Encroachment into the MVCD listed in FAC-003-2-Attachment 1 resulting from natural disasters.[4]

Organization	Agree?	Question 15 Comment
PJM Interconnection		The current version of this standard, FAC-003-1, kept the subject of vegetation outside of the Rights of Way in the standard. Why are outside of Rights of Way vegetation issues not mentioned in FAC-003-2, or some responsibility for looking for outside of Rights of Way imminent threats or issues requiring corrective action plans not addressed?
Response: The SDT thanks you for your comments. Trees outside of the right of way should be identified and removed as necessary as they are identified as a threat to the reliability of the line. This function should be part of a vegetation management program as a follow up to the inspection process. Any vegetation that could pose a threat to the reliability to the line found during the inspection process should be remedied. The purpose statement for FAC-003-2 states that the standard is intended to improve the reliability of the electric transmission system by preventing vegetation related outages that could lead to Cascading.		
BCTC		The new requirement in R4 stipulates that the Transmission Owner is in violation if an encroachment of the CCZ occurs at any time. However, the CCZ changes with each foot of the transmission line from the insulator to the mid-span, depending on loading, actual operating temperature, wind loading, ice loading, maximum design rating, maximum operating load, and so on. Further, Measure M4 requires that the Transmission Owner has evidence demonstrating there were no vegetation encroachments into the CCZ. These requirements may result in having to LIDAR the lines annually, to prove that trees have not encroached upon the CCZ. This would be an extremely onerous and expensive requirement for utilities. BCTC strongly supports the alternative to R4 as recommended in the Comment Form (#15), which is to require immediate removal of the vegetation or immediate implementation of the imminent threat procedure upon discovery of a possible encroachment of the CCZ, thereby proactively preventing an outage. This means a violation would occur only if the imminent threat process is not successfully implemented. This alternative is essentially the same as R2. Therefore, BCTC recommends removing R4 from the standard entirely.

[4] Examples include, but are not limited to, earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods.

[5] Examples include, but are not limited to, logging, animal severing tree, vehicle contact with tree, arboricultural activities or horticultural or agricultural activities, or removal or digging of vegetation.

Organization	Agree?	Question 15 Comment
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the “Minimum Vegetation Clearance Distances”, and Transmission Owners are required to prevent encroachment of vegetation into “Minimum Vegetation Clearance Distances” as observed in real time.		
Associated Electric Cooperative Inc.	Disagree	Associated Electric Cooperative Inc believes this requirement, as written, is unreasonable since it would prevent (or at least result in noncompliance) the intrusion within the Critical Clearance Zone (CCZ) of anything or anyone, including qualified line workers and their tools. It is suggested the words “of vegetation” be added between encroachment and within. The requirement would then read, “Each Transmission Owner shall prevent encroachment of vegetation within the Critical Clearance Zone of its applicable lines with the following exceptions:” The complexity of determining an encroachment into the Critical Clearance Zone is overly burdensome, requiring engineering calculations and possibly the need for precision measurements. The Transmission Owner (TO) cannot demonstrate compliance with the Requirement and its companion Measure, M4, since a negative cannot be proven. Therefore, since the TO must demonstrate compliance (guilty until proven innocent), it is automatically in violation of the Standard.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the “Minimum Vegetation Clearance Distances”, and Transmission Owners are required to prevent encroachment of vegetation into “Minimum Vegetation Clearance Distances” as observed in real time. The SDT, for clarity, did add the phrase “of Vegetation” as requested.		
NPCC	Disagree	The purpose of the standard is "To improve the reliability of the Bulk Electric System by preventing vegetation related outages that could lead to Cascading". We believe that R4 is not the most effective way to achieve this purpose because it does not provide incentive for Transmission Owners to take advantage of modern technology, such as aerial laser survey (ALS) using Light Detection and Ranging technology (LIDAR), that is capable of accurately identifying vegetation which is approaching the CCZ or has encroached into it. In fact R4 provides an incentive not to utilize this technology because Transmission Owners who identify encroachments would be in violation of R4 for each identified encroachment. On the other hand, Transmission Owners who choose to be less proactive often would not identify such encroachments because the CCZ and encroachments of it are generally not easy to determine without taking precise measurements. Unless the line is heavily loaded or the vegetation is significantly overgrown, encroachments of the CCZ would not be readily noticed. In most cases these Transmission Owners would simply remove or cut back incompatible vegetation without taking measurements. The threat to the line would have been eliminated with no encroachment having been identified.R4 presents a dilemma for Transmission Owners that are considering making the significant investment in ALS technology. While the technology would allow them to identify any potential grow-in or fall-in conditions, it would also expose them to the risk of identifying violations of R4, that would otherwise not have been identified. Violation Risk Factors

Organization	Agree?	Question 15 Comment
		(VRFs), Violation Severity Levels (VSLs), and Time Horizons are not included in this Draft, but after making a significant investment in ALS, Transmission Owners could be faced with significant additional cost in terms of NERC penalties. In addition, even if the penalties were relatively low they would be exposing themselves to violations that less proactive Transmission Owners would not be exposed to. In our view R4 as written would, in some cases, have the opposite effect of what is intended because the business case for using ALS is more difficult to make. This will result in less use of ALS and other emerging technology that is likely to be developed. This would result in fewer problems being identified, a small percentage of which will not be discovered until they result in a line trip. Still we believe that the concept of the CCZ is a good one and recommend that R4 be changed so that Transmission Owners are provided with an incentive to invest in the best technology available in order to ensure the highest level of reliability. The opportunity exists to develop the standard in a manner that encourages the industry to take advantage of new technology and manage vegetation in a very proactive way. We recommend that R4 be changed as follows: Modify R4 to require Transmission Owners to immediately implement the imminent threat process defined in R1.4 when they identify instances where the CCZ is approached or encroached upon. Failure to do so would be a violation of R4. Eliminate encroachment of the CCZ as a violation of R4. This would eliminate R2 and incorporate implementation of the imminent threat process into R4.Require Transmission Owners to report to the Regional Entity on a quarterly basis any instances where the imminent threat process was implemented due to an encroachment of the CCZ. This would add a reporting requirement for Transmission Operators. Require Transmission Owners to report to the Regional Entity on a quarterly basis any instances where either a momentary or sustained outage was caused by grow-ins, Active Transmission Line Right of Way blow-ins, or Active Transmission Line Right-of-Way fall-ins. This would add three additional reporting requirements for Transmission Operators. Require Regional Entities to perform additional audits of Transmission Owners that exceed metrics for violations of the CCZ . The metrics would be established in this Standard based upon 100 circuit miles of applicable lines. This would add an additional requirement for Regional Entities. This concept would result in a more rigorous standard than FAC-003-01 because of the additional reporting and auditing requirements. It would drive proactive behavior throughout the industry and provide a significant incentive for Transmisison Owners to invest in new technology such as ALS that is capable of accurately identifying vegetation that has approached or encroached upon the CCZ. We believe that this change would result in the identification of more incipient vegetation-related problems and fewer vegetation-related outages as soon as it was implemented and would best support the purpose of the Standard.

Response: The SDT thanks you for your comments. The SDT concurs that the use of ALS – LiDar technology, while expensive, could enhance reliability. However several team members have made the investment and concur that the technology including interpertation software are not sufficiently mature to be put in a standard. In addition in some cases it would not be cost justifiable over traditional methods of inspection. During the course of our deliberations the team questioned both FERC and RE staff's response to a utility finding encrochments with ALS technology and concluded the auditor would not forgive encrochment even though the Transmission Owner went to extraordinary means to find the encrochment.

