Hydro-Quebec Transenergie (HQT)	Disagree	The purpose of the standard is "To improve the reliability of the Bulk Electric System by preventing vegetation related outages that could lead to Cascading". We believe that R4 is not the most effective way to achieve this purpose because it does not provide incentive for Transmission Owners to take advantage of modern technology, such as aerial laser survey (ALS) using Light Detection and Ranging technology (LIDAR), that is capable of accurately identifying vegetation which is approaching the CCZ or has encroached into it. In fact R4 provides an incentive not to utilize this technology because Transmission Owners who identify encroachments would be in

Organization	Agree?	Question 15 Comment
		violation of R4 for each identified encroachment. On the other hand, Transmission Owners who choose to be less proactive often would not identify such encroachments because the CCZ and encroachments of it are generally not easy to determine without taking precise measurements. Unless the line is heavily loaded or the vegetation is significantly overgrown, encroachments of the CCZ would not be readily noticed. In most cases these Transmission Owners would simply remove or cut back incompatible vegetation without taking measurements. The threat to the line would have been eliminated with no encroachment having been identified.R4 presents a dilemma for Transmission Owners that are considering making the significant investment in ALS technology. While the technology would allow them to identify any potential grow-in or fall-in conditions, it would also expose them to the risk of identifying violations of R4, that would otherwise not have been identified. Violation Risk Factors (VRFs), Violation Severity Levels (VSLs), and Time Horizons are not included in this Draft, but after making a significant investment in ALS, Transmission Owners could be faced with significant additional cost in terms of NERC penalties. In addition, even if the penalties were relatively low they would be exposing themselves to violations that less proactive Transmission Owners would not be exposed to. In our view R4 as written would, in some cases, have the opposite effect of what is intended because the business case for using ALS is more difficult to make. This will result in less use of ALS and other emerging technology that is likely to be developed. This would result in fewer problems being identified, a small percentage of which will not be discovered until they result in a line trip. Still we believe that the concept of the CCZ is a good one and recommend that R4 be changed so that Transmission Owners are provided with an incentive to invest in the best technology available in order to ensure the highest level of reliability. The opportunity exists to develop the standard in a manner that encourages the industry to take advantage of new technology and manage vegetation in a very proactive way. We recommend that R4 be changed as follows: Modify R4 to require Transmission Owners to immediately implement the imminent threat process defined in R1.4 when they identify instances where the CCZ is approached or encroached upon. Failure to do so would be a violation of R4. Eliminate encroachment of the CCZ as a violation of R4. This would eliminate R2 and incorporate implementation of the imminent threat process into R4.Require Transmission Owners to report to the Regional Entity on a quarterly basis any instances where the imminent threat process was implemented due to an encroachment of the CCZ. This would add a reporting requirement for Transmission Operators. Require Transmission Owners to report to the Regional Entity on a quarterly basis any instances where either a momentary or sustained outage was caused by grow-ins, Active Transmission Line Right of Way blow-ins, or Active Transmission Line Right-of-Way fall-ins. This would add three additional reporting requirements for Transmission Operators. Require Regional Entities to perform additional audits of Transmission Owners that exceed metrics for violations of the CCZ. The metrics would be established in this Standard based upon 100 circuit miles of applicable lines. This would add an additional requirement for Regional Entities. This concept would result in a more rigorous standard than FAC-003-01 because of the additional reporting and auditing requirements. It would drive proactive behavior throughout the industry and provide a significant incentive for Transmisison Owners to invest in new technology such as ALS that is capable of accurately identifying vegetation that has approached or encroached upon the CCZ. We believe that this change would result in the identification of more incipient vegetation-related problems and fewer vegetation-related outages as soon as it was implemented and

Organization	Agree?	Question 15 Comment
		would best support the purpose of the Standard.
Response: The SDT thanks you for your comments and suggestions. The reporting and documenting concept that you suggest has been incorporated in part in R2. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Buckeye Power, Inc.	Disagree	Proving vegetation is not in a clearance zone will be difficult without having third-party verification.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
Great River Energy	Disagree	GRE supports the elimination of R4, as vegetation contacts are covered in R5 and R6. A violation should only occur with a vegetation contact. Assessing a violation and fine for a potential reduction in system reliability is not correct. Actual contacts that trip a transmission element have some measurable impact on system reliability even if it is slight. In the event that the SDT chooses not to eliminate R4, GRE would also support the alternative language that is shown under the second bullet.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
WECC	Agree	Yes, R4 as written provides clear guidance to TOs on the minimum radial distance, dependant on line voltage that vegetation is allowed to approach energized conductors. These industry standardized distances will ensure a level of reliability equal to or better than FAC-003-1.
Response: The SDT thanks for your comments. Please see the summary consideration for this question – based on other comments, the SDT made significant revisions to Requirement R4. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and Transmission Owners are required to prevent encroachment of vegetation into "Minimum Vegetation Clearance Distances" as observed in real time.		
National Grid	Agree	National Grid agrees that there should be no encroachments into the CCZ. However, encroachments in the CCZ should NOT be considered a violation. Violations should only be for sustained transmission outages.
Response: The SDT thanks you for your comments. Significant changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the "Minimum Vegetation Clearance Distances", and		

Organization	Agree?	Question 15 Comment
Transmission Owners are required to prevent encroachment of vegetation into “Minimum Vegetation Clearance Distances” as observed in real time.		
Northern California Power Agency (NCPA)	Agree	
WECC Reliability Coordination	Agree	
Response: The SDT thanks you for your positive feedback. Most commenters disagreed with R4. Changes to R4 have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ has been replaced with the “Minimum Vegetation Clearance Distances”, and Transmission Owners are required to prevent encroachment of vegetation into “Minimum Vegetation Clearance Distances” as observed in real time.		

16. Requirements R5, R6, and R7 define that Sustained Outages due to vegetation growing into, blowing together with, and falling into transmission lines are violations (subject to certain exemptions). Therefore, all such outages must be reported as violations of the standard. Do you agree with this change? If not, please explain.

Summary Consideration: Seventy two percent of the respondents agreed with the changes. Multiple commenters made the following points: Questionable cost benefit, not all lines are equal, complicated and burdensome to know precisely where edge of ROW is, the standard should read minimize outages and not prevent them. The majority of the team did not agree there was sufficient argument to support making changes to the requirements based on the comments.

Several commenters pointed out that debris that has been detached from the tree and blown into the conductor and trees from outside the ROW should be exempt. The team adjusted the standard to accommodate debris and falling from outside the ROW.

Organization	Agree?	Question 16 Comment
Western Utility Arborists		The Western Utilities strongly recommend that the requirement under R7 be changed from “shall prevent sustained outages” to “shall minimize sustained outages due to vegetation falling into a conductor.” We note that the word “minimize” was present in earlier drafts of the document. We are concerned about the requirement for utilities to prevent sustained outages from vegetation falling into the conductor from within the active transmission ROW. It is operationally almost impossible to know precisely where the edge of the ROW is in all situations under all conditions. This could lead to an incident where utilities are charged unreasonably? for example, for an outage from a tree that was one foot within the active ROW line. We should not be held liable when reasonable due diligence is practiced. Further, it is not economically feasible for utilities to survey every ROW in the U.S. and Canada to determine precise clearance zones.
Response: Thank you for your comments. The SDT believes it appropriate to require that the Transmission Owner incur no (applicable) vegetation-related outages. Further, industry regulators generally expect Version 2 to be at least as stringent as Version 1 unless a valid technical rationale is presented by the SDT. The SDT believes that the Transmission Owner holds responsibility for knowing the location of the edges of its active rights of way and whether a rooted tree is within or outside the active right of way.		
BCTC		BCTC strongly recommends that the requirement under R7 be changed from “shall prevent sustained outages” to “shall minimize sustained outages due to vegetation falling into a conductor.” We note that the

Organization	Agree?	Question 16 Comment
		word “minimize” was present in earlier drafts of the document. BCTC is concerned about the requirement for utilities to prevent sustained outages from vegetation falling into the conductor from within the active transmission ROW BCTC’s operating area covers rugged and remote terrain, and many areas have accessibility issues. It is operationally almost impossible to know precisely where the edge of the ROW is in all situations under all conditions. Further, it is not economically feasible to accurately survey and marked on the ground the absolute width of all ROW in the province. Therefore, we are concerned about the requirement for utilities to prevent sustained outages from vegetation falling into the conductor from within the active transmission ROW. This could lead to an incident where BCTC is charged unreasonably – for example, for an outage from a tree that was one foot within the active ROW line. We should not be held liable when reasonable due diligence is practiced.
Response: Thank you for your comments. The SDT believes it appropriate to require that the Transmission Owner incur no (applicable) vegetation-related outages. Further, industry regulators generally expect Version 2 to be at least as stringent as Version 1 unless a valid technical rationale is presented by the SDT. The SDT believes that the Transmission Owner holds responsibility for knowing the location of the edges of its active rights of way and whether a rooted tree is within or outside the active right of way.		
Kansas City Power & Light	Disagree	Exceptions should include flying debris including vegetation.
Response: Thank you for your comment. Your suggestion has been incorporated.		
Associated Electric Cooperative Inc.	Disagree	Requirements 5, 6 and 7, as written, compel the Transmission Owner to allocate precious resources to ensuring a vegetation related outage will NEVER occur on any applicable transmission line, regardless of the line's true importance to maintaining electric transmission system reliability. All lines are not created equal; only those which are an IROL or contribute to IROLs should be held to a zero tolerance standard.
Response: Thank you for your comments. FERC Order 693 affirmed that the Standard shall apply to all transmission lines operating above 200kV as well as to designated sub-200kV lines. The Standard was prepared in accordance with FERC Order 693.		
NPCC	Disagree	NPCC participating members request clarification if violations of R5, R6, and R7 result in outages that must be reported.
Response: The SDT appreciates your response. Under NERC’s Compliance Guidelines, any violation of a reliability standard requirement must be self-reported; thus, a violation of Requirement R5, R6 or R7 must result in a report from the Transmission Owner.		
SERC OC Standards Review	Disagree	R5, R6 and R7 should begin with "Subject to its legal rights,”. The requirements, as written, compel the Transmission Operator to allocate precious resources to ensuring that a vegetation outage NEVER will occur

Organization	Agree?	Question 16 Comment
Group		on any transmission line, regardless of that line's true importance to maintaining electric transmission system reliability. All lines are not created equal; only those that are involved in IROLs should be held to a zero tolerance standard. R5, R6, and R7 ensure that version 2 of the standard has reliability requirements equal to version 1; therefore R4 should be removed.
Response: Thank you for your comments. **The SDT certainly agrees that all actions taken by a Transmission Owner must be within its legal rights, but believes that inclusion of "*Subject to its legal rights*" will tend to unnecessarily limit legitimate actions that a Transmission Owner must take to maintain reliability.** **FERC Order 693 affirmed that the Standard shall apply to all transmission lines operating above 200kV as well as to designated sub-200kV lines. The Standard was prepared in consideration of the directives and recommendations contained in FERC Order 693.**		
Florida Power & Light	Disagree	As currently written, Requirements R5, R6 and R7 demand perfection. The only acceptable number for all 150K miles of affected transmission line in the US is 0. The standard should be achievable and enable proactively addressing potential threats to facilities from vegetation. Even using a Six Sigma level of quality and control, processes can achieve a level of 3.4 defects per million opportunities for defect. Each tree on the ROW represents one of those opportunities. FPL has outlined an alternative proposal in response to Question 18.
Response: Thank you for your comments. The SDT believes it appropriate to require that the Transmission Owner incur no (applicable) vegetation-related outages. Further, industry regulators generally expect Version 2 to be at least as stringent as Version 1 unless a valid technical rationale is presented by the SDT.		
Santee Cooper	Disagree	Recommend removing R7 because current and proposed standards do not require the entire right-of-way or Active Transmission Line Right of Way to be clear of vegetation. In this case, a utility should not be penalized if a tree falls from within the right-of-way or Active Transmission Right-of-Way as long they are meeting all the other standards (e.g., minimum vegetation clearance distances). Since fall-ins from just outside of the right-of-way is currently not a compliance issue, it makes sense that a fall-in from within the right-of-way be treated the same. This is especially true for a utility who has elected to acquire a wider right-of-way than another utility. That utility may have a tree(s) growing just inside the right-of-way but still maintains a better clearance distance between trees and conductors than a utility with a narrower right-of-way and no tree encroachment.
Response: Thank you for your comments. While it is true that there is a negligible difference in risk to the electric system for trees just within or just outside the active right of way, the major difference is that the Transmission Owner generally has the right to manage vegetation within the active right of way. Also, while Transmission Owners employ differing active right-of-way widths, this is essentially uncontrollable by the SDT or by regulators.		

Organization	Agree?	Question 16 Comment
Exelon	Disagree	It appears to Exelon that the requirements of the standard have been written and modified at different times and as a result the document lacks a degree of consistency and coherence. While the Standard mentions encroachment of the CCZ and Sustained Outages as potential violations, it is completely silent on how momentary outages should be addressed. Exelon views the following events as a risk continuum that should be addressed in the Standard and handled as a part of the VRFs and VSLs - encroachment of the air gap distance, momentary outages and Sustained Outages.
Response: Thank you for your comments. The Minimum Vegetation Clearance Distance is the calculated spark-over distance derived from the Gallet equations. Therefore a momentary caused by a tree under the circumstances defined in R4 would by definition be a violation of R4.		
Platte River Power Authority	Disagree	The requirement under R7 should be changed from "shall prevent sustained outages" to "shall minimize sustained outages due to vegetation falling into a conductor." We note the word "minimize" was present in earlier drafts of the document. We are concerned about the requirement for utilities to prevent sustained outages from vegetation falling into the conductor from within the active transmission ROW. It is operationally almost impossible to know precisely where the edge of the ROW is in all situations under all conditions. This could lead to an incident where utilities are charged unreasonably - for example, for an outage from a tree that was one foot within the active ROW line. We should not be held liable when reasonable due diligence is practiced.
Response: Thank you for your comments. The SDT believes it appropriate to require that the Transmission Owner incur no (applicable) vegetation-related outages. Further, industry regulators generally expect Version 2 to be at least as stringent as Version 1 unless a valid technical rationale is presented by the SDT. The SDT believes that the Transmission Owner holds responsibility for knowing the location of the edges of its active rights of way and whether a rooted tree is within or outside the active right of way.		
USDA Forest Service, Southwestern Region, Regional Office for AZ and NM	Disagree	I believe that the text for each element should be re-written with the general philosophy that the Transmission Owner shall do everything reasonable to prevent such problems in line with the comment for section 15.Problems should be reported and investigated and a judgment call should be made about whether the Transmission Owner did everything reasonable to avoid the problem.
Response: Thank you for your comments. The purpose of this standard is to improve reliability of the electric transmission system by preventing vegetation-related outages that can lead to cascading by establishing clear and measureable requirements. While the SDT appreciates the value of judgment in the field FERC has indicated that requirements in proposed Standards be equivalent to or more stringent than the same or similar requirements in already approved Standards.		
Consumers Energy Company	Disagree	R5, R6 and R7 should be rewritten as a single requirement for vegetation within the "Active Transmission Line Right of Way" and the exceptions listed. Additionally, a requirement for hazardous trees outside of the "Active

Organization	Agree?	Question 16 Comment
		Transmission Line Right of Way" should be incorporated into this draft and similar exceptions listed for natural disasters, third-party, and animal causes.
Response: Thank you for your comments. Requirements R5, R6 and R7 deal with three distinct types of outages which may pose different risks or severity in terms of impact to the electric system. The SDT chose to break the three requirements apart to allow application of different Violation Risk Factors because blow-in and fall-in interruptions do pose a significantly lower risk of causing a cascading blackout event. **Regarding incorporating a requirement to address hazardous trees outside the Active Right-of-Way, Transmission Owners generally have the right to manage vegetation within the Active Transmission Right-of- Way. These rights will not always exist beyond the Active Transmission Right-of-Way.**		
NV Energy (fka Sierra Pacific / Nevada Power Co.)	Disagree	We strongly recommend that the requirement under R7 be changed from “shall prevent sustained outages” to “shall minimize sustained outages due to vegetation falling into a conductor.” We note that the word “minimize” was present in earlier drafts of the document. We are concerned about the requirement for utilities to prevent sustained outages from vegetation falling into the conductor from within the active transmission ROW. It is operationally almost impossible to know precisely where the edge of the ROW is in all situations under all conditions. This could lead to an incident where utilities are charged unreasonably ? for example, for an outage from a tree that was one foot within the active ROW line. We should not be held liable when reasonable due diligence is practiced. Further, it is not economically feasible for utilities to survey every ROW in the U.S. and Canada to determine and document precise clearance zones. Such costly effort would not produce any benefit to the reliability of the bulk electric system.
Response: Thank you for your comments. The SDT believes it appropriate to require that the Transmission Owner incur no (applicable) vegetation-related outages. Further, industry regulators generally expect Version 2 to be at least as stringent as Version 1 unless a valid technical rationale is presented by the SDT. The SDT believes that the Transmission Owner holds responsibility for knowing the location of the edges of its active rights of way and whether a rooted tree is within or outside the active right of way.		
San Diego Gas & Electric	Disagree	We recommend that the requirement under R7 be changed from "shall prevent sustained outages" to "shall minimize sustained outages due to vegetation falling into a conductor." The word minimize was present in earlier drafts of the document. We are concerned with the requirement for utilities to prevent sustained outages from vegetation falling into the conductor from within the active transmission Right of Way. It is operationally almost impossible to know precisely where the edge of the ROW is in all situations under all conditions. This could lead to an incident where utilities are charged unreasonably.
Response: Thank you for your comments. The SDT believes it appropriate to require that the Transmission Owner incur no (applicable) vegetation-related outages. Further, industry regulators generally expect Version 2 to be at least as stringent as Version 1 unless a valid technical rationale is presented by the SDT. The SDT believes that the Transmission Owner holds responsibility for knowing the location of the edges of its active rights of way and whether a rooted tree is within or outside the active right of way.		

Organization	Agree?	Question 16 Comment
Hydro One Networks Inc.	Disagree	A further exception would be a sustained outage where the conductor has moved outside of the critical clearance zone. This could occur under conditions of heavy icing, operating outside the line rating or excessive wind. These would not necessarily be the result of a natural disaster. Also, it is recommended that the requirement for R7 be revised to “Each Transmission Owner shall minimize (“minimize” replacing “prevent”) Sustained Outages of applicable lines due to vegetation falling into a conductor”.. A fall in is a random occurrence and the likelihood that this would be the cause or contribute to a cascading event is very remote. These types of outages are rare and can be considered similar in nature to an insulator flashover or a hardware failure, which have not been given any association with cascading events. The purpose of the standard is to prevent cascading events and it is suggested that this remain the focus and not introduce other types of outages on a selective basis.
Response: Thank you for your comment. The Critical Clearance Zone (CCZ) has been removed from the standard. **The SDT concurs that fall in events present a lower risk to the system than grow in events. Requirements R5, R6 and R7 have been drafted to address three distinct types of outages which may pose different risks or severity in terms of impact to the electric system. The SDT chose to break the three requirements apart to allow application of different Violation Risk Factors and Violation Severity Levels.**		
Arizona Public Service Company	Disagree	APS strongly recommends that the requirement under R7 be changed from “shall prevent sustained outages” to “shall minimize sustained outages due to vegetation falling into a conductor.” We note that the word “minimize” was present in earlier drafts of the document. We are concerned about the requirement for utilities to prevent sustained outages from vegetation falling into the conductor from within the active transmission ROW. It is operationally almost impossible to know precisely where the edge of the ROW is in all situations under all conditions. This could lead to an incident where utilities are charged unreasonably ? for example, for an outage from a tree that was one foot within the active ROW line. We should not be held liable when reasonable due diligence is practiced. Further, it is not economically feasible for utilities to survey every ROW in the U.S. and Canada to determine precise clearance zones.
Response: Thank you for your comments. The SDT believes it appropriate to require that the Transmission Owner incur no (applicable) vegetation-related outages. Further, industry regulators generally expect Version 2 to be at least as stringent as Version 1 unless a valid technical rationale is presented by the SDT. The SDT believes that the Transmission Owner holds responsibility for knowing the location of the edges of its active rights of way and whether a rooted tree is within or outside the active right of way.		
Entergy Services	Disagree	1. If a version of R4 that states an encroachment to the Critical Clearance Zone is a violation, Entergy disagrees with the need for R5, R6, and R7 because it is redundant to R4. An outage cause by vegetation: a) growing into the line b) blowing into the line and c) falling into the conductor would require the vegetation to break the Critical Clearance Zone. If these requirements stay in the standard, an outage of the above nature would mean the entity violated two requirements, R4 and R5, R6, or R7. 2. Entergy is amenable to keeping

Organization	Agree?	Question 16 Comment
		R5, 6, and 7 if R4 is removed from the standard. 3. If approved, we suggest that R5, 6, and 7 not apply to trees from off the right of way.
Response: Thank you for your comments. Requirements R5, R6 and R7 have been drafted to address three distinct types of outages which may pose different risks or severity in terms of impact to the electric system. The SDT chose to break the requirements apart to allow application of different Violation Risk Factors and Violation Severity Levels. R4 has been drafted to clarify that clearance encroachments are violations of the Standard. Matters of being assessed two violations for a single event are addressed in the NERC compliance sanctions guideline.		
Salt River Project	Disagree	Recommend that the requirement under R7 be changed from "shall prevent sustained outages" to "shall minimize sustained outages due to vegetation falling into a conductor". We understand that the word "minimize" was present in earlier drafts of the document. We are concerned about the requirement to prevent sustained outages from vegetation falling into the conductor from within the active transmission ROW. It is operationally almost impossible to know precisely where the edge of the ROW is in all situations under all conditions. This could lead to an incident where a utility is charged unreasonably - for example, for an outage from a tree that was one foot within the active ROW line. We should not be held liable when reasonable due diligence is practiced. Furthermore, it is not economically feasible for utilities to survey every ROW to determine precise clearance zones.
Response: Thank you for your comments. The SDT believes it appropriate to require that the Transmission Owner incur no (applicable) vegetation-related outages. Further, industry regulators generally expect Version 2 to be at least as stringent as Version 1 unless a valid technical rationale is presented by the SDT. The SDT believes that the Transmission Owner holds responsibility for knowing the location of the edges of its active rights of way and whether a rooted tree is within or outside the active right of way.		
Hydro-Quebec Transenergie (HQT)	Disagree	HQT request clarification if violations of R5, R6, and R7 result in outages that must be reported. A further exception would be a sustained outage where the conductor has moved outside the critical clearance zone. This could occur under conditions of heavy icing, operating outside the line rating or excessive wind.
Response: Thank you for your comments. Regarding your question on reporting of violations, under NERC's Compliance Guidelines, any violation of a reliability standard requirement must be self-reported; thus, a violation of Requirement R5, R6 or R7 must result in a report from the Transmission Owner. In addition, the revised standard includes compliance elements, including the need to provide periodic reports of specific vegetation-related outages. **The Critical Clearance Zone (CCZ) is defined by the movement of the conductor between no load and its rating. The Standard does not apply to events which occur outside of the CCZ.**		
Southern California Edison	Agree	Q16: SCE agrees in part with the establishment of R5, R6 and R7, however, we note that the opening of each requirement repeats a slightly altered version of the FAC-002-2 purpose statement. We find such

Organization	Agree?	Question 16 Comment
Company		repetitiveness unnecessary and note that as written, Requirements 5-7 presents a near identical compliance conundrum for Transmission Owners as Requirement 4. Again, Transmission Owners would be required to prove that they did not incur a sustained outage due to a vegetation caused flash-over or vegetation-to-line contact whether it be a grow-in, blow-in or fall-in. Although proving a sustained outage (for cause) did not occur will be difficult and unwieldy, it is not impossible. The simple difference between a Transmission Owner disproving the occurrence of a CCZ incursion and their disproving vegetation caused sustained outages, is that Transmission Owners do in fact keep records of “outages”. Because a Transmission Owner’s record keeping prowess is the only viable option for proving a vegetation caused outage did not occur, SCE respectfully suggests R5, R6 and R7 be revised to read:R5 - "Each Transmission Owner shall document Sustained Outages of applicable lines due to vegetation growing into a conductor operating within its Rating with the following exceptions:"R6 - "Each Transmission Owner shall document Sustained Outages of applicable lines due to vegetation blowing into a conductor operating within its Rating and located within an Active Transmission Line Right of Way with the following exceptions:"R7 - "Each Transmission Owner shall document Sustained Outages of applicable lines due to vegetation falling into a conductor operating within its Rating and located within an Active Transmission Line Right of Way with the following exceptions: "We also note that Footnote 6 is misplaced in the draft and should follow the word “Outages” in each of these requirements.
Response: Thank you for your comments. Requirements R5, R6 and R7 deal with three distinct types of outages which may pose different risks or severity in terms of impact to the electric system. The SDT believes it appropriate to require that the Transmission Owner incur no (applicable) vegetation-related outages. Additionally, the Transmission Owner must document and report outages under NERC’s Compliance Guidelines. However, the SDT chose to break the three requirements apart to allow application of different Violation Risk Factors and Violation Severity Levels. **As to the matter of proving the lack of CCZ incursions, please refer to the SDT’s response to your Question # 15 comments.** **Your suggestion regarding Footnote 6 has been incorporated.**		
Tennessee Valley Authority	Agree	TVA agrees with Comment Question 16.
Response: Thank you for your comments.		
American Electric Power (AEP)	Agree	AEP is in agreement with these changes.
Response: Thank you for your supportive comment.		
City of Tallahassee	Agree	Why have we gone backwards with only "Sustained Outages" being a violation? Even a momentary outage indicates that a violation has occurred if the cause was vegetation related (with the same exceptions). This

Organization	Agree?	Question 16 Comment
		would seem to contradict the proposed R4. If it wasn't a Sustained Outage it wasn't a violation? If you have a sustained outage due to vegetation, you must have violated the CCZ.
Response: Thank you for your comments. The SDT very carefully and thoroughly examined the merits, disadvantages, ease and difficulties of assessing momentary outages as a violation. The result of that effort led to the more precise and field observable aspects of R4. It should be noted that by their very nature the exact causes of "momentary outages" are very challenging to determine and will vary widely from utility to utility. The SDT did not find that such variability was appropriate for a reliability standard, and chose to address this issue with the language in R4.		
Northern Indiana Public Service Company	Agree	While being more specific & explicit, I don't interpret the overall requirement as being any different from the current standard.
Response: Thank you for your comment. Please note that while the current standard did not specifically define an interruption as a violation, the proposed standard explicitly defines outages as violations.		
Orange and Rockland Utilities Inc.	Agree	We agree, but recommend that momentary outages be included as violations of all three requirements as well. Also, the Standard does not directly require reporting of vegetation-related outages although implicitly, outages which are violations of the Standard must be reported. This has lead to some confusion during this comment phase and we suggest that the reporting requirements be directly stated in the Standard.
Response: Thank you for your comments. Under the Compliance section of the new standard section 2 the Transmission Owner is required to report outages.		
Xcel Energy	Agree	We agree, however please add a reference to ?wind gusts 45 miles per hour or greater? to the exception note for this requirement. The exception would read ?1) Sustained Outages of transmission lines that result from sustained winds (45 miles per hour or greater) or gusts due to natural disasters.?
Response: Thank you for your comments. The SDT believes that a fresh gale (see footnote 4) represents an appropriate threshold for exemptions.		
Manitoba Hydro	Agree	Agree with splitting the various events. We note that there is no specific requirement to actually report an outage. The Requirements say that we should Prevent Sustained Outages, but not actually report sustained outages should they occur. In version 1, R3 clearly stated that the Transmission Owner shall report.
Response: Thank you for your comments. Under NERC's Compliance Guidelines, any violation of a reliability standard requirement must be self-reported; thus, a violation of Requirement R5, R6 or R7 must result in a report from the Transmission Owner.		

Organization	Agree?	Question 16 Comment
National Grid	Agree	National Grid agrees with the proposed change, however, Standard FAC-003-2 does not provide outage reporting requirements in R5, R6, R7, or anywhere else in the Standard.
Response: Thank you for your comments. Under NERC's Compliance Guidelines, any violation of a reliability standard requirement must be self-reported; thus, a violation of Requirement R5, R6 or R7 must result in a report from the Transmission Owner. The revised standard includes compliance elements, including the need to provide periodic reports of specific vegetation-related outages.		
Pacific Gas & Electric Co.	Agree	M5, M6 and M7 do not explicitly exclude the exceptions in R5, R6 and R7 and should do so.
Response: Thank you for your comments. The SDT believes that the requirements and measures are properly aligned. The exceptions language is appropriately located in the technical requirement.		
Consolidated Edison Company of New York (CECONY)	Agree	CECONY agrees that outages caused by the factors mentioned are violations of R5, R6, and R7 but we recommend that either the phrase 'momentary outage' be included in the wording or the phrase 'All Outages' replace 'Sustained Outages' to make the requirements clearer.
Response: Thank you for your comments. The SDT very carefully and thoroughly examined the merits, disadvantages, ease and difficulties of assessing momentary outages as a violation. The result of that effort led to the more precise and field observable aspects of R4. It should be noted that by their very nature the exact causes of "momentary outages" are very challenging to determine and will vary widely from utility to utility. The SDT did not find that such variability was appropriate for a reliability standard, and chose to address this issue with the language in R4.		
WECC	Agree	However reporting requirements are not identified in the standard. WECC believes that sustained outages caused by vegetation should be reported to the Regional Entity using the existing reporting requirements in FAC-003-1
Response: Thank you for your comments. Under NERC's Compliance Guidelines, any violation of a reliability standard requirement must be self-reported; thus, a violation of Requirement R5, R6 or R7 must result in a report from the Transmission Owner. The revised standard includes compliance elements, including the need to provide periodic reports of specific vegetation-related outages.		
CenterPoint Energy	Agree	We agree with the exemptions; however, R6 and R7 refer to an "Active Transmission Line Right-of-way" which is not defined as to its limits, so M6 and M7 cannot be determined by definition. See comments to Q3 above relating to the definitions and the examples in the Technical Reference.
Response: Thank you for your comments. The SDT asserts that the Transmission Owner is responsible for defining the Active Transmission Line Right of Way. Additionally please refer to the response to Question 3. Note that the SDT made significant changes to clarify R5, R6 and R7 and the associated		

Organization	Agree?	Question 16 Comment
measures.		
Pepco Holdings, Inc	Agree	There is no need for three separate requirements if the incident is a Sustained Outage, but there is nothing inherently wrong with the three requirements.
Response: Thank you for your comments. Requirements R5, R6 and R7 have been drafted to address three distinct types of outages which may pose different risks or severity in terms of impact to the electric system. The SDT chose to break the requirements apart to allow application of different Violation Risk Factors and Violation Severity Levels.		
Northeast Utilities	Agree	Agree that contacts resulting in sustained outages due to vegetation from within the active transmission line right-of-way should constitute a violation of the Standard. However, this Standard is written for a zero tolerance of any vegetation caused outages or encroachment into the CCZ. One vegetation-caused outage or one CCZ encroachment may not result in a potential Cascading effect. Agree with the use of different violation risk factors (VRF's) and violation severity levels (VSL's) for each of the three outage classes. Also - how are outage violations to be reported - there is no provision in the revision for the reporting process and requirements (specifics on the type of violation). Will this be addressed in the Compliance Section yet to be added? Suggest in both R6 and R7, move the phrase "within an Active Transmission Line Right of Way" to immediately follow "vegetation".
Response: Thank you for your comments. The SDT believes it appropriate to require that the Transmission Owner incur no (applicable) vegetation-related outages. Further, industry regulators generally expect Version 2 to be at least as stringent as Version 1 unless a valid technical rationale is presented by the SDT. **Requirements R5, R6 and R7 have been drafted to address three distinct types of outages which may pose different risks or severity in terms of impact to the electric system. The SDT chose to break the requirements apart to allow application of different Violation Risk Factors and Violation Severity Levels.** **Regarding your question on reporting of violations, under NERC's Compliance Guidelines, any violation of a reliability standard requirement must be self-reported; thus, a violation of Requirement R5, R6 or R7 must result in a report from the Transmission Owner. In addition, the revised standard includes compliance elements, including the need to provide periodic reports of specific vegetation-related outages.** **Your suggested wording change to requirements R6 and R7 was evaluated by the SDT. The SDT asserts that the original wording is appropriate.**

17. R8 is a new requirement which separates the implementation of the annual plan from the requirement to have an annual plan. Do you agree with R8? If not please explain.

Summary Consideration: The SDT modified the Requirement for implementation of the work plan (now R9 in the revised standard) after reviewing these comments. Commenters focused on two main areas. First, there was a suggestion that the work plan wording be amended to include a note that it was only required on the Active Right of Way. Requirement R1 clearly limits the scope of the TVMP to work on the entity's Active Transmission Line Rights of Way - and the "annual work plan" is one element of the overall TVMP. The second overriding theme was that the standard be re-ordered to better tie the requirement to have a plan and the requirement to implement a plan. Some commenters suggested that the requirement to implement the annual work plan be embedded as part of Requirement R1, and the SDT did not make this change. The requirement to "have" a TVMP is administrative and the requirement to "implement" the annual work plan is a real-time requirement – by keeping these requirements separate, each requirement can be assigned an appropriate VRF. The SDT is offering for comment a proposed re-ordering of the Standard that provides a more logical sequence to the Standard which, if supported by stakeholders, can be applied to Draft 3 of the standard.

For Draft 2, the SDT also removed the wording "within the extent of its easements and/or legal rights." The justification for removing these words was to remove the possibility that the TO would be held to the maximum criteria or be limited to the minimum criteria outlined in their easements.

R9. Each Transmission Owner shall implement its annual work plan for vegetation management to accomplish the purpose of this standard.

Deleted: R8

Deleted: within the extent of its easement and/or legal rights

Organization	Agree?	Question 17 Comment
Central Maine Power Company		Central Maine Power Company suggests that R9 read as A Transmission Owner shall implement its annual work plan within the Active Right of Way to the the extent of its easements or legal rights.
Response: The SDT thanks you for your response. In response to overwhelming industry comments The SDT has removed the words "within the extent of its easements and/or legal rights". The SDT also feels that the Active Right of Way concept is supported adequately in Requirement R1 which limits the scope of the TVMP (and the annual work plan) to the entity's Active Rights of Way.		
British Columbia Transmission Corp		BCTC understands that it's possible to have an annual plan and not implement it. However, we feel that the document itself would be easier to follow if it was re-organized so that the requirement to have the plan is kept together with the requirement to implement it.
Response: The SDT thanks you for your response. The SDT proposes a new sequence for the technical Requirements R1-R11 and seeks industry feedback as requested in Question 4 of the Second Comment Form.		

Organization	Agree?	Question 17 Comment
Western Utility Arborists		The Western Utilities understands that it's possible to have an annual plan and not implement it. However, we feel that the document itself would be easier to follow if it was re-organized so that the requirement to have the plan is kept together with the requirement to implement it.
Response: The SDT thanks you for your response. The SDT proposes a new sequence for the technical Requirements R1-R11 and seeks industry feedback as requested in Question 4 of the Second Comment Form.		
SERC Vegetation Management Subcommittee (VMS)	Disagree	While the SERC VMS agrees in principle, we believe that the Requirement, as written, is "open ended" and could be interpreted to be in conflict with the "Active Rights of Way" concept. Clarifying the intent for the annual plan to focus on the Active Rights of Way will prevent incorrect interpretations. The SERC VMS suggest that the Requirement be reworded to read: ?Each Transmission Owner shall implement its annual work plan for vegetation management within the Active Right of Way to accomplish the purpose of this standard within the extent of its easements and or legal rights.?
Response: The SDT thanks you for your response. The SDT considered your request at length but feels that the Active Right of Way concept is supported adequately in Requirement R1 which limits the scope of the TVMP (and the annual work plan) to the entity's Active Rights of Way.		
JEA	Disagree	See comment from #3.
Response: Thank you for your comment. Please see the response to comments on #3. .		
Salt River Project	Disagree	The document would be easier to follow if the two elements would be kept together in the same requirement (similar to comments in #4, #6, & #14 above). It makes the standard longer than necessary and creates redundancy.
Response: The SDT thanks you for your response. The reason that the development of the annual plan and the implementation of the plan were separated was to apply the appropriate VRF's and VSL's to each. The SDT feels that the current organization is appropriate because development of the annual work plan is a sub-part of the development of the Transmission Vegetation Management Program and should be separate from the implementation requirement for the annual plan.		
SERC OC Standards Review Group	Disagree	The SERC OCSRG suggests that the Requirement be reworded to read: "Each Transmission Owner shall implement its annual work plan for vegetation management within the Active Rights of Way." Any further verbiage is confusing, ambiguous or unnecessary.
Response: The SDT thanks you for your response. The SDT considered your request at length but feels that the Active Right of Way concept is supported adequately in the definition and elsewhere in the standard. The SDT did, however, remove the last phrase of the sentence, "within the extent		

Organization	Agree?	Question 17 Comment
of its easement and/or legal rights.”		
Florida Power & Light	Disagree	The standard goes to great length to specify the Active Transmission Right-of-Way but omits its reference in requirement R9. The inclusion of this term in Requirement R9 adds consistency to the application of the standard. FPL suggests the following change: "Each Transmission Owner shall implement its annual work plan for vegetation management to accomplish the purpose of this standard within the extent of its easement and/or legal rights in the Active Transmission Line Right-of-Way."
Response: The SDT thanks you for your response. Due to industry comments the SDT revised the wording on this requirement to delete the words “within the extent of its easements and/or legal rights”. The SDT also feels that the Active Right of Way concept is supported adequately in the Requirement R1 which limits the scope of the TVMP (and the annual work plan) to the entity’s Active Rights of Way.		
Southern Company	Disagree	While we agree in principle, we feel Requirement R9 as written is “open ended” and could be interpreted to be in conflict with the “Active Rights of Way” concept. Clarifying the intent for the annual plan to focus on the Active Rights of Way will prevent incorrect interpretations. We suggest that the Requirement be reworded to read: Each Transmission Owner shall implement its annual work plan for vegetation management within the Active Right of Way to accomplish the purpose of this standard within the extent of its easements and or legal rights.
Response: The SDT thanks you for your response. Due to industry comments the SDT revised the wording on this requirement to delete the words “within the extent of its easements and/or legal rights”. The SDT also feels that the Active Right of Way concept is supported adequately in Requirement R1 which limits the scope of the TVMP (and the annual work plan) to the entity’s Active Rights of Way.		
E.ON U.S.	Disagree	E.ON U.S. believes that the Requirement, as written, is “open ended” and could be interpreted to be in conflict with the "Active Rights of Way" concept. Clarifying the intent for the annual plan to focus on the Active Rights of Way will prevent incorrect interpretations. We suggest that the Requirement be reworded to read: “Each Transmission Owner shall implement its annual work plan for vegetation management within the Active Right of Way to accomplish the purpose of this standard within the extent of its easements and or legal rights.”
Response: The SDT thanks you for your response. The SDT agrees with your comments and has removed the words “within the extent of its easements and/or legal rights”. The SDT also feels that the Active Right of Way concept is supported adequately in Requirement R1 which limits the scope of the TVMP (and the annual work plan) to the entity’s Active Rights of Way.		
Exelon	Disagree	Strike "within the extent of it's easement and / or legal rights." This is unnecessary and will cause confusion. The annual work plan as required to be developed per R1.3 requires consideration of permitting, scheduling and regulatory limitations.

Organization	Agree?	Question 17 Comment
Response: The SDT thanks you for your response. After reviewing the industry comments there was broad support for your suggestion and the requirement has been revised to reflect your suggestion.		
NV Energy (fka Sierra Pacific / Nevada Power Co.)	Disagree	We understand that it is possible to have an annual plan and not implement it. However, we feel that the document itself would be easier to follow if it was re-organized so that the requirement to have the plan is kept together with the requirement to implement it.
Response: The SDT thanks you for your response. The SDT feels that the current organization is appropriate because development of the annual work plan is a sub-part of the development of the Transmission Vegetation Management Program and should be separate from the implementation requirement for the annual plan. The SDT proposes a new sequence for the technical Requirements R1-R11 and seeks industry feedback as requested in Question 4 of the Second Comment Form.		
San Diego Gas & Electric	Disagree	We feel that the document itself would be easier to follow if it was re-organized so that the requirement to have the plan is kept together with the requirement to implement the plan.
Response: The SDT thanks you for your response. The SDT feels that the current organization is appropriate because development of the annual work plan is a sub-part of the development of the Transmission Vegetation Management Program and should be separate from the implementation requirement for the annual plan. The SDT proposes a new sequence for the technical Requirements R1-R11 and seeks industry feedback as requested in Question 4 of the Second Comment Form.		
Baltimore Gas & Electric Company	Disagree	As in question no. 14 above for R1.2, it would seem to make more sense to combine R1.3 & R9 as follows: "Require development and implementation of an annual plan that?."
Response: The SDT thanks you for your response. The reason that the development of the annual plan and the implementation of the plan were separated was to apply the appropriate VRF's and VSL's to each. The SDT feels that the current organization is appropriate because development of the annual work plan is a sub-part of the development of the Transmission Vegetation Management Program and should be separate from the implementation requirement for the annual plan.		
Pepco Holdings, Inc	Disagree	THE SDT has introduced the term Active Transmission Line Right of Way. R9 should use this term to avoid any misinterpretation.
Response: The SDT thanks you for your response. In response to industry comments The SDT has removed the words "within the extent of its easements and/or legal rights". The SDT also feels that the Active Right of Way concept is supported adequately in Requirement R1 which limits the scope of the TVMP (and the annual work plan) to the entity's Active Rights of Way.		

Organization	Agree?	Question 17 Comment
Great River Energy	Disagree	GRE both Agrees and Disagrees. GRE agrees with the separation between having an annual plan and implementing it. However, GRE suggests removing all the words after vegetation management.
Response: The SDT thanks you for your response. After reviewing the industry comments there was broad support for your suggestion and the requirement has been revised to reflect your suggestion.		
City of Tallahassee	Disagree	Combined with Question 6. R9 needs to have the same flexibility that R1.3 has. As written, it could be argued that you have to do everything in your annual plan, AND anything in addition due to the changing conditions. This contradicts what is put forth in the white paper. I would add "as modified per R1.3" after "implement it's annual work plan for vegetation management"
Response: The SDT thanks you for your response. The SDT feels that the "flexibility" of the annual plan is built into the development of the plan and that same flexibility carries through to the implementation.		
Tampa Electric Company	Disagree	Good start. R9 must also address the flexibility which is addressed in R1.3. As written, R9 does not do this. In addition, R9 states "within the extent of its easement and/or legal right..". This could create another set of conflicting criteria, where the utility has a long term "interim corrective action plan".
Response: The SDT thanks you for your response. The SDT feels that the "flexibility" of the annual plan is built into the development of the plan and that same flexibility carries through to the implementation. The SDT does agree with the possible confusion the words "within the extent of its easement and/or legal rights" could cause and has consequently removed these words from the requirement.		
USDA Forest Service, Southwestern Region, Regional Office for AZ and NM	Disagree	This standard needs to be broadened to include evaluation of the good faith efforts by the Transmission Owner to coordinate with the USFS on development of the work plan. A mechanism should be developed to allow the Transmission Owner to evaluate the good faith efforts of the USFS.
Response: The SDT thanks you for your response. The Standard is a continental reliability standard. While the SDT agrees with you that every Transmission Owner should strive for mutually beneficial relationships with the various landowners and other entities involved in vegetation management, it would be outside the purvey of this effort to outline specific relationships.		
Arizona Public Service Company	Disagree	APS understands that it's possible to have an annual plan and not implement it. However, we feel that the document itself would be easier to follow if it was re-organized so that the requirement to have the plan is kept together with the requirement to implement it.
Response: The SDT thanks you for your response. The SDT feels that the current organization is appropriate because development of the annual work plan is a sub-part of the development of the Transmission Vegetation Management Program and should be separate from the implementation		

Organization	Agree?	Question 17 Comment
requirement for the annual plan. The SDT proposes a new sequence for the technical Requirements R1-R11 and seeks industry feedback as requested in Question 4 of the Second Comment Form.		
SERC Compliance Staff	Agree	Vegetation management practices should be extended areas outside of the active rights-of-way (ROW) to the extent necessary to prevent vegetation-related outages. This should include the identification and removal of trees that could impact transmission line operation similar to the practice of identifying danger trees off of the ROW. The requirement as written could serve to reward those entities that, for whatever reason, have insufficient right-of-way widths. From a practical perspective, it should not be necessary to perform clear cutting of non-active ROW, but Entities should be held responsible for any outages that occur due to contact with vegetation within their legal rights to control.
Response: The SDT thanks you for your response. After reviewing the industry comments there was broad support to remove any wording referring to the easement rights. The SDT agreed with this view and has revised the requirement.		
ITC HOLDINGS	Agree	Clarifying the intent for the annual plan is to focus on the Active Rights of Way will prevent interpretation conflicts
Response: The SDT thanks you for your response. The SDT agrees with your observation, but also points out that the requirement for an annual work plan (sub-part 1.3) is part of Requirement R1, which specifically states its applicability to Active Transmission Line Rights of Way. Therefore, the SDT respectfully feels that your concern is addressed without additionally placing such verbiage in R8 (now R9).		
American Electric Power (AEP)	Agree	AEP agrees with this change.
Response: The SDT thanks you for your comments. The SDT modified the requirement, based on stakeholder comments, to remove the last phrase, "within the extent of its easement and/or legal rights."		
Tennessee Valley Authority	Agree	TVA agrees with Comment Question 17
Response: The SDT thanks you for your comment. The SDT modified the requirement, based on stakeholder comments, to remove the last phrase, "within the extent of its easement and/or legal rights."		
Platte River Power Authority	Agree	The separation allows lower sanctions and penalties to be assessed for a weak plan and higher sanctions and penalties to be assessed for not implementing an annual plan. However, we feel that the standard itself would be easier to follow if it was re-organized so that the requirement to have a plan is kept together with the requirement to implement it.

Organization	Agree?	Question 17 Comment
Response: The SDT thanks you for your response. The reason that the development of the annual plan and the implementation of the plan were separated was to apply the appropriate VRF's and VSL's to each. The SDT feels that the current organization is appropriate because development of the annual work plan is a sub-part of the development of the Transmission Vegetation Management Program and should be separate from the implementation requirement for the annual plan. The SDT proposes a new sequence for the technical Requirements R1-R11 and seeks industry feedback as requested in Question 4 of the Second Comment Form.		
American Transmission Company	Agree	ATC agrees with the requirement to implement the annual work plan, but recommends striking the words "within the extent of its easement and/or legal rights". The emphasis for this requirement is to execute the annual work plan. The white paper already speaks to the point that it is a best practice for utilities to exercise their legal rights. If we agree that the goal is to prevent outages, then we can simply end this requirement with "implement its annual work plan for vegetation management." Propose Changes to R9: Each Transmission Owner shall implement its annual work plan for vegetation management.
Response: The SDT thanks you for your response. After reviewing the industry comments there was broad support for your suggestion and the requirement has been revised to reflect your suggestion.		
Ameren	Agree	We recommend striking, or modifying, the words "within the extent of its easement and/or legal rights" as they may be introducing an unintended compliance quagmire. For example, if the easement is extraordinarily wide but reliability and the work plan do not dictate that the work plan apply to the entire easement, how will compliance be measured? The work plan should recognize easement or legal rights issue. Therefore, the emphasis for this requirement should be to execute the annual work plan. The white paper already speaks to the point that it is a best practice for utilities to exercise their legal rights. By tagging the words on to the requirement, we are adding unnecessary compliance validation to this requirement for both industry and the regulators. If a clarifying sentence is required, we would suggest that R9 stop with the word standard and a new sentence be added, "The work plan should address easement or legal/rights"
Response: The SDT thanks you for your response. After reviewing the industry comments there was broad support for your suggestion and the requirement has been revised to reflect your suggestion.		
MRO NERC Standards Review Subcommittee	Agree	The MRO both Agrees and Disagrees. The MRO agrees with the separation between having an annual plan and implementing it. However, the MRO suggests removing all the words after vegetation management.
Response: The SDT thanks you for your response. After reviewing the industry comments there was broad support for your suggestion and the requirement has been revised to reflect your suggestion.		

Organization	Agree?	Question 17 Comment
Midwest ISO Stakeholders Standards Collaborators	Agree	We recommend striking the words "within the extent of its easement and/or legal rights". The emphasis for this requirement is to execute the annual work plan. The white paper already speaks to the point that it is a best practice for utilities to exercise their legal rights. By tagging the words on to the requirement, we are adding unnecessary compliance validation to this requirement for both industry and the regulators. By the way this is written, it could be interpreted different ways. If we agree that the goal is to prevent outages, then we can simply end this requirement with "accomplish the purpose of the standard". Each Transmission Owner would be accountable to manage compliance with this standard and public relations in their service area.
Response: The SDT thanks you for your response. After reviewing the industry comments there was broad support for your suggestion and the requirement has been revised to reflect your suggestion.		
Duke Energy Corporation	Agree	Duke agrees with the requirement to implement the annual work plan, but recommends striking the words "within the extent of its easement and/or legal rights". The emphasis for this requirement is to execute the annual work plan. The white paper already speaks to the point that it is a best practice for utilities to exercise their legal rights. If we agree that the goal is to prevent outages, then we can simply end this requirement with "accomplish the purpose of the standard". Each Transmission Owner will be accountable to manage compliance with this standard.
Response: The SDT thanks you for your response. After reviewing the industry comments there was broad support for your suggestion and the requirement has been revised to reflect your suggestion.		
CenterPoint Energy	Agree	R9 requires implementation of the annual work plan "within the extent of its [the Transmission Owner's] easement and/or legal rights." All measures and compliance should be determined on this basis as well. This concept should also be carried through the definitions for "Active Transmission Line Right-of-way" and "Critical Clearance Zone", or for any definition of clearances should the Standard continue to utilize such terms.
Response: The SDT thanks you for your response. In response to industry comments The SDT has removed the words “within the extent of its easements and/or legal rights”. The SDT also feels that the Active Right of Way concept is supported adequately in the definition and in Requirement R1 which limits the scope of the TVMP (and the annual work plan) to the entity’s Active Rights of Way.		
Progress Energy Florida	Agree	While Progress Energy agrees with the change, the term “annual plan” should be a defined term including threshold elements.
Response: The SDT thanks you for your response. The SDT feels that the annual plan is adequately defined between the descriptions in the Standard (sub section 1.3) and in the technical reference document.		

<table>
<tr><th>Organization</th><th>Agree?</th><th>Question 17 Comment</th></tr>
<tr><td>Southern California Edison Company</td><td>Agree</td><td>Q17: SCE agrees in part with the inclusion of R9, however, we believe R9 should be revised and renumbered to replace proposed R3. In SCE’s view, the act of implementing a Transmission VM program encompasses both inspection and maintenance activities. SCE respectfully suggests that proposed R9 be revised to read: "Each Transmission Owner shall implement and follow its Vegetation Management Program to the extent allowed by existing easement and/or legal rights."</td></tr>
<tr><td colspan="3">Response: The SDT thanks you for your response. The SDT separates the vegetation inspections from the annual work plan because of partly due to the fundamental importance of the inspection process, and partly because a key purpose of an inspection is to provide input to the formation of the annual work plan. The SDT also points out that the TVMP is comprises the overarching processes and standards for program management, while the annual plan is the specific annual activities to accomplish the goals set forth in the program. In addition, the SDT modified the requirement, based on many other stakeholder comments, to remove the last phrase, “within the extent of its easement and/or legal rights.”</td></tr>
<tr><td>FirstEnergy</td><td>Agree</td><td>FirstEnergy agrees with the intent of R9, but the standard should be clarified by removal of the word "easement". As written the standard is open to interpretation between "easement" and active right of way. It is important to have the term "legal rights" remain in the standard. The Transmission Owner should be held accountable to fully enforce the legal rights outlined in maintaining the active right of way. This will lead to a more reliable transmission system.</td></tr>
<tr><td colspan="3">Response: The SDT thanks you for your response. Due to industry comments the SDT revised the wording on this requirement to delete the words “within the extent of its easements and/or legal rights”. While we agree and state in the technical reference document that clearing to the maximum extent is in most cases the best practice, there are particular situations where a clear cut policy would not be in the best interest of the Transmission Owner or the landowner. The SDT also feels that the Active Right of Way concept is supported adequately in Requirement R1 which limits the scope of the TVMP (and the annual work plan) to the entity’s Active Rights of Way.</td></tr>
<tr><td>Pacific Gas & Electric Co.</td><td>Agree</td><td>PG&E agrees with the requirement to implement the annual work plan, but recommends removing the language "within the extent of its easement and/or legal rights".</td></tr>
<tr><td colspan="3">Response: The SDT thanks you for your response. After reviewing the industry comments there was broad support for your suggestion and the requirement has been revised to reflect your suggestion.</td></tr>
<tr><td>Entergy Services</td><td>Agree</td><td>Entergy would like to note that requirements R1.3 and R9 are administrative requirements that add marginal value to the reliability of the Transmission System. Since entities are required to have flexible annual plans, deviations from the annual plan only need to be documented and these requirements will be met. Entergy utilizes annual plans as a good practice but sees limited value with the inclusion in this standard.</td></tr>
<tr><td colspan="3">Response: The SDT thanks you for your response. After reviewing the industry comments there was broad concern that the current wording could</td></tr>
</table>

Organization	Agree?	Question 17 Comment
cause confusion with the wording "within the extent of its easements and/or legal rights". Consequently the SDT agreed with this view and has revised the requirement to address these concerns. The SDT respectfully disagrees that sub section 1.3 and R9 are administrative requirements and only add marginal value to the reliability of the system. Requirement R8 (now R9) is a real-time requirement, not an administrative requirement.		
Nebraska Public Power District	Agree

Response: Thank you for your positive response. The SDT modified the requirement, based on many other stakeholder comments, to remove the last phrase, "within the extent of its easement and/or legal rights."		

18. If you have further suggestions for improving this standard or the technical reference document, please offer them.

Summary Consideration: The overall industry feedback provided to this question reiterated concerns expressed in previous comments above. Most were related to the Critical Clearance Zone and associated issues of measurability, enforceability and practicality.

Organization	Question 18 Comment
Associated Electric Cooperative Inc.	R10 and R11: Associated Electric Cooperative Inc does not believe the Reliability Coordinator (RC) is the appropriate entity to determine whether or not selected sub-200 kv transmission lines should be subject to this standard. The planning horizon for the RC is typically much shorter than the time needed to incorporate a sub-200 kv transmission line into a vegetation management program. Associated recommends Planning Coordinator be designated as the applicable functional entity and be substituted wherever Reliability Coordinator appears in the Standard. M1.4: The language in M1.4, requiring immediate communication of an imminent threat to the Transmission Operator, is inconsistent with the Applicability in Section A.4.1.1 which designates the Transmission Owner as the responsible entity. M4: The preparation and retention of inspection reports, imminent threat reports, quality assurance reports, etc. is appropriate. These reports would not, however, absolutely demonstrate the Transmission Owner had experienced no vegetation encroachments into the Critical Clearance Zone. A negative cannot be proven. M6 and M7: The Transmission Owner is again expected to demonstrate a negative to prove compliance. Section C: Associated Electric Cooperative Inc recognizes the Standard, as posted, is a first draft for comments and will likely be revised before submittal for ballot. However, the Compliance section should be posted for an adequate comment period prior to balloting.
Response: The SDT thanks you for your comments. **The drafting team has made significant changes to the draft standard in response to industry comments, including the replacement of RC with PC.** **R1.4 and M1.4 are changed and the inconsistency has been resolved.** **R4 and M4 are changed such that real time observations during inspections and patrols replace the previous condition of proving a negative. In addition, the revised standard does not use the concept of the Critical Clearance Zone.** **M6 and M7 have been changed so that the proof of a negative is not required.** **The SDT had developed compliance elements for the industry to review in the second comment period.**	
NPCC	NPCC requests that the Standard Drafting Team review the compliance and reporting requirements for consistency and adequacy.

<table>
<tr><th>Organization</th><th>Question 18 Comment</th></tr>
<tr><td colspan="2">Response: The SDT thanks you for your comments. The drafting team has made significant changes to the draft standard in response to industry comments. Compliance elements have been added to the second draft of the standard.</td></tr>
<tr><td>WECC Reliability Coordination</td><td>R10 Should a dispute arise, how are those disputes resolved. Who keeps the list.

R10 What is acceptable methodology given the lack of interpretation of unacceptable risk of instability(R 10.2) or cascading failures. There is no definition of the consequences if a sub 200kv line is left off the list for vegetation management, and caused a cascading outage or placed the grid at an unacceptable risk of instability.</td></tr>
<tr><td colspan="2">Response: The SDT thanks you for your comments The drafting team has made significant changes to the draft standard in response to industry comments.

The RC has been replaced with the PC in R9 and R10.

This standard requires the PC to prepare and keep the list. Requiring the list to be developed in consultation with the TO ensures that the list will be available to the TO for the purposes in this Standard. The revised language should eliminate any disputes as the PC is ultimately the responsible entity for developing the list.

R10 was revised and now uses terminology that replicates terms within the IROL definition in the NERC Glossary of Terms for reliability standards. The intent is for the PC to use the same methods that determine those lines which are elements of an IROL be used to determine sub 200kV lines which are applicable to this standard.

While the planning study or similar analysis as cited in M10 could contain errors, it is not the intent of this standard to determine the competency of the PC or the results of PC any PC's analysis.</td></tr>
<tr><td>Western Area Power Administration, Upper Great Plains Region</td><td>1) Proactive utilities are implementing policies that call for the removal of all vegetation that could grow into the Critical Clearance Zone . Such policies are not without resistance from landowners, environmental groups, etc. One of the arguments used by such groups is that NERC/FERC do not require removal of the trees. It would very helpful if this document included the practice of removing vegetation capable of encroaching within the Critical Clearance Zone as a reasonable or acceptable practice under this Standard.

2) We can foresee a possible public backlash if this Standard is adopted as written. We see many utilities needing rate increases to cover the additional costs of implementing and monitoring the more stringent requirements of this proposal. We also believe that the more stringent requirements will have no noticeable impact on reliability. So you'll have the public paying more and seeing no change in reliability and questioning why.</td></tr>
<tr><td colspan="2">Response: The SDT thanks you for your comments. Significant changes have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ concept has been replaced with the concept of minimum vegetation clearance distances, and Transmission Owners are required to prevent encroachment of vegetation into minimum vegetation clearances distances as observed in real time. The Standard Drafting team has found that this Standard can not establish any legal basis to require Transmission Owners to exercise rights that do no</td></tr>

exist within their transmission line easements or permits.	
Progress Energy Florida	To avoid interpretation errors and provide clarity, the Applicability section for Facilities (4.2) of FAC-003 should include a statement that the standard only applies to vegetation within the Active Transmission Line Right of Way. For example, a fall-in from outside of the Active Transmission Line Right of Way that causes a sustained outage is not a violation of this standard. Any encroachment/outage initiated by vegetation falling from outside of the Active Transmission Line Right of Way should be excluded from violations. The Critical Clearance Zone concept is academically elegant, but when applied in the field, it presents significant implementation, interpretation and enforcement issues: the complexity of determining compliance could have the unintended negative consequences to reliability; removal of vegetation will likely be delayed because of the complexity and accuracy required to determine compliance prior to tree removal; certification that no violations have occurred will require lengthy and costly calculations and survey measurements; the standard refers to Ratings in the determination of line sags and Ratings is not a tightly defined term, PRC-023 requires relays to hold lines in beyond the line Ratings; how will PRC-023 requirements be factored into the Critical Clearance Zone concept. The Critical Clearance Zone concept introduces more complexity and ambiguity into the standard than it resolves. The drafting team needs to develop an alternative to the Critical Clearance Zone concept that is simple, easy to apply and clearly defines at what point a violation occurs. There are over 158,000 line miles of AC Transmission above 200kV in the United States, covering a Right of Way area potentially as large as 3,000 to 4,000 square miles (an area roughly equivalent to Rhode Island and Delaware combined). With billions of stems of managed vegetation, in and along the right of way, even six-sigma performance would result in a number of outages on a system this large. With countless VM processes and assessments that take place daily, it is unrealistic/unreasonable to expect zero-tolerance for random vegetation events (the transmission system is planned/operated to handle at least any single contingency).
Response: The SDT thanks you for your comments. Significant changes have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ concept has been replaced with the concept of minimum clearance distances, and Transmission Owners are required to prevent encroachment of vegetation into minimum vegetation clearances distances as observed in real time. **The exclusion you request for vegetation falling through the MVCD, regardless of its being form inside or outside the right-of-way, has been added.** **Due to the industry impact that arises from zero tolerance for vegetation-related sustained outages, the Drafting Team tried several approaches but could not find a mechanism in the standard development process to establish a non-zero threshold for outages that was acceptable to FERC staff, because Standard revisions may not lead to less emphasis on reliability.** **The PRC-023 Standard seeks to ensure that transmission protective relays are properly set such that they do not trip a transmission element unnecessarily. This FAC-003 Standard seeks to prevent vegetation related Sustained Outages by requiring Transmission Owners to maintain their Active Transmission Line Rights of Way to be sufficiently clear. These two Standards are not mutually exclusive nor conflict with each other.**	
Kansas City Power & Light	The title and explanation for Table 1 in Attachment 1 is not clear as to it's usage and applicability. It is being confused with the correlation with a minimum clearance and not as a component or building block of the Critical Clearance Zone. Under R10, there may be other methods for consideration of assessing reliability significance of the sub-200 kV lines other than what is

<table>
<tr><th>Organization</th><th>Question 18 Comment</th></tr>
<tr><td></td><td>listed. Suggest the Drafting Team consider other criteria that an RC should consider in its processes.

R10.2 is redundant with R10.1. IROL by definition are those operating limits that represent instability, uncontrolled separation or cascading. Suggest removing R10.2.

Under M1.3 the measure requires the annual plan to cover a calendar year. An annual plan may cover a cycle growing season to growing season using the inspection to verify the next seasons work.

Suggest removing the language for calendar year.M5, M6, M7 The measures should be requesting the evidence that it has violated the requirements. Good standing programs should not have to defend good practice by providing useless reports. The FAC-003-1 existing requirement R4 for reporting sustained outages is a reasonable and sustainable method that should be retained.R10 should include a periodic review period of annually. Any requirement to maintain current documentation should have a review period.</td></tr>
<tr><td colspan="2">Response: The SDT thanks you for your comments. Significant changes have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ concept has been replaced with the concept of minimum clearance distances, and Transmission Owners are required to prevent encroachment of vegetation into minimum vegetation clearances distances as observed in real time.

Under M10 (now M11) the language now allows the criteria used in planning studies and analysis to be acceptable measures for R10 (now R11).

The redundancy in 10.1 and 10.2 you found has been removed.

The reference to the calendar year that was in M1.3 has been removed.

M5, M6, M7 language has been changed. These measures now rely on the certification reports to the RE reporting will occur for both full compliance and any violations. The revised standard includes data retention periods as well as more detailed compliance information.</td></tr>
<tr><td>Western Area Power Administration, Rocky Mountain Region</td><td>1. Further clarification of the definition of the active right-of-way appears to be required. For example, if a tree falls from an area controlled by the utility which is outside of the normal width of the actively managed right-of-way, but this area is not reserved or "intended for other facilities", could this be a violation of a Standards requirement? The narrative discussion within the white paper seems to imply that it is not, but the "intended for other facilities" requirement within Standards definition implies that it would be.

2. As currently presented, FAC-003-2 requires an impractical and unrealistic level of performance from the industry. This level of performance is unwarranted for the overwhelming number and expanse of transmission facilities to which the Standards are applicable. Many of these facilities, such as radial load lines, are not critical Transmission OwnerT or IROL facilities and have a minimal impact on overall grid reliability. The rigorous zero tolerance level of performance is only warranted for those lines that are critical Transmission OwnerT or IROL facilities.

3. The Standards should clearly identify any and all reporting requirements.</td></tr>
<tr><td colspan="2">Response: The SDT thanks you for your comments.

1. The definition of the Active Transmission Line Right of Way states it is “A strip of land that is occupied by active transmission facilities. This corridor</td></tr>

Active Transmission Line Rights of Way to be sufficiently clear. These two Standards are not mutually exclusive nor conflict with each other.	
Southern California Edison Company	SCE notes that Section C (Compliance) is incomplete and that the associated levels of Non-Compliance listed in FAC-003-1 may be different from those proposed for FAC-003-2. SCE reserves the right to revise its initial comments and submit additional comments regarding the requirements, measures and compliance portions of FAC-003-2.
Response: The SDT thanks you for your comments. Draft 2 will be a complete Standard for you to review.	
SERC OC Standards Review Group	The SERC OCSRG recommends that the definition of "Active Rights of Way" be revised as follows: "A strip of land, designated by the Transmission Owner, that is occupied by active transmission facilities. This corridor does not include the inactive or unused part of the Right of Way set aside by the Transmission Owner for other facilities or uses." The SERC SOSRG recommends that this standard should exclude radial to load facilities and, for consistency, all 200 kV and above lines should not be included in the standard unless they meet the same requirements as sub 200 kV lines.
Response: The SDT thanks you for your comments. The SDT opted to retain the "bright line" of 200kV without further qualifications such as radial to load transmission facilities, due to the directive given by FERC Order 693 (paragraph 706 "we did not intend to make this Reliability Standard applicable to fewer facilities than it currently is with the 200 kV bright line applicability, but to extend the applicability to lower-voltage facilities that have an impact on reliability".	
Western Utility Arborists	Any standard that is developed should not contain advisory-type language? it should be declarative in tone. For example, in R1.4, the ending clause that begins "and may include actions" should be removed because it is advisory in nature. The suggested actions are not even the responsibility of the vegetation management program. ADDITIONAL COMMENTS We have prepared, and will submit via email, additional comments regarding our online submission. If the ability to submit them electronically is not available on this website, we will send the complete document via email to Harry Tom and would ask that it be reviewed and considered by the drafting team.
Response: The SDT thanks you for your comments. The phrase in R1.4, "and may include actions" has been removed from the revised standard in support of your suggestion. **Please refer to the various responses to your comments provided in the individual questions. The changes to the standard in this reposting and the responses to your comments on questions 1-17 are intended to serve as a reply to your various comments.**	
Florida Power & Light	FPL believes the Vegetation Management standard should concentrate on grow-in tree issues that contribute to cascading or blackout events as stated in the purpose statement. Fall-in trees from either on or off ROW do not in-and-of themselves cause cascading or blackout events. Transmission systems are appropriately designed to handle incidental outages under N-1 conditions which are the case in fall-in type outages. Requirements relating to fall-in and blow-in outages (R6 and R7), which deal with incidents resulting from

Organization	Question 18 Comment
	force majeure or acts of God, should be removed to allow resources to be allocated to addressing events related to grow in interruptions. Because of an utter lack of control or such situations, no Standard or regulation places a duty on one to control force majeure or acts of God, yet that is precisely what R6 and R7 intend to do. If R6 and R7 stay in its current form, this will be yet another reason why this Standard as written will be unenforceable. FPL recommends the following approach. The entire US Transmission system was built under the National Electric Safety Code (C2). That code uses the Reference Component as the initial building block for establishing the lowest height of a conductor for all operating and designed environmental conditions. Over most open land this distance is 14 feet. FPL recommends creating a new requirement to clearly define a trimming standard. New Requirement At time of trimming, trees under conductors should be trimmed or removed so that the average growth would remain below the Reference Component of Rule 232 in the National Electric Safety Code C2. The wire zone should extend to the blowout distance calculated at 39 miles per hour (Fresh Gale) not to exceed the Active Transmission Right-of-Way. Where the Transmission Owner can not achieve that clearance, they shall have a permanent (ex. raised conductor) or interim (ex. short trim cycles) corrective action plan in place to prevent tree wire conflicts. Permanent corrective action plans should reside in the Transmission Owner's vegetation program record keeping system (database) for application when that line is maintained or inspected. Trees to the side of the ROW should be maintained at the edge of the Active Transmission Right-of-Way. The value in this approach is in its application by arborists and tree trimmers in field conditions. This approach is clear and measurable without a surveyor or an engineer present. The line design calculations were made to the NESC Standard at the time the line was built and incorporate all potential conductor locations within its flight path. As it stands now if there is a violation to R4, R5, R6, or R7 it is already too late. The standard should seek to identify and correct poor performers before they create a reliability threat to the system. In the field, a poor performer has many trees close to the line and will have to do many emergency cuts. It will also have more momentary interruptions before it has a single Sustained interruption. Sustained Interruptions have a history of contributing to cascading and blackout events. The standard should measure performance and penalize poor performance. The changes below reflect performance measurements with a graduated penalty applied to the metric. Change R2 to read Each Transmission Owner shall implement its Imminent Threat procedure when the Transmission Owner has knowledge, obtained through normal operating practices or notification from others, that the tree / conductor distance is less than the minimum clearance distance as specified in Table 2 of ANSI Z133.1-2006 (the minimum approach distance for qualified line-clearance arborists or qualified line-clearance trainees). Transmission Owners are to document and report activation of the Imminent Threat Procedure for violation of Table 2. Activation of the Imminent Threat Procedure for other causes shall not be reportable. The Violation Severity level should read: Activation of the Imminent Threat Procedure for encroachment of Table 2 of ANSI Z133.1-2006 (the minimum approach distance for qualified line-clearance arborists or qualified line-clearance trainees) has the following severity level: Lower ? Greater than 5 per 1000 miles of line and less than 7 Moderate ? Greater than 7 per 1000 miles of line and less than 9 High - Greater than 9 per 1000 miles of line and less than 13 Severe - Greater than 13 per 1000 miles of line

Organization	Question 18 Comment
	Trees inside of Table 2 can only safely be trimmed under a clearance from the system operator, using special techniques under a line right of way from the system operator, or by a lineman with a live line permit from the system operator. No utility wants to let a tree get so close to energized lines such that it has to take the line out of service for a tree trim. It should be noted that Table 2 represents an established industry standard which is normally found placarded on the side of every tree trimming easement truck and bucket truck. It is minimum knowledge for every qualified line-clearance tree person under OSHA regulations. This is a distance that field personnel understand. New R5 to read: Each Transmission Owner shall minimize Momentary Outages of applicable lines due to vegetation growing into a conductor with the following exceptions:? Sustained Outages of applicable lines that result from natural disasters.? Sustained Outages of applicable lines that result from human or animal Activity. The Violation Severity level should read: Lower ? Having Momentary Outages Greater than 3 per 1000 miles of line and less than 6 Moderate ? Having Momentary Outages Greater than 6 per 1000 miles of line and less than 8 High - Having Momentary Outages Greater than 8 per 1000 miles of line and less than 12 Severe - Having Momentary Outages Greater than 12 per 1000 miles of line New R6 to read: Each Transmission Owner shall minimize Sustained Outages of applicable lines due to vegetation growing into a conductor with the following exceptions:? Sustained Outages of applicable lines that result from natural disasters.? Sustained Outages of applicable lines that result from human or animal Activity. The Violation Severity level should read: Lower ? Moderate ? High - Having Sustained Outages Greater than 1 per 1000 miles of line Severe - Having Sustained Outages of 2 or greater per 1000 miles of line These VSL's listed above constitute a strawman for discussion. The drafting team could request historical performance data from Transmission Owners to statistically evaluate where the VSL should be set. As time progresses, future performance data could be re-evaluated to reset the limits. These changes bring the standard back in line with measurable and auditable requirements which provide practical field measurements to the personnel who can make the difference. These parameters provide measurements to indicate the tree health of the system. On a separate note, FPL believes that clarifying information captured in footnotes within the standard should specifically be referenced and made part of the standard. These notes add clarity and better define the standard requirements.

Response: The SDT thanks you for your comments. Significant changes have been made to the current draft of the Standard based upon substantive

Organization	Question 18 Comment
industry comment. The essential changes are: The CCZ concept has been replaced with the concept of minimum clearance distances, and Transmission Owners are required to prevent encroachment of vegetation into minimum vegetation clearances distances as observed in real time. The Drafting Team reviewed the exclusion in R6 and R7 and reached consensus that the stated exclusions are adequate to exclude force majeure or acts of God. This posting includes under R1 the new section 1.6. That would make the proposal you offer related to maintaining the height of trees above ground level to be a method for the TO to select. The language also allows TOs to select a separation distance between the conductor and the vegetation. When lines traverse terrain with significant changes in elevation within spans the latter method may be more practical. Changes made to utilize the MVCD as observed in real time will provide the clarity and measurability you requested. R2 has been revised to ensure that the process is used only for conditions that require immediate actions to prevent a sustained outage. Other factors which under some conditions would not pose an imminent threat of a sustained outage were purposely omitted to provide clarity and consistency of application. Since R2 is binary requirement its VSL cannot be gradated as you suggest. R5 has been left as a binary requirement with a zero tolerance in lieu of a gradated metric in the requirement as you suggest. Due to the industry impact that arises from zero tolerance for vegetation-related sustained outages, the Drafting Team tried several approaches but could not find a mechanism in the standard development process to establish a non-zero threshold for outages. Momentary outages are purposely not included because of the challenges they pose during investigation. These problems often lead to unreliable, inconsistent, false, or missing reports. Furthermore momentary outages caused by vegetation have not been a historical cause of cascading or widespread outages.	
Santee Cooper	The SDT should clarify that Transmission lines operated at 200 kV and above is for lines that are network facilities. Radial load transmission facilities operated at 200 kV and above should not be subject to this standard as they would not lead to SOLs or IROLs. M2 requires evidence that a Transmission Owner implemented its imminent threat procedure upon knowledge of a Critical Clearance Zone breach. M4 requires evidence that there were NO encroachments into the Critical Clearance Zone. These two measures are in conflict with one another. If a utility provides evidence for M2 then they are in violation based upon M4.M4 and M5 requires a utility to provide "proof to the negative". These measures should be removed from the standard. R10, R11, M10, and M11 should be removed from this standard as critical facilities are identified through the PRC standards.
Response: The SDT thanks you for your comments. Regarding your request to line applicability to only network lines above 200 kV FERC in order 693 paragraph 706 stated “we did not intend to make this Reliability Standard applicable to fewer facilities than it currently is with the 200 kV bright line applicability, but to extend the applicability to lower-voltage facilities that have an impact on reliability”. The standard drafting team therefore does not see that honoring your request as one that would be	

Organization	Question 18 Comment
permissible. **Regarding the conflicts you cite between M2 and M4, please note the revisions in this posting for R2, R4 and the associated measures. The conflict you reference should now be resolved since the distance in R4 is not the exclusive basis for implementing R2 and the concept of the "CCZ" has been removed from the revised standard.** **In M4, the language is now changed to remove the "proving a negative" dilemma.** **There is a 200 kV bright line for applicability in this standard; therefore it is appropriate for the applicability for sub 200 kV lines to be determined within this standard in lieu of the PRC standards.** **Significant changes have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ concept has been replaced with the concept of minimum clearance distances, and Transmission Owners are required to prevent encroachment of vegetation into minimum vegetation clearances distances as observed in real time.**	
Southern Company	We would like to re-emphasize our concern over the zero tolerance philosophy of FAC-003-1 which is continued in this proposed revision. FAC-003 has been singled out as the only zero tolerance NERC standard. Compliance should not be based on the encroachment of vegetation into a theoretical, pre-defined zone, but on the occurrence of a sustained outage, as stated in the document's Purpose Statement. We agree with the philosophy utilized in other NERC standards where a clearly discernible compliance event signals a review of the Transmission Owner's plans, policies, and procedures to determine the effectiveness of the entity's programs and spirt toward compliance. Applicability Section 4.2 describes the Facilities pertinent to this Standard. Recommendation is to restructure the sentence by relocating the parenthetical phrase: Transmission lines operated at 200kV or higher, and transmission lines operated below 200kV designated by the Reliability Coordinator as being subject to this standard ("applicable lines") including but not limited to those that cross lands owned by federal, state, provincial, public, private, or tribal entities. Requirement R3Recommend rephrasing to say: Each Transmission Owner shall conduct vegetation inspections of all applicable lines in accordance with the frequency specified in its transmission vegetation management program. Requirement 10The standard does not mention whether or not the results of this specific assessment methodology are supposed to be compiled and maintained. The resulting information could be labeled as sensitive and possibly critical since the loss would place the grid at an unacceptable risk of instability, separation, or cascading failures. If the resulting information becomes auditable (subject to discovery and posting) then precautions must be taken that are comparable to those designed to preserve the integrity of critical assets or critical cyber assets. We would like to express our sincere appreciation and thanks the drafting team for their efforts.
Response: The SDT thanks you for your comments. **Due to the industry impact that arises from zero tolerance for vegetation-related sustained outages, the Drafting Team tried several approaches but could not find a mechanism in the standard development process to establish a non-zero threshold for outages that was acceptable FERC staff**	

Organization	Question 18 Comment
because revisions to a Standard may not lead to less emphasis on reliability. **The standard has been revised to remove the violation for encroachment into a theoretical zone and is now based on an observed encroachment in real time inside a distance where flashover becomes a possibility.** **The Drafting Team considered the applicability wording with the (“applicable lines”) to be acceptable as written.** **R3 has been revised as you recommended.** **The Drafting Team agrees that documentation regarding the methodology used to determine applicability of lines below 200 kV should have similar precautions for confidentiality as other critical assets or critical cyber assets.** **The issue of transmission line applicability is addressed in FERC Order 693.**	
Bonneville Power Administration	There is a typographical error / omission in the Technical Reference on Page 36, which states, "R6. Each Transmission Owner shall prevent Sustained Outages of applicable lines due to the blowing together of vegetation and a conductor with (sic) Active Transmission Line Right of Way) operating within design blow-out conditions) with the following exception: . . . " I believe the intent is for the statement to read "due to the blowing together of vegetation and a conductor WITHIN Active Transmission Line Right of WAY". This change is needed to make the technical reference consistent with R6. as it appears in the Standard, the definition of Active Transmission Line Right of Way on Page 5 of the Technical Reference, as well as the terminology used on Page 37 in describing Fall-into outages. This needs correction.
Response: The SDT thanks you for your comments. The technical reference error is noted and has been corrected by the SDT.	
Public Service Electric and Gas Company	These comments were prepared by Richard Wolowicz, Manager Vegetation Management, on behalf of Public Service Electric and Gas Company ("PSE&G"). PSE&G also joins with and supports the comments filed by the Edison Electric Institute (EEI) in this matter.
Response: The SDT thanks you for your comments. Please see our response to EEI.	
FirstEnergy	FE provides these additional comments for consideration: 1. Regarding the Applicable Facilities - Section 4.2.2 would be more appropriately placed under Sec. 5 "Effective Dates" since it deals with the timeframe the Transmission Owner has to implement its Transmission Vegetation Management Program on sub-200 kV lines.-Section 4.2.3 - We suggest removing this section. First energy does not agree that this standard should dictate the amount of time a Transmission Owner has to obtain compliance with this standard for newly acquired transmission lines. It should be the responsibility of every organization to "self-report" its compliance issues and planned mitigation plans for all standards when they acquire new lines or facilities. If the SDT believes this should be explicitly stated, then it should recommend to NERC that explicit language be placed in the NERC Rules of Procedure. No other standards set timetables for newly acquired facilities and this standard should be no exception. 2. Regarding R1.1, this subrequirement requires the Transmission Owner to specify the methodologies it uses to control vegetation. It

Organization	Question 18 Comment
	should be clear that not all of these methodologies are required to be deployed in every situation (as explained in the white paper pg.12). We suggest rewording the requirement as follows: "R1.1. Specify the methodologies that the Transmission Owner may use to control vegetation." 3. R1.5 requires a process for "interim corrective action" be specified in the Transmission Vegetation Management Program. However, the standard does not explicitly specify that this corrective action be implemented when the Transmission Owner is constrained from performing vegetation maintenance as planned. 4. As written, in addition to the responsible RC, R10 may imply that this requirement is also the responsibility of the Transmission Owner(s) and neighboring RC(s) due to the use of the term "jointly". Also, R10 should require the RC submit the list of designated lines below 200 kV to the Transmission Owner(s) and neighboring RC(s) within a reasonable time-frame after its completion. We suggest rewording and addition of subrequirements to R10 as follows: R10. Each Reliability Coordinator, in consultation with its Transmission Owner(s) and neighboring Reliability Coordinator(s), shall prepare and keep current a list of designated applicable lines that are operated below 200kV, if any, which are subject to this standard. R10.1. The RC shall submit the list to the impacted Transmission Owner(s) within 30 calendar days of completion and/or revision. R10.2. The RC shall submit the list to its neighboring RC(s) within 30 calendar days of completion and/or revision. Lastly, measure M9 will need to add sub-measures for the proposed additions above. 5. Requirement R10 should require that the RC ONLY uses the assumptions detailed in R10.1 and R10.2 to designate a line as significant. Also, R10.1. should reference the IROL methodology standard FAC-011 since it directly ties into this requirement. Also, in R10.2, "grid" should be replaced with "BES" and the term "failures" is not necessary. We suggest re-wording R10, R10.1 and R10.2 as follows: R10. Each Reliability Coordinator shall document its method for assessing the reliability significance of sub-200kV lines and shall be based only on the following: R10.1 Transmission lines whose loss would result in the exceedance of an Interconnection Reliability Operating Limit (IROL) as determined by standard FAC-011. R10.2 Transmission lines whose loss would place the BES at an unacceptable risk of instability, separation, or cascading.

Response: The SDT thanks you for your comments.

The placement of Section 4.2.2 was chosen to allow the TO time to bring those lines into compliance which are identified by future studies well after the effective dates in Section 5.

The SDT chose to leave Section 4.2.3 as it does provide a reasonable time allowance (limitation) to bring the subject lines into compliance. {note for a newly acquired line to have not previously been subject to the standard it may have been 1) owned and operated by a private entity such as a mining company that was not connected to the grid, 2) was a de-energized line not in operation until it was acquired by the TO, 3) was previously operated at

Organization	Question 18 Comment
less than 200kV but was insulated for an operated at 200kv or higher, or 4) some similar situation to 1-3 above} The SDT sees this Section as following the Rules of Procedure Standard Applicability Section as noted on page 9 to "identify any limitations on the applicability of the standard based on electric facility characteristics". **The SDT modified Requirement R1, Part 1.1 as suggested. The standard does not explicitly state that the interim corrective action process in 1.5 must be implemented. The SDT suggests that the other requirements in the standard related to outages and imminent threats and encroachment provide necessary and sufficient incentives for TOs to utilize the process when and if required.** **R9 and R10 (now R10 and R11) have been revised to replace the RC with the PC as the applicable functional entity. The verbiage "in consultation with" has been replaced by "shall consult with its Transmission Owner(s) and neighboring Planning Coordinators to obtain input to develop the list". Since this list is prepared by the PC for the TO to know of any sub 200 kV line(s) that the TO must maintain, the SDT does not see a benefit to adding a requirement that the PC will provide the list to the TO.** **The SDT chose to keep the word "grid" in lieu of BES to avoid confusion related to the fact that the BES generally includes all lines above 100 kV as defined by the Regional Reliability Organization and this standard does not.** **Other changes were made in the language of R9 and R10 to which incorporate parts of recommendations from other commenters and FE. Requirement R10, Parts 10.1 and 10.2 were redundant, and Part 10.1 was deleted and Part 10.2 was translated into a separate requirement, R11.**	
Midwest ISO Stakeholders Standards Collaborators	FAC-003-1 lacks clarity that is essential for understanding what is necessary for compliance. The proposed FAC-003-2 needs to be simplified to aid with field implementation and compliance interpretation. Currently, it does not provide the clarity and simplification needed by Transmission Owners and regulatory bodies to enhance reliability.
Response: The SDT thanks you for your comments. Significant changes have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ concept has been replaced with the concept of minimum clearance distances, and Transmission Owners are required to prevent encroachment of vegetation into minimum vegetation clearances distances as observed in real time. These changes should add the clarity and simplification that your and other commenters suggested was needed for field implementation.	
SERC Compliance Staff	SERC staff continues to find the Applicability section of the standard to be confusing and contentious. While we recognize it is the intent this section to make the standard applicable t all entities that own transmission lines that operate at greater than 200 kV, this section should not be written to be applicable to transmission lines. Only registered entities can be held accountable for compliance with the standards. SERC staff believes the applicability should be rewritten to include Transmission Owners, Distribution Providers, and Generation Owners that own transmission lines with the characteristics defined in Section 4.2. This would eliminate the need to make register, for example, a Distribution Provider that own a 230 kV line that serves load as a Transmission Owner and make them subject to the requirements of FAC-001 and FAC-002. SERC Staff also suggest the applicability could be handled as it is in PRC-005-1 where the applicability is qualified as 'distribution provider that owns..' and 'generator owner that owns..' or in a similar manner that captures the appropriate subgroup but does not include unintended entities. SERC Staff believes a flashover between vegetation and overhead ungrounded supply conductors that occurs, whether or not the

Organization	Question 18 Comment
	flashover results in a Sustained Outage, is clear evidence of an unallowable encroachment of vegetation into the space that should be avoided and thus should be identified as evidence of a violation of the standard. SERC staff has also found that excluding outages resulting from "earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner?" results in inconsistencies in reporting because of the inconsistency of the Transmission Owners' definitions of same. If such exceptions are to be allowed, a consistent method of determining the acceptability of those exemptions should be pursued.

Response: The SDT thanks you for your comments.

The intent of the Facilities section under Applicability which you suggest is confusing and contentious, was chosen to follow the Reliability Standards direction under Applicably, specifically "if not applicable to the entire North American bulk power system, then a clear identification of the portions to which the standard applies…"

The issue you raise with respect to Distribution Owners and Generation Owners does not appear to be supported when one reviews the definition of a Transmission Owner in the NERC Glossary "The entity that owns and maintains transmission facilities." The SDT is concerned that your suggestion will add confusion to the standard." PRC-005-1 properly addresses the coordination needed between transmission protection and the interface with distribution protection at the point of transformation. There is no comparable expectation for vegetation maintenance on the low voltage side of a transmission to distribution transformer to be subject to this standard. Simply put, either someone owns transmission or does not. It is of no matter whether they may also be a DP or GO. Until the functional model includes provisions to state that "all transmission is not equal", the applicability should remain.

Your concern about flashovers that do not result in Sustained Outages needing to be stated as violations of this standard has been discussed at length by this SDT. The interest is to have a Standard that is not subject the levels of uncertainty associated with any automatic operation which is returned to service by either manual or automatic means. These events are very often not possible to identify, many times misidentified often occur during conditions that have several possible explanations (such as high winds blowing conductors together, wind-blown debris, lightning, contamination flashovers during the onset of wind and rain storms) and do not have a historical basis for ever creating a cascading event. Inclusion of these events as violations in the standard could also cause significant additional costs for extensive investigations by TOs to prove their "innocence" for events that any properly designed and operated transmission system should withstand with no more challenge that the far greater number of lightning, and equipment failure events (cross-arms, insulators, conductor splices, poles) nor ever been the subject of momentary opera being.

Members of the SDT attempted to get the TADS reporting requirements to clearly identify those faults on transmission lines that required maintenance to return the line to service. If such a definition was entertained, then a great deal of the uncertainty is cleared. However there are still conditions where trees and poles are found down after apparent high wind conditions in locations remote to the nearest weather reporting station that depend on assumptions as to which fell first the pole or the trees. The zero tolerance nature of this standard and the Penalty Matrix values should not be tied to anything with a high degree of assumption and uncertainty. Therefore the standard has been revised and worded to have the violation of MVCD as observed in real time.

As an added note there is unnecessary confusion caused by simply labeling the automatic operation line operations as momentary, sustained, and/or locked-out. If a line is not reclosed within moments of the automatic interruption, but is later "test closed" was the line truly unavailable? Was the

Organization	Question 18 Comment
reclosing signal/command properly performed initially? Did the TOP ever truly lose control of this line if all that was required was another close attempt? The true nature of the loss of a line is manifested when it is known that a clearance must be issued such that the line is removed from the TOP's control. **The SDT has reviewed the data on vegetation related reported outages on the NERC website. There are 223 reports of outages in that data covering the period January 2004 to March 2009. The associated documentation with these events indicate that TOs are supplying supportive information to indicate that the level of any disaster exclusion is sufficient to identify that design criteria was exceeded. Further specifics on the threshold for each disaster would not ensure that weather data would be adequate to support each location/situation.**	
ITC HOLDINGS	V1 was a better written standard and had clear requirements on reporting and who was to report violations etc. When and how are violation to be reported is not mentioned in the V2. The standard should clearly identify all reporting requirements. Standard development should focus on practicality for the field personnel in terms of implementing the standard and enforceability. Version 2 is not as user friendly for field personnel and ambiguous at best which requires an impractical and unrealistic level of performance from the industry. This standard needs to stress that it applies to vegetation within the Active Transmission Right of Way. Vegetation from outside the active ROW, falling through the Critical Clearance Zone should not be a violation. V2 needs further clarification of the definition of the active ROW.
Response: The SDT thanks you for your comments. The issue of reporting has been addressed in the compliance section of the revised standard. **The changes made to R4 focus on the practicality for field implementation that you suggest. The exclusion you request for vegetation falling through the MVCD, regardless of its being form inside or outside the right-of-way, has been added.** **The definition of the active right of way was debated at length and determined to be best stated in its current form.**	
Exelon	Applicability. 4.2.2 is unclear. If 4.2.2 is intended to cover Generator Owner interconnections, say so uniquivocally. Do not rely on future changes to the NERC Registry Criteria or other "global" solutions if the intent is to make the standard applicable to Generation Owners who own generator leads. Exelon would like to reemphasize our concern with implementing the requirements if the Gallet equation derived Critical Clearance Zone is used. ANSI A300 part 1 and part 7 should be part of the standard as they provide independently recognized valid methods and guidance to conduct maintenance on the ROW corridor.
Response: The SDT thanks you for your comments. **The issue you raise with respect to Generation Owners does not appear to be supported when one reviews the definition of a Transmission Owner in the NERC Glossary "The entity that owns and maintains transmission facilities." The SDT is concerned that this suggestion to add the Generation Owner will add confusion to the standard." The SDT does not agree there is ambiguity. Either an entity is a TO or not.** **The Gallet Equations distances were chosen in lieu of ANSI A300 for clearances because the Gallet is a distance that is necessary to prevent flashover.**	

Organization	Question 18 Comment
The ANSI values are related to worker and public safety not flashover between the conductor and the vegetation.	
Central Maine Power Company	The White paper is an important support document and should remain as an attached reference to FAC 003. The white paper should clarify that capable tree species should always be removed from the border zone, except in selected areas where topography includes deep ravines.
Response: The SDT thanks you for your comments. The standard was designed to allow the Transmission Owner the flexibility to design its TVMP. Further, ANSI A300 is also footnoted in the standard as a "best practice". The White Paper will remain a reference for this Standard and text has been added to try to provide additional guidance as you suggest.	
American Electric Power (AEP)	The definition for Critical Clearance Zone (Critical Clearance Zone) on page 2 of the proposed draft Standard does not specify the Rating (summer, winter, normal, emergency, etc.). This suggests that different Critical Clearance Zone s apply at different times of the year and thus that vegetation in the area might be outside the Critical Clearance Zone at certain times of the year and inside the Critical Clearance Zone at other times. AEP suggests that this may not have been the intent of the drafting team. Also, the term "design blowout" is not defined; thus, it appears that it will be up to the Transmission Owner and the auditor to determine the bounds of the Critical Clearance Zone . AEP again suggests that this may not have been the intent of the drafting team. Requirement R9 contains the clause "within the extent of its easement and/or legal rights". This intent of this clause is unclear and its rationale is not obvious. AEP suggests that this clause be removed or at least reworded for clarity.
Response: The SDT thanks you for your comments. The CCZ concept has been replaced with the concept of minimum clearance distances, and Transmission Owners are required to prevent encroachment of vegetation into minimum vegetation clearances distances as observed in real time. The verbiage you suggested removing form R8 (now R9) was removed. Finally, the new Requirement R1 should address the concern about sag and blowout in that it talks about planning to keep vegetation out of all positions the conductor may be for all design conditions.	
Platte River Power Authority	The white paper ensures consistent interpretation of the standard. Perhaps the lack of such a paper in the first version of the standard contributed to the varying interpretations.
Response: The SDT thanks you for your comments. The White Paper will accompany this Version as a Reference document.	
City of Tallahassee	Attachment I. Titles are different between page 8 and 9. Page 8 should have (D) after Distances. Page 9 should have indication that it is "continued" since the table spans multiple pages.
Response: The SDT thanks you for your comments. The SDT has reformatted the table in Attachment 1 of the Standard.	
Northern California	Section A. 5. Effective Dates: This is extremely vague and I would not know the actual effective date. Whose regulatory approval is

Organization	Question 18 Comment
Power Agency (NCPA)	needed? If this is meant to leave flexibility between FERC and the Canadian entities, please write it that way. Most effective dates are clear and concise, i.e., "the first month following approval by FERC". Let's clear this up and avoid a subsequent interpretation request.
Response: The SDT thanks you for your comments. The wording of this portion of the standard (the Standard's effective date) is governed by NERC policy. The process for approval is different in different jurisdictions – some Canadian Provinces approve a standard when it is approved by the NERC Board of Trustees, other Provinces have other mechanisms for approving standards. For entities that operate in the United States, the FERC is the regulator that must approve the standard. As written, the standard will become effective in the United States the first calendar day of the first calendar quarter one year after FERC approval.	
Northern Indiana Public Service Company	While I very much respect the industry commitment and expertise of the drafting team members, the resulting revised standard reflects an effort to "revolutionize" the standard, when an "evolution" of the current standard would better serve the interests of system reliability. The kinds of wholesale changes proposed in this revision evoke real concerns about governmental regulations being a moving target and in many aspects, backs away from requirements that have led to real progress in UVM made since the 2003 blackout. For example, our company has invested tens of thousands of dollars and countless man-hours to comply with provisions of the existing standard only to see them simply done away with under the proposed revised standard. These investments were made based on an industry consensus standard as well as a realization that the requirements were reasonable and essential to improving system reliability. Where is the evidence that the current standard is not working as intended? What has changed in the last few years to warrant a complete re-write of the current standard? Most UVM professionals will agree there are some changes that need to be made to address FERC's concerns and to clarify intent. However, as presently written, I will recommend our T.O. vote against adoption of FAC-003-2.
Response: The SDT thanks you for your comments. Significant changes have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The Critical Clearance Zone concept has been replaced with the concept of minimum clearance distances, and Transmission Owners are required to prevent encroachment of vegetation into minimum vegetation clearances distances as observed in real time. Moreover, certain language changes were needed to comply with directives in FERC Order 693. The changes proposed are meant to capitalize on programs already implemented, not to discard them.	
Tampa Electric Company	Good start. However, this will need additional work and review predicated on the above comments.
Response: The SDT thanks you for your comments. Significant changes have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ concept has been replaced with the concept of minimum clearance distances, and Transmission Owners are required to prevent encroachment of vegetation into minimum vegetation clearances distances as observed in real time.	
Orange and Rockland Utilities Inc.	Clearance 1 has been eliminated from this draft. Version 2 as drafted only requires that Transmission Owners address vegetation that approaches the Critical Clearance Zone . This is essentially equivalent to Clearance 2 in version 1, a minimum clearance. Although unlikely this could result in some Transmission Owners adopting a just in time vegetation management concept that focuses on

Organization	Question 18 Comment
	maintaining minimum clearances, rather than removing incompatible vegetation or achieving greater clearances. Although R1 requires Transmission Owners to design their Transmission Vegetation Management Programs to control vegetation there is no clear requirement to address incompatible vegetation early and aggressively. The drafting team should revisit this and consider returning to some form of Clearance 1 or requiring the Transmission Vegetation Management Program to address removal of incompatible vegetation within their easement rights.
Response: The SDT thanks you for your comments. **The SDT did revisit and reconsider reinserting a Clearance 1. The issue of how and when to remove or control “incompatible vegetation” was also revisited. The SDT decided to leave C1 and the methods to control (or remove) “incompatible vegetation” to the discretion of the TO. Such discretionary measures do not meet the qualifications to be a requirement within a standard.** **Please take a comprehensive look at all the requirements in the standard we are now re-submitting with this posting. Compliance with these requirements will ensure that the TO maintained vegetation such that 1) no controllable sustained interruptions have occurred, 2) no imminent threats were left unaddressed, 3) all the separation distances between the conductors and vegetation every time they were observed were greater than the distance necessary to prevent a flashover.** **Compliance with each of the above requirements can be achieved with inspection and pruning cycles on a frequent basis such as annually, or on a longer term basis such as every 4 years where warranted by local conditions. There are numerous examples in the industry of these different approaches being both appropriate and effective. Just because a “shorter cycle” is utilized, does not mean that a compromised or “just-in-time” concept is has placed the adequate level of reliability of the grid at risk.**	
American Transmission Company	FAC-003-1 lacks clarity that is essential for understanding what is necessary for compliance. The proposed FAC-003-2 needs to be simplified to aid with field implementation and compliance interpretation. Currently, it does not provide the clarity and simplification needed by Transmission Owners and regulatory bodies to enhance reliability. Requirement 1.3: The proposed requirement does not allow enough flexibility for making changes to the Annual Plan. We believe that changes to the Annual Plan should be allowed even if that means delaying something until the next Annual Plan. Our Proposed Changes: Have an annual plan that identifies the applicable lines to be maintained and associated work to be performed. Adjustments to the annual plan are permissible. We believe that our proposed language accomplishes the SDT's intent while allowing for appropriate flexibility.
Response: The SDT thanks you for your comments. Significant changes have been made to the current draft of the Standard based upon substantive industry comment. Those changes, including the removal of the concept of the CCZ, address and provide the clarity and simplifications you suggest are needed for field implementation of the standard. R1.3 has been revised for to provide clarity. **These R1.3 changes do not explicitly remove the “within the year” clause as you requested, however we do not see the inclusion of that language as restricting appropriate flexibility. It is expected that the annual work plan will be flexible to adjust to changing condition and findings which occur after the plan is first issued for the year, then adjusted within the year as appropriate. Adjustment made within a year may mean accelerating work to the current year that was not in the current year’s plans as well as extending work that was initially planned for this year into the future. And when**	

<table>
<tr><th>Organization</th><th>Question 18 Comment</th></tr>
<tr><td colspan="2">disasters occur, the SDT has addressed an appropriate extension.</td></tr>
<tr><td>Xcel Energy</td><td>Attachment 1, Table I- Change the title of the table from "Proposed Minimum Vegetation Clearance Distances" to "Critical Clearance Zone Distances". The reason being is that the general public could interpret this table to mean that this is all the clearance that is required by a utility at the time of pruning.

Section C, Violation Severity Levels- There is some inconsistency between the C.2 chart and the contents of the Standard and the White Paper. For example, the White Paper specifies that an exception to an R6 blowing together violation would exist for sustained winds of gusts of 45 miles per hour or greater.

As to R7, the Standard itself notes that a violation only occurs if the vegetation falling into the line is from within the ROW ? C 2 does not incorporate that requirement. There are two approaches: either note the exemptions within the C 2 chart, or add a footnote to the chart along these lines: "This chart summarizes various provisions, the details of which are more fully set forth in the Standard and White Paper?. We would recommend the later approach.

General suggestions:

1) It appears that the FAC-003 Standard is the only "zero tolerance" standard, in some respects. Is this reasonable?

2) There appears to be "advisory" language in this version of the Standard. This type of language should be part of the White Paper, not the Standard itself.

3) Utilities need more support from FERC to deal with regional roadblocks within the USFS regarding the implementation of IVM. The Memorandum of Understanding is not universally accepted within all regions of the USFS.</td></tr>
<tr><td colspan="2">Response: The SDT thanks you for your comments. Significant changes have been made to the current draft of the Standard based upon substantive industry comment parts of those changes address or remove the issues you raise for exemption and footnotes for Table 1.

Table 1 in not intended to be used by TOs to determine how much to prune. This table provides the actual physical separation distances, which if observed, will ensure that flashover from the line to vegetation will not occur. When conditions exist such that the separation is reduced the risk of flashover will become significant. The risk increases as the separation is reduced. Therefore this value represent a threshold which if not violated will prevent flashover, as such it is a valid physical basis for R4 compliance.

This standard allows the TO to use any combination of pruning, removals of vegetation at ground level, frequency(cycles) of planned maintenance, enhanced inspections, off-cycle corrective maintenance, etc to prevent violations occurring due to vegetation causing a non-exempted sustained outage or MVCD violation.

Due to the industry impact that arises from zero tolerance for vegetation-related sustained outages, the Drafting Team tried several approaches but could not find a mechanism in the standard development process to establish a non-zero threshold for outages that was acceptable to FERC staff because revisions to Standards may not produce less emphasis on reliability.</td></tr>
</table>

Organization	Question 18 Comment
The advisory language in R1.4 has been removed. **The SDT discussed with NERC and FERC the need for support with the USFS issues. The SDT concluded that FERC has no power to change the rights or restrictions within any permit or easement document across privately owned or publicly owned.** **Therefore any efforts to improve permits or reduce limitation on permits or easements on federal lands must be handled through other available methods.**	
Ameren	While FAC-003-1 lacks clarity that is essential for understanding what is necessary for compliance, the proposed FAC-003-2 needs to be simplified to aid with field implementation and compliance interpretation. Currently, it does not provide the clarity and simplicity needed by Transmission Owners to implement and regulatory bodies to monitor in a manner that will enhance reliability.
Response: The SDT thanks you for your comments. Significant changes have been made to the current draft of the Standard based upon substantive industry comment. Those changes address and provide the clarity and simplification you suggest are needed for field implementation of the standard.	
Long Island power Authority	1) Disagree with R1.1. The proposed standard is too lenient on the program documentation required for an effective program. R1.1 should include the words " the program will document the program objectives, method of site evaluation, the definition of action thresholds, the control methodologies, and how the monitoring program is established". There is a wide gulf between listing IVM methodologies and a vegetation program implementing A300. 2) CHANGE: Within Applicable Facilities listed in section 4.2 the phrase Transmission Line should be changed to Overhead Transmission Line. The NERC Glossary definition of transmission Line is: " A system of structures, wires, insulators and associated hardware that carry electric energy from one point to another in an electric power system. Lines are operated at relatively high voltages varying from 69 kV up to 765 kV, and are capable of transmitting large quantities of electricity over long distances." The accompanying white paper states the standard is addressing the impact of vegetation growth on overhead transmission lines. The intent of this standard is the development and implementation of a vegetation management program for overhead transmission lines only. By specifically stating "overhead transmission lines in Section 4.2 there will be no possibility of an occurrence of an auditor requesting a vegetation management program for underground lines.
Response: The SDT thanks you for your comments. In R1.1 the SDT chose to direct the TO to specify the methods used to control vegetation vs specifying a menu of items that may not be applicable to several TOs due to the limited types of vegetation in their areas. The SDT considered the issue of overhead versus underground and concluded that no further clarification was needed. Further, ANSI A300 is referenced in the Standard as a best management practice. The SDT leaves up to the TO the extent to which it wishes to apply A300.	
USDA Forest Service, Southwestern Region, Regional Office for AZ and NM	I'm having trouble getting comments to "stick" in this section of the form. I have a general concern with the opening paragraph of R1. The wording seems to encourage a Transmission Owner to develop a Transmission Vegetation Management Program in a vacuum. The US Forest Service definitely wants input into the development of an annual work plan and USFS land use authorizations include a requirement for USFS approval of vegetation management plans. It seems much more reasonable to require the Transmission

Organization	Question 18 Comment
	Vegetation Management Program to reflect USFS or any other landowner resource management considerations. This tactic would require more "up front" work, but the end result is a plan which would reflect reasonable landowner input and where the disagreements could be settled ahead of time rather than being left for the night shift. I also believe that some kind of dispute resolution process is needed outside the control of either the Transmission Owner or the USFS. I think that NERC could fill that role very well.
Response: The SDT thanks you for your comments. Underlying landowner rights are outside the purview of this Standard. However, the SDT recognizes the value in "up front" input between landowners and transmission Owners. Notice that in this posting of the standard within Requirement 1 at 1.3.4 the transmission vegetation management program shall "take into consideration permitting and scheduling requirements from landowners and regulatory authorities". Such consideration should aid in addressing the issues you raise.	
Consumers Energy Company	The annual work plan should be designed to avoid vegetation growing into a violation of the Critical Clearance Zone or whatever minimum distance is acceptable. Since the plan can change throughout the year, it needs to be flexible, it should be stated that the plan at a minimum must provide adequate funding to prevent vegetation growth from violating the minimum clearance distance. The flexibility of change should be limited to changing to address emergent needs for vegetation management and not reductions in funding that delay maintenance in the hopes that additional funding at some future point in time will be adequate to remove the backlog of vegetation maintenance. The Purpose of the standard should be revised to state "(To maintain minimum clearance sufficient to avoid any vegetation-related Sustained Outages for all applicable conditions) for all Transmission Lines covered by this Standard" as provided by FERC in Order 693, Paragraph 731. The purpose as stated in FAC-003-2 waters down the intent of FERC to "improve the reliability" and is only applicable to "outages that could lead to cascading".
Response: The SDT thanks you for your comments. The purpose statement language was chosen to explicitly state the outcome to be achieved by this standard. The requirements themselves address, among other things, the Sustained Outages and minimum clearances along with the required supporting language. This separation between the purpose and the requirements appears more appropriate to the SDT. Significant changes have been made to the current draft of the Standard based upon substantive industry comment. The essential changes are: The CCZ concept has been replaced with the concept of minimum clearance distances, and Transmission Owners are required to prevent encroachment of vegetation into minimum vegetation clearances distances as observed in real time. Further, funding is not an issue addressed by this Standard.	
National Grid	National Grid has the following comments: 1. Transmission Owners should be able to define their own inspection "year" and not be locked into a calendar year time frame. National Grid performs inspections at least once per vegetation growth year. Under our Vegetation Management Program, growth years are not skipped, and our inspections occur prior to new growth every year. For example, a transmission right-of-way may be inspected in December 2008 and the right-of-way is next inspected in February 2010. Under this scenario, the inspections occurred 14 months apart, but only one growth year occurred between inspections, and each inspection is ahead of the next year's growth. Transmission Owners need this flexibility to deal with regional growth rate differences and climate. 2. Section C., Compliance, of Draft Standard FAC-003-2 states "To be added". Issuance of Draft Standard FAC-003-2 should have been delayed for comments until all sections were complete. This section is likely to include the outage reporting and self-certification

<table>
<tr><th>Organization</th><th>Question 18 Comment</th></tr>
<tr><td></td><td>requirements. Transmission Owners need the opportunity to comment on these items.