Initially the team approached the FERC staff in a meeting in Washington with a proposal that an encrochment not be a violation if the Transmission Owner implemented the imminent threat procedure successfully before an interruption occurred. The concept was rebuffed by the FERC Staff as a step

Organization	Agree?	Question 15 Comment
backwards from version 1. **The SDT very carefully and thoroughly examined the merits, disadvantages, ease and difficulties of assessing momentary outages as a violation. The result of that effort led to the more precise and field observable aspects of R4. It should be noted that by their very nature the exact causes of "momentary outages" are very challenging to determine and will vary widely from utility to utility. The SDT did not find that such variability was appropriate for a reliability standard, and chose to address this issue with the language in R4.** **Due to the industry impact that arises from zero tolerance for vegetation-related sustained outages, the Drafting Team tried several approaches but could not find a mechanism in the standard development process to establish a non-zero threshold for outages that was acceptable to FERC staff because Standard revisions to already approved standards may not lead to less emphasis on reliability.**		
Western Area Power Administration, Upper Great Plains Region	Disagree	R4 as proposed would do nothing to improve the reliability of the BES. In fact, we believe that R4 (as currently proposed) would impose significantly more stringent requirements than most Transmission Owners have interpreted FAC-003-1 to require. We believe that if the proposed interpretation would have been offered under FAC-003-1 that there would have be a great backlash against that Standard. It is our believe that current annual certifications of compliance for FAC-003-1 by Transmission Owners don't use "any infringement of the CCZ by any piece of vegetation at any time" as their measure for compliance. It could be argued that this proposal would actually do more to curtail accurate reporting of potential violations. We believe that making an infringement into the CCZ a violation and having that violation carry a six (or seven) figure fine would do more to discourage accurate reporting than any other system under discussion. Making the Transmission Owner prove that an incursion into the CCZ didn't happen would force an inventory of every inch of the R/W which is a gigantic waste of resources. Being tasked with proving that something didn't happen could be compared with our justice system declaring suspects will be considered guilty until they are proven innocent. This is a flawed and blatantly unfair concept and not a productive way of attaining the Purpose stated in this document. Western (UGPR) is disappointed by the "zero tolerance" nature of this document and its interpretation that "any infringement of the CCZ by any piece of vegetation at any time" constitutes a violation. We are not aware of any other NERC standard that is zero tolerance and question why vegetation is singled out to bear the brunt when several other factors could contribute to a system cascading event (i.e. relay problems, system configuration, operator issues, etc). In summation, we believe that a zero tolerance document being applied with "guilty until proven innocent" principles would do much to create an increasingly adversarial relationship between regulators and the industry.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
SERC Vegetation Management Subcommittee (VMS)	Disagree	The concept of the CCZ is useful as a mental model to visualize required vegetation management work. While this is a good conceptual tool to drive consistent terminology and proper vegetation management practices, it remains theoretical in nature and impractical to measure on a span by span basis. The complexity of determining

Organization	Agree?	Question 15 Comment
		an encroachment into the CCZ is overly burdensome due to the need for survey accuracy measurements and engineering evaluations. In addition, this complexity leads to questions about the ability to audit this requirement. These complexities introduce reliability and audit issues when encroachments into this conceptual area are defined as violations. The SERC VMS believes the Sustained Outage, as defined by other measures in this standard, should be the non-compliance measure. We suggest that the CCZ concept be kept in the technical white paper and that all references to the CCZ be removed from the body of the standard.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Progress Energy Florida	Disagree	The definition of Critical Clearance Zone includes too many academic and theoretical elements. It is impossible to provide evidence that vegetation did not encroach into the Critical Clearance Zone during TVMP cycles. Furthermore, the operations staff performing periodic ground and aerial inspections would need to determine the CCZ for each foot of transmission line to assure compliance with the standard as it is currently written. The CCZ concept can neither be implemented or enforced as written. The CCZ refers to Ratings which is defined in the Glossary of Terms as "The operational limits of a transmission system element under a set of specified conditions." This definition is too broad to be a consistently enforceable term from one utility or region to the next. As it is currently written, no exemption exists for vegetation falling from outside the Active Transmission Line Right of Way into, or lodging in, the theoretical CCZ.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Kansas City Power & Light	Disagree	As proposed, Requirement R4 and corresponding Measure M4 will be highly subjective and impractical for the industry to implement. The determination of a violation due to encroachments into the Critical Clearance Zone will be subjective in nature due to field judgments, is random and not initiated by a known system event. It also will not be feasible for utilities to fulfill R4 requirements to ensure and provide evidence that any encroachments into Critical Clearance Zones have not occurred on their system throughout the year. Requirement R4 is not required since in the remaining requirements of FAC-003-2 contain the principal elements for compliance in ensuring the reliability of the bulk power system related to vegetation management of the transmission system. Specifically, the remaining requirements provide that a transmission vegetation plan be maintained, implemented and regularly reviewed whereby utilities must perform the requisite vegetation clearance work in order to prevent any sustained outages on the bulk power system. A sustained outage due to vegetation is a known, measurable event to which a penalty sanction will be invoked and therefore provides the required impetus for adherence to standard FAC-003-2.Requirement R4 and the associated measure M4 should therefore be removed from the proposed standard

Organization	Agree?	Question 15 Comment
		language.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Western Area Power Administration, Rocky Mountain Region	Disagree	As discussed in the Technical Reference document and question #11 above, the CCZ is a complicated theoretical envelope surrounding all rated operating positions of the conductor. Its dynamic shape is constantly changing and is contingent upon location within the span. Calculation of the size and shape of CCZ is based, in part, upon the design parameters of the transmission facility. However, as-built or long term maintenance conditions can often diverge from the original design requirements over time. Ground elevations can also change as a result of man made or natural causes from the original design elevations recorded on plan and profile engineering drawings. Consequently, accurate field measurement of the as-built CCZ is extremely problematic and strategies that utilize the calculation of allowable right-of-way tree heights can be hindered by unrecorded deviations from the original design criteria. Allowable tree height strategies also become increasingly more difficult and impractical with increasing extremes in terrain. While the CCZ is a very important concept for an effective vegetation management program it is far to theoretical, dynamic, and impractical to field measure for use as a clear and precise boundary for regulatory purposes. As such, R4 as written should be deleted from the Standards. Further, the requirement to provide evidence of something that has not occurred (no vegetation encroachments of the CCZ) is also impractical. General industry interpretation of R1.2.2 in version 1 of the Standards is that the specific Clearance 2 distance is the precise boundary that is not to be encroached verses the broader area that is ultimately mapped out as the conductor moves through "all rated electrical operating conditions". Only the Clearance 2 distance value is a clear, precise number that can be accurately observed and measured in the field. If there is a persistence to retain the CCZ concept as a requirement within the Standards, the second bullet option above regarding the initiation of the imminent threat process upon discovery of a possible encroachment is the preferred option. Since a potential encroachment into the CCZ is not a violation under this option, exact determination of the CCZ boundary is no longer as essential. Rather, the focus is on triggering mitigation to vegetation problems to prevent outages. However, as with question #11 above, there is still no practical way to determine for regulatory purposes those "potential encroachment" situations that legitimately require initiation of the imminent threat process from those "potential encroachment" situations that do not. Under this option the utility is really motivated to initiate the imminent threat process to avoid an impending outage. As such, the occurrence of an outage becomes the only clear, precise and observable means to determine a Standards violation. A proposed alternative to ensure a level of reliability equal to or better than FAC-003-1 is to retain the Clearance 2 requirement (without the imprecise "all rated electrical operating conditions" language) in combination with the sustained outage requirements of R5, R6 and R7. If an additional margin of safety is determined to be required, industry performance can be adjusted to become more proactive by increasing the minimum Clearance 2 distance to a value greater than the proposed version 2 Gallet equation (table 1) values. Thinking in terms of the

Organization	Agree?	Question 15 Comment
		CCZ concept, it is obvious that a larger Clearance 2 value translates into a larger CCZ envelope. A larger CCZ envelope in turn triggers mitigation for possible CCZ encroachments sooner.
Response: The SDT thanks you for your comments and proposed alternatives. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Progress Energy Carolinas	Disagree	The definition of Critical Clearance Zone includes too many academic and theoretical elements. It is impossible to provide evidence that vegetation did not encroach into the Critical Clearance Zone during TVMP cycles. Furthermore, the operations staff performing periodic ground and aerial inspections would need to determine the CCZ for each foot of transmission line to assure compliance with the standard as it is currently written. The CCZ concept can neither be implemented or enforced as written. The CCZ refers to Ratings which is defined in the Glossary of Terms as "The operational limits of a transmission system element under a set of specified conditions." This definition is too broad to be a consistently enforceable term from one utility or region to the next. As it is currently written, no exemption exists for vegetation falling from outside the Active Transmission Line Right of Way into, or lodging in, the theoretical CCZ.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Southern California Edison Company	Disagree	Q15: SCE does not agree that proposed R4 was written in the most effective way because it establishes a zero tolerance enforcement policy. SCE agrees that a CCZ incursion should be addressed promptly, but we do not agree that a CCZ incursion is equivalent to a vegetation-to-line contact, or that a CCZ incursion represents an imminent threat of flash-over. As written, proposed R4 would require Transmission Owners to prove that a Critical Clearance Zone incursion has not occurred. Short of a daily ground or aerial inspection of every applicable transmission line, it is clearly impossible for a Transmission Owner to monitor their active Right of Way on a 24/7/365 basis to ensure a CCZ incursion will not or has not occurred. Bearing in mind that even the most robust of Transmission VM programs may occasionally identify an anomalous condition (in or outside the active ROW) that left untreated could lead to a flash-over or vegetation-to-line contact, the identification of such conditions typically occur during scheduled aerial or ground patrols and addressed timely. Of the two alternatives offered, SCE finds the first option (second bullet item) to be the most palatable. However, even that option leaves significant doubt as to practical enforcement, because a Transmission Owner could still be found in violation of two separate requirements (R4 and R5, R4 and R6 or R4 and R7) should a vegetation-to-line contact (resulting in a sustained outage) occur. This situation amounts to regulatory double jeopardy. SCE believes that by any reasonable legal or regulatory measure, requiring a Transmission Owner to prove that a CCZ incursion did not

Organization	Agree?	Question 15 Comment
		occur is impractical and virtually impossible to enforce in a fair and impartial manner. Further, SCE believes that proposed R4 and corresponding M4 detracts from the purported goal of FAC-003-2 and should be removed.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
SERC OC Standards Review Group	Disagree	The requirement, as written, compels the Transmission Operator to allocate precious resources to ensuring that a vegetation encroachment NEVER will occur on any transmission line, regardless of that line's true importance to maintaining electric transmission system reliability. All lines are not created equal; only those that are involved in IROLs should be held to a zero tolerance standard. R4, if retained, should begin with "Subject to its legal rights," and insert the word "vegetation" between prevent and encroachment. Vegetation, which falls through the Critical Clearance Zone or falls to lodge within the Critical Clearance Zone, should not be included as violations of the Critical Clearance Zone. The concept of the Critical Clearance Zone is useful as a mental model to visualize required vegetation management work. While this is a good conceptual tool to drive consistent terminology and proper vegetation management practices, it remains theoretical in nature and impractical to measure on a span by span basis. The complexity of determining an encroachment into the Critical Clearance Zone is overly burdensome due to the need for survey accuracy measurements and engineering evaluations. In addition, this complexity leads to questions about the ability to audit this requirement. These complexities introduce reliability and audit issues when encroachments into this conceptual area are defined as violations. The SERC OCSRG believes the Sustained Outage, as defined by other measures in this standard, should be the non-compliance measure. We suggest that the Critical Clearance Zone concept be kept in the technical white paper and that all references to the Critical Clearance Zone be removed from the body of the standard. R5, R6, and R7 ensure that version 2 of the standard has reliability requirements equal to version 1; therefore R4 should be removed.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time. The SDT, for clarity, did add the phrase "of Vegetation" as requested.		
Western Utility Arborists		The new requirement in R4 stipulates that the Transmission Owner is in violation if an encroachment of the CCZ occurs at any time. However, the CCZ changes with each foot of the transmission line from the insulator to the mid-span, depending on loading, actual operating temperature, wind loading, ice loading, maximum design rating, maximum operating load, and so on. Further, measure M4 requires that the Transmission Owner has evidence demonstrating there were no vegetation encroachments into the CCZ. To provide evidence demonstrating there were no vegetation encroachments into the CCZ would be an extremely onerous task and an expensive requirement for the Utilities. The Western Utilities strongly supports the alternative to R4 as recommended in the

Organization	Agree?	Question 15 Comment
		Comment Form (#15), which is to require immediate removal of the vegetation or immediate implementation of the imminent threat procedure upon discovery of a possible encroachment of the CCZ, thereby proactively preventing an outage. This means a violation would occur only if the imminent threat process is not successfully implemented. This alternative is essentially the same as R2. Therefore, the Western Utilities recommend removing R4 from the standard entirely.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Florida Power & Light	Disagree	NERC standards require the Transmission Owner certify annually that they are in compliance to the standard for the entire year. Since there is no way that a Transmission Owner could monitor every span of line every minute of every day, Requirement R4 cannot be certified. A Transmission owner can only certify that at the time inspected the system met the specification in the standard and that implementation of its Transmission Vegetation Management Plan maintains these specifications. As stated earlier, the Critical Clearance Zone is difficult to accurately identify in the field and without an outage it would be difficult for an auditing body to find and validate. Requirements R4-R7 are reactive in nature. They are violations after the event has occurred or when the tree - wire relationships are so close that emergency action is the only recourse for the Transmission Owner. The standard needs to drive the Transmission Owner to identify and remove trees threatening the system in a proactive fashion. A Transmission Owner should never be in violation for timely action to remove a threat to the system.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Santee Cooper	Disagree	Recommend replacing the word "prevent" in R4 to "monitor". The first alternative that requires immediate removal of vegetation or immediate implementation of the imminent threat procedure would be a Requirement that could be measured. In addition, if an encroachment is found it needs to be eliminated and the first alternative specifies immediate removal. If R4 is left as written, how can you provide evidence that there has been no encroachments within the Critical Clearance Zone.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		

Organization	Agree?	Question 15 Comment
Southern Company	Disagree	The Critical Clearance Zone is a concept that adequately describes the salient functionality a Transmission Owner must consider when determining acceptable clearances. However, the practicality of a requirement that forbids even one encroachment in the Critical Clearance Zone presents a problem for not only the field personnel doing the vegetation work, but also the Regional Entity that must enforce the requirement. This zone changes not only from one span to another, it also changes at each location along each span. The reality is that the difference in encroaching into the zone and not encroaching into the zone is a matter of a fractional inch. In order to prove non-compliance or to defend compliance at a particular site, all vegetation work would have to be postponed for survey accuracy equipment and appropriately trained personnel to be brought to the site, measurements and calculation to be made and consequently a determination rendered. This hardly seems worthwhile when the vegetation could simply be cut, the threat removed and the vegetation work could continue on down the transmission line. As stated in a previous comment, there could be many examples given of encroachments into this theoretical zone that would neither threaten the transmission line conductor nor cause a reduction in the capacity of the transmission line. This concept would be better suited to be a “trigger point” that, if found, would be incentive for the Transmission Owner to either take immediate action or ensure future activities are appropriately scheduled and implemented. This action may be as urgent as implementation of the immediate threat procedure or as non-urgent as making sure that the upcoming maintenance on that line is scheduled appropriately. If a sustained outage occurs due to an encroachment, the outage should be the compliance measure.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the “Minimum Vegetation Clearance Distances”, and Transmission Owners are required to prevent encroachment of vegetation into “Minimum Vegetation Clearance Distances” as observed in real time.		
E.ON U.S.	Disagree	The concept of the Critical Clearance Zone is useful as a mental model to visualize required vegetation management work. While this is a good conceptual tool to drive consistent terminology and proper vegetation management practices, it remains theoretical in nature and impractical to measure on a span by span basis. The complexity of determining an encroachment into the Critical Clearance Zone is overly burdensome due to the need for survey accuracy measurements and engineering evaluations. In addition, this complexity leads to questions about the ability to audit this requirement. These complexities introduce reliability and audit issues when encroachments into this conceptual area are defined as violations. We believe the Sustained Outage, as defined by other measures in this standard, should be the non-compliance measure. We suggest that the Critical Clearance Zone concept be kept in the technical white paper and that all references to the Critical Clearance Zone be removed from the body of the standard.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the “Minimum Vegetation Clearance Distances”, and Transmission Owners are required to prevent encroachment of vegetation into “Minimum Vegetation Clearance Distances” as observed in real time.		