3. With the elimination of Clearance 1 and reducing Clearance 2 clearances, there is concern that FERC will view Standard FAC-003-2 as a watered down version of Standard FAC-003-1.</td></tr>
<tr><td colspan="2">Response: The SDT thanks you for your comments.

1. It is recognized that most work management systems typically allow for planned work to be performed within a “band of dates” around a specific end date, such as one-third or one-fourth of an interval. These partial intervals allow for the normal variations that occur in work scheduling. When work is completed within that band of dates it is considered completed “as scheduled”. Compliance to R2 should be examined for the example conditions you offer since you are addressing the implementation of the inspections. If the frequency was stated in the vegetation management program as once per calendar year, and if the work was completed “as scheduled” then the TO would be compliant.

2. The compliance elements are included with the second posting of the standard and will be subject to stakeholder comments.

3. Effort were undertaken to address in the standard various elements for outages, imminent threats and clearances in a manner that was responsive to a substantial number of industry concerns. The SDT is striving to meet industry stakeholder concerns with a standard that will be approved by its ballot pool, the NERC BOT, and regulatory authorities, including FERC</td></tr>
<tr><td>Pacific Gas & Electric Co.</td><td>1) The standard should be clear that it applies to all Federal and Non-Federal land. PG&E further recommends additional language specifically dealing with Federal land such as application of ANSI A300.

2) The standard should specify applicability inside substations.</td></tr>
<tr><td colspan="2">Response: The SDT thanks you for your comments. This Standard states in the applicability section that all lands are subject to the standard. Further, ANSI A300 is footnoted in the Standard. Substation facilities are not included in this Standard. This will be addressed in the White Paper.</td></tr>
<tr><td>NV Energy (fka Sierra Pacific / Nevada Power Co.)</td><td>These comments were made with collaboration with other Western Utilities in a conference on this topic held in Denver. Any standard that is developed should not contain advisory-type language? it should be declarative in tone. For example, in R1.4, the ending clause that begins “and may include actions” should be removed because it is advisory in nature. The suggested actions are not even the responsibility of the vegetation management program. NV Energy and the other Western Utilities support the development of this white paper as a way to help ensure consistent interpretation of the standard. Perhaps the lack of such a paper in the first version of the standard contributed to the varying interpretations by the auditors. The utilities understand however that this document is not a legal document and is not binding.</td></tr>
<tr><td colspan="2">Response: The SDT thanks you for your comments. Please refer to the various responses to your comments provided in the individual questions. (R1.4 was modified to eliminate the list of possible actions and the use of the word, “may.”)

The changes to the standard in this reposting and the responses to your comments on questions 1-17 are intended to serve as a reply to your various</td></tr>

Organization	Question 18 Comment
comments.	
San Diego Gas & Electric	We feel that any advisory-type language should be removed from the standard and replaced with wording that is in a declarative tone. We support the development of the white paper as a way to help ensure consistent interpretation of the standard.
Response: The SDT thanks you for your comments. The advisory-type language has been removed form R 1.4	
Hydro One Networks Inc.	Please see our comments on question 3.
Response: The SDT thanks you for your comments. Please see the response to comments on question 3.	
Edison Electric Institute	Overall Comments EEI strongly believes that companies are responding assertively to the requirements in FAC-003-1 and that the existing standard is effective in supporting an adequate level of reliability. The central issue with FAC-003-1 and the draft version 2 centers on circumstances where vegetation encroachments into clearance zones take place and do not result in interruptions. EEI understands that a potentially broad range of interpretations are being applied to the existing standard, resulting in potential violations due to clearance encroachments of any possible design position of the conductor being violations, as well as Sustained Outages. Version 2 should clarify this issue in the context of focusing the industry in the direction that is most effective in establishing an adequate level of reliability. The technical comments provided by EEI seek to address this critical issue. Quantitative analysis on vegetation-related line outages or violations made publicly available do not support the need for a substantive revision of the standard. Analysis needs to recognize a broader range of facts in a consistent manner. Analysis needs to consider whether violations resulted in a Sustained Outage, whether all outages and vegetation encroachment were voluntarily reported prior to enactment of Section 215, or the facts and circumstances surrounding violations. For example, while some entities may perceive a decline in industry performance, it may be that companies are reporting much more completely than in the past. Much more rigorous analysis is needed before concluding that the existing standard must be made tougher. Rather than focusing on whether the standard should be more stringent, EEI believes that the emphasis in the standard development process should focus on practicality, both for field personnel in terms of implementing the standard, and enforceability. Revisions to the existing standard should therefore seek to a) respond to issues raised by FERC in Order No. 693 b) where possible, clarify ambiguities in the requirements, and c) improve industry understanding, practicality, and enforceability. For example, it is impractical to seek development of a ?bright line? set of performance requirements. The standard needs to recognize both the diversity of the continent in terms of geography, topography, and climate, and the critical need to provide field personnel with workable performance requirements. Bottom line; it is very important to recognize that the ultimate goal of the standard is to ensure that vegetation management is conducted in order to maintain an adequate level of reliability, and the industry is achieving this goal. The standard should aim for increasing clarity in the requirements without sacrificing flexibility, since companies expect high monetary penalties associated with Sustained Outages caused by vegetation. In addition, a continued ?zero tolerance? approach to vegetation management will emphasize operational excellence. Seeking ?zero tolerance? on momentary outages is equivalent to pursuit of

Organization	Question 18 Comment
	operational perfection, which is achievable only at extraordinary expense to customers. Therefore, the Standard will be most effective if its elements encourage proactive behavior and provide incentives for Transmission Owners to identify and address vegetation clearance issues before they result in momentary interruptions or Sustained Outages. Vegetation Outage Data In Order No. 693, Paragraph 732, FERC ordered NERC to collect and analyze transmission outage data to inform development of the revised standard. EEI encourages the drafting team and NERC Standards Committee to request that NERC collect and analyze this critically important information. Such analysis provides an important foundation for determining whether the standard can ensure an adequate level of reliability as required by Section 215.Applicability Order No. 693, Paragraph 708, directs NERC to 'develop an acceptable definition that covers facilities that impact reliability but balances extending the applicability of this standard against unreasonably increasing the burden on transmission owners.' In the order, FERC appears to accept the 200-kv threshold, however, continues to ask about these other critical facilities. EEI recommends that the drafting team develop a definition of 'sub- 200kv critical facilities' for use in the standard. Reliance on Reliability Coordinators for developing their own definition raises the likelihood of inconsistent approaches and applications of the term. In addition, the drafting team should consider whether such critical facilities might require expanding applicability to entities other than Transmission Owners. Annual Plan as a Defined Term In order to aid in compliance enforcement and industry compliance, the term 'annual plan' should be a defined term.
Response: The SDT thanks you for your comments. Significant changes have been made to the current draft of the Standard based upon substantive industry comment. We agree with many of your points. The SDT developed R2 to promote proactive behavior by requiring the recording and documentation of imminent threat procedure implementations. The NERC Transmission Availability Data System is set up to collect the outage data as directed by the FERC. In the revised standard, to address the sub 200 kV facilities to be subject to the standard, the SDT chose the Planning Coordinator (rather than the Reliability Coordinator) for that task. The Planning Coordinator has the wide area view and appropriate time horizon perspective to identify sub 200 kV facilities. The SDT considered the situation where non-TO facilities such as generator “leads” would be subject to this Standard. There is an ongoing discussion within NERC with regard to registration of Generator Owner’s as limited TO’s. Annual plans have relevance within this Standard’s context and are not needed elsewhere. Therefore a glossary definition is not necessary.	
Consolidated Edison Company of New York (CECONY)	CECONY does not feel that, as currently written, the Standard would effectively enhance reliability throughout the industry. We recommend that stricter language be used in the Standard specifically requiring the industry to remove incompatible species on Active ROWs. This should reduce the number of outages resulting from vegetation grow-ins and vegetation fall-ins from inside the Active ROW and help maintain a higher level of reliability. This is currently done at the state level (in NY) and the revised wording in the Federal Standard may help promote consistency industry-wide and avoid confusion. Also, the concept of the Critical Clearance Zone is theoretically strong but it needs to be made simpler for the auditors and field inspectors.
Response: The SDT thanks you for your comments. Significant changes have been made to the current draft of the Standard based upon substantive industry comment. We agree with many of your points. The SDT developed R2 to promote proactive behavior by requiring the recording and documentation of imminent threat procedure implementations. The NERC Transmission Availability Data System is set up to collect the outage data as directed by the FERC. . In the revised standard, To address the sub 200 kV facilities to be subject to the standard the SDT chose the Planning	

Organization	Question 18 Comment
Coordinator (rather than the Reliability Coordinator) for that task. The Planning Coordinator has the wide area view and appropriate time horizon perspective to identify sub 200 kV facilities. The SDT considered the situation where non-TO facilities such as generator "leads" would be subject to this Standard. There is an ongoing discussion within NERC with regard to registration of Generator Owner's as limited TO's. Annual plans have relevance within this Standard's context and are not needed elsewhere. Therefore a glossary definition is not necessary.	
WECC	Reporting requirements are not identified in the standard. WECC believes that sustained outages caused by vegetation should be reported to the Regional Entity using the existing reporting requirements in FAC-003-1 (Transmission Owners report outages to the Regional Entity). Reports of sustained outages to the Reliability Coordinator should be made for reliability purposes and not compliance purposes. The Reliability Coordinator should not be required to report vegetation outages of individual Transmission Owners to the compliance department.
Response: The SDT thanks you for your comments. The revised Standard reflects changes in reporting requirements.	
Arizona Public Service Company	APS has a comment to NERC on picking the standard drafting team. FAC-003 is a vegetation management standard not an engineering standard. The team members should have been chosen based on managing the vegetation program not because they were engineers. Any standard that is developed should not contain advisory-type language? it should be declarative in tone. For example, in R1.4, the ending clause that begins "and may include actions" should be removed because it is advisory in nature. The suggested actions are not even the responsibility of the vegetation management program. APS supports the development of this white paper as a way to help ensure consistent interpretation of the standard. Perhaps the lack of such a paper in the first version of the standard contributed to the varying interpretations by the auditors. The utilities understand however that this document is not a legal document and is not binding.
Response: The SDT thanks you for your comments. The members of the SDT were selected based on their expertise – the following was taken from the SDT Nomination form: **Candidates should have expertise in one or more of the following areas:** - **Transmission line rights-of-way (ROW) vegetation management or ROW maintenance** - **Transmission line design and ratings** - **Regulatory or legal considerations in ROW maintenance** - **Existing codes and good practices in vegetation management** **Most of the SDT members have expertise in vegetation management.** **The SDT has removed the advisory language in R1.4. The SDT has professional foresters, vegetation managers, system operators and regulators.**	
Baltimore Gas & Electric	The Applicability Section of the Reliability Standards (4.2 Facilities) defines the Transmission Lines (Applicable Lines) that must comply to the reliability standard. This section should clearly state that the scope is limited to the facilities that are Bulk Electric System facilities

Organization	Question 18 Comment
Company	consistent with the Bulk Electric System definition as defined by the Regional Entity. Regarding M5, M6, M7:The intention of these paragraphs is unclear to me as written. At first glance, it appeared that the paragraphs were asking for a negative to be proven, e.g. prove that you didn't have any tree-related outages. Anther possible meaning is that utilities have to justify the cause of any outage that may occur. As such, the burden of proof is on the Transmission Owner to provide evidence that an outage was not caused by trees. If an outage were to occur but the Transmission Owner could not find any evidence of the cause, the wording in these paragraphs suggests that by default, the outages will be classified as tree-related. If these paragraphs are intended to assign an outage cause to an outage that has already occurred, then perhaps they could be reworded to say something to the effect of: "Transmission Owner shall provide results of investigation into all transmission outages?? "If these paragraphs are not intended to assign an outage cause to an outage that already occurred, but to provide a mechanism to report outage performance that is currently covered in M3 and M4 in FAC-003-1, then perhaps they could be reworded to say something to the effect of: "Transmission Owner shall provide documentation of tree-related outage performance on a quarterly basis. Investigation results for unknown outages shall also be provided on a quarterly basis." Or as one last suggestion, the wording could simply be: " The Transmission Owner has evidence that there was a Sustained Tree-related Outage?. Regarding the Tech. Reference, I thought that overall it was helpful and will be valuable to help provide guidance for Transmission Vegetation Management Program development and implementation. The area that covers the Active/Inactive R/W should be more clearly explained and illustrated, particularly with respect to the towers with space for another circuit on one side of the structures.
Response: The SDT thanks you for your comments. Significant changes have been made to the current draft of the Standard based upon substantive industry comment. The old M5, M6, and M7 have changed in a manner that should clarify their interpretation as you requested. The CCZ concept has been replaced with the concept of minimum clearance distances, and Transmission Owners are now required to prevent encroachment of vegetation into minimum vegetation clearances distances as observed in real time. **Reporting requirements are included in the compliance section with this posting.** **The SDT will attempt to incorporate your suggestions on illustrations for double circuits in the white paper with the final posting of this standard.**	
Duke Energy Corporation	FAC-003-1 lacks clarity that is essential for understanding what is necessary for compliance. The proposed FAC-003-2 needs to be simplified to aid with field implementation and compliance interpretation. Currently, it does not provide the clarity and simplification needed by Transmission Owners and regulatory bodies to enhance reliability.
Response: The SDT thanks you for your comments. Significant changes have been made to the current draft of the Standard based upon substantive industry comment. The CCZ concept has been replaced with the concept of minimum clearance distances, and Transmission Owners are required to prevent encroachment of vegetation into minimum vegetation clearances distances as observed in real time. These changes are directed at the clarity and simplification you requested for effective field implementation and compliance interpretation.	
CenterPoint Energy	The proposed FAC-003-2 has gone FAR beyond what was contemplated by the Commission in FERC Order 693 and equates to a total re-writing of the Standard for no apparent reason. The Commission's determination dealt with the following areas: (1) applicability; (2)

Organization	Question 18 Comment
	inspection cycles; and (3) minimum clearances on National Forest Service lands. For instance in Paragraph 729, the Commission states, "As proposed in the NOPR, the Commission approves Reliability Standard FAC-003-1 with no proposed modification on the issue of clearances. The Commission reaffirms its interpretation that FAC-003-1 requires sufficient clearances to prevent outages due to vegetation management practices under all applicable conditions?." Rewriting the minimum clearances introduced a new set of confusing definitions, and further burdens the Transmission Owners with new documentation requirements with little if any benefit when compared to the Clearance 2 concept in the existing Standard. A preferred approach would have been to incorporate the following few items into the existing Standard: (1) the RC versus the RRO; (2) the designation of a specific inspection frequency; (3) the Gallet equation; and (4) the applicability to National Forest Service lands. We agree that the removal of requirements for quarterly reporting of outages, Clearance 1, and personnel qualifications reduces the burden on the Transmission Owners and does not affect the purpose of the standard to prevent vegetation outages. The Standard could meet its purpose and be streamlined by considering the following changes:1. Delete the new terms and definitions for "Active Transmission Line Right-of-way" and "Critical Clearance Zone" and revert back to a Clearance 2 requirement while replacing the IEEE 516 standard distances with the Gallet equation standard distances.2. Delete R2, M2, R4 and M4 which refer to the "Critical Clearance Zone" and rely on R5, M5, R6, M6, R7, and M7 which refer to the prevention of Sustained Outages.3. Delete R1.5 and M1.5 as a requirement and measure, but footnote the "interim corrective action process" as a best practice as was ANSI A300 in R1.1.
Response: The SDT thanks you for your comments. Significant changes have been made to the current draft of the Standard based upon substantive industry comment. Items such as the CCZ concept has been replaced with the concept of minimum clearance distances, and Transmission Owners are required to prevent encroachment of vegetation into minimum vegetation clearances distances as observed in real time. Note that the SAR for this project included a list of items to be addressed in the revised standard – and these items included not only the directives in Order 693, but other issues identified during the initial implementation of the standard and during the refinement of the SAR.	
Entergy Services	Entergy requests that the proposed FAC-003-2 revision continue work on clarifying the above mentioned "Disagree" items and appreciates the consideration of the above comments in the development of the standard. A clear understanding of all standard requirements by the industry is needed to make certain field implementation is achieved and that ultimately we improve system reliability.
Response: The SDT thanks you for your comments. Significant changes have been made to the current draft of the Standard based upon substantive industry comment. Those changes were made in part for the clarity that you and others requested in order to ensure that practical field implementation may be achieved.	
Alberta Electric System Operator	The AESO is also a signatory to the joint ISO/RTransmission Owner Council Standards Review Committee comments which reflect our comments to the other questions in the Comment Form.
Response: The SDT thanks you for your comments. Please see the SDT's responses to the ISO/RTO SRC comments.	
JEA	M5, 6 and 7 ask the entity to prove the negative. This type of evidence is problematic, and may result in nothing better than the entity

Organization	Question 18 Comment
	making an attestation that the event did not occur, thus this measure is not useful. With well over 100,000 miles of transmission covered by this standard, even six-sigma performance would result in vegetation related issues. It is unreasonable to expect zero-tolerance for vegetation events and unnecessary for the industry (and customers) to expend resources to attempt to meet this level of compliance when the transmission system is planned and operated to handle any single contingency, which means that a vegetation contact should not, in isolation, cause a major problem to the bulk power system. This standard needs work to make it clear, unambiguous, feasible and enforceable.
Response: The SDT thanks you for your comments. Significant changes have been made to the current draft of the Standard based upon substantive industry comment. **The SDT pursued an approach to develop a metric that would not have a zero-tolerance for outages. Discussion with FERC led the SDT to the conclusion that such an approach would not be acceptable.** **Changes made to the old M5, M6 and M7 in this new draft should alleviate the "prove a negative" dilemma.**	
Independent Electricity System Operator	We recommend removing the Transmission Owner as the one to define a major storm, this task should be left to an applicable regulatory body only, for consistency in assessing such an event. Also, we recommend footnote #5 specify that planned removal of vegetation by the utility is not part of the exceptions, because in our view this activity is a component of the vegetation management program and that outages should be preventable. There is a typo in R6. The numeral "4" should be superscripted.
Response: The SDT thanks you for your comments. Significant changes have been made to the current draft of the Standard based upon substantive industry comment **The SDT has reviewed the data on vegetation related outages that TO have reported on the NERC website. There are 223 reports of outages in that data covering the period January 2004 to March 2009. The associated documentation with these events indicate that TO are supplying supportive information to indicate that the level of any disaster exclusion (including major storms) is sufficient to reasonably identify conditions that exceed design criteria. Further specific on the threshold for each disaster (or storm) would not ensure that weather data would be adequate to support each location/situation.** **Random human error in felling trees whether by loggers, homeowners or vegetation removal crews has not been associated with cascading events and remains a valid exclusion. The related safety risks and equipment damages tend to effectively self-control this type of activity.** **The typographical error in what was R6 (now R7) has been corrected.**	
Salt River Project	We question the method used in determining the clearance distances for Vegetation near Transmission Lines. First is the use of the Gallet Equation. Although the Gallet Equation is more definitive than using IEEE 516 as identified in the current standard, we have questions from an engineering prespective as to how and why this method was chosen for vegetation management. It is stated in the Technical Reference paper that the Gallet Equation is a well known method of computing the required strike distance for proper insulation coordination. It is our understanding it's purpose is for designing towers, to define the "tower window" or opening inside of a

Organization	Question 18 Comment
	tower under normal conditions. Because this is not a method designed specifically for vegetation management, what is the basis for applying this to vegetation management? Was there, or could there be testing done? We would find it definitive to substantiate the calculated equation assertions with test data from actual energized flashover distances to vegetation. The testing ought to include dry and misting conditions at 200+ kilovolt levels on a sampling of fresh cut common vegetation types. Reputable EHV testing facilities where such tests can be performed exist within the United States and Canada. Is there additional information to clarify why this method was used to help establish clearance distances for vegetation near transmission lines? Second, it is expected that each utility needs to define their "Critical Clearance Zone". It is outlined in the Technical Reference document how complicated it is to define this clearance area. As the conductor moves throughout its "flight path", the minimum clearance shell surrounding the conductor moves along with it. The shape and size of the Critical Clearance Zone around the conductors is irregular and will change depending on where a conductor segment is located within the span. At mid-span, where the potential for conductor movement is the greatest due to sag and wind deflection, the corresponding Critical Clearance Zone is also the largest and most irregular. With the size, shape, and area of the Critical Clearance Zone dramatically changing as one progresses along a span, identifying the precise location and boundary of the Critical Clearance Zone around the conductor in the field becomes very problematic. There are many variables that are involved at any point along a line and at any given time (loading, operating temperature, wind, maximum design rating, maximum operating loading and so on). Therefore, even if the exact size and shape of the Critical Clearance Zone is known, it becomes nearly impossible to field correlate and accurately "superimpose" the Critical Clearance Zone" around the conductor. Therefore, it seems unreasonable to expect each utility to develop and implement a defensible and auditable clearance zone. We strongly support the development of the Technical Reference document. This would have been helpful if it was available for the first version, as it will help both utilities and auditors. We recommend that this be included in the revised version and subsequent future revisions. Please note that as FAC-003-2 goes through additional revisions prior to finalization, the Technical Reference document needs to be revised to reflect the final revisions prior to implementation.
Response: The SDT thanks you for your comments. The SDT engaged TO personnel who were technical experts with significant experience and credentials in transmission line insulation coordination theory and applications. The purpose of the change to the Gallet derived distances was to provide a set of specific distances that would ensure that flashover would not occur provided those distances were not breeched under expected outdoor operating conditions. These distances are applicable to the wire with respect to structure components, vegetation or any other object at ground potential level. These values have already been proven for dry and wet conditions and need no further testing. **We have made changes in R2 and R4 that should remove the problems you have raised regarding the CCZ and how it is "nearly impossible" to apply under field conditions.**	
Northeast Utilities	In section 4.2.2. the time period for bringing sub 200-kV lines into compliance with the standard states a 12 month period following the designation of the lower voltage lines by the Reliability Coordinator. This can present problems if the RC designates the lines during the course of a plan year, because budgets may not have been established or funded for the additional work. It is suggested that the time period be revised to state, "by the end of the following calendar or budget year after the designation of lower voltage lines", allowing for a full calendar/budget year that can be planned and budgeted to bring lines into compliance.

Organization	Question 18 Comment
	There is concern over the use of the Critical Clearance Zone and making this the "bright line" where encroachment at any time under any conditions is a violation of the standard. The Critical Clearance Zone is a very detailed and calculated zone. It is improbable that an accurate determination of the Critical Clearance Zone could be made in the field. Mere encroachment should not constitute a violation. If the encorachment can be determined and corrected once found - this should be an acceptable practice. It is reasonable for utilities to spend the time, money and manpower to actively manage rights-of-way, and dealing with encroachment issues which can be identified. Many potential encroachments will not be identifiable unless one can accurately identify the Critical Clearance Zone in all cases in all areas at all times. Also, there is some concern over how the requirements are set up for violations of the Critical Clearance Zone and for sustained outages. A sustained outage due to vegetation within the active transmission right-of-way is a violation under R.5, R.6 and R.7. It is also possible that the outage is a violation of the Critical Clearance Zone under R.4. The standard implies that a utility could be assessed multiple violations of the standard for one outage with multiple penalties. Is this the desired intent? Finally, version 1 had clear requirements on what was to be reported, when the reports were required, and who was to submit reports. Is it intended that the standard rely solely on self-reports? Version 2 makes no mention of what is to be reported when a violation occurs, or of any other reports. Is reporting going to be left up to the Regional Entity to establish?
Response: The SDT thanks you for your comments. **The standard was revised to replace the Reliability Coordinator with the Planning Coordinator as the entity responsible for identifying lines sub 200 kV for which there should be a TVMP. By moving to the Planning Coordinator, there should be ample time to address the annual work plan. With its focus on "planning horizon" issues (> 1 year), the PC provides the necessary look-ahead that the RC did not. As soon as a sub-200 kV line is designated as being applicable to this standard, it is understood the subject line could potentially place the grid at risk of instability, separation or cascading. A 12 month period to perform any vegetation maintenance seems reasonable to the SDT.** **Significant changes have been made to the current draft of the Standard based upon substantive industry comment. Items such as the CCZ concept has been replaced with the concept of minimum clearance distances, and Transmission Owners are required to prevent encroachment of vegetation into minimum vegetation clearances distances as observed in real time. Reporting requirements have been addressed in the compliance section of the revised Standard.**	
Hydro-Quebec Transenergie (HQT)	HQT recommends that the Standard Drafting Team review the compliance and reporting requirements for consistency and adequacy. Applicability 4.2.3 contradict first part of Applicability 4.2.1 and that of former Applicability 4.3
Response: The SDT thanks you for your comments. The SDT reviewed your concern and did not see a contradiction.	
BCTC	Any standard that is developed should not contain advisory-type language—it should be declarative in tone. For example, in R1.4, the ending clause that begins "…and may include actions…" should be removed because it is advisory in nature. The suggested actions are not even the responsibility of the vegetation management program. BCTC supports the development of this white paper as a way to help ensure consistent interpretation of the standard. Perhaps the lack

Organization	Question 18 Comment
	of such a paper in the first version of the standard contributed to the varying interpretations by the auditors. The utilities understand however that this document is not a legal document and is not binding.
Response: The SDT thanks you for your comments. R1.4 has been changed to remove the advisory type language.	

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. SC approved SAR for initial posting (January 11, 2007).
2. SAR posted for comment (January 15–February 14, 2007).
3. SAR posted for comment (April 10–May 9, 2007).
4. SC authorized moving the SAR forward to standard development (June 27, 2007).

Proposed Action Plan and Description of Current Draft:

This is the second posting of the proposed revisions to the requirements and measures in the standard. The drafting team added compliance elements to the standard and requests posting for a 45-day comment period.

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Drafting team considers comments, makes conforming changes, posts for 45-day second comment period.	August 2009
2. Drafting team considers comments, makes conforming changes, posts for 30-day third comment period.	February 2010
3. Drafting team considers comments, makes conforming changes, and requests SC approval to proceed to pre-ballot comment period.	April 2010
4. First ballot of standards.	May 2010
5. Recirculation ballot of standards.	June 2010
6. Board adopts standards.	August 2010

Definitions of Terms Used in Standard+

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Active Transmission Line Right of Way — A strip of land that is occupied by active transmission facilities. This corridor does not include the inactive or unused part of the Right of Way intended for other facilities.

Vegetation Inspection — The systematic examination of vegetation conditions on an Active Transmission Line Right of Way. This inspection may be combined with a general line inspection. The inspection includes the documentation of any vegetation that may pose a threat to reliability prior to the next planned inspection or maintenance work, considering the current location of the conductor and other possible locations of the conductor due to sag and sway for rated conditions.

A. Introduction

1. **Title:** Transmission Vegetation Management Program

2. **Number:** FAC-003-2

3. **Purpose:** To improve the reliability of the electric transmission system by preventing those vegetation related outages that could lead to Cascading.

4. **Applicability:**

   4.1 Functional Entities:

   4.1.1 Transmission Owner

   4.1.2 Planning Coordinator

   4.2 Facilities:

   4.2.1 Transmission lines (“applicable lines”) operated at 200kV or higher, and transmission lines operated below 200kV designated by the Planning Coordinator as being subject to this standard including but not limited to those that cross lands owned by federal1, state, provincial, public, private, or tribal entities.

   4.2.2 Transmission lines operated below 200kV designated by the Planning Coordinator as being subject to this standard become subject to this standard 12 months after the date the Planning Coordinator initially designates the transmission line as being subject to this standard.

   4.2.3 Existing transmission lines operated at 200kV or higher which are newly acquired by a Transmission Owner and were not previously subject to this standard, become subject to this standard 12 months after the acquisition date of the transmission lines.

5. **Effective Dates:**

   In those jurisdictions where regulatory approval is required, the first calendar day of the first calendar quarter one year after applicable regulatory authority approval for all requirements; or, in those jurisdictions where no regulatory approval is required, the first calendar day of the first calendar quarter one year following Board of Trustees adoption.

[1] EPAct 2005 section 1211c: *“Access approvals by Federal agencies”*

B. Requirements

R1. Each Transmission Owner shall have a documented transmission vegetation management program that describes how it conducts work on its Active Transmission Line Rights of Way to prevent Sustained Outages due to vegetation, considering all possible locations the conductor may occupy under the effects of sag and sway throughout its operating range under rated conditions. The transmission vegetation management program shall: *[Violation Risk Factor — Lower][Time Horizon — Long-term planning]*

1.1. Specify the methods that the Transmission Owner may use to control vegetation.[2]

1.2. Specify a Vegetation Inspection frequency of at least once per calendar year that takes into account local[3] and environmental factors.

1.3. Require an annual work plan. An annual work plan shall:

1.3.1. Identify the applicable lines to be maintained.

1.3.2. Identify the work to be performed and methods to be used.

1.3.3. Be flexible to adjust to changing conditions and to findings from Vegetation Inspections. Adjustments to the plan within the year are permissible.

1.3.4. Take into consideration permitting and scheduling requirements from landowners or regulatory authorities.

1.4. Require a process or procedure for response to an imminent threat of a vegetation-related Sustained Outage. The process or procedure shall specify actions which shall include communication of the threat to the responsible control center.

1.5. Specify an interim corrective action process for use when the Transmission Owner is temporarily constrained from performing vegetation maintenance as planned.

1.6. Specify the maintenance strategies used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that Table 1 clearances in Attachment 1 are never violated. The maintenance strategies shall consider the sag and sway of the conductor throughout its operating range under rated conditions.

R2. Each Transmission Owner shall implement its imminent threat process or procedure when the Transmission Owner has actual knowledge of such a threat,

---

[2] ANSI A300, Tree Care Operations — Tree, Shrub, and Other Woody Plant Maintenance — Standard Practices, while not a requirement of this standard, is considered to be an industry best practice.

[3] Local factors include items such as treatment cycle, extent and type of treatment, and their relationship to the normal growth rate.

obtained through normal operating practices. *[Violation Risk Factor — Medium][Time Horizon — Real Time]*

R3. Each Transmission Owner shall conduct Vegetation Inspections of all applicable lines (as measured in line miles) in accordance with the frequency specified in its transmission vegetation management program, unless constrained by natural disasters[4]. When constrained by a natural disaster, the Transmission Owner shall conduct the Vegetation Inspection(s) within six months or a period agreed to by its Regional Entity, whichever is greater. *[Violation Risk Factor — Medium][Time Horizon — Operations Planning]*

R4. Each Transmission Owner shall prevent encroachment of vegetation into the Minimum Vegetation Clearance Distances (MVCD) listed in FAC-003-2 - Attachment 1 for its applicable lines as observed in real-time operating between no-load and their Rating, with the following exceptions: *[Violation Risk Factor — Medium][Time Horizon — Real Time]*

- Encroachment into the MVCD listed in FAC-003-2-Attachment 1 resulting from natural disasters.[4]
- Encroachment into the MVCD listed in FAC-003-2-Attachment 1 resulting from human or animal activity.[5]
- Encroachment into the MVCD listed in FAC-003-2-Attachment 1 resulting from falling vegetation.

R5. Each Transmission Owner shall prevent Sustained Outages[6] of applicable lines that are identified as an element of an Interconnection Reliability Operating Limit (IROL) (or Major WECC Transfer Path) due to vegetation growing into a conductor operating between no-load and its Rating, with the following exceptions: *[Violation Risk Factor — High][Time Horizon — Real Time]*

- Sustained Outages of applicable lines that result from natural disasters.[4]
- Sustained Outages of applicable lines that result from human or animal activity.[5]

R6. Each Transmission Owner shall prevent Sustained Outages[6] of applicable lines that are not an element of an IROL (or major WECC Transfer Path) due to vegetation growing into a conductor operating between no-load and its Rating, with the following exceptions: *[Violation Risk Factor — Medium][Time Horizon — Real Time]*

- Sustained Outages of applicable lines that result from natural disasters.[4]

---

[4] Examples include, but are not limited to, earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods.

[5] Examples include, but are not limited to, logging, animal severing tree, vehicle contact with tree, arboricultural activities or horticultural or agricultural activities, or removal or digging of vegetation.

[6] Multiple Sustained Outages on an individual line, if caused by the same vegetation, shall be considered as one outage regardless of the actual number of outages within a 24-hour period.

- Sustained Outages of applicable lines that result from human or animal activity.[5]

R7. Each Transmission Owner shall prevent Sustained Outages[6] of applicable lines due to the blowing together of vegetation and a conductor within an Active Transmission Line Right of Way (operating within design blow-out conditions) with the following exception: *[Violation Risk Factor — Medium][Time Horizon — Real Time]*

- Sustained Outages of applicable lines that result from natural disasters[4] or wind-blown debris.

R8. Each Transmission Owner shall prevent Sustained Outages[6] of applicable lines due to vegetation falling into a conductor from within an Active Transmission Line Right of Way with the following exceptions: *[Violation Risk Factor — Medium] [Time Horizon — Real Time]*

- Sustained Outages of applicable lines that result from natural disasters[4] or wind-blown debris.
- Sustained Outages of applicable lines that result from human or animal activity.[5]

R9. Each Transmission Owner shall implement its annual work plan for vegetation management to accomplish the purpose of this standard. *[Violation Risk Factor — Medium] [Time Horizon — Operations Planning]*

R10. Each Planning Coordinator shall prepare and review annually, a list of lines that are operated below 200kV, if any, which are subject to this standard. Each Planning Coordinator shall consult with its Transmission Owner(s) and neighboring Planning Coordinators to obtain input to develop the list. *[Violation Risk Factor — Lower] [Time Horizon — Long-term Planning]*

R11. Each Planning Coordinator shall develop and document its method for assessing the reliability significance of sub-200kV transmission lines whose loss would place the grid at an unacceptable risk of instability, separation, or cascading failures. *[Violation Risk Factor — Lower] [Time Horizon — Long-term Planning]*

C. Measures

M1. The Transmission Owner has a documented transmission vegetation management program (paper or electronic copy of dated, current, in force document with specified elements) that describes how it conducts work on its Active Transmission Line Rights of Way to prevent Sustained Outages due to vegetation, considering all possible locations the conductor may occupy under the effects of sag and sway throughout its operating range under rated conditions. (R1)

1.1. The Transmission Owner's transmission vegetation management program documentation specifies the methods that the Transmission Owner may use to control vegetation.

1.2. The Transmission Owner's transmission vegetation management program documentation specifies a Vegetation Inspection frequency of at least once per calendar year that takes into account local and environmental factors.

1.3. The Transmission Owner's transmission vegetation management program contains an annual work plan which:

1.3.1. Identifies the applicable lines to be maintained

1.3.2. Identifies the work to be performed and the methods used

1.3.3. Shows flexibility to adjust to changing conditions and to findings from Vegetation Inspections

1.3.4. Considers permitting and scheduling requirements from landowners or regulatory authorities.

1.4. The Transmission Owner's transmission vegetation management program documentation specifies an imminent threat process or procedure for responding to imminent threats of a vegetation-related Sustained Outage including communication of the threat to the responsible control center.

1.5. The Transmission Owner's transmission vegetation management program documentation specifies the interim corrective action process for use when the Transmission Owner is temporarily constrained from performing vegetation maintenance as planned.

1.6. The Transmission Owner's transmission vegetation management program documentation specifies the maintenance strategies used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that Table 1 clearances in Attachment 1 are never violated. The maintenance strategies consider the sag and sway of the conductor throughout its operating range under rated conditions.

M2. The Transmission Owner has evidence of the implementation of its vegetation imminent threat process or procedure showing what was done with dates and activities accomplished. (R2)

M3. The Transmission Owner has evidence that it conducted Vegetation Inspections in accordance with Requirement R3.

M4. The Transmission Owner has evidence from inspections that indicate there was no vegetation encroachment into the Minimum Vegetation Clearance Distances listed in FAC-003-2-Attachment 1 for its applicable lines as observed in real-time operating between no-load and their Rating, considering exceptions. (R4)

M5. The Transmission Owner's self-certification reports are adequate evidence of no Sustained Outage of any applicable line that is identified as an element of an IROL (or Major WECC Transfer Path) due to vegetation growing into a conductor operating between no-load and its Rating. (R5)

M6. The Transmission Owner's self-certification reports are adequate evidence of no Sustained Outage of any applicable line that is not identified as an element of an IROL (or Major WECC Transfer Path) due to vegetation growing into a conductor operating between no-load and its Rating. (R6)

M7. The Transmission Owner's self-certification reports are adequate evidence of no Sustained Outage of any applicable line due to the blowing together of vegetation and a conductor within the Active Transmission Line Right of Way. (R7)

M8. The Transmission Owner's self-certification reports are adequate evidence of no Sustained Outage of any applicable line due to vegetation falling into a conductor from within the Active Transmission Line Right of Way. (R8)

M9. The Transmission Owner has evidence that it is implementing, or has implemented, its annual work plan. An example of evidence is a paper or electronic copy of work plan and work records. (R9)

M10. The Planning Coordinator has evidence that it consulted with its Transmission Owner(s) and neighboring Planning Coordinator(s), prepared and reviewed annually a list of designated sub-200kV transmission lines, if any, which are subject to this standard. (R10)

M11. The Planning Coordinator has documented evidence such as planning study criteria or other analysis used to develop its method for assessing the reliability significance of sub-200kV lines whose loss would place the grid at an unacceptable risk of instability, separation, or cascading failures. (R11)

D. Compliance

1. Compliance Monitoring Process

1.1 Compliance Enforcement Authority

Regional Entity

1.2 Compliance Monitoring Period and Reset Timeframe

Not Applicable

1.3 Compliance Monitoring and Enforcement Processes:

Compliance Audits

Self-Certifications

Spot Checking

Compliance Violation Investigations

Self-Reporting

Complaints

Periodic Data Submittals for Sustained Outages caused by vegetation

1.4 Data Retention

The Transmission Owner and Planning Coordinator shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

- The Transmission Owner shall retain as evidence of Requirements 1 through 9, Measures 1 through 9 for three years.
- The Planning Coordinator shall retain evidence of Requirement 10 and 11, Measure 10 and 11 for one year.

If a Transmission Owner or Planning Coordinator is found non-compliant, it shall keep information related to the non-compliance until found compliant.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.5 Additional Compliance Information

The Transmission Owner shall report quarterly to its Regional Entity, or the Regional Entity's designee, Sustained Outages of its transmission lines determined by the Transmission Owner to have been caused by vegetation, including the following:

The name of the circuit(s), the date, time and duration of the outage; a description of the cause of the outage; other pertinent comments; and any countermeasures taken by the Transmission Owner, and Sustained Outage Category based on the following:

- Category 1A — Grow-ins: Sustained Outages caused by vegetation growing into applicable lines that are identified as an element of an IROL (or Major WECC Transfer Path) by vegetation inside and/or outside of the Active Transmission Line ROW;
- Category 1B — Grow-ins: Sustained Outages caused by vegetation growing into applicable lines but are not identified as an element of an IROL (or Major WECC Transfer Path) by vegetation inside and/or outside of the Active Transmission Line ROW;
- Category 2 — Fall-ins: Sustained Outages caused by vegetation falling into lines from within the Active Transmission Line ROW;
- Category[7] 4 — Blowing together: Sustained Outages caused by vegetation and lines blowing together from within the Active Transmission Line ROW.

[7] Category 3 reporting is eliminated.

Violation Severity Levels

R#	Violation Risk Factor	Violation Severity Level			
		Lower	Moderate	High	Severe
R1	Lower	The Transmission Owner has a transmission vegetation management program, but the transmission vegetation management program is missing one of the following: Requirement 1, Part 1.1, or Requirement 1, Part 1.2	The Transmission Owner has a transmission vegetation management program, but the transmission vegetation management program is missing either Requirement R1, Part 1.5 or Requirement R1, Part 1.1 and Part 1.2	The Transmission Owner has a transmission vegetation management program, but the transmission vegetation management program is missing up to two of the following parts of Requirement R1: Parts 1.3, 1.4 and 1.6	The Transmission Owner does not have transmission vegetation management program or the transmission vegetation management program is missing all of the following Parts of Requirement R1: Parts 1.3, 1.4 and 1.6
R2	Medium				The Transmission Owner did not implement its imminent threat process or procedure when the Transmission Owner had actual knowledge of such a threat, obtained through normal operating practices
R3	Medium	The Transmission Owner inspected greater than 75% but less than 100% of the total line miles specified by its transmission vegetation management program.	The Transmission Owner inspected greater than 50% but less than or equal to 75% of the total line miles specified by its transmission vegetation management program.	The Transmission Owner inspected greater than 25% but less than or equal to 50% of the total line miles specified by its transmission vegetation management program.	The Transmission Owner inspected less than or equal to 25% of the total line miles specified by its transmission vegetation management program.
R4	Medium				The Transmission Owner has failed to prevent vegetation from encroaching into the minimum vegetation clearance distance.

R#	Violation Risk Factor	Violation Severity Level			
		Lower	Moderate	High	Severe
R5	High				The Transmission Owner incurred a Sustained Outage due to vegetation growing into an applicable transmission line that is identified as an element of an IROL (or Major WECC Transfer Path).
R6	Medium				The Transmission Owner incurred a Sustained Outage due to vegetation growing into an applicable transmission line that is not identified as an element of an IROL (or Major WECC Transfer Path).
R7	Medium				The Transmission Owner incurred a Sustained Outage due to the blowing together of vegetation and a conductor of an applicable transmission within an Active Transmission Line Right of Way.
R8	Medium				The Transmission Owner incurred a Sustained Outage due to vegetation falling into an applicable transmission from within an Active Transmission Line Right of Way.
R9	Medium	The Transmission Owner failed to implement 5% or less of its annual work	The Transmission Owner failed to implement more than 5% but less than or	The Transmission Owner failed to implement more than 10% but less than or equal to	The Transmission Owner failed to implement more than 15% of its annual work

R#	Violation Risk Factor	Violation Severity Level			
		Lower	Moderate	High	Severe
		plan.	equal to 10% of its annual work plan.	15% of its annual work plan.	plan.
R10	Lower	The Planning Coordinator failed to consult with one of its Transmission Owners or one of its adjacent Planning Coordinators in developing its list of designated sub-200kV transmission lines, if any, that are subject to this standard..	The Planning Coordinator failed to consult with more than one of its Transmission Owners or more than one of its adjacent Planning Coordinators in developing its list of designated sub-200kV transmission lines, if any, that are subject to this standard.	The Planning Coordinator has not annually reviewed its list of designated sub-200kV transmission lines, if any, that are subject to this standard.	The Planning Coordinator has not prepared a list of designated sub-200kV transmission lines, if any, that are subject to this standard.
R11	Lower	The Planning Coordinator has not documented its method for assessing the reliability significance of sub-200kV lines.	The Planning Coordinator has not considered lines whose loss would place the grid at an unacceptable risk of instability, separation, or cascading failures in developing its method for assessing the reliability significance of sub-200kV lines.	NA	The Planning Coordinator has not developed a method for assessing the reliability significance of sub-200kV lines.

Regional Variances

None identified.

Standard Development Roadmap

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed:

1. SC approved SAR for initial posting (January 11, 2007).
2. SAR posted for comment (January 15–February 14, 2007).
3. SAR posted for comment (April 10–May 9, 2007).
4. SC authorized moving the SAR forward to standard development (June 27, 2007).

Proposed Action Plan and Description of Current Draft:

This is the second posting of the proposed revisions to the requirements and measures in the standard. The drafting team added compliance elements to the standard and requests posting for a 45-day comment period.

Future Development Plan:

Anticipated Actions	Anticipated Date
1. Drafting team considers comments, makes conforming changes, posts for 45-day second comment period.	August 2009
2. Drafting team considers comments, makes conforming changes, posts for 30-day third comment period.	February 2010
3. Drafting team considers comments, makes conforming changes, and requests SC approval to proceed to pre-ballot comment period.	April 2010
4. First ballot of standards.	May 2010
5. Recirculation ballot of standards.	June 2010
6. Board adopts standards.	August 2010

Definitions of Terms Used in Standard+

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Active Transmission Line Right of Way — A strip of land that is occupied by active transmission facilities. This corridor does not include the inactive or unused part of the Right of Way intended for other facilities.

~~**Critical Clearance Zone** — The area mapped by the radial distance around a conductor specified in Table I of Attachment 1 to reliability standard FAC-003-2 — Transmission~~

Vegetation ~~Management Program when the conductor is energized and operating between no-load and its Rating, including the design blowout, however, the zone shall not extend beyond the limits~~**Inspection —** The systematic examination of ~~the~~vegetation conditions on an Active Transmission Line Right of Way. This inspection may be combined with a general line inspection. The inspection includes the documentation of any vegetation that may pose a threat to reliability prior to the next planned inspection or maintenance work, considering the current location of the conductor and other possible locations of the conductor due to sag and sway for rated conditions.

A. Introduction

1. **Title:** Transmission Vegetation Management Program

2. **Number:** FAC-003-2

3. **Purpose:** To improve the reliability of the ~~Bulk Electric System~~electric transmission system by preventing those vegetation related outages that could lead to Cascading.

4. **Applicability:**

   Functional Entities:

   - Transmission Owner
   - ~~Reliability~~Planning Coordinator

   Facilities:

   - Transmission lines (“applicable lines”) operated at 200kV or higher, and transmission lines operated below 200kV designated by the ~~Reliability~~Planning Coordinator as being subject to this standard including but not limited to those that cross lands owned by federal1, state, provincial, public, private, or tribal entities.
   - Transmission lines operated below 200kV designated by the ~~Reliability~~Planning Coordinator as being subject to this standard become subject to this standard 12 months after the date the ~~Reliability~~Planning Coordinator initially designates the transmission line as being subject to this standard.
   - Existing transmission lines operated at 200kV or higher which are newly acquired by a Transmission Owner and were not previously subject to this standard, become subject to this standard 12 months after the acquisition date of the transmission lines~~s~~.

5. **Effective Dates:**

   In those jurisdictions where regulatory approval is required, the first calendar day of the first calendar quarter one year after applicable regulatory authority approval for all requirements; or, in those jurisdictions where no regulatory approval is required, the first calendar day of the first calendar quarter one year following Board of Trustees adoption.

[1] EPAct 2005 section 1211c: “*Access approvals by Federal agencies*~~”~~ ”

B. Requirements

R1. Each Transmission Owner shall have a documented transmission vegetation management program ~~designed to control vegetation~~ that describes how it conducts work on its Active Transmission ~~Lines'~~ Line Rights of Way to prevent Sustained Outages due to vegetation, considering all possible locations the conductor may occupy under the effects of sag and sway throughout its operating range under rated conditions. The transmission vegetation management program shall: *[Violation Risk Factor – Lower][Time Horizon – Long-term planning]*

1.1. Specify the ~~methodologies~~ methods that the Transmission Owner ~~uses~~ may use to control vegetation.[2]

1.2. Specify a ~~vegetation inspection~~Vegetation Inspection frequency of at least once per calendar year that takes into account local[3] and environmental factors.

1.3. Require an annual work plan ~~that identifies~~. An annual work plan shall:

1.3.1. Identify the applicable lines to be maintained ~~and associated~~

1.3.2. Identify the work to be performed ~~during the year. It shall~~ and methods to be used

1.3.3. Be flexible to adjust to changing conditions and to findings from ~~vegetation inspections.~~ Vegetation Inspections. Adjustments to the plan within the year are permissible. ~~The plan shall~~

1.3.4. Take into consideration permitting and scheduling requirements from landowners or regulatory authorities. ~~It shall support the objectives of the transmission vegetation management program and use the methodologies outlined in the transmission vegetation management program.~~

1.4. Require a process or procedure for response to an imminent ~~threats~~ threat of a vegetation~~-~~-related Sustained Outage. The process or procedure shall specify actions which shall include ~~immediate~~ communication of the threat to the ~~Transmission Operator, and may include actions such as a temporary reduction in line Rating, switching lines out of service, or other actions.~~responsible control center.

1.5. Specify an interim corrective action process for use when the Transmission Owner is temporarily constrained from performing vegetation maintenance as planned.

---

2 ANSI A300, Tree Care Operations – Tree, Shrub, and Other Woody Plant Maintenance – Standard Practices, while not a requirement of this standard, is considered to be an industry best practice.

3 Local factors include items such as treatment cycle, extent and type of treatment, and their relationship to the normal growth rate.

1.6. Specify the maintenance strategies used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that Table 1 clearances in Attachment 1 are never violated. The maintenance strategies shall consider the sag and sway of the conductor throughout its operating range under rated conditions.