Organization	Agree?	Question 15 Comment
Bonneville Power Administration	Disagree	R4 states that the Transmission Owner is in violation of the Standard if the Critical Clearance Zone is encroached upon. The CCZ, as defined by the Standard, changes along the transmission line from the insulator to mid-span, depending on loading, actual operating temperature, wind and ice loading, maximum design rating and operating load, etc. Also, the tandem, Measure M4, requires that the Transmission Owner has evidence demonstrating that there has been no vegetation encoachments in the CCZ along its transmission system. In order to meet the letter of the Standard, that is to provide evidence that no encroachments in the CCZ have occurred under all manner of these fluid environmental and operating conditions, the Transmission Owner would have to employ the highest level of modeling technology available, which would seem to be LiDAR technology. The standard should not be written in such a manner so that it requires, by all intent and purpose, a Transmission Owner to acquire a particular technology. BPA recommends that the Alternative represented by "the second bullet" above, be used rather than R4 in its present state, or that R.4. be simply dropped and R1.4 modified to state that the imminent threat procedures include immediate removal of encroachments into the Critical Clearance Zone. Also, the term "immediate" implies instantaneous response. The use of another term is recommended, such as "as immediate as human health and safety considerations allow, in order to prevent the possibility of flashover".
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Public Service Electric and Gas Company	Disagree	An additional clarifying exception in the footnotes to R4 consisting of a tree that is located off of the transmission owner's right of way falling into the CCZ should be added to the encroachment exceptions. Transmission owners should not be found in violation of the standard for falling vegetation located off of the TO's property.
Response: The SDT thanks you for your comments. The SDT has added the exception you requested. Note that the exception applies to any falling vegetation regardless of its location. **3. Brief encroachment into the Minimum Vegetation Clearance Distances listed in Attachment 1 resulting from falling vegetation.**		
FirstEnergy	Disagree	Providing evidence to prove that there were no encroachments of the CCZ is difficult at best. An occurrence of an encroachment does not necessarily translate to an outage. The CCZ is dynamic and difficult to measure exactly from span to span and day to day and is dependent on environmental and line conditions. The costs to comply with this requirement as written are difficult to justify considering that reliability may not be improved at all. FirstEnergy believes that the first alternative above should be used and is a more logical approach from both a reliability and compliance standpoint. Furthermore, since the first alternative is already covered by the currently proposed wording of R2, the only changes needed to the standard are to remove the proposed R4 and M4 and re-number the requirements.

Organization	Agree?	Question 15 Comment
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
MRO NERC Standards Review Subcommittee	Disagree	The MRO believes R4 should be eliminated as vegetation contacts are covered in R5 and R6. A violation should only occur with a vegetation contact. Assessing a violation and fine for a potential reduction in system reliability is not correct. Actual contacts that trip a transmission element have some measurable impact on system reliability even if it is slight.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Midwest ISO Stakeholders Standards Collaborators	Disagree	The second bulleted alternative above is the best approach, but it should be improved by changing the imminent threat trigger from "encroachment of the CCZ" to "encroachment within some observed, field distance that is a multiple of the Gallet distances referenced in Table I". We have recommended changes to accomplish this in Requirement R2 (see our response to Question #11 above), and R4 should simply be deleted. While the CCZ is valuable to understanding the movement of conductors, it cannot be readily applied in the field. This field application challenge is noted in the Technical Reference Document (pages 29 & 30).The way R4 is currently stated, the Transmission Owner would be in violation of R4 for any CCZ encroachment not due to natural disasters or human or animal activity. This would include a tree falling from outside the right of way corridor that passes through the theoretical CCZ. Furthermore, Transmission Owners would be required to self-certify compliance with R4, and we don't think there's any way to do that. Clearly the approach of assessing violations for CCZ encroachment is unworkable. Likewise, the third alternative listed above is untenable. The tiered approach could have a mitigating effect on violations, but it would require the same inspection effort and postponement of vegetation management that makes the first alternative unworkable. Both the first and third alternatives would require very significant additional expenditures for surveys and documentation in an impossible attempt to certify compliance - money that would be better spent controlling vegetation.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time. The proposed standard revision specifies the MVCD as a starting point and TO's may apply multiples at their own discretion in order to achieve their TVMP objectives and adhere to applicable safety standards.		
SERC Compliance Staff	Disagree	The concept of the Critical Clearance Zone is useful as a mental model to visualize required vegetation

Organization	Agree?	Question 15 Comment
		management work. While this is a good conceptual tool to drive consistent terminology and proper vegetation management practices, it is impractical to measure on a span by span basis. The complexity of determining an encroachment into the Critical Clearance Zone is overly burdensome due to the need for survey accuracy measurements and engineering evaluations. While it may be a technically sound approach to designate the clearance zone to be tied to the conductor movement envelope as found in the NESC, this results in a banana-shaped zone that is difficult to substantiate in the field by entity and compliance personnel. We suggest that the Critical Clearance Zone concept be kept in the technical white paper and that all references to the Critical Clearance Zone be removed from the body of the standard.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
ITC HOLDINGS	Disagree	First, it's impossible to determine that no encroachments into the CCZ have occurred at any time and determination of the CCZ from the field perspective is problematic. The standard is ambiguous and it seems like clear cutting is the underlining message that is wanted. Determining an encroachment into the CCZ is problematic due to the need for survey accuracy measurements and engineering evaluations. This will also lead to questions about the ability to audit this requirement. The CCZ changes in size and shapes continuously in each and every span and will be difficult to monitor. This would require field personnel to spend numerous hours estimating and attempting to measure potential encroachments of the CCZ. The way R4 is currently written the Transmission Owners would be required to self-certify compliance with R4, and which we don't think this is possible. This will lead to audit issues with more scrutinizing and potentially more penalties or fines. It is important to recognize that the ultimate goal of the standard is to ensure that vegetation management is conducted in order to maintain an adequate level of reliability, and not to precisely measure clearance zones. Alternative 2 would be the most logical choice, depending on easement/legal rights, with changes that would eliminate any reference to a trigger point into the encroachment zone of the CCZ to; measuring encroachment to a fix distance (Gallet tables) observed by field personnel
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Tennessee Valley Authority	Disagree	TVA recommends that R4 be removed from this standard. Since this is a "zero tolerance" standard with substantial penalties for controllable vegetation related outages there is an overwhelming incentive for the Transmission Owner to proactively perform inspections, preventative maintenance, inpections and corrective maintenance to prevent potential outages. As such, R4 does not add any value to improving reliability while causing numerous

Organization	Agree?	Question 15 Comment
		unresolvable problems.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Exelon	Disagree	The first bullet is unworkable in the real world. It will be virtually impossible to prove that "no encroachments of the CCZ have occurred anywhere at any time during the compliance period". The effort to do this will not enhance reliability. In fact, in may harm reliability by requiring unnecessary investments and O&M expenditures that could be better spent on real reliability enhancements. Exelon agrees, subject to the development of a workable definition of the CCZ, that the second bullet is the preferred approach.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Central Maine Power Company	Disagree	Central Maine Power Company suggests the second alternative to R4 as recommended above, which is to require immediate removal of the vegetation or immediate implementation of the imminent threat procedure upon discovery of a possible encroachment of the critical clearance zone, thus preventing an outage. This alternative is similar to R2, therefore R4 may not be required.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
American Electric Power (AEP)	Disagree	AEP disagrees with the proposed requirement that violations be automatically declared if the CCZ is encroached. Instead, AEP would support a standard utilizing the first alternative proffered in these comment questions. While the CCZ is an interesting theoretical concept, it is not realistically feasible in the field to implement a concept that depends on accurate measurements and calculations. Further, the proposed requirement offends common notions of reliable maintenance methods, because it demands that forestry crews stop work if they see a potential encroachment and that surveyors and engineers be brought in to take detailed measurements and perform complex calculations to determine whether an encroachment has in fact occurred. The need for a reliable transmission grid would be much better served by a standard utilizing the first alternative, in which no violation occurs in the event of an encroachment as long as the TO implements its imminent threat procedure and removes the vegetation. While seemingly technically appealing, the CCZ concept is fraught with implementation difficulties. It should not be used as a Pass/Fail zero-tolerance decision point to determine whether a violation has occurred.

Organization	Agree?	Question 15 Comment
		After all, a zero-defect condition has not been achieved in many other aspects of electric utility operation. For instance, the utility industry attempts every year to conduct its business without any workplace deaths, yet deaths occur every year. Many millions of dollars are spent by North American utilities to promote safety programs and safe work procedures, but some work-related vehicle accidents and personal injuries still occur. Also, utilities aggressively investigate electric switching errors and have instituted rigorous dispatcher-training programs, but a few switching errors still occur. For an industry in which billions of stems of vegetation must be managed, even a high six-sigma level of quality would still result in a few cases annually of imperfectly managed vegetation. It is unreasonable to expect zero-tolerance perfection with the CCZ concept. Also, with the way R4 is worded, a tree falling from outside the right of way would result in a violation if it passed through the CCZ, whether it resulted in an outage or not. It is not appropriate to place a burden on the TO for such circumstances outside the TO's control. As R4 is written, it appears that there is no way that a TO could certify at the end of the year that it has maintained a CCZ free of encroachments, even if no outages occurred. AEP believes a more effective and reliability-centered approach would be one where TOs are expected to implement their imminent threat procedure if vegetation is encroaching upon the Gallet equation distance. If TOs act accordingly and remove the vegetation without incurring an outage, then they would not be in violation. However, if the TOs knew of vegetation encroaching upon the Gallet equation distance but failed to implement their imminent threat process, they would be in violation and be obliged to report the event.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Platte River Power Authority	Disagree	This requirement should be removed completely. It is too stringent and it is impossible to prove compliance through documentation. Encroachemnt of Clearance 2 (or CCZ) should be addressed in the imminent threat procedure.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
City of Tallahassee	Disagree	VEHEMENTLY DISAGREE! The purpose of the standard is to prevent vegetation related outages. A violation should occur if an outage occurs. As written, R4 and M4 would be impossible to prove or disprove. It is not like we can get up there with a tape measure and measure it. R2 requires action if the CCZ is "approached". This is undefined and subject to a myriad of interpretations. Evidence is hard enough to obtain to the satisfaction of the Compliance Monitor. To require sufficient evidence to prove that something didn't occur is a tremendous burden and is not a wise expenditure of vegetation management dollars. Let us spend the money on trimming and not on paperwork. As an alternative replace "encroachment within the Critical Clearance Zone" with "vegetation caused

Organization	Agree?	Question 15 Comment
		outages". This would allow the same exceptions and is much easier to prove or disprove with a breaker operation. Although this would result in the cause of every breaker operation being tracked, it is a tangible evidence requirement and leaves very little room for interpretation. The levels of fines have already shown that vegetation management is a serious standard and we had better comply.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Northern Indiana Public Service Company	Disagree	It will be impossible for a T.O. to provide "evidence" that no encroachments of the C.C.Z. occurred at any time during the year. This approach will be a compliance nightmare and is unworkable. How does one prove this never happens? You can't monitor every span of every line at all times. Obviously, whenever a T.O. has a preventable outage, that should be a violation. To address the issue of preventing outages before they occur and penalizing T.O.'s who don't take proper steps to prevent them, I prefer the approach of immediate removal of threatening vegetation that encroaches within a "threat trigger/action threshold" clearance distance per the T.O.'s formal imminent threat procedure. This "threat trigger/action threshold" clearance would be established by the T.O. and be a specific requirement under a revised FAC-003.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Tampa Electric Company	Disagree	This is a good start. The Critical Clearance Zone (CCZ) is a very real and practical concept; however, it is not transferable to field conditions. This could result in a "fill in the blank" standard relative to what the Critical Clearance Zone will be in terms of distance. As I read this, it will be a sliding scale from insulator to mid span and back for each designated line voltage. The max wind speed to be used and other assumptions behind the determination of this zone may be as involved a Gallet's formula. This will lead to complications during operational inspection and verification of these clearances.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Orange and Rockland Utilities Inc.	Disagree	We believe that R4 is not the most effective way to achieve the purpose of the Standard. As previously stated the CCZ and encroachments of it are generally not possible to identify in the field without taking precise measurements. The CCZ changes in size and shape continuously throughout each and every span. In many

Organization	Agree?	Question 15 Comment
		cases the CCZ can be very large, and the position of the conductor with respect to encroaching vegetation within the CCZ can be relatively far apart. Such cases would typically not be identified as encroachments of the CCZ by visual inspections. Only those instances where the vegetation is significantly overgrown would be readily identifiable. R4, as written presents a problem in terms of compliance, certification of compliance, and auditing because precise measurements of every span are impractical and costly to perform. Certification of compliance would require field personnel to spend valuable time estimating and attempting to measure potential encroachments of the CCZ. R4 does not provide incentive for Transmission Owners to deploy modern technology that is better able to identify encroachments of the CCZ with a reasonable amount of accuracy, such as ALS and LIDAR which are described in the response to Question 11. In fact R4 might provide an incentive not to utilize this technology because Transmission Owners who identify encroachments using ALS which would otherwise not have been identified would be in violation of R4. Transmission Owners that choose to be less proactive often would not identify such encroachments and would be at less risk of violating R4. The effect could be less frequent use of ALS and other technology that may emerge. This would result in fewer problems being identified, a small percentage of which may not be discovered until they result in a line trip. We believe that the best way to achieve the purpose of this Standard is to encourage proactive behavior which prevents vegetation-related outages throughout the entire industry. R4 does not achieve this in the most effective way. We recommend the following: Eliminate encroachment of the CCZ as a violation of R4. Require Transmission Owners to immediately implement the imminent threat process defined in R1.4 when they identify instances where vegetation has grown within a specific distance as described in the response to Question 11 regarding R2. This would essentially combine R2 and R4.Require Transmission Owners to report to the Regional Entity any instances where the imminent threat process was implemented due to a vegetation-related clearance encroachment. This would add a reporting requirement for Transmission Owners. Require Regional Entities to perform additional audits of Transmission Owners that exceed metrics for vegetation-related clearance encroachments. The metrics should be established in the Standard based upon 1000 circuit miles of applicable lines. This would add an additional requirement for Regional Entities. Modify R5, R6, and R7 to include preventing momentary outages as well as Sustained Outages. We believe that this concept would result in a more rigorous standard because of the additional requirements, but would focus the industry's attention in a more effective fashion. We believe it would result in fewer vegetation-related interruptions and a higher level of reliability soon after implementation, and would therefore best support the purpose of the Standard.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the “Minimum Vegetation Clearance Distances”, and Transmission Owners are required to prevent encroachment of vegetation into “Minimum Vegetation Clearance Distances” as observed in real time. **The SDT very carefully and thoroughly examined the merits, disadvantages, ease and difficulties of assessing momentary outages as a violation, and chose to address this issue with the language in R4.**		