R2. Each Transmission Owner shall implement its imminent threat process or procedure when the Transmission Owner has actual knowledge of such a threat, obtained through normal operating practices ~~or notification from others, that the Critical Clearance Zone is approached by vegetation to prevent an encroachment of the Critical Clearance Zone.~~. *[Violation Risk Factor – Medium][Time Horizon – Real Time]*

R3. Each Transmission Owner shall conduct ~~inspections~~Vegetation Inspections of all applicable lines (as measured in line miles) in accordance with the frequency specified in its transmission vegetation management program~~.~~, unless constrained by natural disasters[4]. When constrained by a natural disaster, the Transmission Owner shall conduct the Vegetation Inspection(s) within six months or a period agreed to by its Regional Entity, whichever is greater. *[Violation Risk Factor – Medium][Time Horizon – Operations Planning]*

R4. Each Transmission Owner shall prevent encroachment ~~within~~of vegetation into the ~~Critical~~Minimum Vegetation Clearance ~~Zone of~~ Distances (MVCD) listed in FAC-003-2 - Attachment 1 for its applicable lines as observed in real-time operating between no-load and their Rating, with the following exceptions: *[Violation Risk Factor – Medium][Time Horizon – Real Time]*

- ~~Encroachments of~~Encroachment into the ~~Critical~~MVCD listed in FAC-003-2-Attachment 1 resulting from natural disasters.[4]
- ~~Encroachments of~~ Encroachment into the ~~Critical~~MVCD listed in FAC-003-2-Attachment 1 resulting from human or animal activity.[5]
- Encroachment into the MVCD listed in FAC-003-2-Attachment 1 resulting from falling vegetation.

R5. Each Transmission Owner shall prevent Sustained Outages[6] of applicable lines~~[7]~~ that are identified as an element of an Interconnection Reliability Operating Limit (IROL) (or Major WECC Transfer Path) due to vegetation growing into a conductor operating between no-load and its Rating, with the following exceptions: *[Violation Risk Factor – High][Time Horizon – Real Time]*

---

[4] Examples include, but are not limited to, earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods.

[5] Examples include, but are not limited to, logging, animal severing tree, vehicle contact with tree, arboricultural activities or horticultural or agricultural activities, or removal or digging of vegetation.

[6] Multiple Sustained Outages on an individual line, if caused by the same vegetation, shall be considered as one outage regardless of the actual number of outages within a 24-hour period.

- Sustained Outages of applicable lines that result from natural disasters.[4]
- Sustained Outages of applicable lines that result from human or animal activity.[5]

R6. Each Transmission Owner shall prevent Sustained Outages[6] of applicable ~~lines[6]~~ lines that are not an element of an IROL (or major WECC Transfer Path) due to vegetation growing into a conductor operating between no-load and its Rating, with the following exceptions: *[Violation Risk Factor – Medium][Time Horizon – Real Time]*

- Sustained Outages of applicable lines that result from natural disasters.[4]
- Sustained Outages of applicable lines that result from human or animal activity.[5]

R7. Each Transmission Owner shall prevent Sustained Outages[6] of applicable lines due to the blowing together of vegetation and a conductor within an Active Transmission Line Right of Way (operating within design blow-out conditions) with the following exception: *[Violation Risk Factor – Medium][Time Horizon – Real Time]*

- Sustained Outages of applicable lines that result from ~~sustained winds or gusts due to natural disasters.4~~natural disasters[4] or wind-blown debris.

R8. Each Transmission Owner shall prevent Sustained Outages[6] of applicable ~~lines[6]~~ lines due to vegetation falling into a conductor from within an Active Transmission Line Right of Way with the following exceptions: *[Violation Risk Factor – Medium] [Time Horizon – Real Time]*

- Sustained Outages of applicable lines that result from natural disasters~~.~~[4] or wind-blown debris.
- Sustained Outages of applicable lines that result from human or animal activity.[5]

R9. Each Transmission Owner shall implement its annual work plan for vegetation management to accomplish the purpose of this standard~~ within the extent of its easement and/or legal rights.~~. *[Violation Risk Factor – Medium] [Time Horizon – Operations Planning]*

R10. Each ~~Reliability~~Planning Coordinator ~~in consultation with its Transmission Owner(s) and neighboring Reliability Coordinator(s)~~ shall ~~jointly~~ prepare and ~~keep current,~~ review annually, a list of ~~designated applicable~~ lines that are operated below ~~200~~200kV, if any, which are subject to this standard. Each Planning Coordinator shall consult with its Transmission Owner(s) and neighboring Planning Coordinators to obtain input to develop the list. *[Violation Risk Factor – Lower] [Time Horizon – Long-term Planning]*

~~**R10.**~~ Each ~~Reliability~~Planning Coordinator shall develop and document its method for assessing the reliability significance of sub-200kV ~~lines considering all of the following:~~

~~**R10.1** Transmission lines whose loss would result in the exceedance of an Interconnection Reliability Operating Limit (IROL)~~

R11. ~~**R10.2**~~ ~~Transmission~~ transmission lines whose loss would place the grid at an unacceptable risk of instability, separation, or cascading failures. *[Violation Risk Factor – Lower] [Time Horizon – Long-term Planning]*

C. Measures

M1. The Transmission Owner has a documented transmission vegetation management program ~~designed to control~~ (paper or electronic copy of dated, current, in force document with specified elements) that describes how it conducts work on its Active Transmission Line Rights of Way to prevent Sustained Outages due to vegetation ~~on the Active Transmission Line Right of Way.~~, considering all possible locations the conductor may occupy under the effects of sag and sway throughout its operating range under rated conditions. (R1)

1.1. The Transmission Owner's transmission vegetation management program documentation specifies the ~~methodologies~~methods that the Transmission Owner ~~uses~~may use to control vegetation.

1.2. The Transmission Owner's transmission vegetation management program documentation specifies a ~~vegetation inspection~~Vegetation Inspection frequency of at least once per calendar year that takes into account local and environmental factors. ~~This inspection frequency shall be at least once per calendar year.~~

1.3. The Transmission Owner's transmission vegetation management program ~~requires~~contains an annual work plan ~~and it~~ which:

1.3.1. Identifies the applicable lines to be maintained ~~and related vegetation management work to be performed during the calendar year while taking into consideration~~

1.3.2. Identifies the work to be performed and the methods used

1.3.3. Shows flexibility to adjust to changing conditions and to findings from Vegetation Inspections

1.3.4. Considers permitting and scheduling requirements from landowners or regulatory authorities.

1.4. The Transmission Owner's transmission vegetation management program ~~requires~~ documentation specifies an imminent threat process or procedure for responding to imminent threats of a vegetation-related Sustained Outage including ~~immediate~~ communication of the threat to the ~~Transmission Operator, and may include a temporary reduction in line Rating, switching lines out of service, and/or other actions that may be taken until the threat is relieved~~responsible control center.

1.5. The Transmission Owner's transmission vegetation management ~~program~~program documentation specifies the interim corrective action process for use when the Transmission Owner is temporarily constrained from performing vegetation maintenance as planned.

1.6. The Transmission Owner's transmission vegetation management program documentation specifies the maintenance strategies used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that Table 1 clearances in Attachment 1 are never violated. The maintenance strategies consider the sag and sway of the conductor throughout its operating range under rated conditions.

M2. The Transmission Owner has evidence ~~that it implemented its~~ of the implementation of its vegetation imminent threat process or procedure ~~when it obtained knowledge that the Critical Clearance Zone~~showing what was ~~approached by vegetation.~~done with dates and activities accomplished. (R2)

M3. The Transmission Owner has evidence that it conducted ~~vegetation inspections of all applicable transmission lines~~Vegetation Inspections in accordance with ~~the frequency specified in its transmission vegetation management program. (~~Requirement R3~~)~~.

M4. ~~The Transmission Owner has evidence such as inspection records, imminent threat reports or quality assurance reports, demonstrating there were no vegetation encroachments into the Critical Clearance Zone.~~The Transmission Owner has evidence from inspections that indicate there was no vegetation encroachment into the Minimum Vegetation Clearance Distances listed in FAC-003-2-Attachment 1 for its applicable lines as observed in real-time operating between no-load and their Rating, considering exceptions. (R4)

M5. The Transmission ~~Owner has~~Owner's self-certification reports are adequate evidence ~~that there was not a~~ of no Sustained Outage of ~~an~~ any applicable line that is identified as an element of an IROL (or Major WECC Transfer Path) due to vegetation growing into a conductor operating between no-load and its Rating. (R5)

M6. The Transmission Owner's self-certification reports are adequate evidence of no Sustained Outage of any applicable line that is not identified as an element of an IROL (or Major WECC Transfer Path) due to vegetation growing into a conductor operating between no-load and its Rating. (~~R5~~R6)

M7. The Transmission ~~Owner has~~Owner's self-certification reports are adequate evidence ~~that there was not a~~of no Sustained Outage of ~~an~~ any applicable line due to the blowing together of vegetation and a conductor within the Active Transmission Line Right of Way. (~~R6~~R7)

M8. The Transmission ~~Owner has~~Owner's self-certification reports are adequate evidence ~~that there was not a~~of no Sustained Outage of ~~an~~any applicable line due to vegetation falling into a conductor from within the Active Transmission Line Right of Way. (~~R7~~R8)

M9. The Transmission Owner has evidence that it is implementing, or has implemented, its annual work plan. ~~(R8~~An example of evidence is a paper or electronic copy of work plan and work records. (R9)

M10. The ~~Reliability~~Planning Coordinator has evidence that it consulted with its Transmission Owner(s) and ~~adjacent Reliability~~neighboring Planning Coordinator(s), prepared and ~~kept current~~reviewed annually a list of designated sub-200kV transmission lines, if any, which are subject to this standard. (~~R9~~R10)

M11. The ~~Reliability~~Planning Coordinator has documented evidence ~~that it has defined its methods~~such as planning study criteria or other analysis used to develop its method for assessing the reliability significance of sub-200kV lines ~~and has developed selection criteria for listing any sub-200kV lines. (R10~~whose loss would place the grid at an unacceptable risk of instability, separation, or cascading failures. (R11)

D. Compliance

All compliance information is new and shown without "track changes" for ease in reading

1. Compliance Monitoring Process

1.1 Compliance Enforcement Authority

Regional Entity

1.2 Compliance Monitoring Period and Reset Timeframe

Not Applicable

1.3 Compliance Monitoring and Enforcement Processes:

Compliance Audits

Self-Certifications

Spot Checking

Compliance Violation Investigations

Self-Reporting

Complaints

Periodic Data Submittals for Sustained Outages caused by vegetation

1.4 Data Retention

The Transmission Owner and Planning Coordinator shall keep data or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:

- The Transmission Owner shall retain as evidence of Requirements 1 through 9, Measures 1 through 9 for three years.
- The Planning Coordinator shall retain evidence of Requirement 10 and 11, Measure 10 and 11 for one year.

If a Transmission Owner or Planning Coordinator is found non-compliant, it shall keep information related to the non-compliance until found compliant.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.5 Additional Compliance Information

The Transmission Owner shall report quarterly to its Regional Entity, or the Regional Entity's designee, Sustained Outages of its transmission lines determined by the Transmission Owner to have been caused by vegetation, including the following:

The name of the circuit(s), the date, time and duration of the outage; a description of the cause of the outage; other pertinent comments; and any countermeasures taken by the Transmission Owner, and Sustained Outage Category based on the following:

- Category 1A — Grow-ins: Sustained Outages caused by vegetation growing into applicable lines that are identified as an element of an IROL (or Major WECC Transfer Path) by vegetation inside and/or outside of the Active Transmission Line ROW;
- Category 1B — Grow-ins: Sustained Outages caused by vegetation growing into applicable lines but are not identified as an element of an IROL (or Major WECC Transfer Path) by vegetation inside and/or outside of the Active Transmission Line ROW;
- Category 2 — Fall-ins: Sustained Outages caused by vegetation falling into lines from within the Active Transmission Line ROW;
- Category[8] 4 — Blowing together: Sustained Outages caused by vegetation and lines blowing together from within the Active Transmission Line ROW.

[8] Category 3 reporting is eliminated.

Violation Severity Levels

R#	Violation Risk Factor	Violation Severity Level			
		Lower	Moderate	High	Severe
R1	Lower	The Transmission Owner has a transmission vegetation management program, but the transmission vegetation management program is missing one of the following: Requirement 1, Part 1.1, or Requirement 1, Part 1.2	The Transmission Owner has a transmission vegetation management program, but the transmission vegetation management program is missing either Requirement R1, Part 1.5 or Requirement R1, Part 1.1 and Part 1.2	The Transmission Owner has a transmission vegetation management program, but the transmission vegetation management program is missing up to two of the following parts of Requirement R1: Parts 1.3, 1.4 and 1.6	The Transmission Owner does not have transmission vegetation management program or the transmission vegetation management program is missing all of the following Parts of Requirement R1: Parts 1.3, 1.4 and 1.6
R2	Medium				The Transmission Owner did not implement its imminent threat process or procedure when the Transmission Owner had actual knowledge of such a threat, obtained through normal operating practices
R3	Medium	The Transmission Owner inspected greater than 75% but less than 100% of the total line miles specified by its transmission vegetation management program.	The Transmission Owner inspected greater than 50% but less than or equal to 75% of the total line miles specified by its transmission vegetation management program.	The Transmission Owner inspected greater than 25% but less than or equal to 50% of the total line miles specified by its transmission vegetation management program.	The Transmission Owner inspected less than or equal to 25% of the total line miles specified by its transmission vegetation management program.
R4	Medium				The Transmission Owner has failed to prevent

R#	Violation Risk Factor	Violation Severity Level			
		Lower	Moderate	High	Severe
					vegetation from encroaching into the minimum vegetation clearance distance.
R5	High				The Transmission Owner incurred a Sustained Outage due to vegetation growing into an applicable transmission line that is identified as an element of an IROL (or Major WECC Transfer Path).
R6	Medium				The Transmission Owner incurred a Sustained Outage due to vegetation growing into an applicable transmission line that is not identified as an element of an IROL (or Major WECC Transfer Path).
R7	Medium				The Transmission Owner incurred a Sustained Outage due to the blowing together of vegetation and a conductor of an applicable transmission within an Active Transmission Line Right of Way.
R8	Medium				The Transmission Owner incurred a Sustained Outage

R#	Violation Risk Factor	Violation Severity Level			
		Lower	Moderate	High	Severe
					due to vegetation falling into an applicable transmission from within an Active Transmission Line Right of Way.
R9	Medium	The Transmission Owner failed to implement 5% or less of its annual work plan.	The Transmission Owner failed to implement more than 5% but less than or equal to 10% of its annual work plan.	The Transmission Owner failed to implement more than 10% but less than or equal to 15% of its annual work plan.	The Transmission Owner failed to implement more than 15% of its annual work plan.
R10	Lower	The Planning Coordinator failed to consult with one of its Transmission Owners or one of its adjacent Planning Coordinators in developing its list of designated sub-200kV transmission lines, if any, that are subject to this standard..	The Planning Coordinator failed to consult with more than one of its Transmission Owners or more than one of its adjacent Planning Coordinators in developing its list of designated sub-200kV transmission lines, if any, that are subject to this standard.	The Planning Coordinator has not annually reviewed its list of designated sub-200kV transmission lines, if any, that are subject to this standard.	The Planning Coordinator has not prepared a list of designated sub-200kV transmission lines, if any, that are subject to this standard.
R11	Lower	The Planning Coordinator has not documented its method for assessing the reliability significance of sub-200kV lines.	The Planning Coordinator has not considered lines whose loss would place the grid at an unacceptable risk of instability, separation, or cascading failures in developing its method for assessing the reliability significance of sub-200kV lines.	NA	The Planning Coordinator has not developed a method for assessing the reliability significance of sub-200kV lines.

Regional Variances

None identified.

FAC-003-1 Mapping to Proposed NERC Reliability Standard FAC-003-2

Standard FAC-003-1 NERC Board Approved	Comment	Proposed Standard FAC-003-2
0. Definitions	**0.** The definition of Active Transmission Line Right of Way was added in response to FERC 693 and industry comments. The glossary definition of Vegetation Inspection was changed in response to industry comments.	**Active Transmission Line Right of Way** — A strip of land that is occupied by active transmission facilities. This corridor does not include the inactive Right of Way or unused part of the Right of Way intended for other facilities. **Vegetation Inspection** — The systematic examination of vegetation conditions on an Active Transmission Line Right of Way. This inspection may be combined with a general line inspection. The inspection includes the documentation of any vegetation that may pose a threat to reliability prior to the next planned inspection or maintenance work, considering the current location of the conductor and other possible locations of the conductor due to sag and sway for rated conditions.
1. Title: Transmission Vegetation Management Program	**1. Title:** No Change (N/C)	**1. Title:** Transmission Vegetation Management Program
3. Purpose: To improve the reliability of the electric transmission systems by preventing outages from vegetation located on transmission rights-of-way (ROW) and minimizing outages from vegetation located adjacent to ROW, maintaining clearances between transmission lines and vegetation on and along transmission ROW, and reporting vegetation related outages of the transmission systems to the respective Regional Reliability Organizations (RRO) and the North American Electric Reliability Council (NERC).	**3. Purpose:** Changed to a shorter more concise purpose statement. The various explanatory objectives are now addressed within the standard’s requirements.	**3. Purpose:** To improve the reliability of the electric transmission system by preventing those vegetation related outages that could lead to Cascading.
4. Applicability:	**4. Applicability:**	**4. Applicability:**

4.1. Transmission Owner	4.1 N/C	**4.1. Functional Entities** 4.1.1. Transmission Owner 4.1.2. Planning Coordinator
4.2. Regional Reliability Organization 4.3. This standard shall apply to all transmission lines operated at 200 kV and above and to any lower voltage lines designated by the RRO as critical to the reliability of the electric system in the region.	4.2 Removed Regional Reliability Organization in response to FERC Order 693 and later added Planning Coordinator in lieu of Reliability Coordinator in response to industry comments to the October 27, 2008 comments. 4.3 (Note that the version 1 section 4.3 is now covered in version 2 section 4.2) 4.2.1 Added reference to lines that cross lands owned by federal, state, provincial, public, private, or tribal entities. Changed RRO to Planning Coordinator 4.2.2. Added criterion to identify the time frame provided to manage sub 200kV lines to the standard after the Planning Coordinator has determined that they are subject to the standard. 4.2.3. Added criterion to specify when a newly acquired line above 200kV will become	**4.2. Facilities** 4.2.1. Transmission lines ("applicable lines") operated at 200kV or higher, and transmission lines operated below 200kV designated by the Planning Coordinator as being subject to this standard including but not limited to those that cross lands owned by federal[1], state, provincial, public, private, or tribal entities. 4.2.2. Transmission lines operated below 200kV designated by the Planning Coordinator as being subject to this standard become subject to this standard 12 months after the date the Planning Coordinator initially designates the transmission line as being subject to this standard. 4.2.3. Existing transmission line(s) operated at 200kV or higher that are newly acquired by a Transmission Owner and were not previously subject to this standard, become subject to this standard 12 months after the acquisition date of the transmission line(s).

[1] EPAct 2005 section 1211c: *"Access approvals by Federal agencies"*

	subject to the standard.	
Effective Dates: **5.1** One calendar year from the date of adoption by the NERC Board of Trustees for Requirement 1 and 2. **5.2** Sixty calendar days from the date of adoption by the NERC Board of Trustees for the Requirements 3 and 4.	**Effective Dates:** Consistency with standards approval process for a standard revision.	**5. Effective Dates:** In those jurisdictions where regulatory approval is required, the first calendar day of the first calendar quarter one year after applicable regulatory authority approval for all requirements; or, in those jurisdictions where no regulatory approval is required, the first calendar day of the first calendar quarter one year following Board of Trustees adoption.
R1. The Transmission Owner shall prepare, and keep current, a formal transmission vegetation management program (TVMP). The TVMP shall include the Transmission Owner's objectives, practices, approved procedures, and work specifications[1]. **R1.1.** The TVMP shall define a schedule for and the type (aerial, ground) of ROW vegetation inspections. This schedule should be flexible enough to adjust for changing conditions. The inspection schedule shall be based on the anticipated growth of vegetation and any other environmental or operational factors that could impact the relationship of vegetation to the Transmission Owner's transmission lines. **R1.2** The Transmission Owner, in the TVMP, shall identify and document the clearances between vegetation and any overhead, ungrounded supply concoctors taking into consideration transmission line voltage, the effects of ambient temperature on conductor sag under maximum design loading, and the effects of wind velocities on conductor sway.	**R1.** Changed R1 to be a TVMP "documentation" requirement not an implementation requirement. Items changed or modified were removed Clearance 1 (which was a fill in the blank) Clearance 2 was replaced by MVCD (to find a more acceptable alternative to MAID), added the frequency of at least once per calendar year to Vegetation Inspections, moved imminent threat action from the original R1.5 to the new requirement R2, removed personnel qualifications (they were fill-in-the-blank), replaced the term "mitigation measures " with "interim corrective action process" to avoid conflict with NERC's use of the term "imminent threat:, specified that maintenance strategies to achieve clearance must consider the sag and sway under all rated conditions, and clarified that this applies on the active transmission line ROW. Added requirements for the documentation of an annual work plan	**R1.** Each Transmission Owner shall have a documented transmission vegetation management program that describes how it conducts work on its Active Transmission Line Rights of Way to prevent Sustained Outages due to vegetation, considering all possible locations the conductor may occupy under the effects of sag and sway throughout its operating range under rated conditions. The transmission vegetation management program shall: **1.1.** Specify the methods that the Transmission Owner may use to control vegetation. **1.2.** Specify a Vegetation Inspection frequency of at least once per calendar year that takes into account local and environmental factors. **1.3.** Require an annual work plan. An annual work plan shall: **1.3.1.** Identify the applicable lines to be maintained **1.3.2.** Identify the work to be performed and methods to be used **1.3.3.** Be flexible to adjust to changing conditions and to findings from Vegetation Inspections. Adjustments to the plan within the year are permissible. **1.3.4.** Take into consideration permitting and scheduling requirements from landowners or

Specifically, the Transmission Owner shall establish clearances to be achieved at the time of vegetation management work identified herein as Clearance 1, and shall also establish and maintain a set of clearances identified herein as Clearance 2 to prevent flashover between vegetation and overhead ungrounded supply conductors. **R1.2.1.** Clearance 1 — The Transmission Owner shall determine and document appropriate clearance distances to be achieved at the time of transmission vegetation management work based upon local conditions and the expected time frame in which the Transmission Owner plans to return for future **R1.2.2.** Clearance 2 — The Transmission Owner shall determine and document specific radial clearances to be maintained between vegetation and conductors under all rated electrical operating conditions. These minimum clearance distances are necessary to prevent flashover between vegetation and conductors and will vary due to such factors as altitude and operating voltage. These Transmission Owner-specific minimum clearance distances shall be no less than those set forth in the Institute of Electrical and Electronics Engineers (IEEE) Standard 516-2003 (*Guide for Maintenance Methods on Energized Power Lines*) and as specified in its Section 4.2.2.3, Minimum Air Insulation Distances without Tools in the Air Gap. **R1.2.2.1** Where transmission system transient		regulatory authorities. **1.4.** Require a process or procedure for response to an imminent threat of a vegetation-related Sustained Outage. The process or procedure shall specify actions which shall include communication of the threat to the responsible control center. **1.5.** Specify an interim corrective action process for use when the Transmission Owner is temporarily constrained from performing vegetation maintenance as planned. **1.6.** Specify the maintenance strategies used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that Table 1 clearances in Attachment 1 are never violated. The maintenance strategies shall consider the sag and sway of the conductor throughout its operating range under rated conditions.

overvoltage factors are not known, clearances shall be derived from Table 5, IEEE 516-2003, phase-to-ground distances, with appropriate altitude correction factors applied. **R1.2.2.2** Where transmission system transient overvoltage factors are known, clearances shall be derived from Table 7, IEEE 516-2003, phase-to-phase voltages, with appropriate altitude correction factors applied **R1.3.** All personnel directly involved in the design and implementation of the TVMP shall hold appropriate qualifications and training, as defined by the Transmission Owner, to perform their duties. **R1.4.** Each Transmission Owner shall develop mitigation measures to achieve sufficient clearances for the protection of the transmission facilities when it identifies locations on the ROW where the Transmission Owner is restricted from attaining the clearances specified in Requirement 1.2.1. **R1.5.** Each Transmission Owner shall establish and document a process for the immediate communication of vegetation conditions that present an imminent threat of a transmission line outage.		
R2. The Transmission Owner shall create and implement an annual plan for vegetation management work to ensure the reliability of the system. The plan shall describe the methods used, such as manual clearing, mechanical	**R2.** Reduced the verbiage, moved the "create" function and other documentation activities/actions into new R1.section 1.3, and moved the implementation function into R9.	**R9.** Each Transmission Owner shall implement its annual work plan for vegetation management to accomplish the purpose of this standard.

clearing, herbicide treatment, or other actions. The plan should be flexible enough to adjust to changing conditions, taking into consideration anticipated growth of vegetation and all other environmental factors that may have an impact on the reliability of the transmission systems. Adjustments to the plan shall be documented as they occur. The plan should take into consideration the time required to obtain permissions or permits from landowners or regulatory authorities. Each Transmission Owner shall have systems and procedures for documenting and tracking the planned vegetation management work and ensuring that the vegetation management work was completed according to work specifications.		
R3. The Transmission Owner shall report quarterly to its RRO, or the RRO's designee, sustained transmission line outages determined by the Transmission Owner to have been caused by vegetation.	Reporting requirements are now located in the compliance section, A**dditional Compliance Information,** as required by "NERC Standard format", specifically, reporting outages in and of itself does not improve reliability.	**Additional Compliance Information** The Transmission Owner shall report quarterly to its Regional Entity, or the Regional Entity's designee, Sustained Outages of its transmission lines determined by the Transmission Owner to have been caused by vegetation, including the following: The name of the circuit(s), the date, time and duration of the outage; a description of the cause of the outage; other pertinent comments; and any countermeasures taken by the Transmission Owner, and Sustained Outage Category based on the following: • Category 1A — Grow-ins: Sustained Outages caused by vegetation growing into applicable lines that are identified as an element of an IROL (or Major WECC Transfer Path) by vegetation inside and/or outside of the Active Transmission Line ROW; • Category 1B — Grow-ins: Sustained Outages caused by vegetation growing into applicable lines but are not identified

		as an element of an IROL (or Major WECC Transfer Path) by vegetation inside and/or outside of the Active Transmission Line ROW; • Category 2 — Fall-ins: Sustained Outages caused by vegetation falling into lines from within the Active Transmission Line ROW; • Category[2] 4 — Blowing together: Sustained Outages caused by vegetation and lines blowing together from within the Active Transmission Line ROW.
R4. The RRO shall report the outage information provided to it by Transmission Owner's, as required by Requirement 3, quarterly to NERC, as well as any actions taken by the RRO as a result of any of the reported outages.	This is now covered in the **Additional Compliance Information** as is appropriate for all reporting issues.	
NOTE: Below are new requirement in Version 2 that were not in Version 1 and were not mapped above.		
	The new Version 2 of the standard now has a separate requirement for documenting and implementing the imminent threat.	**R2.** Each Transmission Owner shall implement its imminent threat procedure when the Transmission Owner has actual knowledge of such a threat, obtained through normal operating practices
	The new Version 2 of the standard now has a separate requirement for documenting and implementing the Vegetation Inspections.	**R3.** Each Transmission Owner shall conduct Vegetation Inspections of all applicable lines (as measured in line miles) in accordance with the frequency specified in its transmission vegetation management program, unless constrained by natural disasters[5]. When constrained by a natural disaster, the Transmission Owner shall conduct the

[2] Category 3 reporting is eliminated.

		Vegetation Inspection(s) within 6 months or a period agreed to by its Regional Entity, whichever is greater
	The new Version 2 utilizes MVCD, a technically justifiable separation distance at which flashover will not occur, and applies it to real time observations to provide the clarity needed for field applications. The combination of choosing an effective maintenance strategy (R1 section 1.6), effective inspections (R3), and annual work performance (R9), will ensure a high level of reliability while imminent threat implementation (R2) and MVCD findings (R4) will provide the feedback to the Transmission Owner necessary to in make improvements in the overall maintenance of vegetation.	**R4.** Each Transmission Owner shall prevent encroachment of vegetation into the Minimum Vegetation Clearance Distances ("MVCD") listed in FAC-003-2-Attachment 1 for its applicable lines as observed in real-time operating between no-load and their Rating with the following exceptions:
	R5, R6, R7 and R8 explicitly state that sustained outages from vegetation are violations of this standard. This removes the implicit interpretation that is currently in Version 1. R5 and its companion R6 apply to grow-ins. R5 applies to the most significant circuits and is separated from R6 to allow application of the most appropriate VRF. R7 addresses blowing together and R8 addresses fall-ins.	**R5.** Each Transmission Owner shall prevent Sustained Outages of applicable lines that are identified as an element of an Interconnection Reliability Operating Limit (or Major WECC Transfer Path in the Western Interconnection) due to vegetation growing into a conductor operating between no-load and its Rating with the following exceptions: • Sustained Outages of applicable lines that result from natural disasters. • Sustained Outages of applicable lines that result from human or animal activity. **R6.** Each Transmission Owner shall prevent Sustained Outages of applicable lines that are not an element of an Interconnection Reliability Operating Limit (or Major WECC Transfer Path in the Western

		Interconnection) due to vegetation growing into a conductor operating between no-load and its Rating with the following exceptions: • Sustained Outages of applicable lines that result from natural disasters. • Sustained Outages of applicable lines that result from human or animal activity. **R7.** Each Transmission Owner shall prevent Sustained Outages of applicable lines due to the blowing together of vegetation and a conductor within an Active Transmission Line Right of Way (operating within design blow-out conditions) with the following exception: • Sustained Outages of applicable lines that result from natural disasters or wind-blown debris. **R8.** Each Transmission Owner shall prevent Sustained Outages of applicable lines due to vegetation falling into a conductor from within an Active Transmission Line Right of Way with the following exceptions: • Sustained Outages of applicable lines that result from natural disasters or wind-blown debris. • Sustained Outages of applicable lines that result from human or animal activity.
	Two separate and distinct elements in this standard were created to remove confusion about the difference between the TVMP (a document) and the annual work plan. The annual work plan documentation is in R1	**R9**. Each Transmission Owner shall implement its annual work plan for vegetation management to accomplish the purpose of this standard.

	section 1.3 and the implementation of the annual work plan is in R9,	
	In response to FERC order 693 and industry comment, the PC has been assigned as the appropriate functional entity to prepare the list of applicable lines below 200 kV.	**R10**. Each Planning Coordinator shall prepare and keep current, a list of lines that are operated below 200 kV, if any, which are subject to this standard. Each Planning Coordinator shall consult with its Transmission Owner(s) and neighboring Planning Coordinators to obtain input to develop the list.
	This requirement captures the methodology and the parameters to be used by each PC to assess the significance of sub 200 kV lines.	**R11.** Each Planning Coordinator shall develop and document its method for assessing the reliability significance of sub-200kV transmission lines whose loss would place the grid at an unacceptable risk of instability, separation, or cascading failures.

Unofficial Comment Form for Transmission Vegetation Management Standard FAC-003-2 (Project 2007-07)

Please **DO NOT** use this comment form. Please use the electronic comment form located at the link below to submit comments on the proposed standard. Comments must be submitted by **October 24, 2009**. If you have questions please contact Harry Tom at harry.tom@nerc.net.

http://www.nerc.com/filez/standards/Vegetation-Management_Project_2007-7.html

Opening Remarks:
The SDT appreciates the valuable responses provided by the industry and other stakeholders on this Standard revision. We have worked diligently, utilizing those comments and directives in FERC Order 693 to improve this revision.

Given the importance and complexity of this standard, the SDT felt it was appropriate to develop and provide a comprehensive Technical Reference Document (White Paper) to assist in the interpretation and application of this standard. This companion document is included in this posting of FAC-003-2.

We are optimistic that this Standard fully satisfies stakeholder concerns and FERC Order 693 and believe this version will be ready for balloting after this comment period.

Background Information:
The Vegetation Management Standard Drafting Team (SDT) prepared a proposed revision of FAC-003-1 in accordance with the scope as contained in the Standard Authorization Request (SAR). The SAR includes addressing FERC directives in Order 693. These included:

- Removal of 'fill in the blank' components where the Transmission Owner determines the requirement with no limits or direction. Examples include Clearance 1 and "personnel requirements" in version 1.
- Removal of references to the Regional Reliability Organization (RRO) and replacement with the correct designation of Regional Entity (RE).
- Application of new NERC Drafting Team Guidelines (DTG) to the standard. Examples include the replacement of the current compliance section with Violation Risk Factors (VRFs) and Violation Severity Levels (VSLs) as referenced in the Sanction Guidelines. Additionally, documentation and implementation elements are separated into different requirements in the proposed standard as required by the DTG.
- Address the applicability and appropriateness of IEEE 516 in determining clearance distances.
- Address applicability of this standard to sub 200kV lines that could place the grid at an unacceptable risk of instability, separation, or cascading failures.
- Address a minimum vegetation inspection frequency that accounts for local factors.
- Address applicability to federal lands.

The initial proposed revision was posted for industry comment during a public comment period from October 27, 2008 to November 25, 2008. The SDT received comments from 66 separate entities on the initial posting of this proposed standard revision. The completed

Consideration of Comments document spans 279 pages making it one of the largest comment documents for any of the NERC draft standards. There were 17 specific questions and a summary question in the posting.

After careful consideration of FERC Order 693 and all comments from the stakeholders, the Standards Drafting Team (SDT) made revisions to the proposed second in order to make it stronger, clearer and more practical for field implementation. These revisions are fully articulated in the mapping document and should be reviewed by the reader. The SDT also developed a Technical Reference Document (White Paper) to clarify the intent and purpose of each requirement found in FAC-003-2. Many of the significant revisions are, however, highlighted in the following:

The key difference between the current standard and this posting is the requirement that certain vegetation outages are violations of the standard (R5, R6, R7 and R8). These requirements, in a clear and unambiguous manner, address prevention of Sustained Outages due to vegetation.

Key differences between first posting and second posting of proposed FAC-003 -2 include:

- Replaced the Critical Clearance Zone (CCZ) concept found in R4 with a practical field measurement to address commenter's concerns.
- Eliminated the CCZ as the trigger of imminent threat in R2 to address commenters' concerns.
- Added a new part to Requirement R1 - TVMP (1.6) to address commenters' concerns regarding the elimination of Clearance 1. This change requires that the TO account for anticipated conductor movement.
- Developed VRFs and VSLs consistent with the NERC Drafting Team Guidelines.
- Created a second grow-in outage requirement to allow for different VRF levels based on the actual criticality of the line.

The SDT believes that this posting is an improvement over both the FAC 003-1 and the October 27, 2008 posting of FAC 003-2. The following illustrates examples of these improvements.

1. The purpose statement was shortened to be in line with the Drafting Team Guidelines for a more concise purpose statement. The various explanatory objectives in the current standard's Purpose statement are now addressed within the body of the requirements of this second revision.
2. Revised the purpose statement in response to comments about the use of the term Bulk Electric System.
3. The TVMP Requirement found in R1 was re-written to clarify that the objective of the TVMP is to improve reliability by preventing Sustained Outages due to vegetation.
4. Requirement R1, Part 1.6 now requires that the TO effectively describe the strategies used to prevent tree and conductor conflicts, replacing "Clearance 1".
5. Requirement R4 replaces the CCZ concept with a practical "real time" method of observing/measuring vegetation that could cause spark-over.
6. Requirement R2 eliminates the CCZ trigger for the Imminent Threat Process in favor of a more practical field implementation strategy.

7. Defined Vegetation Inspection as a NERC Glossary term. This definition recognizes that vegetation inspections can be performed concurrently with other transmission line inspections.
8. Defined Active Transmission Line Right-of-Way as NERC Glossary term. This limits applicability of the requirements to the portion of the ROW with active transmission facilities.
9. Established a minimum inspection frequency of one calendar year to address FERC concerns about inspection cycles. This also includes a provision to address impact of natural disasters on schedule attainment.
10. Clarified Applicability section to include all types of land ownerships to address FERC concerns identified in Order 693.
11. Established clear process and responsibility to identify and designate sub 200kV lines which will be subject to the provisions of this standard.
12. Developed VRFs in accordance with the Drafting Team Guidelines to better reflect impact/risk to the reliability of the grid.
13. Developed separate requirements for documentation and implementation of the Imminent Threat Process, Vegetation Inspections, and the Annual Work Plan in accordance with the Drafting Team Guidelines.
14. Replaced Clearance 2 with Minimum Vegetation Clearance Distance (MVCD) based on the Gallet equation. This removes the ambiguity about hypothetical versus real-time clearance while still accounting for conductor movement in R1, Part 1.6.
15. Replaced the Reliability Coordinator (RC) with the Planning Coordinator (PC) as the appropriate entity to designate applicable sub 200kV lines.
16. Clarified Interim Corrective Action Plan as "temporary" in nature when the TO is constrained from getting adequate clearance. The Interim Corrective Action Plan also replaces the term Mitigation Plan avoiding conflicts with the Compliance term "Mitigation Plan."
17. Eliminated the reporting requirement for Category 3 (fall-in from outside the ROW) outages.
18. Assigned new Sustained Outage reporting categories (1A, 1B, 2 and 4) which will allow tracking and trending to use historical outages.

Analysis of Industry Comments:
Disagreements were high for questions 1, 7, 11, and 15, with values of 52%, 47%, 57% and 94% respectively. Those disagreements related to the use of the term "Bulk Electric System" in the purpose statement, the identification of actions required of the Transmission Operator when implementing the imminent threat procedure in Requirement R1.4, the use of "approaching" the calculated boundary of the Critical Clearance Zone as the threshold for implementation of the imminent threat procedure in requirement R2, and the use of the calculated boundary of the Critical Clearance Zone as a surface for determining clearance violations in R4. The comments contained numerous suggestions for changes to address the disagreements. The other questions were given mostly agreeable remarks; however some changes were made based on those comments.

The SDT has posted its response to the comments submitted in response to the last draft of this standard. The team updated its Technical Reference to align with the changes made to the proposed standard, updated the "mapping" document, and added an implementation plan. Please review these documents and then answer the following questions.

***Please use the electronic comment form to submit your final responses to NERC.**

1. As stated in the background information above, in response to industry comments, the Requirement for documentation of a TVMP (the new R1) is revised. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

   ☐ Agree

   ☐ Disagree

   Comments:

2. As stated in the background information above, in response to industry comments, the Requirement for implementation of Imminent Threat process/procedure (the new R2) is revised. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

   ☐ Agree

   ☐ Disagree

   Comments:

3. As stated in the background information above, in response to industry comments, the Requirement for conducting Vegetation Inspections (the new R3) is revised. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

   ☐ Agree

   ☐ Disagree

   Comments:

4. As stated in the background information above, in response to industry comments, the Requirement for preventing vegetation encroachments (the new R4) is revised. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

   ☐ Agree

   ☐ Disagree

   Comments:

5. As stated in the background information above, in response to industry comments, the Requirement for preventing Sustained Outages due to grow-ins on IROL or Major WECC Transfer Paths (the new R5) is developed. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

   ☐ Agree

☐ Disagree

Comments:

6. As stated in the background information above, in response to industry comments, the Requirement for preventing Sustained Outages due to grow-ins on non-IROL or Major WECC Transfer Paths (the new R6) is developed. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

☐ Agree

☐ Disagree

Comments:

7. As stated in the background information above, in response to industry comments, the Requirement for preventing Sustained Outages due to blowing together of vegetation and transmission line conductors (the new R7) is developed. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

☐ Agree

☐ Disagree

Comments:

8. As stated in the background information above, in response to industry comments, the Requirement for preventing Sustained Outages due to fall-ins of vegetation (the new R8) is developed. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

☐ Agree

☐ Disagree

Comments:

9. As stated in the background information above, in response to industry comments, the Requirement for implementation of annual work plan (the new R9) is developed. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

☐ Agree

☐ Disagree

Comments:

10. As stated in the background information above, in response to industry comments, the Requirement for the preparation of list for sub 200kV transmission lines by the

Planning Coordinator (the new R10) is developed. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

☐ Agree

☐ Disagree

Comments:

11. As stated in the background information above, in response to industry comments, the Requirement for the Planning Coordinator to document method for identification of applicable sub-200kV transmission lines (the new R11) is developed. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

☐ Agree

☐ Disagree

Comments:

12. The SDT received suggestions from commenters to re-sequence the requirements contained in the standard to improve the logical flow of this document. The SDT submits for consideration a proposed alternative sequence. Do you agree with the proposed alternative sequencing? If not, please recommend a suggested sequence.

Proposed Alternative Sequence	Current Sequence	Description
R1	R11	PC to document method to determine sub 200kV lines
R2	R10	PC to prepare list of sub 200kV lines
R3	R1	Document TVMP
R4	R3	Conduct Vegetation Inspections
R5	R9	Implement Annual Work Plan
R6	R2	Implement Imminent Threat
R7	R4	Prevent Vegetation Encroachments
R8	R8	Prevent Fall-in Outages
R9	R7	Prevent Blow-in Outages
R10	R6	Prevent Grow-in Outages (non-IROL lines)
R11	R5	Prevent Grow-in Outages (IROL lines)

* If the standard is re-sequenced, it will be reflected in the next version.

☐ Agree

☐ Disagree

Comments:

13. The Implementation Plan proposes an effective date that gives entities at least a year to become fully compliant. Do you agree with this implementation plan? If not, please indicate what should be changed and indicate why.

☐ Agree

☐ Disagree

Comments:

14. Do you have further questions about the standard that the Technical Reference document (White Paper) does not clear up? If so, please elaborate and propose additions.

Comments:

15. As stated in the background information above, in response to industry comments, the applicability section is revised to replace Reliability Coordinator with Planning Coordinator. Do you agree with these changes? If not, please explain and propose an alternative.

☐ Agree

☐ Disagree

Comments:

16. As stated in the background information above, in response to industry comments, changes were made to the definitions. Do you agree with these changes? If not, please explain and propose an alternative.

☐ Agree

☐ Disagree

Comments:

17. When compared to Version 1, does this proposed Version 2 of the standard either maintain or improve overall electric reliability? Please provide a technical basis for your response?

☐ V2 Does maintain or improve overall reliability

☐ V2 Does not maintain or improve overall reliability

Comments:

18. Besides the comments you have already provided for the preceding questions, do you have further suggestions for improving this standard? If so, please elaborate.

Table of Contents

Introduction

This document is intended to provide supplemental information and guidance for complying with the requirements of Reliability Standard FAC-003-2. It is a supporting document and provides explanatory background to the requirements of the Standard. The intentions of the Standard Drafting Team in developing many key areas of this Revision are also explained in this document.

The purpose of the Standard is to improve the reliability of the electric transmission system by preventing those vegetation related outages that could lead to Cascading.

Compliance with the Standard is mandatory and enforceable.

Disclaimer

This supporting document may explain or facilitate implementation of reliability standard FAC-003-2 — Transmission Vegetation Management but does not contain any additional mandatory requirements subject to compliance review.

Definition of Terms

Active Transmission Line Right of Way* — A strip of land that is occupied by active transmission facilities. This corridor does not include the inactive Right of Way or unused part of the Right of Way intended for other facilities.

Examples of inactive or unused portions of corridors include:

1) The portions of the right of way acquired to accommodate future facilities. Power plant exits are examples where large rights of way are obtained for maximum corridor utilization and may currently have fewer lines constructed.
2) The portion of the right of way where corridor edge zones (i.e., buffer zones) are provided for vegetation to exist.
3) The portions of the right of way where double-circuit structures are installed but only one circuit is currently strung with conductors.
4) Portions of the right of way with deactivated transmission lines that are unavailable for service.

Vegetation Inspection** — The systematic examination of vegetation conditions on an Active Transmission Line Right of Way. This inspection may be combined with a general line inspection. The inspection includes the documentation of any vegetation that may pose a threat to reliability prior to the next planned inspection or maintenance work, considering the current location of the conductor and other possible locations of the conductor due to sag and sway for rated conditions.

*To be added to the NERC glossary of terms with final approval of this standard revision
** This term is listed in the NERC glossary of terms, but has been modified for the purposes of this standard and is to be modified in the NERC glossary of terms with final approval of this standard revision

Applicability of the Standard

4. *Applicability:*

Functional Entities:

- *Transmission Owner*
- *Planning Coordinator*

Facilities:

- *Transmission lines ("applicable lines") operated at 200kV or higher, and transmission lines operated below 200kV designated by the Planning Coordinator as being subject to this standard including but not limited to those that cross lands owned by federal[1], state, provincial, public, private, or tribal entities.*
- *Transmission lines operated below 200kV designated by the Planning Coordinator as being subject to this standard become subject to this standard 12 months after the date the Planning Coordinator initially designates the transmission line as being subject to this standard.*
- *Existing transmission lines operated at 200kV or higher which are newly acquired by a Transmission Owner and were not previously subject to this standard, become subject to this standard 12 months after the acquisition date of the transmissions lines.*

[1] EPAct 2005 section 1211c: *"Access approvals by Federal agencies"*

The reliability objective of this NERC Vegetation Management Standard ("Standard") is to prevent vegetation-related outages which could lead to Cascading by effective vegetation maintenance while recognizing that certain outages such as those due to vandalism, human errors and acts of nature are not preventable. Operating experience clearly indicates that trees that have grown out of specification could contribute to a cascading grid failure, especially under heavy electrical loading conditions.

Serious outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations. To properly reduce and manage this risk, it is necessary to apply the Standard to applicable lines on any kind of land or easement, whether they are Federal Lands, state or provincial lands, public or private lands, franchises, easements or lands owned in fee. For the purposes of the Standard and this technical paper, the term "public lands" includes municipal lands, village lands, city lands, and a host of other governmental entities.

The Standard addresses vegetation management along applicable overhead lines that serve to connect one electric station to another. However, it is not intended to be applied to lines sections inside the electric station fence or other boundary of an electric station or underground lines.

The Standard is intended to reduce the risk of Cascading involving vegetation. It is not intended to prevent customer outages from occurring due to tree contact with all transmission lines and voltages. For example, localized customer service might be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. However, this Standard is not written to address such isolated situations which have little impact on the overall Bulk Electric System. In fact, the inclusion of such a transmission line (which does not lead to the undesirable conditions listed in Requirement R11) on the Planning Coordinator's list of sub-200kV lines may constitute a violation of Requirement R11.

Vegetation growth is constant and always present. Unmanaged vegetation poses an increased outage risk when numerous transmission lines are operating at or near their Rating. This poses a significant risk of multiple line failures and Cascading. On the other hand, most other outage causes (such as trees falling into lines, lightning, animals, motor vehicles, etc.) are statistically intermittent. The probability of occurrence of these events is not dependent on heavy loads. There is no cause-effect relationship which creates the probability of simultaneous occurrence of other such events. Therefore these types of events are highly unlikely to cause large-scale grid failures.

In preparing the original vegetation management standard in 2005, industry stakeholders set the threshold for applicability of the standard at 200kV. This was because an unexpected loss of lines operating at above 200kV has a higher probability of initiating a widespread blackout or cascading outages compared with lines operating at less than 200kV. Thus, the 200kV threshold was an arbitrary proxy for those circuits whose Sustained Outage might lead to a Cascade.

The NERC vegetation management standard FAC-003-1 also allowed for application of the standard to "critical" circuits (critical from the perspective of initiating widespread blackouts or cascading outages) operating below 200kV. While the percentage of these circuits is relatively low, it remains a fact that there are sub-200kV circuits whose loss could contribute to a widespread outage. Given the very limited exposure and unlikelihood of a major event related to these lower-voltage lines, it would be an imprudent use of resources to apply the Standard to all sub-200kV lines. The drafting team, after evaluating several alternatives, selected the Planning Coordinator as the best entity to determine applicable lines below 200kV that are subject to this standard in a time horizon that best matches requirements for vegetation management methods.

Transmission Vegetation Management Program

R1. *Each Transmission Owner shall have a documented transmission vegetation management program that describes how it conducts work on its Active Transmission Line Rights of Way to prevent Sustained Outages due to vegetation, considering all possible locations the conductor may occupy under the effects of sag and sway throughout its operating range under rated conditions. The transmission vegetation management program shall: [Violation Risk Factor: Lower][Time Horizon: Long-term planning]*

M1. *The Transmission Owner has a documented transmission vegetation management program (paper or electronic copy of dated, current, in force document with specified elements) that describes how it conducts work on its Active Transmission Line Rights of Way to prevent Sustained Outages due to vegetation, considering all possible locations the conductor may occupy under the effects of sag and sway throughout its operating range under rated conditions. (R1)*

The purpose of the Standard is to prevent vegetation-related outages that can result in Cascading. Under Requirement R1, each Transmission Owner is required to have a transmission vegetation management program (TVMP) designed to control vegetation on the Active Transmission Line Right of Way. The TVMP is an important component of the Standard because it is the formal document that Transmission Owners use to manage vegetation to achieve the purpose of the Standard. An adequate TVMP formally establishes the guidelines that are used by the Transmission Owner to plan and perform vegetation work that is necessary to prevent transmission outages and minimize risk to the transmission system.

Requirement R1 is concerned with the content of the TVMP and supporting documents, but does not address implementation of the elements of the TVMP. Other requirements address implementation of the TVMP. For example, sub-part 1.2 requires Transmission Owners to specify a vegetation inspection frequency. However, sub-part 1.2 does not address implementation of the inspection. This is addressed in Requirement R3.

The numbered "Parts" of Requirement 1 are elements of Requirement 1 and, while these parts identify performance that is mandatory, these parts do not constitute separate Requirements. For assessing compliance, each requirement has a single Violation Risk Factor and a single set of Violation Severity Levels so that compliance is assessed with the requirement, "in total."

Methods to Control Vegetation

R1

> ***1.1*** *The transmission vegetation management program shall specify the methods that the Transmission Owner may use to control vegetation.*[2]

[2] *ANSI A300, Tree Care Operations — Tree, Shrub, and Other Woody Plant Maintenance – Standard Practices, while not a requirement of this standard, is considered to be an industry best practice.*

M1

> ***1.1*** *The Transmission Owner's transmission vegetation management program documentation specifies the methods that the Transmission Owner may use to control vegetation.*

Each Transmission Owner is required to specify the methods used to control vegetation on applicable lines in its transmission vegetation management program. The methods specified in the transmission vegetation management program under this requirement are the methods that will be applied to the development and implementation of the annual work plan (1.3 and R9).

The intent of Requirement R1, Part 1.1 is for the Transmission Owner to list and generally describe the vegetation management methods that are used on its Active Transmission Line Rights of Way. Transmission Owners are not required to deploy each of the methods listed in every situation. Nor are they required to provide a detailed description of each method, although these may exist in the Transmission Owner's specifications. Instead, the methods listed under this requirement are intended to provide a menu of vegetation management options that the Transmission Owner may deploy when developing and implementing its annual work plan based upon the many different circumstances that are typically encountered.

Pruning is an inefficient maintenance method. Removal is always superior to pruning in ensuring tree conflicts do not occur.

In general, the best management practice for the Transmission Owner is to exercise its maximum legal rights to achieve the objectives of the transmission vegetation management program. This minimizes the possibility of conflicts between energized conductors and vegetation. Since this is not always possible, the Transmission Owner's strategy should be to use its prescribed vegetation maintenance methods to work towards or achieve the maximum use of the Active Transmission Line Right of Way.

The following are several examples of how methods could be specified in the transmission vegetation management program under this requirement. These are offered as examples only and numerous other methods could be included in the transmission vegetation management program. More detailed descriptions would typically be included in the Transmission Owner's internal specifications and procedures. In summary, methods must be applied in a sound biological manner.

Mechanical Clearing — Remove all trees and brush in the Active Transmission Line Right of Way. Cut or mow all stumps to 3 inches or less above grade. De-limb and windrow on the edge of the right of way those larger trees that could be obstructive to other line maintenance activities.

Selective Mechanical Tree Removal — Selectively remove with chain saws or mechanized equipment all tall-growing species of trees, as listed in the specifications. Chemically treat the stumps of re-sprouting trees with the herbicide mixtures identified in the specification within one hour of making the cut. All low-growing species of shrubs and trees, as listed in the specification, will be preserved unless otherwise noted.

Low-Volume Foliar Selective Herbicide Treatment — Selectively treat with herbicide all tall-growing species of trees as listed in the specification which are less than ten feet in height, using the low-volume foliar herbicide mixture and application process listed in the specification. All low-growing species of shrubs and trees, as listed in the specification will be preserved unless otherwise noted.