Organization	Agree?	Question 15 Comment
American Transmission Company	Disagree	While the CCZ is valuable to understanding the movement of conductors, it cannot be readily applied in the field. This field application challenge is noted in the Technical Reference Document (pages 29 & 30).The way R4 is currently stated, the Transmission Owner would be in violation of R4 for any CCZ encroachment not due to natural disasters or human or animal activity. This would include a tree falling from outside the right of way corridor that passes through the theoretical CCZ. Furthermore, Transmission Owners would be required to self-certify compliance with R4, and ATC does not think there is a practical way to do that. Clearly, the approach of assessing violations for CCZ encroachment is unworkable. ATC believes that R4 should be deleted.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the “Minimum Vegetation Clearance Distances”, and Transmission Owners are required to prevent encroachment of vegetation into “Minimum Vegetation Clearance Distances” as observed in real time.		
Xcel Energy	Disagree	The way this requirement is written may require a utility to prove a negative. In other words, prove that we did not have trees encroaching into the CCZ at any time. This is impossible to prove. We propose the following language: ?The TO shall not have a encroachment within the CCZ which was not dealt with by utilizing the imminent threat procedure before experiencing a Sustained Outage, with the following exceptions 1) Encroachment of the CCZ that result for natural disasters 2) Encroachment of the CCZ that result from human or animal activity."
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the “Minimum Vegetation Clearance Distances”, and Transmission Owners are required to prevent encroachment of vegetation into “Minimum Vegetation Clearance Distances” as observed in real time.		
Ameren	Disagree	The second bulleted alternative above is the best approach, but it should be improved by changing the imminent threat trigger from "encroachment of the CCZ" to "encroachment within some observed, field distance that is defined in the Plan. This would allow Transmission Owners to define for field personnel a CCZ that accomplishes some multiple of the Gallet distances referenced in Table I" but is easy to determine and apply. We have recommended changes to accomplish this in Requirement R2 (see our response to Question #11 above), and R4 should simply be deleted. While the CCZ is valuable to understanding the movement of conductors, it cannot be readily applied in the field. This field application challenge is noted in the Technical Reference Document (pages 29 & 30).The way R4 is currently stated, the Transmission Owner would be in violation of R4 for any CCZ encroachment not due to natural disasters or human or animal activity. This would include a tree falling from outside the right of way corridor that passes through the theoretical CCZ. Furthermore, Transmission Owners would be required to self-certify compliance with R4, and we don't think there's any way to do that. Clearly the approach of assessing violations for CCZ encroachment is unworkable. Likewise, the third alternative listed above is untenable. The tiered approach could have a mitigating effect on violations, but it would require the same

Organization	Agree?	Question 15 Comment
		inspection effort and postponement of vegetation management that makes the first alternative unworkable. Both the first and third alternatives would require very significant additional expenditures for surveys and documentation in an impossible attempt to certify compliance - money that would be better spent controlling vegetation.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Nebraska Public Power District	Disagree	NPPD disagree with an encroachment being a violation. A lot of time would need to be spent to determine if an encroachment occurred and in a self regulating environment, reporting would be minimal if any. The Transmission Owner would be in violation for any non natural event. Even a tree falling into the ROW passing through CCZ would be in violation of R4. Difficult at best to enforce. We need to spend time keeping the ROW cleared and less time inspecting for possible encroachments.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Long Island power Authority	Disagree	The Standard is about preventing outages and having an effective program. An effective program should allow for the identification of a threat and the removal of the threat prior to a vegetation caused outage. I prefer alternative 2. If a vegetation caused outage should occur or if the Regional Entity determines a violation occurred based on a compliance investigation then the entity is in violation of this requirement.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
USDA Forest Service, Southwestern Region, Regional Office for AZ and NM	Disagree	The wording appears too strong. Who can predict the unforeseen circumstances that inevitably arise. If the standards require the reporting of encroachments, the ensuing report can help determine if the Transmission Owner did everything reasonable to avoid the problem. It seems like the standard should be written to require the Transmission Owner to do everything reasonable to avoid the problem. A judgment call would still be needed to evaluate the performance.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		

Organization	Agree?	Question 15 Comment
Manitoba Hydro	Disagree	Manitoba Hydro asserts that the reliability of the system is measured by outage, not by the possibility of an outage, and therefore if the overall vegetation management system (plan-patrol-discover-mitigate) is effective in preventing an outage, then the reliability of the system has been maintained, and the intent of the reliability standard achieved. Therefore, we propose that the second bullet above is the preferred alternative, and that R2 and R4 be combined as the violation of R4 would then imply a violation of R2.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Consumers Energy Company	Disagree	The CCZ does not provide adequate clearance and the imminent threat procedure if successfully implemented only works IF YOU KNOW ABOUT THE VEGETATION THAT THREATENS THE CCZ which cannot be ensured with yearly inspections. Consumers Energy believes that the Clearance 2 distances in FAC-003-1 provide more reliability than the CCZ proposed in this draft or any of the alternatives disused above.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Pacific Gas & Electric Co.	Disagree	PG&E believes a "minimum clearance distance" or "do not encroach zone" is a critical element of this standard and necessary to achieve the stated purpose of preventing vegetation caused outages. Preventing vegetation encroachments will prevent outages. However, PG&E disagrees with using the CCZ as a minimum clearance requirement because it is ambiguous and subject to wide variations and interpretation. CCZ is a good concept to aid in understanding movement of conductors but is a theoretical calculation and would be very difficult if not impossible to enforce. PG&E suggests using a clearly defined distance such as Gallet equation plus a safety margin to assure there is no chance of spark over. Two times Gallet would be a reasonable clearance requirement to assure a spark over does not occur and eliminate the ambiguity of the CCZ as the "do not encroach zone".
Response: The SDT thanks you for your comments. The SDT discussed the Gallet plus alternative suggested by PG&E. Due to the tremendous variation of design standards, the team decided that the decision as to how much a margin for error to use belonged to the individual TO. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time. The threat of a violation is believed sufficient to motivate a Transmission Owner to maintain a larger clearance.		

Organization	Agree?	Question 15 Comment
NV Energy (fka Sierra Pacific / Nevada Power Co.)	Disagree	The new requirement in R4 stipulates that the Transmission Owner is in violation if an encroachment of the CCZ occurs at any time. However, the CCZ changes with each foot of the transmission line from the insulator to the mid-span, depending on loading, actual operating temperature, wind loading, ice loading, maximum design rating, maximum operating load, and so on. Further, Measure M4 requires that the Transmission Owner has evidence demonstrating there were no vegetation encroachments into the CCZ. These requirements may result in having to LIDAR the lines annually, to prove that trees have not encroached upon the CCZ. This would be an extremely onerous and expensive requirement for utilities. NV Energy strongly supports the alternative to R4 as recommended in the Comment Form (#15), which is to require immediate removal of the vegetation or immediate implementation of the imminent threat procedure upon discovery of a possible encroachment of the CCZ, thereby proactively preventing an outage. This means a violation would occur only if the imminent threat process is not successfully implemented. This alternative is essentially the same as R2. Therefore, we recommend removing R4 from the standard entirely.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
San Diego Gas & Electric	Disagree	The new requirement in R4 stipulates that the Transmission Owner is in violation if an encroachment of the Critical Clearance Zone (CCZ) occurs at any time. However, the CCZ changes with each foot of the transmission line from the insulator to the mid-span, depending on loading, actual operating temperature, wind loading, ice loading, maximum design rating, maximum operating load, and so on. Further, Measure M4 requires that the Transmission Owner have evidence demonstrating there were no vegetation encroachments into the CCZ. These requirements may result in having to LIDAR the lines annually to prove that trees have not encroached upon the CCZ. This would be an extremely oerous and expensive requirement for utilities. We strongly support the alternative to R4 as recommended in the Comment Form, which is wto require immediate removal of the vegetation or immediate implementation of the imminent threat procedure upon discovery of a possible encroachment of the CCZ, thereby proactively preventing an outage. This means a violation would occur only if the imminent threat process is not successfully implemented. This alternative is essentially the same as R2. Therefore, we recommend removing R4 from the standard entirely.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Hydro One Networks Inc.	Disagree	A statement is needed that this requirement applies to the active right of way. Outside of the active right of way there is no guarantee that this can be achieved. As noted in the question above, it may be very difficult with the