Side Pruning — Prune trees adjacent to the Active Transmission Line Right of Way that have grown to an extent that they have encroached upon or will soon encroach upon the clearances listed in the specification. In cases where specified clearances can not be achieved due to Active Transmission Line Right of Way width restrictions, remove branches to prevent entry into the Active Transmission Line Right of Way.

ANSI A300 – Best Management Practices for Tree Care Operations

Transmission Owners have the option of adopting the procedures and practices contained in an industry-recognized ANSI Standard known as A300 for use as a central component of its vegetation management program. The following is a description of A300.

Introduction

Integrated Vegetation Management (IVM) is a best management practice conveyed in the American National Standard for Tree Care Operations, Part 7 (ANSI 2006) and the International Society of Arboriculture’s *Best Management Practices: Integrated Vegetation Management* (Miller 2007). IVM is consistent with the requirements in FAC-003-02, and it provides practitioners with what industry experts consider to be the most appropriate techniques to apply to electric right of way projects in order to exceed those requirements.

IVM is a system of managing plant communities whereby managers set objectives, identify compatible and incompatible vegetation, consider action thresholds, and evaluate, select and implement the most appropriate control method or methods to achieve set objectives. The choice of control method or methods should be based on their environmental impact and anticipated effectiveness, along with site characteristics, security, economics, current land use and other factors.

Planning and Implementation

Best management practices provide a systematic way of planning and implementing a vegetation management program. While designed primarily with transmission systems in mind, it is also

applicable to distribution projects. As presented in ANSI A300 part 7 and the ISA best management practices, IVM consists of 6 elements:

1) Set Objectives
2) Evaluate the Site
3) Define Action Thresholds
4) Evaluate and Select Control Methods
5) Implement IVM
6) Monitor Treatment and Quality Assurance

The setting of objectives, defining action thresholds, and evaluating and selecting control methods all require decisions. The planning and implementation process is cyclical and continuous, because vegetation is dynamic and managers must have the flexibility to adjust their plans. Adjustments may be made at each stage as new information becomes available and circumstances evolve.

Set Objectives

Objectives should be clearly defined and documented. Examples of objectives can include promoting safety, preventing outages caused by vegetation growing into electric facilities and minimizing them from trees growing outside the right of way, maintaining regulatory compliance, protecting structures and security, restoring electric service during emergencies, maintaining access and clear lines of sight, protecting the environment, and facilitating cost effectiveness.

Objectives should be based on site factors, such as workload and vegetation type, in addition to available human, equipment and financial resources. They will vary from utility to utility and project to project, depending on line voltage and criticality, as well as topographical, environmental, fiscal and political considerations. However, where it is appropriate, the overriding focus should be on environmentally-sound, cost effective control of species that potentially conflict with the electric facility, while promoting compatible, early successional, sustainable plant communities.

Work Load Evaluations

Work-load evaluations are inventories of vegetation that could have a bearing on management objectives. Work load assessments can capture a variety of vegetation characteristics, such as location, height, species, size and condition, hazard status, density and clearance from conductors. Assessments should be conducted considering voltage, conductor sag from ambient temperatures and loading, and the potential influence of wind on line sway.

Evaluations can be comprehensive or point sample, and can be done to obtain information on an entire program or an individual project. Comprehensive evaluations account for vegetation that could potentially affect management objectives, including hazard trees. Program-level comprehensive evaluations can be made of all target vegetation on a system, while project-level evaluations focus on vegetation relevant to a specific job. Comprehensive evaluations provide the advantage of supplying a complete set of data upon which to base management decisions. On the other hand, comprehensive surveys can be impractical for utilities with large numbers of trees, limited human and financial resources, or both.

Point sampling offers an alternative for utilities for which comprehensive inventories are impractical. Point sampling is cost effective, and has a proven track record for reasonable accuracy. A common method involves dividing a management area (a system or project) into equal-sized units and selecting a random sample sufficient to statistically represent the total work quantity. Random selection eliminates the chance of bias on the part of the investigator. Every plant or plant community of interest within each selected area is inventoried, with collected data used to forecast the total workload.

Evaluate and Select Control Methods

Control methods are the process through which managers achieve objectives. The most suitable control method best achieves management objectives at a particular site. Many cases call for a combination of methods. Managers have a variety of controls from which to choose, including manual, mechanical, herbicide and tree growth regulators, biological, and cultural options.

Manual Control Methods

Manual methods employ workers with hand-carried tools, including chainsaws, handsaws, pruning shears and other devices to control incompatible vegetation. The advantage of manual techniques is that they are selective and can be used where others may not be. On the other hand, manual techniques can be inefficient and expensive compared to other methods. If pruning is necessary, it should comply with ANSI A300 Part 1 (ANSI 2001) and ISA best management practices for utility pruning (Kempter 2004).

Mechanical Control Methods

Mechanical controls are done with machines. They are efficient and cost effective, particularly for clearing dense vegetation during initial establishment, or reclaiming neglected or overgrown rights of way. On the other hand, mechanical control methods can be non-selective and disturb sensitive sites.

Tree Growth Regulator and Herbicide Control Methods

Tree growth regulators and herbicides are essential for effective vegetation management. Tree growth regulators (TGRs) are designed to reduce growth rates by interfering with natural plant processes. TGRs can be helpful where removals are prohibited or impractical by reducing the growth rates of some fast-growing species.

Herbicides control plants by interfering with specific botanical biochemical pathways. Herbicide use can control individual plants that are prone to re-sprout or sucker after removal. When trees that re-sprout or sucker are removed without herbicide treatment, dense thickets develop, impeding access, swelling workloads, increasing costs, blocking lines-of-site, and deteriorating wildlife habitat. Treating suckering plants allows early successional, compatible species to dominate the right of way and out-compete incompatible species, ultimately reducing work.

Cultural Control Methods

Cultural methods modify habitat to discourage incompatible vegetation and establish and manage desirable, early successional plant communities. Cultural methods take advantage of seed banks of native, compatible species lying dormant on site. In the long run, cultural control is the most desirable method where it is applicable.

A cultural control known as cover-type conversion provides a competitive advantage to short-growing, early successional plants, allowing them to thrive and eventually out-compete unwanted tree species for sunlight, essential elements and water. The early successional plant community is relatively stable, tree-resistant and reduces the amount of work, including herbicide application, with each successive treatment.

Wire-Border Zone

The wire-border zone technique is a management philosophy that can be applied through cultural control. W.C. Bramble and W.R. Byrnes developed it in the mid-1980s out of research begun in 1952 on a transmission right of way in the Pennsylvania State Game Lands 33 Research and Demonstration project (Yahner and Hutnik (2004).

The wire zone is the section of a utility transmission right of way directly under the wires and extending outward about 10 feet on each side. The wire zone is managed to promote a low-growing plant community dominated by grasses, herbs and small shrubs (under 3 feet in height at maturity). The border zone is the remainder of the right of way. It is managed to establish small trees and tall shrubs (under 25 feet in height at maturity). When properly managed, diverse, tree-resistant plant communities develop in wire and border zones. The communities not only protect the electric facility and reduce long-term maintenance, but also enhance wildlife habitat, forest ecology and aesthetic values.

Although the wire-border zone is a best practice in many instances, it is not necessarily universally suitable. For example, standard wire-border zone prescriptions may be unnecessary where lines are high off the ground, such as across low valleys or canyons, so the technique can be modified without sacrificing reliability.

One way to accommodate variances in topography is to establish different regions based on wire height. For example, over canyon bottoms or other areas where conductors are 100 feet or more above the ground, only a few trees are likely to be tall enough to conflict with the lines. In those cases, trees that potentially interfere with the transmission lines can be removed selectively on a case-by-case basis.

In areas where the wire is lower, perhaps between 50-100 feet from the ground, a border zone community can be developed throughout the right of way. Note that in many cases, conductor attachment points are more than 50 feet off the ground, so a border zone community can be cultivated near structures. Where the line is less than 50 feet off the ground, managers could apply a full wire-border zone prescription.

An environmental advantage of this type of modification is stream protection. Streams often course through the valleys and canyons where lines are likely to be elevated. Leaving timber or border zone communities in canyon bottoms helps shelter this valuable habitat, enabling managers to achieve environmentally sensitive objectives.

Implement Integrated Vegetation Management (IVM)

All laws and regulations governing IVM practices and specifications written by qualified vegetation managers must be followed. IVM control methods should be implemented on regular work schedules, which are based on established objectives and completed assessments. Work should progress systematically, using control measures determined to be best for varying conditions at specific locations along a right of way. Some considerations used in developing schedules include the importance and type of line, vegetation clearances, work loads, growth rate of predominant vegetation, geography, accessibility, and in some cases, time lapsed since the last scheduled work.

Clearances Following Work

Clearances following work should be sufficient to meet management objectives, including preventing trees from entering the Minimum Vegetation Clearance Distance, electric safety risks, service-reliability threats and cost.

Monitor Treatment and Quality Assurance

An effective program includes documented processes to evaluate results. Evaluations can involve quality assurance while work is underway and after it is completed. Monitoring for quality assurance should begin early to correct any possible miscommunication or misunderstanding on the part of crewmembers. Early and consistent observation and evaluation also provides an opportunity to modify the plan, if need be, in time for a successful outcome.

Utility vegetation management programs should have systems and procedures in place for documenting and verifying that vegetation management work was completed to specifications. Post-control reviews can be comprehensive or based on a statistically representative sample. This final review points back to the first step and the planning process begins again.

Summary

IVM offers among others, a systematic way of planning and implementing a vegetation management program as presented in ANSI A300 Part 7. This methodology enables a program to comply with the NERC *Transmission Vegetation Management Program* standard (FAC-003-2). Managers should select control options to best promote management objectives.

Vegetation Inspection Frequency

R1

> **1.2** *The transmission vegetation management program shall specify a Vegetation Inspection frequency of at least once per calendar year that takes into account local*[4] *and environmental factors.*

M1

> **1.2** *The Transmission Owner's transmission vegetation management program documentation specifies a Vegetation Inspection frequency of at least once per calendar year that takes into account local and environmental factors.*

[4] Local factors include items such as treatment cycle, extent and type of treatment, and their relationship to the normal growth rate.

The Transmission Owner's Transmission Vegetation Management Program (TVMP) shall specify the frequency of vegetation inspections. The inspection frequency is required to be at least once per calendar year. Transmission Owners should consider local and environmental factors that could warrant more frequent inspections. Such factors may include anticipated growth rates of the local vegetation, length of the growing season for the geographical area, limited Active Transmission Line Right of Way widths, rainfall amounts, etc.

Annual Plans

R1

> ***1.3.*** *The transmission vegetation management program shall require an annual work plan. An annual work plan shall:*
>
> ***1.3.1*** *Identify the applicable lines to be maintained*
>
> ***1.3.2*** *Identify the work to be performed and methods to be used*
>
> ***1.3.3*** *Be flexible to adjust to changing conditions and to findings from Vegetation Inspections. Adjustments to the plan within the year are permissible.*
>
> ***1.3.4*** *Take into consideration permitting and scheduling requirements from landowners or regulatory authorities.*

M1

> ***1.3*** *The Transmission Owner's transmission vegetation management program contains an annual work plan which:*
>
> ***1.3.1*** *Identifies the applicable lines to be maintained*
>
> ***1.3.2*** *Identifies the work to be performed and the methods used*
>
> ***1.3.3*** *Shows flexibility to adjust to changing conditions and to findings from Vegetation Inspections*
>
> ***1.3.4*** *Considers permitting and scheduling requirements from landowners or regulatory authorities*

The work plan is not intended to be a "span-by-span" detailed description of all work to be performed. It is intended to require the Transmission Owner to annually plan and schedule vegetation work to prevent encroachment into the Minimum Vegetation Clearance Distance. Work plans can vary in their level of detail.

The flexibility to adjust the annual work plan in response to changing conditions must not be invoked in a manner that adversely impacts reliability. The intent of the standard drafting team was to allow adjustments for changing conditions of the vegetation on the Active Transmission Line ROW, emergencies, and other significant changing conditions, and not for budget constraints. Annual work plan adjustments must always ensure the reliability of the electric transmission system.

This Standard requires that the annual work plan be flexible to allow the Transmission Owner to change priorities during the year as conditions or situations dictate. For example, weather conditions (drought) could make herbicide application ineffective during the plan year. Another situational variance could be a major storm that redirects local resources away from planned maintenance. This situation may also include complying with mutual assistance agreements by moving resources off the Transmission Owner's system to work on another system. Examples of adjustments may include deferrals or additions to the annual work plan.

The drafting team cites the following conditions that may result in adjustments to the annual work plan: abnormal weather such as drought, major storms, excessive rainfall, other environmental conditions such as infestation, disease, fire, etc. These conditions may be found as part of a special or scheduled Vegetation Inspection. Examples of annual work plan adjustments that are permitted may include revising the work plan priorities, rescheduling work to another time or selecting alternate vegetation control methods. Changes in land usage made by a property owner, such as timber clearing, may be another condition that warrants an adjustment.

When developing the annual work plan the Transmission Owner should allow time for procedural requirements to obtain permits to work on federal, state, provincial, public, tribal lands. In some cases the lead time for obtaining permits may necessitate preparing work plans more than a year prior to work start dates. Transmission Owners may also need to consider those special landowner requirements as documented in easement instruments.

Vegetation Imminent Threat Procedure

R1.

> ***1.4*** *The transmission vegetation management program shall require a process or procedure for response to an imminent threat of a vegetation-related Sustained Outage. The process or procedure shall specify actions which shall include communication of the threat to the responsible control center.*

M1.

> ***1.4*** *The Transmission Owner's transmission vegetation management program documentation specifies an imminent threat process or procedure for responding to imminent threats of a vegetation-related Sustained Outage including communication of the threat to the responsible control center.*

The term "imminent threat" refers to a vegetation condition which is likely to cause a Sustained Outage at any moment. An imminent threat requires immediate action by the Transmission Owner to alert the responsible control center (usually the Transmission Operator) that there is an increased probability of the occurrence of a Sustained Outage.

Two key elements of an acceptable imminent threat process or procedure are outlined below:

- Specify the vegetation-related conditions that warrant a response:

  Examples of these vegetation-related conditions include vegetation that is near or encroaching into the MVCD (growth issue) or vegetation that presents an imminent danger of falling into the transmission conductor (fall-in issue).

- Notify the responsible control center:

  So that the responsible control center holds situational awareness of known risks to the power system, the Transmission Owner has the responsibility to ensure the proper communication between field personnel and the responsible control center. This will allow the responsible control center to take the appropriate action until the threat is relieved. Appropriate actions may include, but are not limited to, a temporary reduction in the line loading, or switching the line out of service.

  The protocol for contacting the responsible control center should be defined. For example, some Transmission Owners' processes may require a call directly to the responsible control center, while other Transmission Owners may require a call to a supervisor or field forester who will in turn notify the responsible control center .

The urgency of vegetation-related imminent threats may be contrasted with the longer time frames of interim corrective action plans which are developed from a corrective action process as defined in Requirement R1, Part 1.5.

The imminent threat process or procedure should be implemented in terms of minutes or hours as opposed to a longer time frame for interim corrective action plans.

All serious growth or fall-in vegetation-related conditions are not necessarily considered imminent threats under the Standard. For example, some Transmission Owners may have a danger tree identification program that identifies for removal trees with the potential to fall near the line. These trees are not necessarily considered imminent threats under the Standard unless they pose an immediate fall-in threat.

Also, there can be situations involving vegetation that are not considered vegetation-related imminent threats under the Standard. For example, a logging operation on or near the Active Transmission Line Right of Way can pose an immediate threat of a sustained outage and result in the initiation of an imminent threat process in the same manner as the presence of a nearby crane or the notification of a hot-spot on a conductor connector. Although the logging threat in this example tangentially involves vegetation, it is not considered a vegetation-related imminent threat under the Standard.

Interim Corrective Action Process

R1.

1.5. *The transmission vegetation management program shall specify an interim corrective action process for use when the Transmission Owner is temporarily constrained from performing vegetation maintenance as planned.*

M1

1.5 *The Transmission Owner's transmission vegetation management program documentation specifies the interim corrective action process for use when the Transmission Owner is temporarily constrained from performing vegetation maintenance as planned.*

The intent of this requirement is to deal with situations that temporarily prevent the Transmission Owner from performing planned vegetation management work and, as a result, have the potential to put the transmission line at risk. This is not intended to address situations where an alternate work method can be substituted for the planned method. For example, a land owner may prevent the planned use of chemicals but allow the use of mechanical clearing. In this case the Transmission Owner can still perform work sufficient to eliminate the risk to the transmission line and does not need an interim corrective action plan. However, in situations where transmission line reliability is at risk due to a constraint and an alternate work method will not suffice, the Transmission Owner is required to develop a specific interim corrective action plan to mitigate the potential risk to the transmission line during the interim period.

The interim corrective action process should be flexible to provide a framework that can be applied over a wide range of situations to ensure line reliability.

Elements of the interim corrective action process include:

- Identifying locations where the Transmission Owner is constrained from performing planned vegetation maintenance work.
- Developing the specific plan to mitigate the risk associated with not performing the vegetation maintenance work as planned.
- Documenting and tracking the specific plan for each location.

Constraints to performing vegetation maintenance work as planned could result from legal injunctions filed by property owners, the discovery of easement stipulations which limit the Transmission Owner's rights, or other circumstances.

In developing a specific plan to mitigate the risk to the transmission line, the Transmission Owner could consider location-specific measures such as modifying inspection and/or maintenance intervals. Where a legal constraint would not allow any vegetation work, the interim corrective action plan could include limiting the loading on the transmission line.

The Transmission Owner should document and track each specific corrective action work plan by location. This location may be indicated as one span, one tree or a combination of spans on one property where the constraint is considered to be temporary.

Maintenance Strategies

R1.

> ***1.6*** *The transmission vegetation management program shall specify the maintenance strategies used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that Table 1 clearances in FAC-003-2-Attachment 1 are never violated. The maintenance strategies shall consider the sag and sway of the conductor throughout its operating range under rated conditions.*

M1.

> ***1.6*** *The Transmission Owner's transmission vegetation management program documentation specifies the maintenance strategies used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that Table 1 clearances in FAC-003-2-Attachment 1 are never violated. The maintenance strategies consider the sag and sway of the conductor throughout its operating range under rated conditions.*

For a Transmission Owner to develop a specific maintenance strategy, it is important to understand the dynamics of a line conductor's movement. First, the complexities inherent in observing and predicting conductor movement, particularly for field personnel, will be addressed. Then, some examples of maintenance strategies that take into account these complexities will be described.

The phrase in Requirement R1 Part 1.6 that reads ". . . ensure that Table 1 clearances in FAC-003-2-Attachment 1 are never violated." is intended to require the TO to design its maintenance strategies considering all possible locations of the conductor for rated design conditions, and not to suggest that a compliance violation exists merely by a possible future proximity of the conductor to vegetation. Requirement R4 indicates that a real-time MVCD encroachment will result in a compliance violation.

Understanding Conductor Position and Movement

The conductor's position in space at any point in time changes as a reaction to a number of different loading variables. Vertical and horizontal conductor movement results from variations in thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation. Physical loading applied to the conductor affects sag and sway by combining physical factors such as ice and wind loading

When calculating the range of conductor positions, the Transmission Owner should use the same design criteria and assumptions that the Transmission Owner uses when establishing Ratings. Typically, the greatest conductor movement is at mid-span. As the conductor moves through various positions, a spark-over zone surrounding the conductor moves with it. The radius of the spark-over zone may be found by referring to Table 1 ("Minimum Vegetation Clearance Distances") in the standard. For illustrations of this zone and conductor movements, Figures 4 through 6 on the following pages demonstrate these concepts. At the time of making a field observation, however, it is very difficult to precisely know where the conductor is in relation to its wide range of all possible positions. Therefore, Transmission Owners must adopt maintenance strategies that account for this dynamic situation.

Selecting a Maintenance Strategy

To maintain adequate separation between vegetation and transmission line conductors, the Transmission Owner must craft a maintenance strategy that keeps vegetation well away from the spark-over zone mentioned above. In fact, it is generally necessary to incorporate a variety of maintenance strategies. For example, one Transmission Owner may utilize a combination of routine cycles, traditional Integrated Vegetation Management (IVM) techniques and long-term planning. Another Transmission Owner may place a higher reliance on frequent inspections and quick remediation as opposed to a cyclical approach. This variation of strategies is further warranted when factors, such as terrain, legal and other constraints, vegetation types, and climates, are considered in developing a Transmission Owner's specific strategy to satisfying this requirement.

The following is a sample description of one combination of strategies which may be utilized by a Transmission Owner.

A Transmission Owner's basic maintenance strategy could be to remove all incompatible vegetation from the right of way if it has the right to do so and has no constraints. In mountainous terrain, however, this strategy could change to one where the Transmission Owner manages vegetation based on vegetation-to-conductor clearances, since it might not be necessary to remove vegetation in a valley that is far below.

If faced with constraints and assuming a line design with sufficient ground clearance, the Transmission Owner 's strategy could then be to allow vegetation such as fruit trees, but perhaps only up to a given height at maturity (perhaps 10 feet from the ground). If constraints cannot be overcome and if design clearances are sufficient, an exception to the Transmission Owner's 10-foot guideline might be made. Finally, if the Transmission Owner has chosen to utilize vegetation-to-conductor clearance distance methods, the Transmission Owner could have an inspection regimen in place to regularly ensure that any impending clearance problems are identified early for rectification.

Additional information regarding proper maintenance strategies for achieving and ensuring Table I clearances can be found in the "Methods to Control Vegetation" and "Vegetation Inspection Frequency" sections of this document.

For Consideration in Developing a Maintenance Strategy

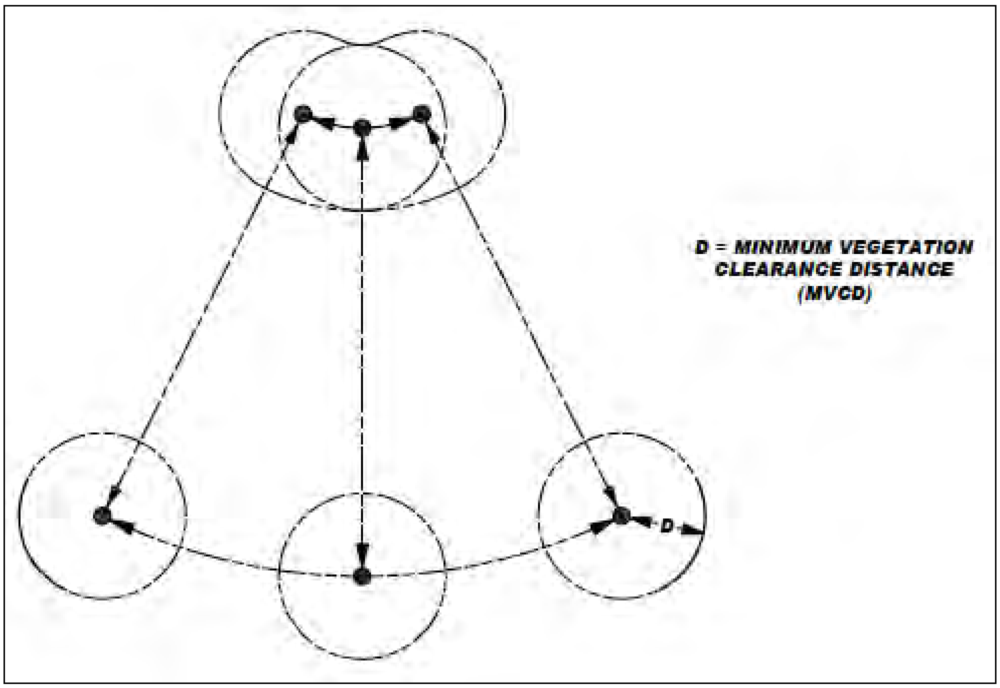

Figure 6

Implement Imminent Threat Procedure

R2. *Each Transmission Owner shall implement its imminent threat process or procedure when the Transmission Owner has actual knowledge of such a threat, obtained through normal operating practices. [Violation Risk Factor- Medium][Time Horizon – Real Time]*

M2. *The Transmission Owner has evidence of the implementation of its vegetation imminent threat process or procedure showing what was done with dates and activities accomplished. (R2)*

Each Transmission Owner must implement its imminent threat process or procedure when the Transmission Owner becomes aware of and confirms the existence of such a vegetation-related threat. The Transmission Owner could learn of the threat through a variety of normal operating practices, including routine line inspections, reports from landowners, observations made by public safety agencies or other utilities, etc. If a situation requires the Transmission Owner to implement its imminent threat process or procedure, it must retain some evidence of the threat and its response as outlined by Measure M2.

Conduct Vegetation Inspections

R3. *Each Transmission Owner shall conduct Vegetation Inspections of all applicable lines (as measured in line miles) in accordance with the frequency specified in its transmission vegetation management program, unless constrained by natural disasters[4]. When constrained by a natural disaster, the Transmission Owner shall conduct the Vegetation Inspection(s) within six months or a period agreed to by its Regional Entity, whichever is greater. [Violation Risk Factor: Medium][Time Horizon: Operations Planning]*

[4] Examples include, but are not limited to, earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods.

M3. *The Transmission Owner has evidence that it conducted Vegetation Inspections in accordance with Requirement R3.*

This requirement is the implementation requirement for the Vegetation Inspections identified in Requirement R1, Part 1.2. The Standard allows Vegetation Inspections to be performed in conjunction with general line inspections. The inspections will be measured in line miles based on the defined inspection frequency.

The measure of “line miles” was selected so that if a Transmission Owner were to fail to completely inspect its system according to its stated frequency, an appropriate Violation Severity Level would be determined based upon the percentage of the system that was actually inspected.

As an example, where a Transmission Owner operates 1,000 miles of 230kV transmission lines with a stated Vegetation Inspection frequency (Requirement R1, Part 1.2) of twice per year; this Transmission Owner will be responsible for inspecting all 1,000 miles of 230kV transmission lines two times during the calendar year. This would yield a “total line miles inspection plan” of 2,000 miles for that calendar year.

Continuing with this example, if the Transmission Owner completed inspections of more than 1900 miles or 95% of its 2,000-mile but not 100% of the full 2000 miles, then, a VSL of “Moderate” would be used in determining a sanction.

In the event that extensive resources are devoted to a lengthy service restoration following a natural disaster on its own system or by assisting another utility, the Transmission Owner is permitted to reasonably postpone its line inspections until the resource constraint is relieved.

Encroachments within the "Minimum Vegetation Clearance Distances"

R4. *Each Transmission Owner shall prevent encroachment of vegetation into the Minimum Vegetation Clearance Distances (MVCD) listed in FAC-003-2-Attachment 1 for its applicable lines as observed in real-time operating between no-load and their Rating, with the following exceptions: [Violation Risk Factor VRF= Medium][Time Horizon – Real Time]*

- *Encroachment into the MVCD listed in FAC-003-2-Attachment 1 resulting from natural disasters.*[4]
- *Encroachment into the MVCD listed in FAC-003-2-Attachment 1 resulting from human or animal activity.*[5]
- *Brief encroachment into the MVCD listed in FAC-003-2-Attachment 1 resulting from falling vegetation.*

[4] Examples include, but are not limited to, earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods.

[5] Examples include, but are not limited to, logging, animal severing tree, vehicle contact with tree, arboricultural activities or horticultural or agricultural activities, or removal or digging of vegetation.

M4. *The Transmission Owner has evidence from inspections that indicate there was no vegetation encroachment into the Minimum Vegetation Clearance Distances listed in FAC-003-2-Attachment 1 for its applicable lines as observed in real-time operating between no-load and their Rating, considering exceptions. (R4)*

This requirement indicates that if a Transmission Owner observes vegetation at a distance less than that prescribed in Table 1 of FAC-003-2-Attachment 1, it is in violation of this standard since sparkover is likely to occur. Requirement R4 refers to observation in "real time". This is an actual field observation or measurement of the conductor-to-vegetation distance and is not to be a calculated separation between the conductor and the vegetation

When possible encroachments of the MVCD are discovered through inspections or other means, the Transmission Owner must take appropriate action, which might include initiating vegetation management activities or implementation of its imminent threat process. If there is a confirmed clearance violation, the Transmission Owner must report to the Regional Entity as appropriate.

Certain exceptions are recognized in the Standard, including provisions for natural disasters and human or animal activity. Also, brief encroachments by falling vegetation are not considered to be a violation.

This requirement applies to transmission lines that are operating within their Rating. If a line is intentionally or inadvertently operated beyond its rating (potentially in violation of other standards), the occurrence of a clearance encroachment would not be a violation of this Standard. An encroachment of the MVCD that results from operation of a transmission line beyond its recognized Rating (for example emergency actions taken by an operator to protect an Interconnection) is beyond the scope of this standard.

Sustained Outages — Vegetation Growing Into Conductor

R5. *Each Transmission Owner shall prevent Sustained Outages*[6] *of applicable lines that are identified as an element of an Interconnection Reliability Operating Limit (IROL) (or Major WECC Transfer Path) due to vegetation growing into a conductor operating between no-load and its Rating, with the following exceptions: [Violation Risk Factor – High][Time Horizon – Real Time]*

- Sustained Outages of applicable lines that result from natural disasters.[4]
- Sustained Outages of applicable lines that result from human or animal activity.[5]

M5. *The Transmission Owner's self-certification reports are adequate evidence of no Sustained Outage of any applicable line that is identified as an element of an IROL (or Major WECC Transfer Path) due to vegetation growing into a conductor operating between no-load and its Rating. (R5)*

R6. *Each Transmission Owner shall prevent Sustained Outages*[6] *of applicable lines that are not an element of an IROL (or Major WECC Transfer Path) due to vegetation growing into a conductor operating between no-load and its Rating, with the following exceptions [Violation Risk Factor – High][Time Horizon – Real Time]*

- Sustained Outages of applicable lines that result from natural disasters.[4]
- Sustained Outages of applicable lines that result from human or animal activity.[5]

M6. *The Transmission Owner's self-certification reports are adequate evidence of no Sustained Outage of any applicable line that is not identified as an element of an IROL (or Major WECC Transfer Path) due to vegetation growing into a conductor operating between no-load and its Rating. (R6)*

[4] Examples include, but are not limited to, earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods.

[5] Examples include, but are not limited to, logging, animal severing tree, vehicle contact with tree, arboricultural activities or horticultural or agricultural activities, or removal or digging of vegetation.

[6] Multiple Sustained Outages on an individual line, if caused by the same vegetation, shall be considered as one outage regardless of the actual number of outages within a 24-hour period.

Vegetation grow-in events have contributed to several major blackouts and present a potential risk to the electric transmission system. Requirements R5 and R6 have been established to convey the seriousness of an outage caused by a vegetation grow-in and to distinguish between lines of differing impact to the system. Outages on certain lines are more likely to cause Cascading than on others. Accordingly, R5 applies to lines associated with IROLs (or major WECC transfer paths) and has been assigned a High Violation Risk Factor due to the higher probability of leading to a Cascading event. R6 applies to lines which are not associated with an

IROL (or major WECC transfer path) and has been assigned a Medium Violation Risk Factor, since outages on such lines are less likely to cause a Cascading event.

Planning Coordinators in planning time, and Reliability Coordinators in real time, determine operating limits for circuits or groups of circuits that may impact interconnected system reliability. The implication is that if these limits are exceeded; cascading, uncontrolled separation, instability, or voltage collapse might occur. Therefore these circuits or groups of circuits need to be protected from the risk of vegetation related outages. Planning Coordinators are required to identify circuits or groups of circuits that make up an IROL in NERC Standard FAC-010, Reliability Coordinators in FAC-011.

In the Western Interconnection there are some circuits or groups of circuits that do not meet the definition of an IROL, but nonetheless are very important to that Interconnection. Theses circuits or groups of circuits are classified as Major WECC Transfer Path(s) in the Western Interconnection. These are found in NERC Standard TOP-007-WECC-1.

It is important to note that for a Sustained Outage to be classified as a vegetation-related event, the conductor must be operating between no load and its Rating when the event occurs. Events that occur when the conductor is operating beyond its Rating would not be classified as vegetation-related Sustained Outages under the Standard.

Vegetation-related Sustained Outages that occur due to natural disasters are beyond the control of the Transmission Owner. These events are not classified as vegetation-related Sustained Outages and are therefore exempt from the Standard. Transmission lines are not designed to withstand the impacts of natural disasters such as tornadoes, hurricanes, severe ice loads, landslides, etc.

Sustained Outages due to human or animal activity are also beyond the control of the Transmission Owner are not classified as vegetation-related Sustained Outages and are therefore exempt from the Standard. Examples of these events may include new plantings of tall vegetation under the transmission line planted since the last Vegetation Inspection, tree contacts with line initiated by vehicles, logging activities, etc.)

Multiple Sustained Outages on an individual line can be caused by the same vegetation. Such events within a 24 hour period are considered to be a single vegetation-related Sustained Outage under the Standard. For example, a Sustained Outage caused by a tree could be mistakenly attributed to something else (e.g. contaminated insulator string, lightning, etc). After the apparent cause of the outage is addressed the line could be re-energized without the root cause being identified and removed. The transmission line could remain energized for a period of time while the thermal loading on the transmission line builds back to the point where the conductor contacts the same tree that caused the earlier Sustained Outage. These multiple outages resulting from the same tree would be considered as a single outage as long as all Sustained Outages occurred within a 24 hour period.

The Transmission Owner must self-certify each year that all vegetation-related Sustained Outages are documented and reported. If no vegetation-related Sustained Outages have occurred, a null report is sufficient documentation of compliance with these requirements.

Sustained Outages — Vegetation and Conductor Blowing Together

R7. *Each Transmission Owner shall prevent Sustained Outages[6] of applicable lines due to the blowing together of vegetation and a conductor within an Active Transmission Line Right of Way (operating within design blow-out conditions) with the following exception: [Violation Risk Factor - Medium][Time Horizon - Real Time]*

- Sustained Outages of applicable lines that result from natural disasters[4] or wind-blown debris.

[4] Examples include, but are not limited to, earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods.

[6] Multiple Sustained Outages on an individual line, if caused by the same vegetation, shall be considered as one outage regardless of the actual number of outages within a 24-hour period.

M7. *The Transmission Owner's self-certification reports are adequate evidence of no Sustained Outage of any applicable line due to the blowing together of vegetation and a conductor within the Active Transmission Line Right of Way. (R7)*

This requirement is intended to prevent vegetation-related risk of a Cascading event on the electric transmission system by requiring the Transmission Owner to manage vegetation such that a vegetation-related Sustained Outage due to blowing together of vegetation and conductor does not occur.

Again, for a Sustained Outage to be classified as a vegetation-related event, the conductor must be operating between no load and its Rating when the event occurs. Events that occur when the conductor is operating beyond its Rating are not classified as vegetation-related Sustained Outages under the Standard. Also, this requirement clarifies that the conductor and the vegetation must be within the Active Transmission Line Right of Way.

Vegetation-related Sustained Outages that occur due to natural disasters are beyond the control of the Transmission Owner. These events are not classified as vegetation-related Sustained Outages and are therefore exempt from the Standard. Transmission lines are not designed to withstand the impacts of natural disasters such as tornadoes, hurricanes, severe ice loads, landslides, etc. Additionally, Sustained Outages due to wind-blown debris, such as large limbs and branches, separated tree tops, etc., are exempt from the Standard.

Multiple Sustained Outages on an individual line can be caused by the same vegetation. Such events within a 24 hour period are considered to be a single vegetation-related Sustained Outage under the Standard. For example, a Sustained Outage caused by a tree could be mistakenly attributed to something else (e.g. contaminated insulator string, lightning, etc). After the apparent cause of the outage is addressed the line could be re-energized without the root cause being identified and removed. The transmission line could remain energized for a period of time while the thermal loading on the transmission line builds back to the point where the conductor contacts the same tree that caused the earlier Sustained Outage. These multiple outages resulting from the same tree would be considered as a single outage as long as all Sustained Outages occurred within a 24 hour period**.**

The Transmission Owner must self-certify each year that all vegetation-related Sustained Outages are documented and reported. If no vegetation-related Sustained Outages have occurred, a null report is sufficient documentation of compliance.

Sustained Outages — Vegetation Falling Into Conductor

R8. *Each Transmission Owner shall prevent Sustained Outages[6] of applicable lines due to vegetation falling into a conductor from within an Active Transmission Line Right of Way with the following exceptions: [Violation Risk Factor - Medium] [Time Horizon - Real Time]*

- *Sustained Outages of applicable lines that result from natural disasters[4] or wind-blown debris.*
- *Sustained Outages of applicable lines that result from human or animal activity.[5]*

[4] Examples include, but are not limited to, earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods.

[5]Examples include, but are not limited to, logging, animal severing tree, vehicle contact with tree, arboricultural activities or horticultural or agricultural activities, or removal or digging of vegetation.

[6] Multiple Sustained Outages on an individual line, if caused by the same vegetation, shall be considered as one outage regardless of the actual number of outages within a 24-hour period.

M8. *The Transmission Owner's self-certification reports are adequate evidence of no Sustained Outage of any applicable line due to vegetation falling into a conductor from within the Active Transmission Line Right of Way. (R8)*

This requirement is intended to prevent vegetation-related risk of a Cascading event on the electric transmission system by requiring the Transmission Owner to manage vegetation to prevent a vegetation-related Sustained Outage due to vegetation falling into a conductor from within the Active Transmission Line Right of Way.

Note that for a Sustained Outage to be classified as a vegetation-related event, the conductor must be operating between no load and its Rating when the event occurs. Events that occur when the conductor is operating beyond its Rating are not classified as vegetation-related Sustained Outages under the Standard. Also, this requirement clarifies that the conductor and the vegetation must be within the Active Transmission Line Right of Way.

Vegetation-related Sustained Outages that occur due to natural disasters are beyond the control of the Transmission Owner. These events are not classified as vegetation-related Sustained Outages and are therefore exempt from the Standard. Transmission lines are not designed to withstand the impacts of natural disasters such as tornadoes, hurricanes, severe ice loads, landslides, etc. Additionally, Sustained Outages due to wind-blown debris, such as large limbs and branches, separated tree tops, etc., are exempt from the Standard.

Sustained Outages due to human or animal activity are beyond the control of the Transmission Owner. These events would not be classified as vegetation-related Sustained Outages and are exempt from the Standard. Examples of these events may include new plantings of tall vegetation under the transmission line planted since the last Vegetation Inspection, tree contacts with line initiated by vehicles, logging activities, etc.

Multiple Sustained Outages on an individual line can be caused by the same vegetation. Such events are considered to be a single vegetation-related Sustained Outage under the Standard.

The Transmission Owner must self-certify each year that all vegetation-related Sustained Outages are documented and reported. If no vegetation-related Sustained Outages have occurred, a null report is sufficient documentation of compliance.

Implement Annual Work Plan

R9. *Each Transmission Owner shall implement its annual work plan for vegetation management to accomplish the purpose of this standard. [Violation Risk Factor: Medium] [Time Horizon: Operations Planning]*

M9. *The Transmission Owner has evidence that it is implementing, or has implemented, its annual work plan. An example of evidence is a paper or electronic copy of work plan and work records. (R9)*

This requirement sets the expectation that the work identified in the annual work plan (Requirement R1, Part 11.3) will be completed as planned.

Documentation or other evidence of the work performed typically consists of signed-off work orders, signed contracts, printouts from work management systems, spreadsheets of planned versus completed work, timesheets, work inspection reports, or paid invoices. Other evidence may include photographs, work inspection reports and walk-through reports.

Documentation is required when the annual work plan is adjusted or not completely implemented as originally planned. The reasons for the deferrals or changes and the expected completion date of postponed work should be documented.

The Transmission Owner's vegetation maintenance work necessary to implement the annual work plan is most effective when performed to the maximum extent allowed by any easement, fee simple and other legal rights. The Transmission Owner, therefore, should endeavor as a best practice to maintain its Active Transmission Line Right of Way to the full extent of its legal rights at all times and in all cases.

Designating Sub-200kV Lines

R10. *Each Planning Coordinator shall prepare and review annually, a list of lines that are operated below 200kV, if any, which are subject to this standard. Each Planning Coordinator shall consult with its Transmission Owner and neighboring Planning Coordinator to obtain to develop the list [Violation Risk Factor: Lower] [Time Horizon: Long-Term Planning]*

M10. *The Planning Coordinator has evidence that it consulted with its Transmission Owner(s) and neighboring Planning Coordinator(s), prepared and reviewed annually a list of designated sub-200kV transmission lines, if any, which are subject to this standard. (R10)*

Requirement R10 assigns to the Planning Coordinator the task of designating sub-200kV lines that are subject to this standard. The Planning Coordinator is appropriate because it operates within a time horizon that allows a vegetation manager to develop and implement the necessary vegetation management plan.

The Standard places the responsibility on the Planning Coordinator for the identification of specific sub-200kV circuits to which the Standard is to be applied. Identification of such sub-200kV circuits is to be done in consultation with the Planning Coordinator's Transmission Owners and neighboring Planning Coordinators. This is intended to ensure that the individual Transmission Owners at the two ends of interconnections will receive identical signals regarding applicability of the Standard to the line in question.

Planning Coordinators, using their methodologies described in R11, will need to conduct the necessary studies and identify candidate sub-200kV transmission lines for potential applicability under the Standard. The Planning Coordinators will next need to consult with its Transmission Owners and neighboring Planning Coordinators to resolve any differences in the selection of sub-200kV transmission lines of common interest. Finally, the Planning Coordinator will need to finalize, adopt, and issue the list of designated sub-200kV lines.

For audit purposes, Planning Coordinators can offer documentation that they have consulted with their Transmission Owners and neighboring Planning Coordinators and that they have reviewed annually the list of designated sub-200kV transmission lines that are subject to the Standard. Documentation may include dated letters, e-mails, spreadsheets, etc.

Documenting Method of Identifying Sub-200kV Lines

R11. *Each Planning Coordinator shall develop and document its method for assessing the reliability significance of sub-200kV transmission lines whose loss would place the grid at an unacceptable risk of instability, separation, or cascading failures. [Violation Risk Factor: Lower] [Time Horizon: Long-term Planning]*

M11. *The Planning Coordinator has documented evidence such as planning study criteria or other analysis used to develop its method for assessing the reliability significance of sub-200kV lines whose loss would place the grid at an unacceptable risk of instability, separation, or cascading failures. (R11)*

Requirement R11 assigns to the Planning Coordinator the task of documenting its methods for assessing the reliability significance of sub-200kV lines. The methods and requirements for assessing significance of transmission lines are complex and spelled out in other prevailing NERC standards. Essentially, however, these methods include activities such as load flow studies, contingency analyses, and transient and dynamic voltage stability studies. Through the use of such studies, the significance of each transmission line to the reliability of the system is determined. Because such activities are already being conducted by the Planning Coordinator(s) to meet other standards, the Planning Coordinator may choose to adopt the same methods for meeting Requirement R11.

Appendix One: Clearance Distance Derivation by the Gallet Equation

The Gallet Equation is a well-known method of computing the required strike distance for proper insulation coordination, and has the ability to take into account various air gap geometries, as well as non-standard atmospheric conditions. When the Gallet Equation and conservative probabilistic methods are combined, i.e. deterministic design, sparkover probabilities of 10^{-6} or less are achieved. This approach is well known for its conservatism and was used to design the first 500kV and 765kV lines in North America [1]. Thus, the deterministic design approach using the Gallet Equation is used for the standard to compute the minimum strike distance between transmission lines and the vegetation that may be present in or along the transmission corridor.

Method Explanation (Gallet Equation)

In 1975 G. Gallet published a benchmark paper that provided a method to compute the critical flashover (CFO) voltage of various air gap geometries [4]. The Gallet Equation uses various “gap factors” to take into account various air gap geometries. Various gap factor values are provided in [1]. If the vegetation in a transmission corridor, e.g. a tree, is assumed electrically to be a large structure then the CFO of such an air gap geometry can be computed for dry or wet conditions using a well established equation proposed by Gallet [1],[2],[4],

$$CFO_A = k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} \tag{1}$$

Where:

k_w is defined as the factor that takes into account wet or dry conditions (dry = 1.0 and wet = 0.96) and phase arrangement (multiply by 1.08 for outside phase), e.g. outside phase and wet conditions = (0.96)(1.08) = 1.037,

k_g is defined as the gap factor (1.3 for conductor to large structure),

D is the strike distance (m),

CFO_A is the CFO for the relative air density (kV).

δ is defined as the relative air density and is approximately equal to (2) where A is the altitude in km,

$$\delta = e^{-\frac{A}{8.6}} \tag{2}$$

$$m = 1.25G_0\left(G_0 - 0.2\right) \tag{3}$$

$$G_0 = \frac{CFO_s}{500 \cdot D} \tag{4}$$

$$CFO_s = k_w \cdot k_g \cdot \frac{3400}{1+\frac{8}{D}} \tag{5}$$

Where CFO_S is the CFO for standard atmospheric conditions (kV). Using (1)-(5), the required CFO_A can be computed using an iterative process.

Once the CFO_A is known, deterministic methods can be used to determine the required clearance distance. If we let the maximum switching overvoltage be equal to the withstand voltage of the air gap (CFO_A - 3σ) then the CFO_A can be written as (6).

$$CFO_A = \frac{V_m}{1 - 3\left(\frac{\sigma}{CFO_A}\right)} \tag{6}$$

Where:

V_m is equal to the maximum switching overvoltage, i.e. the value that has a 0.135% chance of being exceeded,

σ is the standard deviation of the air gap insulation,

CFO_A is the critical flashover voltage of the air gap insulation under non-standard atmospheric conditions.

The ratio of σ to the CFO_A given in (6) can be assumed to be 0.05 (5%) [1]. Thus, (6) can be written as (7).

$$CFO_A = \frac{V_m}{0.85} \tag{7}$$

Substituting (7) into (1) we arrive at (8).

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1 + \frac{8}{D}} \tag{8}$$

Equation 8 relates the maximum transient overvoltage, V_m, to the air gap distance, D. Using (8) to compute the required clearance distance for the specified air gap geometry (conductor to large structure) results in a probability of flashover in the range of 10^{-6}.

Transient Overvoltage

In general, the worst case transient overvoltages occurring on a transmission line are caused by energizing or re-energizing the line with the latter being the extreme case if trapped charge is present. The intent of FAC-003 is to keep a transmission line that is *in service* from becoming de-energized (i.e. tripped out) due to sparkover from the line conductor to nearby vegetation. Thus, the worst case scenarios that are typically analyzed for insulation coordination purposes (e.g. line energization and re-energization) can be ignored. For the purposes of FAC-003-2, the worst case transient overvoltage then becomes the maximum value that can occur with the line energized. Determining a realistic value of transient overvoltage for this situation is difficult because the maximum transient overvoltage factors listed in the literature are based on a switching operation of the line in question. In other words, these maximum overvoltage values (e.g. the values listed in [2], [3] and [5]) are based on the assumption that the subject line is being energized, re-energized or de-energized. These operations, by their very nature, will create the largest transient overvoltages. Typical values of transient overvoltages of in-service lines, as such, are not readily available in the literature because the resulting level of overvoltage is negligible compared with the maximum (e.g. re-energizing a transmission line with trapped charge). A conservative value for the maximum transient overvoltage that can occur anywhere along the length of an in-service ac line is approximately 2.0 p.u.[2]. This value is a conservative estimate of the transient overvoltage that is created at the point of application (e.g. a substation) by switching a capacitor bank without a pre-insertion device (e.g. closing resistors). At voltage levels where capacitor banks are not very common (e.g. 362kV), the maximum transient overvoltage of an "in-service" ac line are created by fault initiation on adjacent ac lines and shunt reactor bank switching. These transient voltages are usually 1.5 p.u. or less [2]. It is well known that these theoretical transient overvoltages will not be experienced at locations remote from the bus at which they were created; however, in order to be conservative, it will be assumed that all nearby ac lines are subjected to this same level of overvoltage. Thus, a maximum transient overvoltage factor of 2.0 p.u. for 242 kV and below and 1.4 p.u. for ac transmission lines 362 kV and above is used to compute the required clearance distances for vegetation management purposes.

The overvoltage characteristics of dc transmission lines vary somewhat from their ac counterparts. The referenced empirically derived transient overvoltage factor used to calculate the minimum clearance distances from dc transmission lines to vegetation for the purpose of FAC-003-2 will be 1.8 p.u.[3].

Example Calculation

An example calculation is presented below using the proposed method of computing the vegetation clearance distances. It is assumed that the line in question has a maximum operating voltage of 550 kV_{rms} line-to-line. Using a per unit transient overvoltage factor of 1.4, the result is a peak transient voltage of 629 kV_{crest}. It is further assumed that the line in question operates at a maximum altitude of 7000 feet (2.134 km) above sea level.

The required withstand voltage of the air gap must be equal to or greater than 629 kV_{crest}. Since the altitude is above sea level, (1) - (5) have to be iterated on to achieve the desired result. Equation (9) can be used as an initial guess for the clearance distance.

$$D_i = \frac{8}{\dfrac{3400 \cdot k_w \cdot k_g}{\left(\dfrac{V_m}{0.85}\right)} - 1} \tag{9}$$

For our case here, V_m is equal to 629 kV, k_w = 1.037 and k_g = 1.3. Thus,

$$D_i = \frac{8}{\dfrac{3400 \cdot k_w \cdot k_g}{\left(\dfrac{V_m}{0.85}\right)} - 1} = \frac{8}{\dfrac{3400 \cdot 1.037 \cdot 1.3}{\left(\dfrac{629}{0.85}\right)} - 1} = 1.535m \tag{10}$$

Using (2)-(5) and (8) the withstand voltage of the air gap is next computed. This value will then be compared to the maximum transient overvoltage.

$$CFO_S = k_w \cdot k_g \cdot \frac{3400}{1 + \dfrac{8}{D}} = 1.037 \cdot 1.3 \cdot \frac{3400}{1 + \dfrac{8}{1.535}} = 737.7kV \tag{11}$$

$$\delta = e^{-\frac{A}{8.6}} = e^{-\frac{2.134}{8.6}} = 0.78 \tag{12}$$

$$G_O = \frac{CFO_S}{500 \cdot D} = \frac{737.7}{(500)\cdot(1.535)} = 0.961 \tag{13}$$

$$m = 1.25 \cdot G_O(G_O - 0.2) = 1.25 \cdot 0.961(0.961 - 0.2) = 0.915 \tag{14}$$

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} = (0.85)(1.037)(1.3)(0.78)^{0.915}\left(\frac{3400}{1+\frac{8}{1.535}}\right) = 499.8kV \tag{15}$$

The calculated V_m is less than 629 kV; thus, the clearance distance must be increased. A few iterations using (2)-(5) and (8) are required until the computed $V_m \geq 629$ kV. For this case it was found that D = 1.978 m (6.49 feet) yielded V_m = 629.3kV. Using this clearance distance the following values were computed for the final iteration.

$$CFO_S = k_w \cdot k_g \cdot \frac{3400}{1+\frac{8}{D}} = 1.037 \cdot 1.3 \cdot \frac{3400}{1+\frac{8}{1.978}} = 908.5kV \tag{16}$$

$$\delta = e^{-\frac{A}{8.6}} = e^{-\frac{2.134}{8.6}} = 0.78 \tag{17}$$

$$G_O = \frac{CFO_S}{500 \cdot D} = \frac{908.5}{(500)\cdot(1.978)} = 0.919 \tag{18}$$

$$m = 1.25 \cdot G_O(G_O - 0.2) = 1.25 \cdot 0.919(0.919 - 0.2) = 0.825 \tag{19}$$

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} = (0.85)(1.037)(1.3)(0.78)^{0.825}\left(\frac{3400}{1+\frac{8}{1.978}}\right) = 629.3kV \tag{20}$$

Therefore, the minimum vegetation clearance distance for a maximum line to line ac operating voltage of 550 kV at 7000 feet above sea level is 1.978 m (6.49 feet). Table 1 provides calculated distances for various altitudes and maximum system operating ac voltages.

Implementation Plan for FAC-003-2

Prerequisite Approvals
There are no other Reliability Standards or Standard Authorization Requests (SARs), in progress or approved, that must be implemented before this standard can be implemented.

FAC-003-2 — Vegetation Management

Revision to Approved Standards and Definitions
There are no proposed revisions to requirements in other already approved standards associated with the approval of FAC-003-2.

The drafting team is proposing the following changes to definitions:

- **Retire the existing approved definition for "Vegetation Inspection:"**
  The systematic examination of a transmission corridor to document vegetation conditions.
- **Implement a new definition for "Vegetation Inspection:"**
  The systematic examination of vegetation conditions on an Active Transmission Line Right of Way. This inspection may be combined with a general line inspection. The inspection includes the documentation of any vegetation that may pose a threat to reliability prior to the next planned inspection or maintenance work, considering the current location of the conductor and other possible locations of the conductor due to sag and sway for rated conditions.
- **Implement a new definition for "Active Transmission Line Right of Way:"**
  A strip of land that is occupied by active transmission facilities. This corridor does not include the inactive or unused part of the Right of Way intended for other facilities.

FAC-003-1 and the existing definition of "Vegetation Inspection" will be retired and the new definitions for "Vegetation Inspection" and "Active Transmission Line Right of Way" will become effective at the same time that FAC-003-2 becomes effective.

Compliance with Standard
The standard applies to Transmission Owners and Planning Coordinators.

Effective Date
The effective date is the date entities are expected to meet the performance identified in this standard. The effective date (for all requirements), for jurisdictions where regulatory approval is required, is the first calendar day of the first calendar quarter one year after applicable regulatory authority. The effective date (for all requirements), for jurisdictions where no regulatory approval is required, is the first calendar day of the first calendar quarter one year following Board of Trustees adoption. The effective date allows the Planning Coordinator time to conduct the analyses needed to identify sub-200kV transmission lines that should be subject to this standard.

Standards Announcement

Comment Period Open
September 9–October 24, 2009

Now available at: http://www.nerc.com/filez/standards/Vegetation-Management_Project_2007-7.html

Project 2007-07: Transmission Vegetation Management

The Transmission Vegetation Management Standard Drafting Team is seeking comments on the following documents **until 8 p.m. EDT on October 24, 2009**:

- FAC-003-2 — Transmission Vegetation Management Program
- Mapping document (comparing FAC-003-1 to FAC-003-2)
- Implementation plan for FAC-003-2
- Technical reference document

This is the second comment period for proposed standard FAC-003-2. The drafting team revised the proposed standard, updated the technical reference document to align with the changes made to the proposed standard, updated the mapping document, and added an implementation plan. The drafting team has also posted its consideration of industry comments received during the previous comment period.

Instructions

Please use this electronic form to submit comments. If you experience any difficulties in using the electronic form, please contact Lauren Koller at Lauren.Koller@nerc.net. An off-line, unofficial copy of the comment form is posted on the project page: http://www.nerc.com/filez/standards/Vegetation-Management_Project_2007-7.html

Next Steps

The drafting team will draft and post responses to comments received during this period. The drafting team will also determine whether to post the standard for an additional comment period or seek approval from the Standards Committee to proceed to balloting.

Project Background

The project is an update to FAC-003-1, which was approved in 2006. The items identified for revision include the incorporation of FERC Order 693 comments related to applicability, procedural repairs to conform to the current standards format and development procedure, technical updates and guidance to address stakeholder suggestions, and the elimination of "fill-in-the-blank" components. More information is available on the project page.

Applicability of Standards in Project

Transmission Owner
Planning Coordinator
Specific facilities (see proposed standard for more information)

Standards Development Process

The Reliability Standards Development Procedure contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

For more information or assistance,
please contact Shaun Streeter at shaun.streeter@nerc.net or at 609.452.8060.

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Consideration of Comments on Vegetation Management FAC-003-2 Standard — Project 2007-07

The Vegetation Management Standard Drafting Team thanks all commenters who submitted comments on the proposed FAC-003-2 — Transmission Vegetation Management Standard. This standard was posted for a 30-day public comment period from September 10, 2009 through October 24, 2009. The stakeholders were asked to provide feedback on the standard through a special Electronic Comment Form. There were 66 sets of comments, including comments from 156 different people from more than 85 companies representing all of the 10 Industry Segments as shown in the table on the following pages.

http://www.nerc.com/filez/standards/Vegetation-Management_Project_2007-7.html

On January 14, 2010, the NERC Standards Committee endorsed the use of Project 2007-07 Vegetation Management as the prototype for the proof-of-concept for using the results-based criteria for developing a reliability standard. The results-based initiative is intended to focus the collective effort of NERC and industry participants on improving the clarity and quality of NERC reliability standards by developing performance, risk and competency-based requirements that accomplish a reliability objective through a defense-in-depth strategy, while eliminating documentation-driven requirements that do not have an impact on bulk power system reliability.

The Standards Committee directed the Vegetation Management SDT to stop work in refining its second draft of the Vegetation Management standard but to inform stakeholders on how the team had used stakeholder comments to refine the technical requirements carried over into draft 3 of the standard. The drafting team did not develop individual responses to the comments submitted by stakeholders on the second draft of FAC-003-2. Instead, the drafting team produced a special summary report that shows all the questions asked and provides a summary indicating how the drafting team used stakeholder comments submitted in response to that question. The special report is posted on the FAC-003 project page identified in the URL above under the title, “Summaries.”

Index to Questions, Comments, and Responses

The Industry Segments are:

1 — Transmission Owners
2 — RTOs, ISOs
3 — Load-serving Entities
4 — Transmission-dependent Utilities
5 — Electric Generators
6 — Electricity Brokers, Aggregators, and Marketers
7 — Large Electricity End Users
8 — Small Electricity End Users
9 — Federal, State, Provincial Regulatory or other Government Entities
10 — Regional Reliability Organizations, Regional Entities

1. As stated in the background information above, in response to industry comments, the Requirement for documentation of a TVMP (the new R1) is revised. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

Orange and Rockland Utilities, Inc.	Agree	Although ORU agrees that each TO should be required to have a documented TVMP, we recommend changing the wording in Sections 1.2 and 1.3.2.In Section 1.2, ORU recommends the wording to read, ‘Specify a Vegetation Inspection of at least once per calendar year.’ The additional wording regarding local and environmental factors may cause unnecessary confusion for some. In Section 1.3.2, the phrase ‘...and methods to be used...’ should be changed to read, ‘...and methods that may be used....’ to be consistent with the wording in Section 1.1. Also, the terms ‘operating range’ and ‘rated conditions’ in R1.6 should be clearly defined in the Standard and added to the NERC Glossary to avoid confusion.
Southern California Edison Company	Agree	Comments: SCE appreciates and agrees with the Drafting Team’s efforts and approach to revising R1. We agree with the assignment of a Violation Risk Factor of “Lower.” However, we would like to suggest certain revisions (included below) for the sake of clarity.R1. Each Transmission Owner shall institute a documented transmission vegetation management program that describes how it conducts work on its Active Transmission Line Rights of Way to prevent Sustained Outages due to vegetation, considering all possible locations the conductor may occupy under the effects of sag and sway throughout its operating range under rated conditions. The transmission vegetation management program shall specify: [Violation Risk Factor - Lower][Time Horizon -Long-term planning]1.1. The methodologies methods that the Transmission Owner may use to control vegetation.1.2. A Vegetation Inspection frequency of at least once per calendar year that takes into account local and environmental factors.1.3. An annual work plan that identifies:1.3.1. The applicable lines to be maintained.1.3.2. The work to be performed and methods to be used.1.3.3. Sufficient flexibility to adjust to changing conditions and to findings from Vegetation Inspections. Adjustments to the plan within the year are permissible. 1.3.4. Necessary permitting and scheduling requirements from landowners or regulatory authorities. 1.4. A process or procedure for responding to an imminent threat of a vegetation related Sustained Outage. The process or procedure shall specify actions that include communication of the threat to the responsible control center.1.5. An interim corrective action process for use when the Transmission Owner is constrained from performing planned vegetation maintenance. 1.6. The maintenance strategies used (such as minimum vegetation-to- conductor distance or maximum vegetation height) to ensure that Table 1 clearances in Attachment 1 are never violated. The maintenance strategies shall consider the sag and sway of the conductor throughout its operating range under rated conditions.
Edison Electric Institute	Agree	EEI generally agrees with changes to draft revised R1. In addition, EEI recommends that the SDT consider an alternative structure for the wording of R 1.6, where the current wording states ‘...specify...maintenance strategies ... to ensure that Table 1 clearances are never violated.’ To improve clarity and better reflect the intent for this requirement as stated in the Technical Paper, EEI suggests consideration of the language directly from the Technical Paper (p. 24). Thus, the requirement could be edited to state: “Maintenance strategies must be designed to a) meet the Table 1 clearances in Attachment 1 and b) consider all possible

Organization	Yes or No	Question 1 Comment
		locations of the conductor for rated design conditions." Companion M 1.6 could be revised to state: "Transmission Owner has evidence of its consideration of the range of all possible positions of conductors and line loading variables."FERC Order No. 693 does not direct NERC to establish minimum inspection cycles. Rather, FERC stated a goal for the Standard to '...assure that transmission owners conduct inspections at reasonable intervals.' (Order 693, P. 720) EEI recommends the SDT consider an alternative to the proposed annual inspection minimum requirement. In some regions of North America for some companies, or for parts of service territories for some companies, inspections for vegetation issues are irrelevant, or, needed significantly less frequently than an annual basis. At the other end of the spectrum, a company-wide annual requirement could inadvertently 'lower the bar.' On either side of the spectrum, a 'one size fits all' approach may have unintended consequences that challenge the ability for companies to maintain realistic inspection cycles. Therefore, EEI recommends that the SDT consider an alternative to R 1.2 to state that descriptions of inspection cycle frequencies should be included in the vegetation management program annual plan under R 1.3, including reasoning for inspection frequency basis. Should the SDT choose to not revise this requirement, EEI notes that provisions of the Standards Development Procedures manual, both for entity variance and regional variance for an area less than an Interconnection in size (Standards Development Procedures, p. 27), may be an alternative to the extent that vegetation issues within a company service territory, or a geographic area that includes parts of several company service territories, reflect conditions that do not require performance at the level stated within a requirement.Revised draft R 1.6 states that maintenance strategies in companies' vegetation management programs must consider 'sag and sway of the conductor throughout its operating range under rated conditions.'Since neither 'operating range' nor 'rated conditions' are defined NERC terms, this requirement could be open to broad interpretation. As a result, EEI recommends that the SDT consider alternatives that will reduce potential ambiguity. FAC-003 currently requires Clearance 2 to be maintained for 'all rated electrical operating conditions.' This suggests to EEI that vegetation clearances should be set in a manner such that required clearances will be maintained for conditions that include line loadings at both Normal and Emergency Ratings. EEI recommends that the SDT consider additional specificity. If the term 'operating range under rated conditions' is retained, it should be clearly defined. For example, the Requirement could include explicit references to Normal Ratings and Emergency Ratings used in other FAC -class Standards, coupled with a Measurement that a Registered Entity can demonstrate that Ratings applied to FAC-003 are the same as those used elsewhere.
National Grid	Agree	National Grid encourages the drafting team to leave the reference to A.N.S.I. A300 in the standard.
PacifiCorp	Agree	PacifiCorp thinks it is very important for improved reliability to directly reference ANSI A300, rather than relegate it to a footnote. ANSI A300 is science-based, and proven to be effective. Directly referencing adherence to A300 will encourage uniform compliance with FAC-003 across North America. Without this reference, PacifiCorp fears grid stability could be threatened by ineffective practices applied by utilities that lack sufficient expertise to manage their systems. PacifiCorp believes that those utilities could create future

Organization	Yes or No	Question 1 Comment
		blackouts due simply to a lack of understanding about proper utility vegetation management practices. Consequently, PacifiCorp urges direct reference to A300 within the standard. PacifiCorp believes eliminating clearance 1 will be detrimental to reliability. Clearance 1 is important for utilities to account for the dynamics of conductor movement and vegetative growth. This required analysis should lead to development of a more informed vegetation management program. Clearance 1 also gives utilities leverage with landowners, governmental agencies and local regulators to achieve the necessary operational clearances. If the only required clearance is the R4 Minimum Vegetation Clearance Distance, landowners and local regulators will push the utility to maintain a little more than those clearances rather than properly taking tree growth into account.
Pepco Holdings, Inc - Affiliates (PHI)	Agree	PHI understands that the SDT was responding to FERC Order 693, but feels there has been a one-size-fits-all approach. An approach as taken in PRC-005 could be used whereby the Transmission Owner could state its basis for vegetation maintenance cycles.Neither -operating range- nor -rated conditions- are defined NERC terms; this requirement could be open to broad interpretation. As a result, PHI recommends that the SDT consider alternatives that will reduce potential ambiguity. FAC-003 currently requires Clearance 2 to be maintained for -all rated electrical operating conditions-. This suggests that vegetation clearances should be set in a manner such that required clearances will be maintained for conditions that include line loadings at both Normal and Emergency Ratings. PHI recommends that the SDT consider additional specificity.
Xcel Energy	Disagree	(a) The requirement in R1.2 that mandates an annual inspection is too onerous. Xcel Energy urges the retention of the provision in the existing standard that allows the Transmission Owner to set the frequency of inspection. In some areas of the country, annual inspections may not be adequate. Yet in other areas, a longer inspection frequency may be perfectly reasonable and practical. Our point is that inspection frequency should not be treated as if it were “one size fits all”. If treated this way, we feel this could pose a risk to reliability and is not likely to be cost-effective. The Transmission Owner should be allowed some flexibility. However, if the drafting team disagrees and determines that an annual inspection is to be mandated, Xcel Energy believes that an exception to the annual inspection is appropriate when a non-subjective advanced technology such as LIDAR is utilized to achieve actual clearance distances. This places the Transmission Owner in a situation where it can rationally determine that the objectively measured distances result in a situation where an inspection need not be performed within the next year. It is suggested that R1.2 be revised to read as follows: Specify a Vegetation Inspection frequency of at least once per calendar year that takes into account local and environmental factors, unless the Transmission Owner, based on a non-subjective advanced technology, such as LIDAR, determines that a longer inspection period is appropriate.(b) R1.5: the word “temporarily” needs to be removed. Some constraints are not of a temporary nature. One example would be the U.S. Forest Service’s refusal to allow trimming or removal in accordance with the Transmission Owner’s vegetation management guidelines; another exists in the case where the easement or other instrument allowing the Transmission Owner to occupy the land does not allow vegetation management

Organization	Yes or No	Question 1 Comment
		in accordance with the Transmission Owner guidelines. In such situations, an interim corrective action process is appropriate but the word “temporarily” is not.(c) Section R1.6 should be reworded. The existing language is troublesome and confusing. A better alternative would be: "Maintenance strategies must be designed to (a) meet the table 1 clearances in attachment 1, and (b) consider all possible locations of the conductor for rated design conditions."
MRO NERC Standards Review Subcommittee	Disagree	A. The requirement in R1.2 that mandates an annual inspection is too onerous. The MRO NSRS urges the retention of the provision in the existing standard that allows the Transmission Owner to set the frequency of inspection. In some areas of the country, annual inspections may not be adequate. Yet in other areas, a longer inspection frequency may be perfectly reasonable and practical. Our point is that inspection frequency should not be treated as if it were “one size fits all”. If treated this way, the MRO NSRS feels this could pose a risk to reliability and is not likely to be cost-effective. The Transmission Owner should be allowed some flexibility. However, if the drafting team disagrees and determines that an annual inspection is to be mandated, the MRO NSRS believes that an exception to the annual inspection is appropriate when a non-subjective advanced technology such as LIDAR is utilized to achieve actual clearance distances. This places the Transmission Owner in a situation where it can rationally determine that the objectively measured distances result in a situation where an inspection need not be performed within the next year. Additionally, the MRO NSRS feels “that takes into account local and environmental factors” is explanatory text and is inappropriate for a requirement. It is suggested that R1.2 be revised to read as follows: Specify a Vegetation Inspection frequency of at least once per calendar year, unless the Transmission Owner, based on a non-subjective advanced technology, such as LIDAR, determines that a longer inspection period is appropriate.B. R1.5: the word “temporarily” needs to be removed. Some constraints are not of a temporary nature. For example, the U.S. Forest Service’s refusal to allow trimming or removal in accordance with the Transmission Owner’s vegetation management guidelines, or in the case where the easement or other instrument allowing the Transmission Owner to occupy the land does not allow vegetation management in accordance with the Transmission Owner guidelines. In such a situation, an interim corrective action process is appropriate but the word “temporarily” is not. What happens if it’s more than “temporarily”?C. R1.6 should be reworded. The existing language is troublesome and confusing. A better alternative would be: "Maintenance strategies must be designed to (a) meet the table 1 clearances in attachment 1, and (b) consider all possible locations of the conductor for rated design conditions." D. R1.3.3 states that the annual work plan shall....”Be flexible to adjust to changing conditions and to findings from Vegetation Inspections. Adjustments to the plan within the year are permissible.” The MRO NSRS is concerned that the wording would not allow a situation where the work plan is not entirely implemented “within the year”. There may be instances where you may be justified to postpone the work planned at the end of the year and must be moved into early part of the following year. We understand that this was the SDT’s intent; however, the text is not clear that it allows for such deferments. We recommend modifying the requirement to read, “Be flexible to adjust to changing conditions and to findings from Vegetation Inspections. Adjustments to the plan including work deferments into a subsequence

Organization	Yes or No	Question 1 Comment
		year's work plan are permissible." E. R1.4 states that a process or procedure for response to an imminent threat of vegetation-related sustained outage is required. The MRO NSRS believes that the term "imminent threat" should be a NERC defined term. F. (R1) Since neither "operating range" nor "rated conditions" are defined NERC terms, this requirement R1 could be open to broad interpretation. As a result, the MRO NSRS recommends that the SDT consider alternatives that will reduce potential ambiguity. FAC-003 currently requires Clearance 2 to be maintained for 'all rated electrical operating conditions.' This suggests that vegetation clearances should be set in a manner such that required clearances will be maintained for conditions that include line loadings at both Normal and Emergency Ratings. The MRO NSRS recommends that the SDT consider additional specificity. Or, we recommend these two terms ("operating range" and "rated conditions") be defined by the SDT.
Consolidated Edison Company of New York Inc.	Disagree	Although CECONY agrees that each TO should be required to have a documented TVMP, we recommend changing the wording in Sections 1.2 and 1.3.2.In Section 1.2, CECONY recommends the wording to read, 'Specify a Vegetation Inspection of at least once per calendar year.' The additional wording regarding local and environmental factors may cause unnecessary confusion for some. In Section 1.3.2, the phrase '...and methods to be used...' should be changed to read, '...and methods that may be used....' to be consistent with the wording in Section 1.1. Also, the terms 'operating range' and 'rated conditions' in R1.6 should be clearly defined in the Standard and added to the NERC Glossary.
FirstEnergy Corp	Disagree	Although we mostly agree with Req. R1, we offer the following suggestions for improvement:Main Req. R1 - We suggest replacing the phrase "that describes how it conducts work" with "that describes vegetation control methods on its Active Transmission Line Right Of Way". We feel our proposed change more accurately describes the intent of the TVMP.Part 1.2 - We feel the phrase "local and environmental factors" is ambiguous and open to varying interpretations. We suggest R1.2 read "Specify a Vegetation Inspection frequency of at least once per calendar year." (Delete the remainder of the sentence).Part 1.3.3 - Regarding the second sentence "Adjustments to the plan within the year are permissible", we feel it would be clearer if it was changed to simply "Adjustments to the plan are permissible". There may be situations beyond the entity's control, where the work plan is not entirely implemented "within the year". These situations would justify the work being postponed and completed in the early part of the following year. FE believes this change maintains the intent of the drafting team based on the reference White Paper that permits deferral of work for various reasons. Part 1.6 - FE believes that this sub-part of R1 is redundant and and suggests it be removed. The primary R1 requirement text already references the need to consider all possible conductor locations and the effects of swag and sway. Additionally, sub-parts 1.1 - 1.5 will achieve the outcome which 1.6 is seeking. Parts 1.1 - 1.5 identify the strategies used to ensure that Table 1 clearances are not violated, which is accomplished through specifying vegetation control methods, requiring an annual inspection, adjusting the work plan to incorporate the inspection findings, allowing time for permitting and scheduling, having an imminent threat procedure and requiring an interim corrective action process. Requiring the Transmission

Organization	Yes or No	Question 1 Comment
		Owner to meet 1.6 by either identifying vegetation to conductor clearance in addition to Table 1, removing all trees on the active ROW, or managing vegetation at a maximum height, as the SDT has suggested, adds specificity that is burdensome and may lead to greater potential for a Transmission Owner to violate its own TVMP, in addition to the requirements already in place. If the SDT wants to merely assure that the TVMP adheres to the clearances specified in Table 1, then we suggest removing Part 1.6, and adding the following wording after "documented transmission vegetation management program" in the body of the text of main Requirement R1: "that adheres to the minimum vegetation clearance distances specified in Table 1 of Attachment 1".
Northern Indiana Public Service Company	Disagree	As written, the definition of "Active Transmission Right of Way" leaves it up to each T.O. to determine what is "active" and what is "inactive" R.O.W. The dimensions or physical description of these areas for any given R.O.W. are not required to be defined or documented by the T.O. in the TVMP or anywhere else for that matter. This creates the possibility for a T.O. to avoid violations of this standard or to inappropriately reduce maintenance activities by simply declaring that any offending vegetation resides in an inactive area. For Example: The T.O. typically maintains a R/W clear of trees 75 ft. to the side of the conductor. However, over a period of time, the T.O. allows trees to encroach in from the sides in several spans so that there is only 50 ft. of side clearance. A tree 60 ft. to the side in this narrowed area falls into the conductors but the T.O. declares the tree to have fallen from an inactive R.O.W. area since it wasn't actively being maintained. This is a major loophole that needs to be addressed. Am in agreement with R1.1 through R1.4. Disagree with the inclusion in R1.5 of the term "temporarily" when there are constraints on completing vegetation maintenance work. It is unimportant whether or not a constraint is temporary or permanent. What is important is that work cannot be completed as planned. When this happens, the T.O. needs to use a corrective process or implement mitigation measures in response to the constraint. The Technical Reference provides examples of permanent constraints such as "the discovery of easement stipulations which limit the T.O.'s rights" along with temporary constraints. This acknowledges the fact that any constraint, regardless of duration, should be addressed through a corrective action process or mitigation plan.
Oncor Electric Delivery	Disagree	Comments: Part 1.3.3. allows adjustments to the plan within the year but does not allow work to be deferred until the next year. This deferral of work impacts 1.3.1, 1.3.2 (possibly 1.3.4) but does not impact the reliability of the line. “Following the Annual Plan” should accommodate a TO responding to changing conditions (to include permitting and scheduling) and should not necessarily place a TO out of compliance. Are adjustments made outside of the plan year considered to be “missing” in Part 1.3.3 by definition of High VSL for R1?Part 1.3.4 states a TO should consider permitting and scheduling requirements in developing their annual plan. What if a TO took into consideration these requirements and the timing of these issues took longer than anticipated? These types of variables may result in the deferral of some line work until the next year. Requirement 1.3 should clarify what the compliance status of a TO if plan specified line work was not implemented that year due to permitting and scheduling issues?Consider: Adjustments to the plan within

Organization	Yes or No	Question 1 Comment
		the year are permissible. This could be inserted at 1.3 to cover all parts or just 1.3.3 and 1.3.4. In its current state, only 1.3.3 (Changes to conditions and Findings from Vegetation Inspections) is addressed.
Vegetation Management Team	Disagree	Comments: Disagree with R1.2 - Inspection Frequency. Very prescriptive. Please consider allowing TO's to select the frequency that best fits their requirements. BGE currently defines their inspection frequency as annually during the non-growing season, October 1 to May 1. Under the proposed language scheduling would be very challenging. Disagree with 1.3.3 which states that the annual work plan shall "Be flexible to adjust to changing conditions and to findings from vegetation inspections. Adjustment to the plan within the year are permissible."This wording would not allow a situation where the work plan is not entirely implemented "within the year". There may be times where one may be justified to postpone work that is planned for the end of the year to be moved to the first part of the following year. We suggest removing the words "within the year" from R.1.3.3Disagree with R1.6 and M1.6 The purpose of the TVMP is to prevent vegetation related outages and improve the reliability of the electric system. The imminent threat provision allows for a procedure to address imminent threats before they become violations. (R1.4). Therefore, as long as the TO follows the imminent threat procedure, then a violation will not result. A violation will result only if the TO does not have an imminent threat procedure or fails to implement that procedure. Merely having an imminent threat is not a violation. By comparison, the new draft states any observed encroachments are reportable violations because the requirements do not permit a procedure to address encroachments. (See R1.6, R3. R4). The better approach would be to require the remediation of encroachments according to a TVMP but not make every found encroachment a violation. An encroachment is not necessarily "likely to cause a Sustained Outage at any moment," the level of severity required to be an imminent threat. (p.20). It is logical to conclude that imminent threats are more severe than encroachments. In fact, the technical report states that an encroachment due to operation of a transmission line beyond its recognized rating is beyond the scope of R4, the requirement for prevention of encroachments. (p.31). If this is the case, just like the process by which the TO is given the opportunity to address imminent threats, encroachments should also be addressed via a pre-determined process before becoming a violation of the standard. Further the requirement as drafted is a disincentive to deploy more sophisticated tools to identify threats to its system, such as software-enabled LiDAR Therefore, we suggest the following changes to the requirements: R1.6: require a process or procedure for response when any [REMOVE: specify the maintenance strategies used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that] Table 1 clearances in FAC-003-2-Attachment 1 are never violated are encroached upon.M1.6: The Transmission Owner's transmission vegetation management program documentation specifies [REMOVE: the maintenance strategies used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that] an encroachment process or procedure for responding if any Table 1 clearances in FAC-003-2-Attachment 1 [REMOVE: are never violated] are encroached upon. The maintenance strategies consider the sag and sway of the conductor throughout its operating range under rated conditions.

Organization	Yes or No	Question 1 Comment
Hydro-Quebec TransEnergie (HQT)	Disagree	Each TO should be required to have a documented TVMP. Recommend changing the wording in Sections 1.2 and 1.3.2.In Section 1.2, recommend changing the wording to read, ‘Specify a Vegetation Inspection frequency.’ The minimum frequecy should be left to the TO according to its system and environment characteristics. also, the additional wording regarding local and environmental factors may cause unnecessary confusion for some. In Section 1.3.2, the phrase ‘...and methods to be used...’ should be changed to read, ‘...and methods that may be used....’ to be consistent with the wording in Section 1.1. Also, the terms ‘operating range’ and ‘rated conditions’ in R1.6 should be clearly defined in the Standard and added to the NERC Glossary to avoid confusion. There is an inconsistency between R1.2 and R3. R1.2 requires the TO to carry out inspections at least once per calendar year. R3 requires the TO to carry out inspections per the frequency defined in its vegetation management program. It is preferred that the TO be allowed to specify the frequency and timing as stated in R3. Once per calendar year is not sensitive to local and environmental factors. For example, facilities in the Northeast are located in an environment where there is a long (7-8 month) dormant period -vegetation does not grow. Specify a frequency of one inspection per dormant period. This inspection could take place between September and April annually. In one dormant period we might inspect in November and inspect again 14 months later in January. We would meet the inspection need per R3, but fail to have inspected in a calendar year, thus violating R1.2. Other TO’s may be located in parts of the country with little or no vegetation and not need a once per calendar year inspection. Thus, R1.2 should allow the TO to specify an inspection program that is sensitive to local and environmental factors, not the calendar.
Independent Electricity System Operator	Disagree	Each TO should be required to have a documented TVMP. Recommend changing the wording in Sections 1.2 and 1.3.2.In Section 1.3.2, the phrase ‘...and methods to be used...’ should be changed to read, ‘...and methods that may be used....’ to be consistent with the wording in Section 1.1. Also, the terms ‘operating range’ and ‘rated conditions’ in R1.6 should be clearly defined in the Standard and added to the NERC Glossary to avoid confusion. There is an inconsistency between R1.2 and R3. R1.2 requires the TO to carry out inspections at least once per calendar year. R3 requires the TO to carry out inspections per the frequency defined in its vegetation management program. It is preferred that the TO be allowed to specify the frequency and timing as stated in R3. Once per calendar year is not sensitive to local and environmental factors. 		located in parts of the country with little or no vegetation and not need a once per calendar year inspection. Thus, R1.2 should allow the TO to specify an inspection program that is sensitive to local and environmental factors, not the calendar.
American Transmission Company	Disagree	FERC Order No. 693 does not direct NERC to establish minimum inspection cycles. Rather, FERC stated a goal for the Standard to '...assure that transmission owners conduct inspections at reasonable intervals.' (Order 693, P. 720)ATC recommends that that the SDT drop the "once per year" language from the requirement and replace it with the following language:"Document a Vegetation Inspection frequency that considers local and environmental factors." ATC believes that this language is in alignment with Commission's Order 693 and responsive to maintaining system reliability.The current language a) limits the ability of an entity to set a longer inspection cycle if its local / environmental and b) requires entities to justify the once per year cycle. ATC believes that the SDT needs to address this concern by making modifications to the requirement in order to prevent entities from allocate funds on efforts that do not benefit the BPS. R 1.3.3 states that the annual work plan shall...."Be flexible to adjust to changing conditions and to findings from Vegetation Inspections. Adjustments to the plan within the year are permissible."ATC is concerned that the wording would not allow a situation where the work plan is not entirely implemented "within the year". There may be instances where you may be justified to postpone the work planned at the end of the year and must be moved into early part of the following year. ATC recommends removing the words "within the year "in R1.3.3.R 1.4 states that a process or procedure for response to an imminent threat of vegetation-related sustained outage is required. ATC believes that the term "imminent threat" should be a NERC defined term. An alternate option is to include the following language "imminent threat as defined by the entity". This makes it clear that the entity is allowed to define the term. ATC recommends that the SDT consider an alternative structure for the wording of R 1.6, where the current wording states '...specify...maintenance strategies ... to ensure that Table 1 clearances are never violated.'To improve clarity and better reflect the intent for this requirement as stated in the Technical Paper, ATC suggests consideration of the language directly from the Technical Paper (p. 24). Thus, the requirement could be edited to state: "Maintenance strategies must be designed to a) meet the Table 1 clearances in Attachment 1 and b) consider all possible locations of the conductor for rated design conditions."R 1.6 states that maintenance strategies in companies' vegetation management programs must consider 'sag and sway of the conductor throughout its operating range under rated conditions.' Since neither 'operating range' nor 'rated conditions' are defined NERC terms, this requirement could be open to broad interpretation. As a result, ATC recommends that the SDT consider alternatives that will reduce potential ambiguity. FAC-003 currently requires Clearance 2 to be maintained for 'all rated electrical operating conditions.' This suggests that vegetation clearances should be set in a manner such that required clearances will be maintained for conditions that include line loadings at both Normal and Emergency Ratings. ATC recommends that the SDT consider additional specificity.

Organization	Yes or No	Question 1 Comment
JEA	Disagree	Please review the work being done by the ad hoc committee headed by Gerry Cauley that is attempting to guide standard development towards results or performance based requirements. It seems that vegetation management can be handled by this approach and that the paperwork requirement for a documented policy produces a heavy paperwork burden without requisite benefit to reliability added. However, the requirement for a documented procedure for "Imminent Threats" is appropriate as this is in essense an emergency response planning requirement. The requirement for an annual work plan is also appropriate as it is a requirement to demonstrate that appropriate planning is being done to meet the objectives of this standard.
Public Service Co. of New Mexico	Disagree	PNM prefers the Clearance 1/Clearance 2 setup. PNM does not like the MVCD classification as it implies - to the general public - that the MVCD is the only clearance needed. The distances are extremely small. We as a utility company realize this is only the "minimum" distance however it will not be interpreted that way by others outside our industry. Either go back to the Clearance 1 & 2 designation or change the MVCD name to illustrate the criticality of these clearances. Suggestions: Critical Vegetation Clearance Distance or Imminent Threat Vegetation Clearance Distance.Secondly, PNM believes there needs to be some sort of minimum qualifications for those individuals responsible for development and implementation of TVMP.
Manitoba Hydro	Disagree	R 1.2 states that the TVMP shall “Specify a Vegetation Inspection frequency of at least once per calendar year that takes into account local3 and environmental factors.”R 1.2 should read: “Specify a Vegetation Inspection frequency of at least once per calendar year.” (and remove the balance of the sentence)R 1.3.3 states that the annual work plan shall....”Be flexible to adjust to changing conditions and to findings from Vegetation Inspections. Adjustments to the plan within the year are permissible.”The wording would not allow a situation where the work plan is not entirely implemented “within the year”. There may be instances where you may be justified to postpone the work planned at the end of the year and must be moved into the following year, or an alternative strategy assigned, pushing the work even further out. Remove the words “within the year “in R1.3.3.R 1.4 states that a process or procedure for response to an imminent threat of vegetation-related sustained outage is required. The term “imminent threat” should be a NERC defined term. The SDT should consider an alternative structure for the wording of R 1.6, where the current wording states ‘...specify...maintenance strategies ... to ensure that Table 1 clearances are never violated.’To improve clarity and better reflect the intent for this requirement as stated in the Technical Paper, consider the language directly from the Technical Paper (p. 24). Thus, the requirement could be edited to state: “Maintenance strategies must be designed to a) meet the Table 1 clearances in Attachment 1 and b) consider all possible locations of the conductor for rated design conditions.”R 1.6 states that maintenance strategies in companies’ vegetation management programs must consider ‘sag and sway of the conductor throughout its operating range under rated conditions.’ Since neither ‘operating range’ nor ‘rated conditions’ are defined NERC terms, this requirement could be open to broad interpretation. As a result, the SDT should consider alternatives that will reduce potential ambiguity. FAC-003 currently requires Clearance 2 to be maintained for ‘all rated

Organization	Yes or No	Question 1 Comment
		electrical operating conditions.' This suggests that vegetation clearances should be set in a manner such that required clearances will be maintained for conditions that include line loadings at both Normal and Emergency Ratings. The SDT should consider additional specificity.
Progress Energy Carolinas, Inc.	Disagree	R 1.3.3 states that the annual work plan shall....”Be flexible to adjust to changing conditions and to findings from Vegetation Inspections. Adjustments to the plan within the year are permissible.”The wording as proposed would not allow situations where the “work plan” is not entirely implemented “within the year”, which conflicts with the requirement to be flexible and adjust to changing conditions. To eliminate this conflict between requirements, PEC recommends removing the words “within the year “in R1.3.3.
Lee County Electric Cooperative	Disagree	R1 1.5 - define 'temporarily'. Alternative: Define a maximum period of time. ex: beyond one inspection cycle, or based on environmental conditions, one growth cycle; or based on when access was restricted - when the last or next inspection occurred or is scheduled to occur.
CenterPoint Energy	Disagree	R1 refers to “Active Transmission Line Rights of Way” which are not defined as to their limits within the Standard. The SDT has indicated in its response to 1st Draft Comments from CenterPoint Energy that the “...Transmission Owner is responsible for defining the Active Transmission Line Right of Way.” However, that determination clause is not included in the current definition. CenterPoint Energy recommends deleting the phrase “on its Active Transmission Line Rights of Way” from R1. The phrase, “...considering all possible locations the conductor may occupy under the effects of sag and sway throughout is operating range and under rated conditions” , by itself defines the airspace that must be maintained. R1.6 adds the MVCD distance requirement to the sag and sway geometry further defining the airspace that must be maintained. R1 requires no specific definition of a right of way.As written, R1 does not address how a utility conducts its work to address the fall-in of trees into an adjacent transmission line. The determination of the limits of the right of way are only necessary in the Standard for determining the reporting exceptions for certain Sustained Outages in R8 (fall-in) as evidenced in measure M8 through self-certification reports.The Standard and the Technical Reference provide no specific justification for defining a 1-year inspection frequency in R1.2. The requirement itself does not take into account “local and environmental factors”, which may indicate a longer inspection frequency is warranted. The Technical Reference states that the inspection frequency is required to be “at least once per calendar year”. The SDT’s only justification for this determination is found in its response to 1st Draft Comments, “...the consensus of the SDT is that inspection of any operating transmission line should be done annually... “. This statement alone is not compelling. No further supporting arguments have been provided. CenterPoint Energy believes that this minimum inspection frequency is arbitrary and is not necessary or appropriate for all registered entities. Registered entities are in the best position to determine appropriate inspection frequencies that take into account local and environmental factors found in their service territories. CenterPoint Energy strongly recommends that R1.2 be revised to allow the registered entity to determine the appropriate inspection frequency for their service territory. The

Organization	Yes or No	Question 1 Comment
		revised R1.2 would read "Specify a Vegetation Inspection frequency that takes into account local and environmental factors to prevent Sustained Outages."
Platte River Power Authority Vegetation Management Group	Disagree	R1. currently says "...under rated conditions". It should say "...under Rated Electrical Operating Conditions" a NERC defined term. Defined as: The specified or reasonably anticipated conditions under which the electrical system or an individual electrical circuit is intend/designed to operate.Although we appreciate the SDT's need to address a minimum vegetation inspection frequency as ordered by FERC directive 693, we believe that system conditions vary too widely from utility to utility and even within utilities to specify a Vegetation Inspection (VI) frequency of at least once per calendar year in R1.2. We think the SDT should consider making the minimum VI broader to cover different vegetation types and local factors. R1.3. Should be consistent in wording with R1.1. and R1.2. as follows: 1.3. Specify an annual work plan that shall:We agree with the SDT to remove the 'fill in the blank' requirement for personnel requirements in FAC-003-1.R1.3.2. "Identify the work to be performed and methods to be used", is redundant as it is address in other requirement in the standard. The work to be performed is included under R1. "...that describes how it conducts work" and the methods to be used is included under R1.1. Specify the methods that the TO may use to control vegetation. R1.3.3. Should read: Be flexible to adjust to changing conditions of the vegetation on the Active Transmission Line ROW, emergencies, and other significant changing conditions found during Vegetation Inspections. Adjustments to the plan within the year are permissible but must always ensure the reliability of the electric transmission system.R1.4. Should be consistent in wording with R1.1. and R1.2. as follows:1.4. Specify a process or procedure...We believe that mitigation measures in R1.4 of FAC-003-1 are better than the new corrective action process in R1.5 of FAC-003-2. However, if it is decided to keep R1.5. the SDT should remove the words "interim" and "temporarily" as they do not provide clarity. Some constraints are permanent or long-term and it would be appropriate to have a corrective action process to address all constraints. R1.6. currently says, "... under rated conditions". It should say, "... under Rated Electrical Operating Conditions" a NERC defined term. We have some concern that the general public will misinterpret the Table 1 clearances in Attachment 1 and expect constant maintenance in order to allow their vegetation to be as close to line as possible at all times. The addition of a critical clearance distance to be achieved at the time of work, similar to the Clearance 1 in FAC-003-1 may explain why you need more clearance distance.
Transmission Owner	Disagree	R1., 1.3.,1.3.2. Should read: Identify the work to be performed. The method does not contribute to reliability and places an un-needed burden on auditor and Transmission Owner. R1., 1.4. The term Imminent Threat is vague. FPL recommends that the Transmission Owner should be directed to define it based on its construction and local environmental conditions.
Salt River Project	Disagree	R1.3: In "Require an annual work plan" recommend changing the word "require" to "define". R1.5: This appears to replace the old R1.4. Suggest changing back to how it was worded in R1.4, a better description.

Organization	Yes or No	Question 1 Comment
		As there was a need to replace "mitigation" and alternative would be to place with "corrective action".
Puget Sound Energy	Disagree	Requirement 1.6, while a good theory statement, does not have the impact of Clearance 1 in the existing standard. When agencies and reluctant landowners look at this standard, they will not see this requirement the same way Clearance 1 is seen. Requirement 1.6 will be seen as a procedural, not a justification for utilizing utility best management practices for vegetation management. R1.6 indicates that the maintenance strategy used must be specified and then identifies "minimum vegetation to conductor distance" as an example strategy. The minimum vegetation to conductor distance as table 1 is titled is the goal of the strategy, but not a strategy. This creates confusion regarding the intention of this requirement. Modify R1.6 to read "Ensure Table 1 Attachment 1 clearances are never violated considering sag and sway of the conductor throughout its operating range under rated conditions and local vegetation characteristics and factors under non-storm weather variances." Because the distances in Table 1 are so small, it could appear to a non-familiar customer or local agency that the standard is becoming less stringent raising even more opportunity for customer resistance and the need to create more unique interim corrective actions to manage. The inability of an entity to follow a consistent plan raises the risk of non-compliance.
Central Maine Power an Energy East Company	Disagree	Suggest that NERC define operating range and rated conditions.
Nebraska Public Power District	Disagree	The requirement in R1.2 should allow the Transmission Owner to set the frequency of inspection. The T.O. should be able to determine what frequency based on their system. We also agree with Xcel on an exemption if new technology such as LIDAR is used. This will allow the T.O. to determine objectively what vegetation needs to be addressed and when.R1.4: "imminent threat" needs to be defined.R1.5: delete "temporarily" from the requirement. This is a difficult word to define and provide guidance on.R1.6 should be reworded using language from the Technical Paper (p. 24). "Maintenance strategies must be designed to (a) meet the table 1 clearances in attachment 1, and (b) consider all possible locations of the conductor for rated design conditions."
Utility Arborist Association	Disagree	The Utility Arborist Association (UAA) considers it imperative to include a requirement for transmission operators to adopt the science-based, industry accepted practices in ANSI A300. ANSI A300 was designed to ensure appropriate and effective practices are implemented, while allowing each utility the flexibility to develop a program that considers site specific factors. The UAA recognizes that there are varying levels of technical competency within the industry among individual utility vegetation management (UVM) programs. While the majority of utilities currently apply A300 routinely, there are still those that do not. We believe that utilities that have failed to implement A300 could potentially become involved in future incidents due to insufficient understanding of effective utility vegetation management practices. The UAA thinks that FAC-003-02 should ensure that all utilities have successful programs to mitigate tree and power line conflicts,

Organization	Yes or No	Question 1 Comment
		regardless of their size, budgets and other available resources. A specific requirement to adherence to A300 will ensure that compliance with FAC-003-02 across North America will be uniform and effective. Without this requirement, we fear that utilities with less robust resources and knowledge may become the weakest link in the electrical system. As such, the UAA strongly encourages the direct reference to A300 within the standard rather than as a footnote.
E.ON U.S.	Disagree	This will add significant cost to vegetation management budgets. The MVCD concept will require the use of LIDAR and will add approximately $250k per year to utility company expenses. These costs include equipment, training, LIDAR survey and personnel costs.
Arizona Public Service	Disagree	Utilities should be held to following ANSI A-300 standards and BMP's for best management practices. By following these standards there wouldn't be a need for the FAC-003 standard. There should not be a footnote but a requirement. Personnel qualifications should be a requirement. There are certification programs through the International Society of Arboriculture that certify a minimum level of competence to manage a vegetation management program. This also requires ongoing training and education to keep up with the latest technologies on UVM. NERC and FERC still need to be aware that federal land agencies are making decisions without any education or knowledge on UVM activities which affect transmission reliability. There needs to be a clearance 1 requirement in the standard. If utilities are required to follow this standard it gives them leverage with dealing with these federal land agencies.
Idaho Power Company	Disagree	We agree with letting the Transmission Owner decide on methods to control vegetation management. We believe personnel qualifications should be included but as determined by the Transmission Owner. We agree that annual inspections should be required. However, we would prefer R1.3 to read as "Specify an annual work plan..." rather than "Require an annual work plan..." to be consistent with the other subsections of the R1 requirements. We believe R1 should allow flexibility to integrate technology, in particular Lidar, as an acceptable patrol.
Ameren	Disagree	Would suggest the term "normal" in front of "sag and sway throughout its operating range"...or " design of" to address the exceptions for environmental conditions.
ISO/RTO Council		The SRC has no comment on this question.

2. As stated in the background information above, in response to industry comments, the Requirement for implementation of Imminent Threat process/procedure (the new R2) is revised. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

Pepco Holdings, Inc - Affiliates (PHI)	Agree	PHI agrees with the requirement but notes that Operating Process is a NERC defined term. The SDT should review the definition and use capitalization for Glossary terms.
NERC Standards Review Subcommittee	Agree	Prefer the distances specified in the current IEEE Standard as opposed to the Gallet equation.
Southern California Edison Company	Agree	SCE generally agrees with the language of the requirement and the assignments. However, it is unclear why the Violation Risk Factor is rated as "Medium," rather than "Lower."
FirstEnergy Corp	Disagree	Although we mostly agree with Req. R2, we offer the following suggestion for improvement. The phrase "actual knowledge" is ambiguous and could be difficult to measure. For instance, if the responsible entity receives a voice mail or email regarding an imminent threat, then that would technically mean he has actual knowledge of the alleged threat; however, only after the entity reviews and confirms the alleged situation can it be judged a true imminent threat. Therefore, we suggest a change from "actual knowledge" to

Organization	Yes or No	Question 2 Comment
		"confirmation".
E.ON U.S.	Disagree	E.ON U.S. believes that requirement to prove “no incident occurred” for an audit would be impossible to accomplishE.ONU.S. believes that the SDT should clarify what is meant by “normal Operating Practices,” specifically identifying what practices are necessary to ensure compliance with the standard.E.ON U.S. believes that the proposed standard is in conflict with TOP-1 (the imminent threat procedure could require an operator to take a line out of service thereby putting the grid at risk).
PacifiCorp	Disagree	PacifiCorp thinks it is very important for improved reliability to directly reference ANSI A300, rather than relegate it to a footnote. ANSI A300 is science-based, and proven to be effective. Directly referencing adherence to A300 will encourage uniform compliance with FAC-003 across North America. Without this reference, PacifiCorp fears grid stability could be threatened by ineffective practices applied by utilities that lack sufficient expertise to manage their systems. PacifiCorp believes that those utilities could create future blackouts due simply to a lack of understanding about proper utility vegetation management practices. Consequently, PacifiCorp urges direct reference to A300 within the standard. PacifiCorp believes eliminating clearance 1 will be detrimental to reliability. Clearance 1 is important for utilities to account for the dynamics of conductor movement and vegetative growth. This required analysis should lead to development of a more informed vegetation management program. Clearance 1 also gives utilities leverage with landowners, governmental agencies and local regulators to achieve the necessary operational clearances. If the only required clearance is the R4 Minimum Vegetation Clearance Distance, landowners and local regulators will push the utility to maintain a little more than those clearances rather than properly taking tree growth into account.
Arizona Public Service	Disagree	The SDT needs to come up with a standardized format for the imminent threat process. All utilities need to be audited the same way. This requirement is too vague since it has a VSL of severe. In the beginning of this document it states the requirement will be clearer and in an unambiguous manner. Here each utility can make up their process and will be audited differently.
BC Transmission Corporation	Disagree	The STD needs to specify a standardized format for the imminent threat process, this will allow for consistency in the audit process which is important because the VSL is severe. If each utility specifies their own process it will be up to the subjectivity of the auditors who often do not have a vegetation management background to determine if the process is adequate.
Lee County Electric Cooperative	Disagree	This requirement seems redundant to R1. 1.4 The process or procedure required in R1. 1.4 includes implementing the procedure. Steps taken to mitigate the threat would be documented and could be considered as implementing the process/procedure. Alternative: either eliminate the new R2 or edit R. 1.4 to

MRO NERC Standards Review Subcommittee	Agree	MRO NSRS suggests that the referenced footnote 5 be modified to include “species epidemics,” such as bark beetles; this footnote 5 should be referenced. Additionally, footnote 5 could be modified to include “species epidemics” between “logging” and “animal severing tree.” R3 states that “Each Transmission Owner shall conduct Vegetation Inspections of all applicable lines (as measured in line miles) in accordance with the frequency specified in its transmission vegetation management program, the MRO NSRS recommends that the phrase “of all applicable lines (as measured in line miles)” be removed from R3. This is understood by

Organization	Yes or No	Question 3 Comment
		Applicability section A4.2.
American Transmission Company	Agree	R 3 states that “Each Transmission Owner shall conduct Vegetation Inspections of all applicable lines (as measured in line miles) in accordance with the frequency specified in its transmission vegetation management program,ATC recommends that the phrase “of all applicable lines (as measured in line miles)” be removed from R 3. This is understood by Applicability section A 4.2.
Southern California Edison Company	Agree	SCE generally agrees with the language of the requirement, but would suggest the following revision to Footnote 4 in order to clarify the text:Examples include, but are not limited to, earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, ice storms, floods, and major storms as defined either by the Transmission Owner or an applicable regulatory body.
Hydro One Networks inc.	Disagree	(a) As compared with the current version, the proposed draft is still excessively prescriptive. Depending on local conditions, an annual inspection may not be necessary. The TO should have the ability to decide on the frequency of the inspections as long as the reliability of the BES is not compromised. For example, vegetation growth in Northeastern North America has long (7-8 months) dormant periods. (b) There seems to be an inconsistency between R1.2 and R3. R1.2 requires the TO to carry out inspections at least once per calendar year. R3 requires the TOs to carry out inspections per the frequency defined in its TVMP. According to our comment in (a) above, the TO should have the prerogative of specifying the frequency and timing as stated in R3. Once per calendar year is not sensitive to local and environmental factors. For example, vegetation growth in North Eastern North America has a long (7-8 month) dormant period. The entity should be able to specify a frequency of one inspection per dormant period. This inspection could take place between September and April annually. In one dormant period there might be an inspection in November, and an inspection again 14 months later in January. Accordingly, R3 is more appropriate. Other TOs may be located in parts of the continent with little or no vegetation and not need a once per calendar year inspection. Thus, R1.2 should allow the TOs to specify an inspection program that is sensitive to local and environmental factors, not the calendar. (c) In addition, VRFs and VSLs are based on percent of “total line miles specified by its TVMP”; this statement should be qualified by including something like “total applicable line miles specified by its TVMP”, as there may be circuits included in a vegetation management program that are not subject to the FAC-003 standard (sub-200kv, non-IROL lines). This also better aligns with the text of R3 (“...shall conduct Vegetation Inspections of all applicable lines...”). Also, we would suggest explicitly stating line kilometers as an acceptable measure for those using the metric system.
Idaho Power Company	Disagree	Include in the exceptions ‘unless constrained by federal and environmental restrictions’ along with natural disasters. Federal agencies can and have prevented vegetation management measures due to environmental, biological, and/or cultural concerns. In footnote 4, insect infestation should be added as a form

Organization	Yes or No	Question 3 Comment
		of natural disaster. Also, recommend changing 'major storms' to 'major events' in this footnote.
National Grid	Disagree	National Grid sees inconsistency between R1.2 and R3. R1.2 requires the TO to carry out inspections at least once per calendar year. R3 requires the TO to carry out inspections per the frequency defined in its vegetation management program. National Grid prefers that the TO be allowed to specify the frequency and timing as stated in R3. Once per calendar year is not sensitive to local and environmental factors. For example, National Grid facilities in the northeast are located in an environment where there is a long (7-8 month) dormant period - vegetation does not grow. National Grid would specify a frequency of one inspection per dormant period. This inspection could take place between September and April annually. In one dormant period we might inspect in November and inspect again 14 months later in January. We would meet the inspection need per R3, but fail to have inspected in a calendar year, thus violating R1.2. Other TO's may be located in parts of the country with little or no vegetation and not need a once per calendar year inspection. Thus, R1.2 should allow the TO to specify an inspection program that is sensitive to local and environmental factors, not the calendar.
Pepco Holdings, Inc - Affiliates (PHI)	Disagree	PHI appreciates the change, however, the SDT has designated the Regional Entity to provide alternate time periods for inspections. This should be the PC or RC. The TO should submit a request for alternate periods to the designated entity.
Salt River Project	Disagree	R1.2 specifies that vegetation inspections are to be conducted at least once per calendar year, yet in R3 it states that the Transmission Owner shall conduct Vegetation Inspections of all applicable lines in accordance with the frequency specified in the transmission vegetation management program. Although SRP conducts its transmission inspections on an annual basis, the Transmission Owner should be allowed to define the inspection frequency based on the operations of their utility company as best defined in their individual TVMP. Whichever definition is approved it should be stated the same in both R1.2 and in R3.
Platte River Power Authority Vegetation Management Group	Disagree	R3 says, "each TO shall conduct Vegetation Inspections of all applicable lines in accordance with the frequency specified in its transmission vegetation management program". However, R1.2. says that the TO shall specify a Vegetation Inspection frequency of at least once per calendar year. The two requirements seem to be inconsistent. We assume that R3 was worded to accommodate a more frequent Vegetation Inspection but it isn't clear.
Hydro-Quebec TransEnergie (HQT)	Disagree	Refer to the response to Question 1.
Independent Electricity System	Disagree	Refer to the response to Question 1.