Organization	Agree?	Question 15 Comment
		first alternative to provide adequate evidence that no encroachment had occurred over the compliance period, as the situation is very difficult to assess along each span to the accuracies (1/100 of a foot) spelled out for the CCZ. It may be more meaningful that the Transmission Owners be able to demonstrate processes, methodologies and actions that can support that vegetation has not entered the CCZ. Another alternative for R4 could then be: Each Transmission Owner shall demonstrate that adequate actions and processes are in place to prevent vegetation from entering the CCZ. The effectiveness of the process can then be evaluated based on methods used for field assessment and performance, i.e., outages and imminent threat reporting. It appears that the second alternative noted above can be combined with R2. It is not clear why there needs to be a separate requirement. Hydro One is not in favour of alternative 3, as this would create added administration with a situation that will be difficult to prove to the accuracy required. LIDAR may be the only means available to provide evidence of a quality needed to produce meaningful statistics, and in many cases this may not be the most efficient use of the limited funding that is available.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Edison Electric Institute	Disagree	Encroachment without a Sustained Outage should not be construed as a violation. The proposed R4 requirement should be removed. EEI strongly believes that this requirement, if approved, is unenforceable. The alternative, to require implementation of the imminent threat procedure, should be considered as a practical approach. In particular, this concern applies to a requirement to prove that no encroachments have existed. This will require extensive work by field personnel, who will be required to make subjective judgments. In addition, determining actual clearance zones in the field would require a span-by-span analysis to be conducted with the rigor of survey level measurements. Calculations made to determine the clearance zones are based on undefined terms and subject to wide variation. Enforcement authorities will be required to make interpretations. EEI believes that the costs of conducting such work will not deliver sufficient benefit to warrant the requirement. Ultimately, there is no basis for determining whether the theoretical clearance zones included in the proposed standard will increase, or even maintain, an adequate level of reliability as provided by the existing standard.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Consolidated Edison Company of New York (CECONY)	Disagree	CECONY disagrees with R4 as currently written. As mentioned in the response to Question 15, performing a field measurement of the CCZ and a field measurement of the vegetation encroaching into the CCZ are complicated, time-consuming efforts. As the CCZ changes along the conductor, so too may the Active ROW dimensions, the vegetation clearances at multiple points, and elevation levels to name a few. Certifying compliance that no

Organization	Agree?	Question 15 Comment
		encroachments have occurred would be very difficult for auditors and field inspectors. Modern laser technology would have to be deployed to take these measurements and CECONY is concerned that, if an encroachment of the CCZ constitutes a violation, utilities would not consider investing in this technology knowing that multiple violations could potentially be found within a single span. Enhanced reliability is achieved when utilities invest in the best available technology and perform proactive inspections on their systems but, as written, R4 would not effectively motivate a utility to follow through with these initiatives. We recommend that the term 'momentary outage' or the phrase 'all outages' be used in R5, R6, and R7 instead of 'Sustained Outages' to avoid confusion throughout the industry. Momentary outages identify a potential failure of the utility's vegetation management program and stating it directly in the Standard clearly sends the message to utilities that all vegetation outages are unacceptable. In summary, we do not agree that encroachments are violations but we do recommend that when a utility identifies vegetation-related imminent threats and takes immediate action, they report this to their Reliability Coordinator. The Reliability Coordinator (RC) could then identify the utilities that have had multiple issues or have exceeded acceptable pre-established reporting limits which, in turn, would help the RC prioritize auditing efforts. This, in our opinion, would enhance reliability more effectively.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time. **The SDT very carefully and thoroughly examined the merits, disadvantages, ease and difficulties of assessing momentary outages as a violation. The result of that effort led to the more precise and field observable aspects of R4. It should be noted that by their very nature the exact causes of "momentary outages" are very challenging to determine and will vary widely from utility to utility. The SDT did not find that such variability was appropriate for a reliability standard, and chose to address this issue with the language in R4.**		
Arizona Public Service Company	Disagree	APS agrees with alternative one. The new requirement in R4 stipulates that the Transmission Owner is in violation if an encroachment of the CCZ occurs at any time. However, the CCZ changes with each foot of the transmission line from the insulator to the mid-span, depending on loading, actual operating temperature, wind loading, ice loading, maximum design rating, maximum operating load, and so on. Further, Measure M4 requires that the Transmission Owner has evidence demonstrating there were no vegetation encroachments into the CCZ. These requirements may result in having to LIDAR the lines annually, to prove that trees have not encroached upon the CCZ. This would be an extremely onerous and expensive requirement for utilities. APS strongly supports the alternative to R4 as recommended in the Comment Form (#15), which is to require immediate removal of the vegetation or immediate implementation of the imminent threat procedure upon discovery of a possible encroachment of the CCZ, thereby proactively preventing an outage. This means a violation would occur only if the imminent threat process is not successfully implemented. This alternative is essentially the same as R2.

Organization	Agree?	Question 15 Comment
		Therefore, APS recommends removing R4 from the standard entirely.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Baltimore Gas & Electric Company	Disagree	One concern with the proposed wording is that the verbiage seems to provide a loophole that will count any fallen tree, or tree with the potential to fall from inside or outside of the R/W (that doesn't meet the criteria in footnotes 4 & 5) that passes or could pass through the CCZ, and that may or may not cause an outage, would qualify as a violation in the std. There is no other language that I can detect in the std. that counters this point. Determination of whether or not a fallen tree, or tree with the potential to fall would qualify would be predicated upon height measurements of the fallen or standing tree(s) relative to the CCZ at max. engineered sag. An alternative wording suggestion is: "Each Transmission Owner shall prevent encroachment within the Critical Clearance Zone of it's applicable lines associated with trees that meet the criteria for grow-ins from on or off the Active right-of-way. Fall-ins from inside or outside of the active right-of-way are not applicable to this sub-requirement." If the occurrence is a violation, reporting of the incident will be an ethical issue and rely on the honesty of the inspector or whomever finds the problem. If it's not a violation, it will be more likely that the incident will be reported and can be treated as "Near Miss' reports are with respect to safety incidents - they provide valuable input to help forestall future more serious incidents. Consequently, I recommend that no violation occur as long as the 'Imminent Threat Procedure' is implemented. Further, if there is no violation associated with Imminent Threat Procedure implementation, I would suggest that falling or standing trees originating from within the active right-of-way that encroached or could encroach in the CCZ be added to the requirement to enhance the 'Near Miss' data pool.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Duke Energy Corporation	Disagree	The second bulleted alternative above is the best approach, but Duke believes it should be improved by changing the imminent threat trigger from "encroachment of the CCZ" to "encroachment within some observed, field distance that is a multiple of the Gallet distances referenced in Table I". We have recommended changes to accomplish this in Requirement R2 (see our response to Question #11 above), and R4 should simply be deleted. While the CCZ is valuable to understanding the movement of conductors, it cannot be readily applied in the field. This field application challenge is noted in the Technical Reference Document (pages 29 & 30).The way R4 is currently stated, the Transmission Owner would be in violation of R4 for any CCZ encroachment not due to natural disasters or human or animal activity. This would include a tree falling from outside the right of way corridor that passes through the theoretical CCZ. Furthermore, Transmission Owners would be required to self-certify compliance with R4. The technological requirements for accurately certifying compliance would be impossible to

Organization	Agree?	Question 15 Comment
		administer. Clearly the approach of assessing violations for CCZ encroachment is unworkable. Likewise, the third alternative listed above is untenable. The tiered approach could have a mitigating effect on violations, but it would require the same inspection effort and postponement of vegetation management that makes the first alternative unworkable. Both the first and third alternatives would require very significant additional expenditures for surveys and documentation in an impossible attempt to certify compliance - money that would be better spent controlling vegetation.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the “Minimum Vegetation Clearance Distances”, and Transmission Owners are required to prevent encroachment of vegetation into “Minimum Vegetation Clearance Distances” as observed in real time.		
CenterPoint Energy	Disagree	It is not reasonable to expect Transmission Owners to devote resources, both human and financial, to prove that vegetation never encroached into the Critical Clearance Zone, anytime-anywhere. R4 and M4 should be deleted.R2 and M2 are sufficient in ensuring a level of reliability equal to or better than FAC-003-1 with some minor wording changes to adopt similar wording of the alternative to R4 that was considered by the drafting team that includes "immediate implementation of the imminent threat procedure" for imminent threats of a vegetation related Sustained Outage in lieu of a nebulous "encroachment of the Critical Clearance Zone". According to the Technical Reference, it is "nearly impossible to field correlate and accurately 'superimpose' the Critical Clearance Zone around the conductor". It not likely that the Transmission Owner will know when the Critical Clearance Zone is approached through field observation. The previous Clearance 2 provided for a specific radial clearance from the conductor that was much easier to observe. (See comments to Q3 above.)
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the “Minimum Vegetation Clearance Distances”, and Transmission Owners are required to prevent encroachment of vegetation into “Minimum Vegetation Clearance Distances” as observed in real time.		
Entergy Services	Disagree	1. Entergy believes that outages caused by vegetation are the most reasonable and objective measures for a violation which is not consistent with the proposed R4. See additional comments in section 16 related to R5, 6, and 7. 2. If R4 remains, Entergy proposes that the most reasonable approach to this requirement is a variation of the second bulleted option. This variation would include wording clarifying that only known encroachments of the Critical Clearance Zone would be considered violations. Entergy is willing to include failures to enact the imminent threat process (which is really a violation of R2) and also known vegetation inside the Critical Clearance Zone. This variation should continue to include the exceptions for natural disaster and human activities. 3. Determining objective, quantifiable encroachments into the Critical Clearance Zone is very challenging in field operations because such determination may require a degree of accuracy only obtainable using survey equipment