Organization	Yes or No	Question 3 Comment
Operator		
ISO New England Inc.	Disagree	Refer to the response to Question 1.
Northeast Power Coordinating Council--RSC	Disagree	Refer to the response to Question 1.
JEA	Disagree	The requirement should simply be that the entity will conduct a Vegetation Inspection at least once per calendar year (per the push for results/performance based requirements). The caveats for natural disasters seem reasonable.
CenterPoint Energy	Disagree	The term “line miles” is not a defined NERC term. The industry terms “structure miles” and “circuit miles” are more common. The NERC Transmission Availability Data System (TADS) utilizes a defined term of “circuit miles” which would be a better choice to avoid confusion and provide the same capability for determining a percent complete status. Transmission Owners are already required to report the number of “circuit miles” of their (greater than or equal to) 200kV transmission line assets annually to TADS.
BC Transmission Corporation	Disagree	The TO's should be required to inspect each line at least once a year. This is critical to eliminating outages and would provide a definite measure for the audit process. The phrase as measured in line miles adds confusion to the requirement. It should state that the applicable lines be inspected along the entire length.
Orange and Rockland Utilities, Inc.	Disagree	There is an inconsistency between R1.2 and R3. R1.2 requires the TO to carry out inspections at least once per calendar year. R3 requires the TO to carry out inspections per the frequency defined in its vegetation management program. It is preferred that the TO be allowed to specify the frequency and timing as stated in R3. Once per calendar year is not sensitive to local and environmental factors. For example, facilities in the Northeast are located in an environment where there is a long (7-8 month) dormant period -vegetation does not grow. Specify a frequency of one inspection per dormant period. This inspection could take place between September and April annually. In one dormant period we might inspect in November and inspect again 14 months later in January. We would meet the inspection need per R3, but fail to have inspected in a calendar year, thus violating R1.2. Other TO’s may be located in parts of the country with little or no vegetation and not need a once per calendar year inspection. Thus, R1.2 should allow the TO to specify an inspection program that is sensitive to local and environmental factors, not the calendar.
Arizona Public Service	Disagree	TO’s should be required to inspected annually. This needs to be in R3 which is stated above. This standard should be consistent so each utility is audited the same.

Organization	Yes or No	Question 3 Comment
FirstEnergy Corp	Disagree	We do not agree with the parenthetical phrase "(as measured in line miles)". Entities may utilize other forms of measurement such as “corridor miles”. The standard should allow the TO to define its own measurement technique and then the VSL for this requirement would be based on a percentage of how much of the TO’s transmission system was missed per the measurement technique defined by the TO. We suggest removing the parenthetical phrase "of all applicable lines (as measured in line miles)" from Req. R3. and add a new subpart of Req. R1 requiring the TO, in its TVMP, to document its method of measuring the applicable lines to be maintained. Corresponding changes to the VSLs are also needed per this proposed revision. The VLS could be revised to read "... inspected greater than x% but less than y% of the Transmission Owner defined measurement technique as defined in sub-part 1.x"
Northern Indiana Public Service Company	Disagree	While I agree with the minimum interval of once a year for vegetation inspections, I have real concerns about using line miles for determining violation severity levels. We conduct vegetation inspections by R.O.W. corridor rather than by circuit or circuit line miles. Multiple circuits or segments of multiple circuits can exisit within the same R.O.W. complicating any calculation of how many line miles are inspected versus not inspected. How about using R.O.W. miles rather than circuit line miles for determining the V.S.L.?
Xcel Energy	Disagree	Xcel Energy does not disagree with the language of R3, however suggests that the referenced footnote 4 be modified to include “species epidemics,” such as bark beetles. It is proposed that footnote 4 have the term “species epidemics” inserted after “landslides” and before “wind shear.”
ISO/RTO Council		The SRC has no comment on this question.

4. As stated in the background information above, in response to industry comments, the Requirement for preventing vegetation encroachments (the new R4) is revised. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

Organization	Yes or No	Question 4 Comment

Western Area Power Administration, Rocky Mountain Region	Agree	
FirstEnergy Corp	Agree	Although we agree with this requirement, we want to point out a potential concern with double violations between R4 and either R5, R6, R7, or R8. Technically if at any point in real-time you violate one of the requirements R5 through R8, you have also violated R4. The SDT may want to consider adding a clarifying statement in R4 to alleviate a double violation such as "This requirement is not applicable when either R5, R6, R7, or R8 is violated".

Organization	Yes or No	Question 4 Comment
ISO New England Inc.	Agree	Falling vegetation should be an exception to an encroachment but a clarification is needed to confirm that any falling tree that gets lodged into another tree and violates the MVCD in real time is also included as part of the falling vegetation exception. Also, if a line is operating beyond its Emergency Rating due to system conditions, encroachments of the MVCD should not be considered a violation of R6. Request that additional clarification be made between the relationship of R1.6 and R4. R1.6 is a documentation requirement that requires that the TVMP specify strategies to ensure that the MVCD clearances are never violated under all operating/rated conditions. R4 is an implementation requirement that makes it a violation to encroach upon the MVCD in real time only. So if we had a situation where there would have been an MVCD encroachment if the conductor was at its lowest position (maximum sag) but, at the time of the observation, the conductor was at a higher position (not at maximum sag), our understanding is that there would be no violation of either R1.6 or R4 since the real time observation determined that the vegetation clearance was greater than the MVCD. This assumes that the strategies required under R1.6 are included in the TVMP.Clarification is needed for what is meant by "...as observed in real-time operating between no-load and their Rating."
Orange and Rockland Utilities, Inc.	Agree	ORU agrees that falling vegetation should be an exception to an encroachment but would like clarification to confirm that any falling tree that gets lodged into another tree and violates the MVCD in real time is also included as part of the falling vegetation exception. Also, if a line is operating beyond its Emergency Rating due to system conditions, encroachments of the MVCD should not be considered a violation of R6. ORU is requesting that additional clarification be made between the relationship of R1.6 and R4. R1.6 is a documentation requirement that requires that the TVMP specify strategies to ensure that the MVCD clearances are never violated under all operating/rated conditions. R4 is an implementation requirement that makes it a violation to encroach upon the MVCD in real time only. So if we had a situation where there would have been an MVCD encroachment if the conductor was at its lowest position (maximum sag) but, at the time of the observation, the conductor was at a higher position (not at maximum sag), our understanding is that there would be no violation of either R1.6 or R4 since the real time observation determined that the vegetation position was greater than the MVCD. This assumes that the strategies required under R1.6 are included in the TVMP.
PacifiCorp	Agree	PacifiCorp suggests inserting "by a qualified observer" after "observed." Otherwise, utilities could be held accountable to train all their workers who might casually encounter vegetation conditions in their work or commutes.
Southern California Edison Company	Agree	SCE generally agrees with the language of the requirement, but believes that the appropriate Violation Risk Factor is "Lower," rather than "Medium." SCE believes that an encroachment, in and of itself, does not necessarily rise to a level of significance that should require self-reporting, nor should such an occurrence necessarily subject the utility to an investigation with potential adverse findings and penalties. Considering the

Organization	Yes or No	Question 4 Comment
		purpose of the standard and the imprecise nature of vegetation management activities, the standard may be overly strict. Further, due to the resistance of certain land owners and/or agency officials to allowing utilities to prune beyond the prescribed minimum tree-to-line clearances, SCE asks the Drafting Team consider changing the term “Minimum Vegetation Clearance Distances” to “Critical Vegetation Clearance Distances".
Xcel Energy	Disagree	(a) Xcel Energy incorporates its response to number 3 above regarding footnote 4, alternatively, footnote 5 could be modified in a similar fashion to include “species epidemics” between “logging” and “animal severing tree.” (b) Xcel Energy suggests that the phrase “Minimum Vegetation Clearance Distances” (MVCD) be changed to “Critical Clearance Distance.” The use of the word “minimum” creates problems for Transmission Owners when dealing with land owners regarding the necessary vegetation management which is to take place on the subject property. “Minimum” creates difficulties in explaining to a land owner why any additional clearance need be obtained. That difficulty would be substantially lessened with the use of a term such as “critical,” which more readily lends itself to an additional distance such that the vegetation never approaches the critical distance.(c) Xcel Energy urges the insertion of “by a qualified observer” after “observed.” Otherwise, a Transmission Owner could have a violation as a result of a drive-by glance by an office clerical worker.
MRO NERC Standards Review Subcommittee	Disagree	A. The MRO NSRS suggests that the phrase “Minimum Vegetation Clearance Distances” (MVCD) be changed to “Critical Clearance Distance.” The use of the word “minimum” creates problems for Transmission Owners when dealing with land owners regarding the necessary vegetation management which is to take place on its easements. “Minimum” creates difficulties in explaining to a land owner why any additional clearance needs to be obtained. That difficulty would be substantially lessened with the use of a term such as “critical”, which more readily lends itself to an additional distance such that the vegetation never approaches the critical distance.B. The MRO NSRS agrees with the intent of including events that would define exceptions for requirements to comply with FAC-003. As an alternative to the approach in the draft Standard of using footnotes, the MRO NSRS recommends that the SDT consider adding a generic “force majeure” statement in the applicability section more specifically stating that companies will not be subject to compliance requirements to the extent that events or circumstances beyond their control limit or prevent their abilities to perform. Here’s an example:Compliance with this standard will not apply should there exist an occurrence, non-occurrence, or other set of circumstances that are beyond the reasonable control of a Registered Entity subject to this Reliability Standard, and are not caused by the fault or negligence of the Registered Entity, including acts of God, strike, flood, drought, earthquake, storm, fire, hurricane, tornado, landslides, logging activities, animals severing trees, lightning, epidemic, war, riot, civil disturbance, sabotage, vandalism, terrorism, or action or inaction by any Governmental Authority or individual that restricts or prevents performance to comply with this Reliability Standard.C. R4 states that “Each Transmission Owner shall prevent encroachment of vegetation into the Minimum Vegetation Clearance Distances (MVCD) listed in FAC-003-2 - Attachment 1........” The MRO NSRS requests the Standard clarify how MVCDs will be interpolated for

Organization	Yes or No	Question 4 Comment
		altitudes not specifically defined in Table 1.
Salt River Project	Disagree	Although the replacement of the Critical Clearance Zone (CCZ) in R4 is an improvement, we still question the use of the Gallet Equation. Although the Gallet Equation is more definitive than using IEEE 516 as identified in the current standard, we question from an engineering perspective as to how and why this method was chosen for vegetation management. The Gallet Equation is a well known method of computing the required strike distance for proper insulation coordination. It is our understanding that the purpose is for designing towers, to define the “tower window” or opening inside of a tower under normal conditions. Because this is not a method designed specifically for vegetation management, there is no basis for applying this to vegetation management. It is recommended that testing be done to justify this method to be used for vegetation management. We would find it definitive to substantiate the calculated equation assertions with test data from actual energized flashover distances to vegetation. The testing ought to include dry and misting conditions at 200+ kilovolt levels on a sampling of fresh cut common vegetation types. Reputable EHV testing facilities where such tests can be performed exist within the United States and Canada.
Platte River Power Authority Vegetation Management Group	Disagree	As the requirement is written it is a violation of the requirement when a possible encroachment of the MVCD is discovered through inspections and such an encroachment should be self-reported to the RE. This is inconsistent with the purpose of the standard to prevent vegetation-related outages that can result in Cascading. We would suggest that appropriate action be taken to correct encroachment of the MVCD but that it wouldn’t be a violation of the requirement until a Sustained Outage has occurred or the imminent treat process has been implemented. R4 refers to observation in real-time. This actual field observation of the MVCD between no-load and its Rating is too subjective and lends itself to too much interpretation by the inspector especially in light of the fact that it could be a self-reported violation if the MVCD is encroached.
Associated Electric Cooperative, Inc.	Disagree	Associated Electric Cooperative Inc. suggests the third exception bullet under R4 is unclear. Is the exception meant to address vegetation from either inside or outside the ROW that: 1) may pass through the MVCD while falling; or, 2) has fallen and may now encroach into the MVCD from its new steady state position?
American Transmission Company	Disagree	ATC agrees with the intent of including events that would define exceptions for requirements to comply with FAC-003. As an alternative to the approach in the draft Standard of using footnotes, ATC recommends that the SDT consider adding a generic force majeure statement in the applicability section more specifically stating that companies will not be subject to compliance requirements to the extent that events or circumstances beyond their control limit or prevent their abilities to perform. Here’s an example:Compliance with this standard will not apply should there exist an occurrence, non-occurrence, or other set of circumstances that are beyond the reasonable control of a Registered Entity subject to this Reliability Standard, and are not caused by the fault or negligence of the Registered Entity, including acts of God, strike, flood, drought, earthquake, storm, fire, hurricane, tornado, landslides, logging activities, animals severing

Organization	Yes or No	Question 4 Comment
		trees, lightning, epidemic, war, riot, civil disturbance, sabotage, vandalism, terrorism, or action or inaction by any Governmental Authority or individual that restricts or prevents performance to comply with this Reliability Standard.Also, R 4 states that “Each Transmission Owner shall prevent encroachment of vegetation into the Minimum Vegetation Clearance Distances (MVCD) listed in FAC-003-2 - Attachment 1........”ATC requests the Standard clarify how MVCDs will be interpolated for altitudes not specifically defined in Table 1.
Consolidated Edison Company of New York Inc.	Disagree	CECONY agrees that falling vegetation should be an exception to an encroachment but would like clarification to confirm that any falling tree that gets lodged into a stable tree and pushes the stable tree beyond the MVCD in real time is also included as part of the falling vegetation exception. CECONY is requesting that additional clarification be made between the relationship of R1.6 and R4. R1.6 is a documentation requirement that requires that the TVMP specify strategies to ensure that the MVCD clearances are never violated under all operating/rated conditions. R4 is an implementation requirement that makes it a violation to encroach upon the MVCD in real time only. So if we had a situation where there would have been an MVCD encroachment if the conductor was at its lowest position (maximum sag) but, at the time of the observation, the conductor was at a higher position (not at maximum sag), our understanding is that there would be no violation of either R1.6 or R4 since the real time observation determined that the vegetation position was greater than the MVCD. This assumes that the strategies required under R1.6 are included in the TVMP.
Idaho Power Company	Disagree	Change the Minimum Vegetation Clearance Distance (MVCD) to Critical Vegetation Clearance Distance (CVCD) to indicate a higher level of importance when dealing with federal agencies and reluctant property owners. Provide a better definition for the term ‘Real Time’. Include in this definition the use of technology to determine if an imminent threat exists to help minimize real time patrols. In footnote 5 provide more information on what agricultural activities includes.
Vegetation Management Team	Disagree	Disagree with R4 and M4. As explained in the comment for R1, encroachments should also be addressed via a pre-determined process before becoming a violation of the standard. Therefore, we suggest the following changes be made to the requirements: R4: Each Transmission Owner shall [REMOVE: prevent encroachment of vegetation into the] implement its vegetation encroachment response process or procedure when the Transmission Owner has actual knowledge of such an encroachment on any Minimum Vegetation Clearance Distances (MVCD) listed in FAC-003-2-Attachment 1 [REMOVE: for its applicable lines as observed in real-time operating between no-load and their Rating.], obtained through implementation of the annual work plan and the TVMP. M4: The Transmission Owner has evidence [REMOVE: from inspections that indicate there was no vegetation encroachment into the Minimum Vegetation Clearance Distances listed in FAC-003-2-Attachment 1 for its applicable lines as observed in real-time operating between no-load and their Rating, considering exceptions.] of the implementation of its vegetation encroachment process or procedure showing actions taken and dates of performance.Likewise, we suggest the following be made to

Organization	Yes or No	Question 4 Comment
		the Violation Severity Levels chart: Severe: [REMOVE: The Transmission Owner has failed to prevent vegetation from encroaching into the minimum vegetation clearance distance.] The Transmission Owner did not implement its vegetation encroachment response process or procedure when the Transmission Owner had actual knowledge of such an encroachment on any Minimum Vegetation Clearance Distances (MVCD) listed in FAC-003-2-Attachment 1 obtained through normal operating practices.
Hydro-Quebec TransEnergie (HQT)	Disagree	Falling vegetation should be an exception to an encroachment but a clarification is needed to confirm that any falling tree that gets lodged into another tree and violates the MVCD in real time is also included as part of the falling vegetation exception. Also, if a line is operating beyond its Emergency Rating due to system conditions, encroachments of the MVCD should not be considered a violation of R6. Request that additional clarification be made between the relationship of R1.6 and R4. R1.6 is a documentation requirement that requires that the TVMP specify strategies to ensure that the MVCD clearances are never violated under all operating/rated conditions. R4 is an implementation requirement that makes it a violation to encroach upon the MVCD in real time only. So if we had a situation where there would have been an MVCD encroachment if the conductor was at its lowest position (maximum sag) but, at the time of the observation, the conductor was at a higher position (not at maximum sag), our understanding is that there would be no violation of either R1.6 or R4 since the real time observation determined that the vegetation clearance was greater than the MVCD. This assumes that the strategies required under R1.6 are included in the TVMP.Clarification is needed for what is meant by “...as observed in real-time operating between no-load and their Rating.”
Independent Electricity System Operator	Disagree	Falling vegetation should be an exception to an encroachment but a clarification is needed to confirm that any falling tree that gets lodged into another tree and violates the MVCD in real time is also included as part of the falling vegetation exception. Also, if a line is operating beyond its Emergency Rating due to system conditions, encroachments of the MVCD should not be considered a violation of R6. Request that additional clarification be made between the relationship of R1.6 and R4. R1.6 is a documentation requirement that requires that the TVMP specify strategies to ensure that the MVCD clearances are never violated under all operating/rated conditions. R4 is an implementation requirement that makes it a violation to encroach upon the MVCD in real time only. So if we had a situation where there would have been an MVCD encroachment if the conductor was at its lowest position (maximum sag) but, at the time of the observation, the conductor was at a higher position (not at maximum sag), our understanding is that there would be no violation of either R1.6 or R4 since the real time observation determined that the vegetation clearance was greater than the MVCD. This assumes that the strategies required under R1.6 are included in the TVMP.Clarification is needed for what is meant by “...as observed in real-time operating between no-load and their Rating.”
Northeast Power Coordinating Council--RSC	Disagree	Falling vegetation should be an exception to an encroachment but a clarification is needed to confirm that any falling tree that gets lodged into another tree and violates the MVCD in real time is also included as part of the falling vegetation exception. Also, if a line is operating beyond its Emergency Rating due to system

Organization	Yes or No	Question 4 Comment
		conditions, encroachments of the MVCD should not be considered a violation of R6. Request that additional clarification be made between the relationship of R1.6 and R4. R1.6 is a documentation requirement that requires that the TVMP specify strategies to ensure that the MVCD clearances are never violated under all operating/rated conditions. R4 is an implementation requirement that makes it a violation to encroach upon the MVCD in real time only. So if we had a situation where there would have been an MVCD encroachment if the conductor was at its lowest position (maximum sag) but, at the time of the observation, the conductor was at a higher position (not at maximum sag), our understanding is that there would be no violation of either R1.6 or R4 since the real time observation determined that the vegetation clearance was greater than the MVCD. This assumes that the strategies required under R1.6 are included in the TVMP.Clarification is needed for what is meant by “...as observed in real-time operating between no-load and their Rating.”
JEA	Disagree	I object to the zero defect concept. I realize that there is pressure from FERC, however Section 215 of the FPA specifically states "The Commission shall give due weight to the technical expertise of the Electric Reliability Organization with respect to the content of a proposed standard or modification to a reliability standard..." The technical feasibility of 0 defects is questionable. The industry should develop an aggressive but acheivable performance level for preventing encroachments etc.
CenterPoint Energy	Disagree	It is not clear how R4’s last bullet, “Encroachment into the MVCD listed in FAC-003-2-Attachment 1 resulting from falling vegetation” is observable as an exception, and the Technical Reference does not clarify it either. It would appear that if a tree branch (e.g. wind-blown or fallen branch debris) was observed hanging on the conductor, but was not causing an outage, that it would be considered an exception. The bullet item should be clarified or deleted.
US Bureau of Reclamation	Disagree	It is not clear why wind blown debris is not listed as an exception. It is also not clear why these exemptions are needed as they are not vegeetation encroachments.
North Carolina Electric Membership Corporation	Disagree	NCEMC has concerns about the enforcement of the requirement.There seems to be an issue with enforcement of the third exemption if any vegetation falls and lodges to create a MVCD violation from inside or outside the ROW.
Pacific Gas and Electric Co.	Disagree	PG&E agrees in principal with R5 but disagrees with the exception for human activity noted in footnote (5), specifically aboriculture, horticulture or agricultural activities. This exception is overly broad and could be interpreted as exempting certian activities (such as planting orchards, xmas tree farms, community tree plantings, etc.) from the standard and will invite legal challenges to the TO’s right to perform vegetation management. PG&E proposes alternative language to the exception as follows: Examples include, but are not limited to, logging, animal severing tree, vehicle contact with tree, digging or removal of tree or new

Organization	Yes or No	Question 4 Comment
		plantings between inspection cycles where the TO does not have actual knowledge. As an alternative, add a generic force majeure statement as described in Q18 #2.
Public Service Co. of New Mexico	Disagree	PNM is not in favor of the current MVCD table 1. This will not provide clarity to the field personnel as to clearance distances. It could cause increasing confusion as to how much clearance needs to be obtained at the time of work. Clearance 1 and 2 were much clearer in that respect.
SCE&G	Disagree	SCE&G has concerns about the enforcement of the requirement. There seems to be an issue with enforcement of the third exemption if any vegetation falls and lodges to create a MVCD violation from inside or outside the ROW.
Duke Energy	Disagree	Since this standard already includes other requirements to implement a transmission vegetation management program to maintain the defined clearances, as well as an imminent threat process or procedure to avoid sustained outages, we believe that Requirement R4 provides no additional reliability benefit and should be deleted. If it is decided that this requirement must be retained, then it needs to be re-written such that it is a performance-based requirement with graduated VSLs. As currently written, this requirement is a binary requirement which carries a single VSL which can only be “Severe”. Such a zero-tolerance approach to preventing encroachments does not provide industry with a reasonable opportunity for success, absent the establishment of overly-aggressive and costly vegetation management programs that carry minimal additional reliability benefit. A performance-based requirement should be developed relative to some metric such as line-mile exposure that will promote high quality vegetation management, optimization of the reliability cost/benefit relationship and deliver the overall end result of improved reliability to the system. The performance-based requirement should be structured for a graduated VSL. Due to this requirement being focused on preventing encroachments rather than sustained outages, we believe that a zero tolerance approach is not warranted to improve reliability.In addition, the third exemption is not clear as it relates to falling vegetation. For example, how would an event be viewed if a tree lodges into another tree or hits another tree causing it to lean such that it is within the MVCD?
Pepco Holdings, Inc - Affiliates (PHI)	Disagree	The definition of Rating includes the word -limits- implying that Rating is a plural term. Does the SDT mean the highest sustained limit (10 minutes? 30 minutes? 24 hours?...)?
Manitoba Hydro	Disagree	The phrase “Minimum Vegetation Clearance Distances” (MVCD) should be changed to “Critical Clearance Distance.” The use of the word “minimum” creates problems for Transmission Owners when dealing with land owners regarding the necessary vegetation management which is to take place on the subject property. “Minimum” creates difficulties in explaining to a land owner why any additional clearance need be obtained. That difficulty would be substantially lessened with the use of a term such as “critical,” which more readily

Organization	Yes or No	Question 4 Comment
		lends itself to an additional distance such that the vegetation never approaches the critical distance.Insert “by a qualified observer” after “observed.” Otherwise, a Transmission Owner could have a violation as a result of a drive-by glance by an office clerical worker.
E.ON U.S.	Disagree	The standard does not specify what is meant by “off/on ROW”.E.ON U.S. questions how NERC plans on enforcing the third bullet
BC Transmission Corporation	Disagree	The standard should limit itself to the prevention of outages. If vegetation encroaches within the MVCD and the TO effectively implements the imminent threat process to prevent an outage this should not be a violation. Additionally this requirement will be very difficult to audit and enforce.
Puget Sound Energy	Disagree	The term, Minimum Vegetation Clearance Distance (MVCD) does not invoke the critical dangerous nature of the close distance to the conductor. A more impactful term such as “critical” would be more appropriate.
Ameren	Disagree	The third bullet point on "falling vegetation" is unclear. Would like to see this clarify whether on ROW and/or off ROW falling trees.
SERC Vegetation Managment Sub-committee (VMS)	Disagree	The VMS has concerns about the enforcement of the requirement.There seems to be an issue with enforcement of the third exemption if any vegetation falls and lodges to create a MVCD violation from inside or outside the ROW.
Progress Energy Carolinas, Inc.	Disagree	There is an issue with the wording of the third exemption when any vegetation from outside the ROW falls and lodges to create a MVCD violation. The wording as proposed could be interpreted as non-compliance due to vegetation from outside of the ROW.
Entergy Services, Inc	Disagree	There may be an issue of the third exemption if vegetation falls and lodges to create a MVCD violation from inside or outside the Right of Way.
Tucson Electric Power Company	Disagree	We feel that the use of the word “Minimum” in Minimum Vegetation Clearance Distance should be “Critical”. Governing/Managing land agencies could use the word Minimum, as an allowable limit argument against the utility and deny needed permissions work as long as there is more than the minimum clearance in on the line. The use of the word critical would indicate the need for additional buffer distance to prevent vegetation caused outages. Additionally is the exception to the rule about falling vegetation from inside or outside the ROW/Easement?

Organization	Yes or No	Question 4 Comment
Nebraska Public Power District	Disagree	Xcel Energy urges the insertion of “by a qualified observer” after “observed.” Otherwise, a Transmission Owner could have a violation as a result of a drive-by glance by an office clerical worker.
ISO/RTO Council		The SRC has no comment on this question.

5. As stated in the background information above, in response to industry comments, the Requirement for preventing Sustained Outages due to grow-ins on IROL or Major WECC Transfer Paths (the new R5) is developed. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

Organization	Yes or No	Question 5 Comment
Orange and Rockland Utilities, Inc.	Agree	ORU agrees that, if a line is operating beyond its Emergency Rating due to system conditions, encroachments of the MVCD should not be considered a violation of R5.
Southern California Edison Company	Agree	SCE generally agrees with the assigned Violation Risk Factor for lines that are an element of an IROL or a WECC transfer path. SCE believes that the bulleted exceptions listed in the new R5 are appropriate.
Tampa Electric Company	Agree	The white paper, on page 33, paragraph 4, defines a sustained outage as vegetation related event, if it occurs within the specified rating of the facility. If the conductor is operating above its rating it states that this “would not be classified as a vegetation related sustained outage under the standard.” If this is so it needs to be stated and/or clarified in the standard itself.
American Transmission Company	Disagree	ATC recommends that the SDT consider the statements in the Technical Paper on pgs. 32-34; i.e. encroachment taking place while a line is operating beyond its rating is not a violation of this Requirement.
FirstEnergy Corp	Disagree	FE suggests a revision of Requirement R5.FE encourages the team to re-evaluate its approach to requirements R5 through R7 and consider changes that would remove the binary aspect of the requirements and permit a graded approach to the VSL structure for a non-compliance of the requirement. Our proposal is to incorporate aspects of R7 (blow in) and R8 (fall in) into both requirements R5 (grow-in IROL) and R6 (grow-in Non-IROL) so that R5 and R6 establish requirements for grow-in, blow-in and fall-in. The proposed requirement for R5 would read: "Each Transmission Owner shall prevent Sustained Outages of applicable lines that are identified as an element of an Interconnection Reliability Operating Limit (IROL) (or Major WECC Transfer Path) due to vegetation growing into a conductor operating between no-load and its Rating, due to the blowing together of a conductor and vegetation rooted within an ActiveTransmission Line Right of Way (operating within design blow-out conditions), or due to vegetation falling into a conductor with the following exceptions:"Similarly, the proposed R6 would read:"Each Transmission Owner shall prevent Sustained Outages of applicable lines that are not an element of an IROL (or major WECC Transfer Path) due to vegetation growing into a conductor operating between no-load and its Rating, due to the blowing together of a conductor and vegetation rooted within an Active Transmission Line Right of Way (operating within design blow-out conditions), or due to vegetation falling into a conductor with the following exceptions:"These requirement changes provide the flexibility needed to establish graded VSLs. FE’s proposed VSL levels are consistent with the reporting categories established in section D 1.5. The root of the requirement is "shall prevent Sustained Outages" and the VSL gauge of how much a VM program missed the mark would then be reflected in the type of vegetation contact. Therefore, we propose VSL levels for both Req. R5 and R6 as follows: grow-in (SEVERE VSL), a fall-in (MODERATE VSL),a blow-in (LOWER VSL).No changes to the Violation Risk Factors or Time Horizons for requirements R5 or R6 are proposed.If the proposal is accepted, conforming changes to the Measures are required.

Organization	Yes or No	Question 5 Comment
WECC	Disagree	I agree with the requiring the prevention of sustained outages due to grow-ins on an identified subsed of all transmission facilities. However, I am concerned over the use of the capitalized term Major WECC Transfer Paths. Because this is not a defined term in the NERC Glossary and is not the complete name of any WECC listing,I suggest the phrase (or Major WECC Transfer Paths)be changed to (or major transfer paths in the Western Interconnection as identified by WECC). In the alternative, the full name of the dcoument known as Table 2 that is referred to in the second draft is "Major WECC Transfer Paths in the Bulk Electric System". Is there going to be a problem with the capitalized term if a definition is not developed, knowing that the capitalized term refers to an existing document?
Tucson Electric Power Company	Disagree	In the footnote examples of human activities, there is an exemption for agricultural activities. The planting of and maintenance of orchards is an agricultural activity that should specifically address as not applying in this exemption.
US Bureau of Reclamation	Disagree	It is not clear what Natural disasters or human activity have to do with growing vegetation. Also it is not clear why falling vegetation or wind blown debris are not listed as exemptions.
Pacific Gas and Electric Co.	Disagree	PG&E agrees in principal with R5 but disagrees with the exception for human activity noted in footnote (5), specifically aboriculture, horticulture or agricultural activities. This exception is overly broad and could be interpreted as exempting certian activities (such as planting orchards) from the standard and will invite legal challenges to the TO’s right to perform vegetation management. PG&E proposes alternative language to the exception as follows: Examples include, but are not limited to, logging, animal severing tree, vehicle contact with tree, digging or removal of tree or new plantings between inspection cycles where the TO does not have actual knowledge. As an alternative, add a generic force majeure statement as described in Q18 #2.
Xcel Energy	Disagree	Please see our comments above concerning footnotes 4 & 5.
JEA	Disagree	Please see the comment to question 4.
Pepco Holdings, Inc - Affiliates (PHI)	Disagree	R5 also uses the term Rating. See comment to Q4.
Puget Sound Energy	Disagree	Regional differences should be addressed through regional standards. The reference to Major WECC Transfer Paths should be removed and allow the region to determine whether to expand the implication of the standard.

Organization	Yes or No	Question 5 Comment
Hydro-Quebec TransEnergie (HQT)	Disagree	The introduction of IROL introduces an unnecessary level of complexity in the standard. The facilities being addressed in the standard impact the Bulk Electric System, and the additional "drilling down" is not needed. R5 and R6 seems to have been introduced just to have different violation risk factor for different types of lines. Delete R5 or R6 after removing the IROL concept.
Independent Electricity System Operator	Disagree	The introduction of IROL introduces an unnecessary level of complexity in the standard. The facilities being addressed in the standard impact the Bulk Electric System, and the additional "drilling down" is not needed.
ISO New England Inc.	Disagree	The introduction of IROL introduces an unnecessary level of complexity in the standard. The facilities being addressed in the standard impact the Bulk Electric System, and the additional "drilling down" is not needed.
Northeast Power Coordinating Council--RSC	Disagree	The introduction of IROL introduces an unnecessary level of complexity in the standard. The facilities being addressed in the standard impact the Bulk Electric System, and the additional "drilling down" is not needed.
BC Transmission Corporation	Disagree	The IROL is not properly defined in this standard it is hard to agree with this requirement if we do not know exactly what this means. Please put foot note #7 back into the document. Why single out WECC and not other reliability councils.
Manitoba Hydro	Disagree	The SDT should consider the statements in the Technical Paper on pgs. 32-34 that encroachment taking place if a line is operating beyond its rating would not be a violation of the Requirement.
ISO/RTO Council		The SRC has no comment on this question.

6. As stated in the background information above, in response to industry comments, the Requirement for preventing Sustained Outages due to grow-ins on non-IROL or Major WECC Transfer Paths (the new R6) is developed. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

Independent Electricity System Operator	Disagree	Refer to the response to Question 5.
Northeast Power Coordinating Council--RSC	Disagree	Refer to the response to Question 5.
WECC	Disagree	same comment as for question 5. Agree with the concept, but concern over the term major WECC Transfer Paths (note that the word major is not capitalized in R6 but it is in R5. Suggest replaceing with the phrase (or major transfer paths in the Western Interconnection as identified by WECC)
Hydro-Quebec TransEnergie (HQT)	Disagree	See answer to Q5.
Manitoba Hydro	Disagree	The SDT should consider the statements in the Technical Paper on pgs. 32-34 that encroachment taking place if a line is operating beyond its rating would not be a violation of the Requirement.
Duke Energy	Disagree	This requirement needs to be re-written such that it is a performance-based requirement with graduated VSLs. As currently written, this requirement is a binary requirement which carries a single VSL which can only be “Severe”. This may drive overly-aggressive and costly vegetation management programs that carry minimal additional reliability benefit. A performance-based requirement should be developed relative to some metric such as line-mile exposure that will promote high quality vegetation management, optimization of the reliability cost/benefit relationship and deliver the overall end result of improved reliability to the system. The performance-based requirement may still be zero tolerance, but should be structured for a graduated VSL.
ISO/RTO Council		The SRC has no comment on this question.

7. As stated in the background information above, in response to industry comments, the Requirement for preventing Sustained Outages due to blowing together of vegetation and transmission line conductors (the new R7) is developed. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

Organization	Yes or No	Question 7 Comment
Northern Indiana Public Service Company	Agree	Have concerns about T.O.'s determining what is "active" and "inactive" R.O.W. which are explained in Question 1 comments.
Southern California Edison Company	Agree	SCE generally agrees with the content of the new R7, but believes it could be combined with the new R8 into a single requirement (a revised new R7). It appears to SCE that both bulleted exceptions listed in the new R8 can also be applied to the new R7. Please see SCE's response to Question 8 below.
E.ON U.S.	Disagree	: E.ON U.S. requests that the SDT add language specifically excluding vegetation outside of an active ROW that could potentially blow into the conductor
North Carolina Electric Membership Corporation	Disagree	An issue exists, as currently worded, in that it does not exclude vegetation entirely off the ROW, under normal weather conditions, that could be blown into the conductor.
SCE&G	Disagree	An issue exists, as currently worded, in that it does not exclude vegetation entirely off the ROW, under normal weather conditions, that could be blown into the conductor.
SERC Vegetation Managment Sub-committee (VMS)	Disagree	An issue exists, as currently worded, in that it does not exclude vegetation entirely off the ROW, under normal weather conditions, that could be blown into the conductor.
Entergy Services, Inc	Disagree	As currently written, the Standard does not exclude vegetation entirely off the Right of Way, under normal weather conditions, that could be blown into the conductor.
Associated Electric Cooperative, Inc.	Disagree	Associated Electric Cooperative Inc agrees with the intent of R7. Perhaps the clarity could be improved by rewording, such as: “Each Transmission Owner shall prevent Sustained Outages6 of applicable lines due to the blowing together of a conductor and vegetation from within an Active Transmission Line Right of Way (operating within design blow-out conditions) with the following exception: [Violation Risk Factor - Medium][Time Horizon - Real Time]o Sustained Outages of applicable lines that result from natural disasters4 or wind-blown debris.
American Transmission Company	Disagree	ATC requests the SDT to clarify “wind-blown debris”. ATC believes the definition should include branches and/or trunks partially severed from the tree.
FirstEnergy Corp	Disagree	FE suggests a removal of R7. See our response to Question 5 for further information.
Tampa Electric Company	Disagree	In the white paper, page 35, paragraph 2, it states that if the conductor is operating above its rating it” would

Organization	Yes or No	Question 7 Comment
		not be classified as vegetation related sustained outage under the standard.” If this is so it needs to be stated and/or clarified in the standard itself. In addition, on page 35, 3rd paragraph, last sentence of the white paper it states,” Additionally, sustained outages due to wind-blown debris, such as large limbs and branches, separated tree tops, etc., are exempt from this standard.” Again if this is so it needs to be stated in the standard. Question for clarification: If the debris that falls is from a tree within the active transmission line ROW is it a violation?
US Bureau of Reclamation	Disagree	It is not clear why Natural disasters or wind blown debris have to do with vegetation blowing together with transmission lines. Also it is not clear why human or animal activity or falling vegetation are not listed as exemptions.
Central Maine Power an Energy East Company	Disagree	Note that R7 applies only to trees growing within the active right of way. Suggest that the standard clearly explain this concept.
Progress Energy Carolinas, Inc.	Disagree	Off ROW vegetation blowing into conductors is nothing more than off ROW vegetation “falling into the line” without permanent deformation of the vegetation (i.e., breaking/uprooting). Since the original design of the line did not require the off ROW vegetation to be removed, off ROW vegetation should not be included in the requirement.R8 as it is currently worded, “Each Transmission Owner shall prevent Sustained Outages of applicable lines due to the blowing together of vegetation and a conductor within an Active Transmission Line Right of Way (operating within design blow-out conditions) with the following exception:” should be reworded as follows... “...due to the blowing together of a conductor and vegetation rooted within the Active Transmission Line Right of Way...)
Xcel Energy	Disagree	Please see our comments above concerning footnotes 4 & 5.
JEA	Disagree	Please see the comment to question 4.
CenterPoint Energy	Disagree	R7 refers to “Active Transmission Line Right of Way” which is not defined as to its limits within the Standard. The SDT has indicated in its response to 1st Draft Comments from CenterPoint Energy that the “...Transmission Owner is responsible for defining the Active Transmission Line Right of Way.” However, that defining clause is not included in the current definition. CenterPoint Energy recommends deleting the phrase, “within an Active Transmission Line Right of Way”, deleting the phrase, “operating within design blow-out conditions”, and revising R7 to read, “Each Transmission Owner shall prevent Sustained Outages of applicable lines due to the blowing together of vegetation and a conductor operating within its designed sway under rated conditions with the following exceptions...”. The terms used in R1 of “sag” and “sway” should be used consistently. R1.6 already requires that maintenance strategies ensure that the MVCD is never violated

Organization	Yes or No	Question 7 Comment
		and “consider the sag and sway of the conductor throughout is operating range and under rated conditions”. This requirement by itself defines the airspace that must be maintained to prevent a Sustained Outage. R7 requires no specific definition of a right of way because R1 already defines the necessary minimum clearance to be maintained at all times.
Transmission Owner	Disagree	This requirement is not congruent with the purpose of this standard. The standard was enacted as a result of the North East Blackout and a history of grid blackouts in which the growth of trees below conductors under load contributed to the situation. Trees blowing into the conductor create no more risk to cascading than causes such as lightning or foreign interference. This requirement should be removed from the standard.
Arizona Public Service	Disagree	This requirement is too vague and needs more clarity. Vegetation in the easement width or permitted ROW shall not blow into the conductors resulting in an outage. If a utility has rights to maintain vegetation there shouldn’t be any outages due to vegetation from blowing into the conductors. There active ROW should be wide enough to prevent these types of outages.
Duke Energy	Disagree	This requirement needs to be re-written such that it is a performance-based requirement with graduated VSLs. As currently written, this requirement is a binary requirement which carries a single VSL which can only be “Severe”. This may drive overly-aggressive and costly vegetation management programs that carry minimal additional reliability benefit. A performance-based requirement should be developed relative to some metric such as line-mile exposure that will promote high quality vegetation management, optimization of the reliability cost/benefit relationship and deliver the overall end result of improved reliability to the system. The performance-based requirement may still be zero tolerance, but should be structured for a graduated VSL.
ISO/RTO Council		The SRC has no comment on this question.

8. As stated in the background information above, in response to industry comments, the Requirement for preventing Sustained Outages due to fall-ins of vegetation (the new R8) is developed. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

Vegetation Management Team	Agree	
WECC RC	Agree	
Western Area Power Administration, Rocky Mountain Region	Agree	
Central Maine Power an Energy East Company	Agree	Active right of way is an important component to R8.
Northern Indiana Public Service Company	Agree	Have concerns about T.O.'s determining what is "active" and "inactive" R.O.W. which are explained in Question 1 comments.
Southern California Edison Company	Agree	SCE agrees with the content of the new R8, but believes that R8 should be combined with the new R7 into a single requirement (a revised new R7). It appears to SCE that both bulleted exceptions listed in new R8 can be applied to a revised new R7 which would then read: NEW R7. Each Transmission Owner shall prevent Sustained Outages of applicable lines due to the blowing together of vegetation and a conductor, or, vegetation falling into a conductor from within an Active Transmission Line Right of Way, with the following exceptions: [Violation Risk Factor - Medium] [Time Horizon - Real Time]o Sustained Outages of applicable lines that result from natural disasters or wind-blown debris.o Sustained Outages of applicable lines that result from human or animal activity.
Tampa Electric Company	Agree	The white paper again states that the conductor is operating within its normal rating. If, when it is operating above its normal rating it is not classified as a vegetation related outage under the Standard, this needs to be clarified in the standard itself.
Arizona Public Service	Disagree	APS understand the concept of active ROW but the SDT needs to clarify trees within the easement or permitted ROW and those outside the ROW. Utilities have a responsibility to maintain those within and shall be held accountable.
American Transmission Company	Disagree	ATC requests the SDT to clarify whether this includes branches partially severed from the tree falling into a conductor from within the active ROW.
FirstEnergy Corp	Disagree	FE suggests a removal of R8. See our response to Question 5 for further information.

Organization	Yes or No	Question 8 Comment
BC Transmission Corporation	Disagree	I strongly recommend that this be changed from “shall prevent sustained outages” to “shall minimize sustained outages due to fall ins. It is operationally almost impossible to know precisely where the edge of the ROW is in all situations under all conditions. This could lead to an incident where utilities are charged unreasonably - for example, for an outage from a tree that was one foot within the active ROW line. We should not be held liable when reasonable due diligence is practiced. Further, it is not economically feasible for utilities to survey every ROW in the U.S. and Canada to determine precise clearance zones.
US Bureau of Reclamation	Disagree	It is not clear why Natural disasters or human or animal activity or wind blown debris have to do with vegetation fall-ins and why they would need to be exempted.
PacifiCorp	Disagree	PacifiCorp suggests inserting “by a qualified observer” after “observed.” Otherwise, utilities could be held accountable to train all their workers who might casually encounter vegetation conditions in their work or commutes.
Pacific Gas and Electric Co.	Disagree	PG&E agrees in principal with R5 but disagrees with the exception for human activity noted in footnote (5), specifically aboriculture, horticulture or agricultural activities. This exception is overly broad and could be interpreted as exempting certian activities (such as planting orchards) from the standard and will invite legal challenges to the TO’s right to perform vegetation management. PG&E proposes alternative language to the exception as follows: Examples include, but are not limited to, logging, animal severing tree, vehicle contact with tree, digging or removal of tree or new plantings between inspection cycles where the TO does not have actual knowledge. As an alternative, add a generic force majeure statement as described in Q18 #2.
Xcel Energy	Disagree	Please see our comments above concerning footnotes 4 & 5.
JEA	Disagree	Please see the comment to question 4.
CenterPoint Energy	Disagree	R8 refers to “Active Transmission Line Right of Way” which is not defined as to its limits within the Standard. The SDT has indicated in its response to 1st Draft Comments from CenterPoint Energy that the “...Transmission Owner is responsible for defining the Active Transmission Line Right of Way.” However, that defining clause is not included in the current definition. CenterPoint Energy recommends deleting the phrase, “within an Active Transmission Line Right of Way”, and revising R8 to read, “Each Transmission Owner shall prevent Sustained Outages of applicable lines due to vegetation falling into a conductor where the Transmission Owner had the legal right or prior permission to remove the vegetation.”Since R1 in the Standard does not address how a Transmission Owner conducts its work to address the fall-in of trees into an adjacent transmission line, R8 may not be needed in the Standard. In the Technical Reference under the Applicability of the Standard, the SDT states that “On the other hand, most other outage causes (such as

Organization	Yes or No	Question 8 Comment
		trees falling into lines....) are statistically intermittent. The probability of occurrence of these events is not dependent on heavy loads. There is no cause-effect relationship which creates the probability of simultaneous occurrence of other such events. Therefore these types of events are highly unlikely to cause large-scale grid failures." This observation made by the SDT would support the removal of R8 from the Standard. R8 appears to be a major driving cause for introducing the new term "Active Transmission Line Right of Way", and removing R8 would avoid the need to introduce this ambiguously defined term and simplify the Standard without significant impact on its intended purpose. The impact of R8 is also diminished by the fact that the majority of fall-ins occur as a result of the exceptions currently stated in the rule and are typically from outside the maintained boundary of the right of way.
E.ON U.S.	Disagree	The standard must be consistent with R4
Transmission Owner	Disagree	This requirement is not congruent with the purpose of this standard. The standard was enacted as a result of the North East Blackout and a history of grid blackouts in which the growth of trees below conductors under load contributed to the situation. Trees falling into the conductor create no more risk to cascading than causes such as lightning or foreign interference. This requirement should be removed from the standard.
Duke Energy	Disagree	This requirement needs to be re-written such that it is a performance-based requirement with graduated VSLs. As currently written, this requirement is a binary requirement which carries a single VSL which can only be "Severe". This may drive overly-aggressive and costly vegetation management programs that carry minimal additional reliability benefit. A performance-based requirement should be developed relative to some metric such as line-mile exposure that will promote high quality vegetation management, optimization of the reliability cost/benefit relationship and deliver the overall end result of improved reliability to the system. The performance-based requirement may still be zero tolerance, but should be structured for a graduated VSL.
ISO/RTO Council		The SRC has no comment on this question.

9. As stated in the background information above, in response to industry comments, the Requirement for implementation of annual work plan (the new R9) is developed. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

Southern California Edison Company	Agree	SCE agrees with the content of the new R9, however, we suggest it be placed immediately after R1 and be identified as the new R2. SCE suggests that the requirement be modified to read: R9(R2). Each Transmission Owner shall implement its annual work plan for VegetationManagement.
Oncor Electric Delivery	Disagree	Comments: See response to Q.1 The VSL for R9 indicate “failure to implement” percentages of the annual work plan for the different VSL levels. There is lack of clarity in how “percentage” is defined. Is percentage based on 1) # of lines in the annual plan vs # lines not worked according to the annual plan or 2) miles of line not implemented vs total miles in the annual plan?
Platte River Power Authority Vegetation Management Group	Disagree	It seems apparent that if you have a work plan (R1.3.) you should implement that plan and M9 specifies the evidence of such implementation is specific to the work plan. However, the requirement is ambiguous as we interpret it to apply only to the work plan as outlined in R1.3. but the last sentence "...to accomplish the purpose of this standard" makes us wonder if perhaps the implementation and documentation required is boarder. We understand that the implementation of the work plan is separated into a separate requirement so that different VRF and VSL can be assigned but it would provide more clarity if the requirement were as follows: R9. Each Transmission Owner shall implement and document its annual work plan for vegetation management to meet R1.3. In cases when the annual work plan is adjusted or not completely implemented as originally planned, the reasons for the deferrals or changes and the expected completion date of the postponed work should be documented as well.

Organization	Yes or No	Question 9 Comment
Nebraska Public Power District	Disagree	NPPD agrees with the wording provided by Xcel Energy. Each Transmission Owner shall implement its annual work plan for vegetation management to accomplish the purpose of this standard, subject to its legal rights.
Central Maine Power an Energy East Company	Disagree	Restore the phrase " within the extent of its easement and/or legal rights" found in FAC 003 1 .
Idaho Power Company	Disagree	Reword R9 to say 'The TO shall implement its annual work plan for vegetation management within its legal rights...'
American Transmission Company	Disagree	Same response as in Question # 1 (addressing R1.3 and R1. 5) ATC believes that Requirement 9 should allow for flexibility in the annual work plan to carry over implementation to the following calendar year.
Manitoba Hydro	Disagree	The annual work plan should allow for justification to carry over the implementation to the following calendar year or years.
PacifiCorp	Disagree	The current language of the requirement places the sole burden for implementation of the annual work plan, including the correction timeframe, on the Transmission Owner. This could be problematic on federal property where local district offices have authority over whether or not to approve vegetation management work. In order to implement their annual work plans, Transmission Owners must obtain approval from any applicable federal agency through that agency's approval process. There are occasions where authorization from that agency may take many months or even years. The language of the requirement should be modified to take this into account; if authorization from the applicable federal agency is not granted within six months, the Transmission Owner should not be subject to penalties or sanctions because these would be associated with actions beyond their control.
Arizona Public Service	Disagree	There should be a footnote that if federal or state agencies fail to approve annual work plans within 90 days of submittal the utility will not be held accountable for not completing its annual work plan or taking into account the time it takes to get approval. We have land agencies that give us approvals within 2 weeks and others that have taken over a year. Utilities are at their mercy on the approval process. If there is turn-over in the land agency the approval process changes again and it is impossible to determine the anticipated timeline by state, tribal and federal agencies.
Salt River Project	Disagree	There should be an additional statement to include "subject to the Transmission Owner's legal rights". This requirement should acknowledge the difficulties Transmission Owner's have working with federal and state

Organization	Yes or No	Question 9 Comment
		agencies that do not approve work plans in a timely manner.
FirstEnergy Corp	Disagree	We agree with this requirement except for the phrase "to accomplish the purpose of this standard". This phrase is unnecessary and could lead to unintended interpretations. It is understood that every requirement in each reliability standard is written to accomplish the purpose of its respective standard, and those words should not be required in the text of the requirements.
Xcel Energy	Disagree	Xcel Energy strongly believes that the requirement that each Transmission Owner shall implement its annual work plan for vegetation management must acknowledge that such vegetation management is subject to the legal rights available to the Transmission Owner. Hence, it is suggested that R9 be revised to read: "Each Transmission Owner shall implement its annual work plan for vegetation management to accomplish the purpose of this standard, subject to its legal rights."
ISO/RTO Council		The SRC has no comment on this question.

10. As stated in the background information above, in response to industry comments, the Requirement for the preparation of list for sub 200kV transmission lines by the Planning Coordinator (the new R10) is developed. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

Superintendent Transmission Maintenance	Agree	Agree with the requirements under R10, however, request further clarification on the source and qualifications of the "Planning Coordinator".
Edison Electric Institute	Agree	First, EEI generally agrees with the draft revised applicability section. In addition and to help reduce ambiguity in the text, EEI asks that the SDT consider additional language in R.10 and R. 11 (and M. 10 and M. 11) that Planning Coordinators be required to include all facilities under 200 kv identified as IROL facilities under FAC-014. For example, the language of the applicability of the Standard could be stated to include all facilities under 200 kv identified under FAC-014 as IROL facilities. The corresponding requirement could be stated as ‘Each Planning Coordinator will notify all Registered Entities under 200 kv for which this Reliability Standard applies.’ EEI also believes that this change would be consistent with the discussion of the issue in Order No. 693 (P. 706)Second, EEI recommends consideration for including in the applicability section of the Standard the phrase from the technical paper, i.e., the Standard will not apply to line sections inside the electric station fence or other boundary of an electric station, or underground lines. (Technical Paper, p. 8) If included, this addition would add much-needed clarity for Registered Entities.In particular, EEI encourages further consideration for lines from generation facilities to network substations. Some Generation Owners have lines greater than a mile in length EEI asks the SDT consider whether to extend applicability of the Standard for Generation Owners that own lines that meeting certain predefined criteria, or other approaches that would clarify the treatment of lines owned by Generation Owners on the generator side of a network substation. Finally, further clarification may be needed on whether the Standard will cover all facilities rated at greater than 200 kv. For example, there may be 230 kv radial lines to distribution deemed exempt from a BPS -defined set of assets. EEI understands that some confusion exists on whether the threshold BPS

Organization	Yes or No	Question 10 Comment
		definition governs applicability for all individual Standards.
Southern California Edison Company	Agree	SCE generally agrees with the requirement, but is concerned about the new role for the Planning Coordinator and the posibility that it will have shared compliance responsibilities for designated lines with the Transmission Owner.
Hydro-Quebec TransEnergie (HQT)	Disagree	NERC standards apply only to BES facilities and not necessarily at voltage level threshold. The standards should not apply to facilities that are not BES. Within a standard there might be exceptions for cases where the standard would apply only to a subset of the BES facilities. The only change between the current standard and the proposed draft is who designates critical lines. In the current standard it was the RRO while in the new standard it is the PC. The RRO (or the PC in the future version) can only designate critical lines among those that are already classified as BES.Furthermore, the purpose of the standard should be changed to read : 'To improve the reliability of the Bulk Electric System by preventing....' since the NERC Standards are designed to be applicable to the BES, not the 'electric transmission system'; or is it the real intention of NERC to have some standards for BES and some for 'electric transmission system'? We would appreciate to have the SDT opinion on this.
Independent Electricity System Operator	Disagree	NERC standards apply only to BES facilities, and not necessarily a voltage level threshold. The standards should not apply to facilities that are not BES. Within a standard there might be exceptions for cases where the standard would apply only to a subset of the BES facilities. This is the case of the FAC-003 current standard and the new draft which both state that the standard applies only to transmission lines operated at 200 kV and above, and to any lower voltage lines designated as critical to the reliability of the electric system in the region. The only change between the current standard and the proposed draft is who designates the above critical lines. In the current standard it was the RRO while in the new standard it is the PC. The RRO (or the PC in the future version) can only designate critical lines among those that are already classified as BES.
Northeast Power Coordinating Council--RSC	Disagree	NERC standards apply only to BES facilities, and not necessarily a voltage level threshold. The standards should not apply to facilities that are not BES. Within a standard there might be exceptions for cases where the standard would apply only to a subset of the BES facilities. This is the case of the FAC-003 current standard and the new draft which both state that the standard applies only to transmission lines operated at 200 kV and above, and to any lower voltage lines designated as critical to the reliability of the electric system in the region. The only change between the current standard and the proposed draft is who designates the above critical lines. In the current standard it was the RRO while in the new standard it is the PC. The RRO (or the PC in the future version) can only designate critical lines among those that are already classified as BES.

Organization	Yes or No	Question 10 Comment
ISO New England Inc.	Disagree	NERC standards apply only to BES facilities. The standards should not apply to facilities that are not BES. Within a standard there might be exceptions for cases where the standard would apply only to a subset of the BES facilities. This is the case of the FAC-003 current standard and the new draft which both state that the standard applies only to transmission lines operated at 200 kV and above, and to any lower voltage lines designated as critical to the reliability of the electric system in the region. The only change between the current standard and the proposed draft is who designates the above critical lines. In the current standard it was the RRO while in the new standard it is the PC. The RRO (or the PC in the future version) can only designate critical lines among those that are already classified as BES.
Public Service Co. of New Mexico	Disagree	PNM disagrees with the use of the "Planning Coordinator." There is no definition of this individual or group of individuals anywhere in the proposed standard or white paper that is apparent. Clarification is needed.
MRO NERC Standards Review Subcommittee	Disagree	R10 states that the PC “consult” with its TOs and neighboring PCs to obtain input for the list of qualifying facilities operated below 200 kV. What does “consult” mean? It is a surrogate for “coordinate” which is being removed from standards because of compliance implications - an entity might be held in violation if another entity did not respond or act to “coordinate” the effort. Also, R11 uses the terms “reliability significance” and “unacceptable risk of instability” which are undefined and not measurable. R11 is the lead requirement and could be moved to new R1 location. Better wording would be “Each PC must develop and document a methodology for determining a list of facilities in its area operated at less than 200 kV whose loss would cause instability, separation or cascading failures on the BES. “ R10 follows directly and would become new R2. Better wording would be “Each PC shall prepare and review annually a list of facilities in its area operated at less than 200 kV which are subject to this standard. This list will be based on information obtained from its TOs. Results will be provided to its TOs and neighboring PCs.”
American Transmission Company	Disagree	See response to Question #11 below.
Platte River Power Authority Vegetation Management Group	Disagree	The requirement is confusing as it infers that it relates to R11 but never states such. It might be clearer if it followed R11, as we believe the correct process should be as stated in the FAC-003-2 Technical Reference: "Planning Coordinators, using their methodologies described in R11, will need to conduct the necessary studies and identify candidate sub-200kV transmission lines for potential applicability under the Standard. The Planning Coordinators will next need to consult with its Transmission Owners and neighboring Planning Coordinators to resolve any differences in the selection of the sub-200kV transmission lines of common interest. Finally, the Planning Coordinator will need to finalize, adopt and issue the list of designated sub-200kV lines". The way it is currently written the Planning Coordinator will need to finalize, adopt and issue the list of designated sub-200kV lines first then consult with its Transmission Operators and neighboring Planning

Organization	Yes or No	Question 10 Comment
		Coordinators and last develop a methodology. We aren't sure why R10 and R11 are separate requirements as they seem to be related and both have the same VRF and time horizon. We believe the two requirements should be combined and placed in sequential order.
US Bureau of Reclamation	Disagree	The role of the Planning Coordinator is inappropriately described in this requirement. The role of the Planning Coordinator as related in the NERC Functional Model is to conduct assessments of transmisssion systems. Planning Coordinators do not implement resource plans (NERC Functional Model Technical Document Page 12 last paragraph). The determination of criticality is an implementation action or operational determination which is reserved for either the Transmission Planner or the Reliability Coordinator. The role of the Planning coordinator is to develop methodologies which are used by others in ensuring reliable BES operation. Specifically the "Planning Coordinator coordinates and evaluates and recommends reinforcement and corrective plans resulting from studies and analysis of system performance and interconnection of facilities." To require the Planning Coordinator to prepare a list of lines which are subject to this standard (critical to the BES) is modifying the role of the Planning Coordinator and should be examined in the context of the role of the Transmission Operator, Transmission Owner, Transmission Planner and Reliability Cooridnator under a separate project.
FirstEnergy Corp	Disagree	We suggest the team consider changes to R10 and R11 to ensure consistency with standard FAC-014 for the transmission facilities that are sub-200kV and deemed as having "reliability significance" and placing the grid at risk for instability and Cascading. FE believes the appropriate set of sub-200kV lines are those identified as being associated with an IROL condition. Utilizing an already established IROL methodology (FAC-010 and FAC-014) eliminates the need for the Planning Coordinator to coordinate with the Transmission Owner(s) alleviating a level of tedious compliance evidence for the Planning Coordinator. Finally, presently missing within the requirement is the need for the Planning Coordinator to submit a list of the reliability significant sub-200kV facilities to the Transmission Owner(s).We propose that requirements R10 and R11 be replace with a single new R10 requirement as follows:"R10 Each Planning Coordinator shall prepare and review annually, a list of lines thatare operated below 200kV, if any, which are subject to this standard. 10.1 The list shall reflect sub-200kV transmission facilities associated with an IROL condition as identified per NERC reliability standard FAC-014. 10.2 The Planning Coordinator shall annually notify its Transmission Owner(s) of the sub-200kV reliability significant facilities that are subject to this standard."No changes to the Violation Risk Factors or Time Horizons for the proposed requirement. We support a VRF of Lower and Time-Horizon of Long-Term Planning.If the proposal is accepted, conforming changes to the Measures are required.Lastly, the team should consider asking NERC to add to its Standards Development issues database a need to revise standard FAC-014 such that the Transmission Owner is notified of all IROL transmission facilities as part of FAC-014. This would allow for changes in FAC-003 that could eliminate the Planning Coordinator as being applicable to the FAC-003 standard.

Organization	Yes or No	Question 10 Comment
ISO/RTO Council	Disagree	We reiterate our comments submitted for Version 1 that the Planning Coordinators and Reliability Coordinators do not have a role in this standard, and requirements R10 and R11 are not needed. Facilities below 200KV are generally not critical on a wide area basis. There may be some facilities that are critical for local service – most likely in metropolitan areas or a very rural system where they are wholly dependent on sub 200KV facilities. Therefore, there is not a need for a wide area assessment by the Planning Coordinator in this standard. Those facilities below 200KV that are vital for local service would already be identified and included in the vegetation management program of the Transmission Owner. Further, facilities that are associated with IROLs, regardless of voltage class, are already identified through the R5 requirements. We understand the SDT's response to our initial comments that FERC expects this standard to require the identification of relevant sub 200KV facilities, but for the reasons presented in these comments, we believe that sub 200KV facilities relevant to wide area reliability are few and there should not be an expectation or requirement for the PCs to identify significant portions of sub 200kv facilities for purposes of this standard. Such facilities should be included only when the PC has documented a need.

11. As stated in the background information above, in response to industry comments, the Requirement for the Planning Coordinator to document method for identification of applicable sub-200kV transmission lines (the new R11) is developed. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

Western Area Power Administration, Rocky Mountain Region	Agree	
Puget Sound Energy	Agree	Assuming the Planning Coordinator is approved through the functional model revisions and entities register for it.
JEA	Agree	Might want to consider adding something along the lines of "for the purposes of vegetation management" at the end to clarify the purpose of the list.
Southern California Edison Company	Agree	SCE generally agrres with the requirement, but is concerned about the role identified for the Planning Coordinator and the possibility that it will have shared compliance responsbilities with the Transmission Owner for certain identified lines.
Public Service Co. of New Mexico	Disagree	Again, see comment from Question 12 - no definition of the term "Planning Coordinator."
American Transmission Company	Disagree	ATC proposes the following:Remove both R10 and R11 because the TPL-002 and TPL-003 standards already require the Transmission Planner and the Planning Coordinator to ensure reliable system operation for loss of single-element and multi-element contingencies. ATC recommends changing the appropriate text in the first two items under A4.2, Facilities: to “. . . transmission lines operated below 200kv that are identified as an element of an IROL or Major WECC Transfer Path”.In addition, TPL-002 and TPL-003 require the TP and PC to identify IROL’s so that the applicability section of this document should use the outcome from those approved Reliability Standards as an input for this standard. Structuring the standard in this way will makes future enhancement efforts more efficient.If the R10 and R11 removal suggestion is rejected, then revise R11 to, “. . . its methodology for assessing which, if any, lines are subject to this standard. The methodology shall describe the process for determining which lines, if any, below 200kV are expected to have an unacceptable

Organization	Yes or No	Question 11 Comment
		instability or cascading outcome due to TPL-002 and TPL-003 conditions.”
NERC Standards Review Subcommittee	Disagree	See comments above in Question 10.
Platte River Power Authority Vegetation Management Group	Disagree	The criteria for assessing the lines whose loss would place the gird at an unacceptable risk of instability, separation, or cascading failures needs to be more clearly defined. We interpret R10 and R11 to mean that any Category B contingency of a sub-200kV line that causes instability, separation, or cascading failure is subject to FAC-003-2. Is this your desired level of assessment?
Hydro-Quebec TransEnergie (HQT)	Disagree	This should apply to all BES transmission facilities. The use of 200kV as a threshold should be removed. See also Q10 answer.
Independent Electricity System Operator	Disagree	This should apply to all BES transmission facilities. The use of 200kV as a threshold should be removed.
ISO New England Inc.	Disagree	This should apply to all BES transmission facilities. The use of 200kV as a threshold should be removed.
Northeast Power Coordinating Council--RSC	Disagree	This should apply to all BES transmission facilities. The use of 200kV as a threshold should be removed.
FirstEnergy Corp	Disagree	We propose the removal of requirement R11. See our response to Question 10 for further details.
ISO/RTO Council		The SRC has no comment on this question.

12. The SDT received suggestions from commenters to re-sequence the requirements contained in the standard to improve the logical flow of this document. The SDT submits for consideration a proposed alternative sequence. Do you agree with the proposed alternative sequencing? If not, please recommend a suggested sequence.

Xcel Energy	Agree	
Hydro-Quebec TransEnergie (HQT)	Agree	As per our answer to Q5, R5 and R6 should be combined to R5 with the elimination of the IROL concept.
American Transmission Company	Agree	ATC agrees generally with the rearrangement. We believe that the proposed requirements R11 and R10 should be removed because can be adequately covered in the applicability section of this document. The remaining proposed reorder would then be okay.
MRO NERC Standards Review Subcommittee	Agree	N/A
ReliabilityFirst Corporation	Agree	This proposed sequence flows better. Feel that R10 and R11 can be combined into one.
JEA	Agree	Would not the Vegetation Inspections be documented in the Work Plan? Perhaps those two should be switched or combined. I'd move Implement Imminent Threat to the end.
Associated Electric Cooperative,	Disagree	Associated Electric Cooperative Inc. believes the current requirements sequence is appropriate.

Organization	Yes or No	Question 12 Comment
Inc.		
Northern Indiana Public Service Company	Disagree	Prefer current sequence except I have no objection to placing the PC requirements at the top of the list.
New Brunswick Power Transmission	Disagree	Propose further revision of "alternate sequence" to R1-4, R6, R5, R7, R10, R11, R9, R8. Suggested proposal reflects dealing with high priority issues first. That is imminent threats must be handled before planned work. Similarly for prevention of outages grow-ins are the most critical, followed by blow-ins and fall-ins.
Central Maine Power an Energy East Company	Disagree	Suggest reverse R4 with R5.
FirstEnergy Corp	Disagree	While we don't have a strong opinion on this, we believe the proposed sequence of R8, R9, R10 and R11 (old R8, R7, R6 and R5) would be better placed in the following order using the teams designated proposed numbering: R11, R10, R8 and R9. This order is suggested so that a greater emphasis on grow-in and IROL is accomplished and that the standard addresses those items first.
ISO/RTO Council		The SRC has no comment on this question.

13. The Implementation Plan proposes an effective date that gives entities at least a year to become fully compliant. Do you agree with this implementation plan? If not, please indicate what should be changed and indicate why.

US Bureau of Reclamation	Agree	
Vegetation Management Team	Agree	
WECC RC	Agree	
Western Area Power Administration, Rocky Mountain Region	Agree	
Xcel Energy	Agree	
American Electric Power	Agree	The one year should be adequate presuming that the Planning Coordinator does not designate significant numbers of facilities below 200 kV. Should this become the case, a year would be insufficient to for implementation.

Organization	Yes or No	Question 13 Comment
MRO NERC Standards Review Subcommittee	Disagree	MRO NSRS does not believe that current proposed implementation time in Facilities 4.2.2 is adequate. Given the time required to conduct a survey to determine if a company's lines are maintained sufficiently to meet the new requirements, in addition to the time and resources (both budgetary and labor) required to implement the results of the survey, we believe that between 24 and 36 months may be required to implement this version of the standard.
SCE&G	Disagree	SCE&G believes that this standard is superior to the existing standard and therefore requests that the effective date be moved up. We also recommend that the new standard be started on a calendar year.
Southern Company	Disagree	SDT should consider a more rapid implementation plan because the new standard has significant improvement over the existing standard. For example, Southern Company feels it could be implemented the first calendar day of the first calendar quarter following approval by the NERC Board of Trustees.
SERC Vegetation Managment Sub-committee (VMS)	Disagree	The VMS believes that this standard is superior to the existing standard and therefore requests that the effective date be moved up. The VMS also recommends that the new standard be started on a calendar year.
Entergy Services, Inc	Disagree	This Standard should move forward prior to the current one year provided, it is far superior to the existing Standard.
ISO/RTO Council	Agree	If this standard retains the need to identify sub 200KV facilities, then one year provides sufficient time for Planning Coordinators to meet R10 and R11.

14. Do you have further questions about the standard that the Technical Reference document (White Paper) does not clear up? If so, please elaborate and propose additions.

Organization	Yes or No	Question 14 Comment
Xcel Energy		(a) To avoid confusion, the diagrams of the ROWs in the White Paper should not have tree-like objects in the Active Transmission Right of Way. If any vegetation is to be shown in those areas, the vegetation should be shrubbery.(b) The discussion on p. 24 indicates that the MVCD is the “spark-over zone.” The MVCD (hopefully to be renamed) should not directly correlate to the spark-over zone. The spark-over zone should be less than the MVCD.
Hydro One Networks inc.		(a) we suggest an illustration of R7 be added. R7 text states “... due to the blowing together of vegetation and a conductor within an Active Transmission Line ROW.” These words could suggest that sustained outages from vegetation (branches) extending within the active ROW, but originating from trees located outside the active ROW, might not be considered a preventable outage. An illustration in the reference paper would provide clarity.(b) Confusion still exists around the determination of the “active transmission line right-of-way”. The diagrams shown in the white paper, though helpful, do not necessarily apply to all field conditions. Specific questions include: Is it up to the Transmission Operator to determine the “active transmission line right-of-way”, particularly in cases where the RoW may not be maintained to the legal boundary? Example 4 in the definition of “active transmission line right-of-way” (pg. 5) uses the words “deactivated” and “unavailable for service”; these terms should be clearly defined, as there can be several degrees of de-activation and entities may interpret them differently.
BC Transmission Corporation		Active ROW needs to be defined in more detail
Arizona Public Service		Active ROW needs to defined in more detail.
Consolidated Edison Company of New York Inc.		CECONY recommends that an illustration of R7 be added to the Technical Reference document. R7 text states “ ... due to the blowing together of vegetation and a conductor within an Active Transmission Line ROW." These words could be interpreted to mean that sustained outages from vegetation (branches) extending into the active ROW, but originating from trees located outside the active ROW, might not be considered a preventable outage. An illustration in the reference paper would provide clarity.
Duke Energy		During the first comment period, it was noted that it was difficult to prove a negative. This will be the case with some of the requirements proposed in this version. For example, it would be beneficial to note in the Technical Reference Paper that documented vegetation inspections that do not identify an encroachment (R4

Organization	Yes or No	Question 14 Comment
		violation) would be proof of compliance. Other examples may exist that the team may consider including for reference.
Entegra Power Group LLC		In some way address dealing with Generator Interconnection Facilities (GIF) which only have a few spans of transmission interconnect. Will this be addressed in a future specific Standard, or as a separate requirement under FAC-003-2? Entegra suggests a much simpler approach can be employed when under 4 spans worth of vegetation can be visually inspected every 1-2 years and trimmed to prevent any possible vegetation impact to subject lines/system.
Tampa Electric Company		In the white paper, page 35, paragraph 2, it states that if the conductor is operating above its rating it "would not be classified as vegetation related sustained outage under the standard." If this is so it needs to be stated and/or clarified in the standard itself. In addition on page 35, 3rd paragraph, last sentence of the white paper it states, " Additionally, sustained outages due to wind-blown debris, such as large limbs and branches, separated tree tops, etc., are exempt from this standard." If this is so it needs to be stated in the standard. Need clarification, if the debris is from trees within the active transmission ROW is it a violation?
Tucson Electric Power Company		In the white paper, the pictorial reference of the active right of way has no reference to show what the minimum distance beyond the conductor envelope should be to establish the width of the active right of way.
US Bureau of Reclamation		It is not clear at what physical point in the BES the is standard would apply; such as from the first structure outside of the substation/switchyard or other demarcation.
National Grid		National Grid suggests an illustration of R7 be added. R7 text states " ... due to the blowing together of vegetation and a conductor within an Active Transmission Line ROW". These words could suggest that sustained outages from vegetation (branches) extending within the active ROW, but originating from trees located outside the active ROW, might not be considered a preventable outage. An illustration in the reference paper would provide clarity that these sustained outages are a violation of R7.
ReliabilityFirst Corporation		No
TVA		no
WECC RC		NO
Associated Electric Cooperative,		No comments

Organization	Yes or No	Question 14 Comment
Inc.		
North Carolina Electric Membership Corporation		None
SCE&G		None
SERC Vegetation Managment Sub-committee (VMS)		None.
Southern Company		None.
Pepco Holdings, Inc - Affiliates (PHI)		PHI has concerns that the reference document has many items that are critical to the determination of compliance.
CenterPoint Energy		Questions are listed below:1. How does the Transmission Owner determine the geometric limits of an “Active Transmission Line Right of Way” to determine how a Sustained Outage is reported under Category 1A, Category 1B, Category 2, and Category 4.2. Why does an “Inactive R.O.W.” contain trees that are within falling distance of an applicable transmission line? (Figure 1 has such a depiction.) Is the “Inactive R.O.W. outside the legal limits of the Transmission Owners’ right of way?3. Why don’t Requirements 5, 6, 7 and 8, and their corresponding Measures 5, 6, 7, and 8, and the Compliance 1.5 Sustained Outage Categories - Category 1A, Category 1B, Category 4, and Category 2 all have the same exceptions listed? For example, R5 has the exceptions for “Sustained Outages of applicable lines that result from natural disasters” and Sustained Outages of applicable lines that result from human or animal activity.” M5 and Category 1A do not contain those exceptions. Category 1A qualifies events to be reported as “inside and/or outside of the Active Transmission Line ROW”, but R5 and M5 do not have such a reference. How will the reporting differentiate between a Sustained Outage caused by improper vegetation management and those caused by natural disasters? FAC-003-1 R3.2 did not require the reporting of certain sustained transmission line outages (e.g. natural disasters, human activity, etc.). It is not clear what the current draft intends to have reported.
Nebraska Public Power District		Remove the tree-like objects from the diagrams of the ROWs in the White Paper. If any vegetation is to be shown in those areas, the vegetation should only be shrubbery.
Entergy Services, Inc		See additional Entergy comments below.

Organization	Yes or No	Question 14 Comment
Orange and Rockland Utilities, Inc.		Suggest an illustration of R7 be added. R7 text states " ... due to the blowing together of vegetation and a conductor within an Active Transmission Line ROW". These words could suggest that sustained outages from vegetation (branches) extending within the active ROW, but originating from trees located outside the active ROW, might not be considered a preventable outage. An illustration in the reference paper would provide clarity.
Hydro-Quebec TransEnergie (HQT)		Suggest an illustration of R7 be added. R7 text states "... due to the blowing together of vegetation and a conductor within an Active Transmission Line ROW". These words could suggest that sustained outages from vegetation (branches) extending within the active ROW, but originating from trees located outside the active ROW, might not be considered a preventable outage. An illustration in the reference paper would provide clarity.Confusion still exists regarding the determination of the "active transmission line right-of-way". The diagrams shown in the white paper, though helpful, do not necessarily apply to all field conditions. Specific questions include: is it up to the Transmission Operator to determine the "active transmission line right-of-way", particularly in cases where the ROW may not be maintained to the legal boundary? Example 4 in the definition of "active transmission line right-of-way" (pg. 5) uses the words "deactivated" and "unavailable for service". The terms active, deactivated, and unavailable for service should be clearly defined as they can easily be interpreted different ways between different entities, and for different situations.
Independent Electricity System Operator		Suggest an illustration of R7 be added. R7 text states "... due to the blowing together of vegetation and a conductor within an Active Transmission Line ROW". These words could suggest that sustained outages from vegetation (branches) extending within the active ROW, but originating from trees located outside the active ROW, might not be considered a preventable outage. An illustration in the reference paper would provide clarity.Confusion still exists regarding the determination of the "active transmission line right-of-way". The diagrams shown in the white paper, though helpful, do not necessarily apply to all field conditions. Specific questions include: is it up to the Transmission Operator to determine the "active transmission line right-of-way", particularly in cases where the ROW may not be maintained to the legal boundary? Example 4 in the definition of "active transmission line right-of-way" (pg. 5) uses the words "deactivated" and "unavailable for service". The terms active, deactivated, and unavailable for service should be clearly defined as they can easily be interpreted different ways between different entities, and for different situations.
ISO New England Inc.		Suggest an illustration of R7 be added. R7 text states "... due to the blowing together of vegetation and a conductor within an Active Transmission Line ROW". These words could suggest that sustained outages from vegetation (branches) extending within the active ROW, but originating from trees located outside the active ROW, might not be considered a preventable outage. An illustration in the reference paper would provide clarity.Confusion still exists regarding the determination of the "active transmission line right-of-way". The diagrams shown in the white paper, though helpful, do not necessarily apply to all field conditions.

Organization	Yes or No	Question 14 Comment
		Specific questions include: is it up to the Transmission Operator to determine the “active transmission line right-of-way”, particularly in cases where the ROW may not be maintained to the legal boundary? Example 4 in the definition of “active transmission line right-of-way” (pg. 5) uses the words “deactivated” and “unavailable for service”. The terms active, deactivated, and unavailable for service should be clearly defined as they can easily be interpreted different ways between different entities, and for different situations.
Northeast Power Coordinating Council--RSC		Suggest an illustration of R7 be added. R7 text states “... due to the blowing together of vegetation and a conductor within an Active Transmission Line ROW”. These words could suggest that sustained outages from vegetation (branches) extending within the active ROW, but originating from trees located outside the active ROW, might not be considered a preventable outage. An illustration in the reference paper would provide clarity.Confusion still exists regarding the determination of the “active transmission line right-of-way”. The diagrams shown in the white paper, though helpful, do not necessarily apply to all field conditions. Specific questions include: is it up to the Transmission Operator to determine the “active transmission line right-of-way”, particularly in cases where the ROW may not be maintained to the legal boundary? Example 4 in the definition of “active transmission line right-of-way” (pg. 5) uses the words “deactivated” and “unavailable for service”. The terms active, deactivated, and unavailable for service should be clearly defined as they can easily be interpreted different ways between different entities, and for different situations.
Vegetation Management Team		The Active ROW definition should be expanded to exclude areas of the ROW that are currently being used for other transmission facilities, such as 110 kV towers etc. As written, it only excludes unused portions of the ROW, abandon lines and the side of structures that have no facilities. Perhaps use “A strip of land that is occupied by applicable transmission facilities.The last paragraph on page 8 of the Technical Reference indicates that the Standard is not applicable to “...line sections inside the electric station or other boundary...” This is somewhat ambiguous on who has the responsibility of assure compliance “inside the fence or other boundary”.
Salt River Project		The Active ROW should be defined in more detail.
Public Service Co. of New Mexico		The Planning Coordinator is not defined. Please clarify who this person(s) are.Additionally there needs to be more specific language regarding the importance of this reliability standard specifically for dealings with Federal, State or Tribal authorities.
American Electric Power		The SDT has done a great job developing this version of the standards, responding to comments, and enhancing the Technical Reference document. We have no other questions at this time.
Utility Arborist Association		The UAA commends the standards drafting team for covering ANSI A300, Part 7 and the International Society

Organization	Yes or No	Question 14 Comment
		of Arboriculture's integrated vegetation management best management practices in the technical reference. The UAA considers the treatment to be a reasonable representation of best practices to use in complying with FAC-003-02. We remain convinced that best management practice implementation is the most effective way to improve reliability. The A300 section in the technical reference is an important contribution in that regard. We reiterate our view that ANSI A300 be included in the requirements rather than as a footnote in the standard.
MRO NERC Standards Review Subcommittee		To avoid confusion, the diagrams of the ROWs in the White Paper should not have tree-like objects in the Active Transmission Right of Way. If any vegetation is to be shown in those areas, the vegetation should be shrubbery.
Northern Indiana Public Service Company		When discussing R4 (Pg. 30), the document brings up the concept of identifying encroachments of the MVCD during inspections but doesn't discuss indicators present in vegetation that has experienced flashover. For example, at the time vegetation is inspected, offending vegetation may be well outside the minumum distance in Table 1, but still exhibit evidence of sparkover such is wilted leaves, scorched limbs, etc. It would be helpful for the document to discuss these and other indicators of encroachment into the MVCD in greater detail.

15. As stated in the background information above, in response to industry comments, the applicability section is revised to replace Reliability Coordinator with Planning Coordinator. Do you agree with these changes? If not, please explain and propose an alternative.

JEA	Agree	I agree this makes sense. Unfortunately, at least in FRCC, every TO has TWO Planning Coordinators so unless the RE or NERC straightens that situation out, there will be confusion as to which has the authority.
E.ON U.S.	Disagree	: E.ON U.S. recommends that the RC remain the responsible entity instead of the Planning Coordinator as RCs are best situated to determine a line's criticality to the region.

Organization	Yes or No	Question 15 Comment
Public Service Co. of New Mexico	Disagree	As stated in several earlier questions, there isn't a definition of who this person(s) are and what their duties are? Should be clearly defined in both the standard and in the white paper.
Pepco Holdings, Inc - Affiliates (PHI)	Disagree	PHI concurs with replacing the Reliability Coordinator with the Planning Coordinator. However, PHI has concerns with the Applicability section. 4.2.1 has (-applicable lines-) immediately following the term -transmission lines-, indicating that all Transmission Lines are applicable lines. We are certain that is not what the SDT meant. Additionally, Transmission Line is a NERC defined term and includes all Facilities 69kV - 765kV. We assume what is meant is to limit the applicability to BES (BPS) Facilities 200kV and above plus Transmission Lines operated below 200kV designated by the Planning Coordinator.PHI also encourages further consideration for lines from generation facilities to network substations. Some Generator Owners have lines greater than a mile in length. The SDT should consider whether to extend applicability of the standard for Generator Owners that own lines that meeting certain predefined criteria, or other approaches that would clarify the treatment of lines owned by Generator Owners on the generator side of a network substation.
Vegetation Management Team	Disagree	Suggest adding BES to the first bullet under A.4.-Facilities: to clarify that FAC-003-2 only applies to the BES. That radial lines supplying distribution substations, etc. aren't part of the standard. The bullet could read: "Bulk Electric System Transmission lines ("applicable lines") operated at 200kV or higher, and transmission lines operated below 200kV designated by the Planning Coordinator as being subject to this standard including but not limited to those that cross lands owned by federal1, state, provincial, public, private, or tribal entities."
US Bureau of Reclamation	Disagree	The role should be examined as part of the functional model description. To modify the role in the inidividual standards may result in holes in the fuctional model roles.
Platte River Power Authority Vegetation Management Group	Disagree	We are still finding confusion within the industry about the function of the Planning Coordinator and registration for Planning Coordinator (a.k.a. the Planning Authority). We think a strong possibility exists that there may be Transmission Owners who don't have a Planning Coordinator or assume that their Balancing Authority or a other registered entity is providing this function for them when in reality they are not. This confusion could present a gap in reliability. At one time there was discussion of removing this function from the Functional Model all together and replacing Planning Coordinator with Transmission Planner in all applicable standards. Although the Planning Coordinator and the Transmission Planner are the same within our organization we believe it will provide clarity to the standard to make it applicable to the Transmission Planner opposed to the Planning Coordinator. The coordination of the Transmission Planner would be between the Transmission Owners and neighboring transmission planners in R10.

Organization	Yes or No	Question 15 Comment
ISO/RTO Council	Agree	If this standard retains the need to identify sub 200KV facilities, then the change of this responsibility from the Reliability Coordinator to the Planning Coordinator is appropriate.

16. As stated in the background information above, in response to industry comments, changes were made to the definitions. Do you agree with these changes? If not, please explain and propose an alternative.

Organization	Yes or No	Question 16 Comment
WECC RC	Agree	
Western Area Power Administration, Rocky Mountain Region	Agree	
Bonneville Power Administration	Agree	“Response Control Center” is not defined in the NERC Glossary of Terms, so it either needs to be added to the Glossary and/or defined within the Standard to be clear regarding its definition.
Edison Electric Institute	Agree	EEI also recommends that the SDT reconsider use of the term ‘applicable lines’ in the revised draft Standard or clarify the definition. The way the Standard is written with the term “applicable lines” in parentheses and quotes after the words “Transmission lines” in section 4, the term “applicable lines” would under normal interpretation rules be interpreted to mean “Transmission lines.” This surely is not the intent of the SDT. If “applicable lines” is meant to be the facilities defined in Section 4, then EEI recommends modifying Section 4 “Facilities” to read: “Facilities (‘applicable lines’)” if that is the intent to the term ‘applicable lines.’ If not, then the term needs a more specific definition.While applicability of the Standard is already described, use of this term in specific requirements could suggest that there may be lines that are otherwise subject to requirements of the Standard and only ‘applicable lines’ are addressed in some requirements. For example, the sentence ‘Sustained Outages of applicable lines that result from natural disaster,’ could be interpreted to refer to lines affected by a natural disaster, or some other subset of all lines subject to the Standard. EEI recommends that the SDT consider revising language of this type to remove the phrase ‘applicable lines.’ In the example cited, the sentence would become a clause reading: ‘Sustained Outages that result from natural disasters.’
National Grid	Agree	National Grid agrees with the new definition for active transmission right-of-way, though it may need further clarification in the Technical reference document. We have concerns that TO’s might consider portions of the original ROW width as not active. For example: Original width of a ROW was 100 feet, however over many decades the maintained width has been reduced to 80 feet. Might the new definition provide incentive for the TO to now define the active ROW as 80 feet? The proposed removal of the requirement to report Category 3 sustained outages provides additional incentive for the TO to adopt this approach.
Southern California Edison Company	Agree	SCE generally agrees with the definitions, but suggests that the "Vegetation Inspection" definition be revised to read: Vegetation Inspection - The systematic examination of vegetation conditions within an Active Transmission Line Right of Way. A Vegetation Inspection may be combined with other transmission facility inspections.

Organization	Yes or No	Question 16 Comment
FirstEnergy Corp	Agree	We agree with the definitions, but want to point out that this is the only standard that would utilize the term Vegetation Inspection, and the current definition is not used anywhere in the currently approved set of NERC standards. Should this definition only be specific to this standard and not a NERC glossary term? Regardless, we do not have an issue either way.
Xcel Energy	Disagree	(a) The definition of Active Transmission Line Right of Way is confusing. There may be other portions of the Right of Way that were not specifically acquired for other facilities (or being used for other facilities), but are not used and are not needed. As drafted, this definition would ignore this fact. Further, by limiting the definition in this manner, it ignores the fact that it may take different portions of the right of way to operate the line (due to the characteristics of the line, size, location, etc.) and address vegetation concerns. It would be more accurate if the “intended for other facilities” portion of the definition were deleted. This would allow the flexibility to address the concerns noted above. Thus it would read: "A strip of land that is occupied by active transmission facilities. This corridor does not include the inactive or unused part of the right of way."(b) The definition of “Vegetation Inspection” should be rewritten to change the documentation requirement for any vegetation which “may pose a threat.” As a practical mater, any vegetation “may” pose a threat. The definition would be better phrased to read: "The systematic examination of vegetation conditions on an Active Transmission Line Right of Way. This inspection may be combined with a general line inspection. The inspection includes the documentation of any vegetation that poses an unacceptable risk to reliability prior to the next planned inspection or maintenance work."
Platte River Power Authority Vegetation Management Group	Disagree	“intended for other facilities” should be struck from the definition of Active Transmission Line Right of Way as it may include deactivated transmission lines, buffer zones or other ROW never intended for other facilities but wider that necessary.
Tucson Electric Power Company	Disagree	1- In the definition of the term “Active Transmission Right of Way” the final sentence should read “This corridor does not include the inactive or unused part of the Right of Way.” Delete intended for other facilities. 2- We propose the following modification to the Vegetation Inspection definition the sentence; “The inspection includes the documentation of any vegetation that may pose a threat unacceptable risk to reliability prior to the next planned inspection or maintenance work”. This would make the language consistent with other language found in M11 of this document.
MRO NERC Standards Review Subcommittee	Disagree	A. The definition of Active Transmission Line Right of Way is confusing. There may be other portions of the Right of Way that were not specifically acquired for other facilities (or being used for other facilities), but are not used and are not needed. It would be more accurate if the text “intended for other facilities” was deleted. Thus it would read: “A strip of land that is occupied by active transmission facilities. This corridor does not include the inactive or unused part of the right of way.”B. The definition of “Vegetation Inspection” should be

Organization	Yes or No	Question 16 Comment
		rewritten to change the documentation requirement for any vegetation which "may pose a threat." As a practical matter, any vegetation "may" pose a threat. The definition would be better phrased to read: "The systematic examination of vegetation conditions on an Active Transmission Line Right of Way. This inspection may be combined with a general line inspection. The inspection includes the documentation of any vegetation that poses an unacceptable risk to reliability prior to the next planned inspection or maintenance work."
Pepco Holdings, Inc - Affiliates (PHI)	Disagree	Active Transmission Line Right of Way should include the buffer needed to maintain clearances. Width needs to be sufficient to maintain clearances. This should be identified by the TO.
CenterPoint Energy	Disagree	Active Transmission Line Right of WayCenterPoint Energy disagrees with the inclusion and definition of "Active Transmission Line Right of Way". "Active Transmission Line Right of Way" is not defined as to its geometric limits within the Standard. The SDT has indicated in its response to 1st Draft Comments from CenterPoint Energy that the "...Transmission Owner is responsible for defining the Active Transmission Line Right of Way." However, that defining clause is not included in the current definition. CenterPoint Energy recommends one of the following options in order of preference:1) Recommend deleting the term "Active Transmission Line Right of Way" from the standard and revising the Requirements, Measures, and Compliance line items accordingly. R1.6 already requires that maintenance strategies ensure that the MVCD is never violated and considers "the sag and sway of the conductor throughout is operating range and under rated conditions". This requirement by itself defines the airspace that must be maintained to prevent a Sustained Outage for grow-ins and blow-ins. R7 would be revised to read "Each Transmission Owner shall prevent Sustained Outages of applicable lines due to the blowing together of vegetation and a conductor operating within its designed sway under rated conditions with the following exceptions...".R8 would be revised to read, "Each Transmission Owner shall prevent Sustained Outages of applicable lines due to vegetation falling into a conductor where the Transmission Owner had the legal right or prior permission to remove the vegetation."2) To parallel the requirement of R1.6, revise the definition of "Active Transmission Line Right of Way" to, "A strip of land that is occupied by applicable lines considering the sag and sway of the conductor throughout its operating range under rated conditions plus the Minimum Vegetation Clearance Distance (MVCD) from Table 1, where applicable lines are defined as transmission lines operating in real time at 200kV or higher and transmission lines operating in real time below 200kV designated by the Planning Coordinator as being subject to this standard, including but not limited to those lines that cross lands owned by federal, state, provincial, public, private, or tribal entities."3) If the SDT and NERC intend for the Active Transmission Line Right of Way limits to be determined based on the Transmission Owner's interpretation, CenterPoint Energy suggests an alternate definition as follows, "Active Transmission Line Right of Way - A strip of land, the dimensions of which are determined by the Transmission Owner, occupied by applicable lines, where applicable lines are defined as transmission lines operating in real time at 200kV or higher and transmission lines operating in real time below 200kV designated by the Planning Coordinator as being

Organization	Yes or No	Question 16 Comment
		subject to this standard, including but not limited to those lines that cross lands owned by federal, state, provincial, public, private, or tribal entities."By making this suggested change to the definition of "Active Transmission Line Right of Way", most of the ambiguity is removed. It is now clear that the standard does not apply to those portions of rights-of-way in which there are no applicable lines, such as 69kV and 138kV lines that the Planning Coordinator has not determined to be subject to the standard. CenterPoint Energy has added the phrase "operating in real time" to make it clear that the standard also does not apply to a right-of-way in which there is a non-operating line which would normally be subject to the standard if it was operating. By adding MVCD and "sag and sway" requirements to the definition of "Active Transmission Line Right of Way", the standard has defined the physical limits necessary to determine if there has been a violation from trees adjacent to the applicable lines. The alternate definition without the MVCD citation clarifies who is to determine the physical limits of the Active Transmission Line Right of Way since none are provided in the definition itself. However, adding such a reference would surmount to a "fill-in-the-blank" requirement which the SDT has found undesirable. Vegetation InspectionCenterPoint Energy disagrees with the definition of "Vegetation Inspection" since it includes the term "Active Transmission Line Right of Way" which is ambiguously defined and not relevant to defining the type of inspection performed. CenterPoint Energy recommends the following definition, "Vegetation Inspection - The systematic examination of vegetation conditions under and adjacent to a transmission line considering the current location of the conductor and other possible locations of the conductor due to sag and sway for rated conditions. This inspection may be combined with a general line inspection. The inspection includes the documentation of any vegetation that may pose a threat to reliability prior to the next planned inspection or maintenance work."
Salt River Project	Disagree	For the definition of "Vegetation Inspection" recommend the following changes:- In the 3rd sentence, the use of "threat", change to "unacceptable risk"- In the 3rd sentence, remove the last statement "...consider the current location of the conductor and other possible locations of the conductor due to sag and sway for rated conditions". The definition is too lengthy and it does not appear this additional language is necessary.
Vegetation Management Team	Disagree	MVCZ should be included in the Definitions of Terms Used in Standard.
Public Service Co. of New Mexico	Disagree	PNM recommends ammending the definition of "Active Transmission Line Right of Way" as follows: A strip of land that is occupied by active transmission facilities. This corridor does not include the inactive or unused part of the Right of Way.PNM recommends ammending "Vegetation Inspection" to include acceptable types of inspection methods i.e. ground patrols, aerial patrols, etc.
Entergy Services, Inc	Disagree	See additional Entergy comments below.
Manitoba Hydro	Disagree	the definition of "active ROW" should include the concept of meeting safe/reliable operation design criteria

Organization	Yes or No	Question 16 Comment
US Bureau of Reclamation	Disagree	The definitions should not include performance measures or suggestions such as "This inspection may be combined with a general lineinspection." The definition is also phrased in terms of a requirement by using "The inspection includes the documentation of any vegetation that may pose a threatto reliability prior to the next planned inspection or maintenance work, considering the current location of the conductor and other possible locations of the conductor due to sag and sway for rated conditions." Both of these quoted phrases should be removed to the requirements section.
Ameren	Disagree	Vegetation Inspection:Need to insert that these inspections are based on inspectors expectation of normal growth and environmental factors or note that the inspector can not determine all hazards from vegetation that may occur from natural disasters or human or animal activity when inspecting. This would be a complimentary statement to the exceptions for actual events that occur in these requirements.
ISO/RTO Council		The SRC has no comment on this question.

17. When compared to Version 1, does this proposed Version 2 of the standard either maintain or improve overall electric reliability? Please provide a technical basis for your response?

Organization	Does or Does Not	Question 17 Comment
Entegra Power Group LLC		No comment
Southern California Edison Company		Uncertain. At this point in time, SCE does not believe that it is possible to predict whether Version 2 will improve overall electric reliability when compared with Version 1 because NERC has not yet demonstrated with documentation that the implementation of Version 1 of FAC-003 has improved electric reliability.

SCE&G	V2 Does maintain or improve overall reliability	As stated, SCE&G believes that this standard version is superior to the previous. Improvement areas include: o Clarification is made that sustained outages are a violation of the requirements. o Separation of imminent threat, vegetation inspections and the annual work-plan have been made. o Minimum clearance distances are realistic and eliminates references outside the standard (via Appendix 1). The fill-in-the-blank aspects are eliminated. o Established a clear process for identifying sub 200kV circuits applicable to the revised standard. o Clarification of the active ROW o This revision eliminates non enhancing aspects of the previous version (e.g. personnel qualifications, category 3 reporting, clearance 1, etc.) o Applies to applicable transmission facilities regardless of location o Focus is made to actual and observable conditions rather than hypothetical conditions. o Addresses the elements of FERC order 693
SERC Vegetation Managment Sub-committee (VMS)	V2 Does maintain or improve overall reliability	As stated, the SERC VMS believes that this standard version is superior to the previous. These improvements include:Clarification is made that sustained outages are a violation of the requirements. Separation of imminent threat, vegetation inspections and the annual work-plan have been made. Minimum clearance distances are realistic and eliminates references outside the standard (via Appendix 1). The fill-in-the-blank aspects are eliminated. It establishes a clear process for identifying sub 200kV circuits applicable to the revised standard. Clarification of the active ROW is made.This revision eliminates non enhancing aspects of the previous version (e.g. personnel qualifications, category 3 reporting, clearance 1, etc.)Applies to applicable transmission facilities regardless of location.Focus is made to actual and observable conditions rather than hypothetical conditions.It addresses the elements of FERC order 693.
American Transmission	V2 Does maintain or improve overall	ATC believes that the standard provides for improved reliability, however, needs to consider ATC’s

Organization	Does or Does Not	Question 17 Comment
Company	reliability	comments to earlier questions.
Bonneville Power Administration	V2 Does maintain or improve overall reliability	BPA believes V2 maintains overall reliability. Although there are many differences between the two versions, the overall differences between version 1 and version 2 appear to have the same impact on reliability.
Consolidated Edison Company of New York Inc.	V2 Does maintain or improve overall reliability	CECONY believes that the Standard does help maintain or improve overall reliability since the requirements for a TVMP are clearly addressed including inspection cycles, responses to imminent threats, reduced ambiguity, and documentation requirements. Also, the fact that real time encroachments are considered violations will make utilities more likely to use LIDAR and other technology without the fear of discovery of an encroachment violation of a condition that has not occurred. This will result in earlier detection of potential problems and will increase reliability. The Transmission Owner should be solely responsible for determining the abilities and training needs of their employees and ensure that capable individuals perform their vegetation management functions.
E.ON U.S.	V2 Does maintain or improve overall reliability	E.ON U.S. believes the proposed revision provides much greater clarity to the requirements than what is currently in place.
Edison Electric Institute	V2 Does maintain or improve overall reliability	EEI applauds the commitment and effort of the SDT and appreciates the revised draft FAC-003 Standard as a complete response to the key issues raised by FERC in Order No. 693:o NERC has addressed applicability issues, balancing the need for covering facilities that impact reliability against unreasonably increasing the burden of transmission owners.o NERC has addressed minimum clearance issues, proposing requirements that will avoid vegetation-related sustained outages for lines on both federal and non-federal lands.o NERC has proposed changes to applicability to better recognize differing needs for active and inactive rights-of-way. o NERC has addressed inspection cycles to ensure that inspections are conducted at reasonable intervals.Overall, EEI believes that the Standard can provide adequate requirements for company vegetation management programs for maintaining clearances on rights-of-way on the Bulk Power System. Compliance with these requirements would, if established as mandatory by FERC, support reliable operation of the Bulk Power System by preventing Sustained Outages caused by vegetation.The electric industry broadly recognizes that several Reliability Standards contain ambiguous terms and requirements, which have resulted in significant challenges for companies in seeking to determine appropriate compliance actions, and for compliance enforcement activities within NERC. EEI strongly supports the general process for improving the Standards development process and content of the Standards as a long-term goal for NERC. In the context of revising

Organization	Does or Does Not	Question 17 Comment
		FAC-003, to the maximum extent practicable EEI encourages the SDT to use defined terms and explicit references. EEI recognizes also that the need to reduce ambiguity must be balanced against the need to adapt flexible requirements and measures that recognize the widely varying vegetation circumstances on the Bulk Power System. This is especially challenging for developing enforceable requirements to address vegetation encroachment issues on transmission rights-of-way.
Tennessee Valley Authority	V2 Does maintain or improve overall reliability	I believe it improves reliability.
Associated Electric Cooperative, Inc.	V2 Does maintain or improve overall reliability	It is Associated Electric Cooperative Inc's opinion that V2 maintains overall reliability as compared to V1. o Developing separate requirements for documentation and implementation of the Imminent Threat Process, Vegetation Inspections, and the Annual Work Plan adds to the clarity of the standard.
North Carolina Electric Membership Corporation	V2 Does maintain or improve overall reliability	NCEMC does believe that this standard version is an improvement to the previous. Improvement areas include:o Clarification is made that sustained outages are a violation of the requirements. o Separation of imminent threat, vegetation inspections and the annual work-plan have been made. o Minimum clearance distances are realistic and eliminates references outside the standard (via Appendix 1). The fill-in-the-blank aspects are eliminated. o Established a clear process for identifying sub 200kV circuits applicable to the revised standard. o Clarification of the active ROW.o This revision eliminates non enhancing aspects of the previous version (e.g. personnel qualifications, category 3 reporting, clearance 1, etc.)o Applies to applicable transmission facilities regardless of locationo Focus is made to actual and observable conditions rather than hypothetical conditions.o Addresses the elements of FERC order 693
Southern Company	V2 Does maintain or improve overall reliability	The new standard differentiates between IROL and non IROL facilities. The use of the Planning Coordinator in lieu of the Reliability Coordinator provides a long term approach to improving reliability. The definition of active ROW helps differentiate between important ROW and less important ROW.
Western Area Power Administration, Rocky Mountain Region	V2 Does maintain or improve overall reliability	The proposed Version 2 of the Standard improves overall system reliability by: 1) Clarifying previously ambiguous requirements of Version 1 regarding what is or is not a violation of the Standard. For example, previously unclear expectations associated with Version 1 requirements R1.2.2. and R3 are now clearly addressed as requirements in Version 2 requirements R4, R5, R6,

Organization	Does or Does Not	Question 17 Comment
		R7 and R8. 2) Providing real time, observable and measurable thresholds for compliance in Version 2 verses the many subjective and "interpreted" thresholds for compliance which were contained in Version 1 requirements. 3) Requiring a series of pro-active, mandatory and graduated actions by the Transmission Owner for preventing vegetation related outages that could lead to cascading events. These "layers of protection" include the formal identification of facilities subject to the standard, the establishment of a credible TVMP and execution of annual plans, mandatory field inspections, prevention of encroachments into Minimum Vegetation Clearance Distances, mitigation of imminent threats, prevention of outages due to fall ins, prevention of outages due to blow ins, and the prevention of outages due to grow ins.
JEA	V2 Does maintain or improve overall reliability	The standard seems to maintain reliability and add clarity.
American Electric Power	V2 Does maintain or improve overall reliability	This standard is a significant improvement in its specificity of the documentation and reporting responsibilities necessary to be fully compliant.
MRO NERC Standards Review Subcommittee	V2 Does maintain or improve overall reliability	Using the Gallet equation puts the tree trimmers closer to the lines than the OSHA standards will allow due to the fact that OSHA recognizes the standard IEEE 516-2003 clearance distances. We recommend revising Table 1 taking into account the IEEE standard.
New Brunswick Power Transmission	V2 Does maintain or improve overall reliability	V2 is a much improved version of the standard in that it provides clarify on a number of issues; the technical reference is a welcome addition and provides critical information for meeting proposed standard.
Superintendent Transmission Maintenance	V2 Does maintain or improve overall reliability	V2 maintains and improves overall system reliability with real-time, observable, and measurable standards that include a thorough approach (inspections, reporting, MVCDs, etc) to minimizing cascading outages caused by vegetation.
Tampa Electric Company	V2 Does maintain or improve overall reliability	V2 represents the growth of the standard via much improved clarification; I have to think that this will result in a much better overall industry understanding of the standard and its requirements. This should result in improved Industry performance and thus will maintain or improve overall reliability. MVCD is improved via Gallet formula, definitions are new & improved, VRF & VSL’s clarify risk and severity.

Organization	Does or Does Not	Question 17 Comment
US Bureau of