Organization	Agree?	Question 15 Comment
		or other sophisticated, costly measuring devices. 4. Entergy is concerned about the challenges of uniform audit ability due to noted uncertainties and the statement of absolute criteria that have to be shown in the negative. If the first bullet option is approved for R4, Entergy suggests the sentence “Evidence will be required to prove that no encroachments of the Critical Clearance Zone have occurred anywhere at the any time during the annual compliance period” be deleted. It is very difficult in regulatory terms to attest that no vegetation has ever crossed the Critical Clearance Zone during the time period being reviewed given the wide range of potential conditions that may not have been detected or even been detectable unless the conditions afforded direct observation. Too many assumptions would have to be made for an entity to self certify to this requirement. If R4 is implemented as stated, those assumptions need to be stated and clarified. 5. If any version of R4 is approved, Entergy suggests that the standard include an exception for trees falling from off the right of way and encroaching the Critical Clearance Zone. For example, a tree that falls from off the right of way. During the fall towards the conductor, the tree could possibly break the Critical Clearance Zone without causing an outage or even a threat of an outage yet still be a violation of the proposed standard. 6. If the second bulleted item is approved, it should be altered to read “a violation would have occurred only if no vegetation imminent threat process was initiated.” 7. Entergy does not feel the third bulleted item is adequately defined to use as a requirement in the standard at this time. 8. Conditions for blow-out, in the development of the Critical Clearance Zone, need to be defined in the standard. Their inclusions, in the white paper only, are not appropriate, as well.
Response: The SDT thanks you for your comments and suggested alternatives. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the “Minimum Vegetation Clearance Distances”, and Transmission Owners are required to prevent encroachment of vegetation into “Minimum Vegetation Clearance Distances” as observed in real time. The SDT addressed your item 5 in subpart 3 in R4. This exception would apply to any falling vegetation outside the right of way or inside the right of way.		
Pepco Holdings, Inc	Disagree	As discussed in our response to Q11, the concept of encroachment into the Critical Clearance Zone is flawed. It is enforceable almost exclusively through self reports. R5, R6 and R7 provide all incentives for the TO to follow its inspection and maintenance plans, and R2, if properly written to remove references to the Critical Clearance Zone provides additional incentives. R4 is not needed and should be deleted. PHI is puzzled where this concept came from. Nowhere in Order 693 is this concept discussed.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon

substantive industry comment. The essential changes are: The CCZ has been replaced with the “Minimum Vegetation Clearance Distances”, and Transmission Owners are required to prevent encroachment of vegetation into “Minimum Vegetation Clearance Distances” as observed in real time. The concept of the CCZ was originally intended to provide an area that could be used to produce a metric for less than “zero tolerance” however that did not materialize.		
JEA	Disagree	As written, demonstration of compliance may not be feasible and would certainly be prohibitively expensive, consuming resources better spent managing vegetation. In general, putting entities in the position of proving something didn't occur is exptremely difficult and burdensome, without really aiding reliability. If the incident was significant, the region would know about it, and investigations can be pursued, if warranted. The first alternative requiring implementation of the imminent threat procedure is a better choice.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the “Minimum Vegetation Clearance Distances”, and Transmission Owners are required to prevent encroachment of vegetation into “Minimum Vegetation Clearance Distances” as observed in real time.		
Salt River Project	Disagree	Disagree with R4 as it is written. The new requirement in R4 stipulates that the Transmission Owner is in violation if an encroachment of the Critical Clearance Zone occurs at any time. However, the Critical Clearance Zone changes with each foot of the transmission line from the insulator to the mid-span, depending on loading, actual operating temperature, wind loading, ice loading, maximum design rating, maximum operating load, and so on. See additional comments in Comment #18 below. Furthermore, Measure M4 requires that the Transmission Owner has evidence demonstrating there were no vegetation encroachments into the Critical Clearance Zone. To provide evidence demonstrating there were no vegetation encroachments into the Critical Clearance Zone would be an extremely onerous task and an expensive requirement for the utilities. We strongly support changing this to the 1st alternative written in Comment #15 "One alternative to R4 required immediate removal of the vegetation or immediate implementation of the immenent threat procedure upon discovery of a possible encroachment of the Critical Clearance Zone, thereby proactively preventing an outage. A violation would have occurred only if the immenent threat process was not successfully implemented." This alternative is essentially the same as R2, therefore, we recommend removing R4 from the standard entirely.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the “Minimum Vegetation Clearance Distances”, and Transmission Owners are required to prevent encroachment of vegetation into “Minimum Vegetation Clearance Distances” as observed in real time.		
Northeast Utilities	Disagree	First - the determination of the CCZ is highly problematic in the field. Second - it is impossible for any utility to certify that no encroachments have occurred at any time unless a utility has completely removed all potentially interferring vegetation on all areas of their transmission system. If the standard is to clear-cut and maintain a tree free right of way, the standard should say so. To determine if vegetation may have violated the CCZ the inspector

		must know at the time of the inspection the ambient temperature, the wind speed, the loading of the line and the actual distances between the vegetation and conductors. Then, the information must be compared to possible extreme operating levels of the line under all conditions to know if the vegetation may violate the CCZ. As stated - it is improbable that this could accurately be performed in the field as the data changes within each segment of a span's length. The first alternative provides the most effective means of addressing encroachment of the CCZ - having an encroachment is not a violation - knowing there is an encroachment and not correcting the problem would be a violation. Implementing the imminent threat procedure and correcting the problem is a more effective approach. Having a zero tolerance for encroachments of the CCZ under all situations and operating conditions would sub-optimize the use of resources. No actual event may have occurred on the system, yet the utilities will be in violation just for a possible or potential problem that even under extreme operating conditions may not actually occur. It would be best if the violations were limited to "known encroachments" (not "possible encroachments") such as would occur if a line were to trip due to vegetation contact, or if there is evidence of any burns. If no action was taken on known encroachments to correct the problem (such as implementation of the imminent threat procedure) then a violation will have occurred. It is doubtful that any utility will be able to certify that at no time has vegetation encroached into the CCZ. Utilities will have to spend an untold amount of resources to verify that there have not been any encroachments during a compliance period - instead of using these resources more effectively in taking proactive measures to manage and control encroaching vegetation. As written, any encroachment into the CCZ is considered a violation of FAC-003-2 (R4). There are exceptions provided for encroachments due to natural disasters and human or animal activity. There is no exception for encroachments due to the failure of a tree(s) outside of the active transmission line ROW. Based on R4, a trip and reclose of a transmission line (no outage) is a violation even if the tree is outside of the active right-of-way; whereas per R6 and R7, a line outage would not be a violation if the tree was outside of the active right-of-way. As written - this is not clear - there should be exceptions to allow for trees falling into the CCZ (and into the active transmission line right-of-way) from outside the limits of the active transmission line right-of-way. Also - how are violations of the CCZ requirement to be reported - there is no provision for the reporting process and requirements (specifics on the type of violation). Will this be addressed in the Compliance Section yet to be added?
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.
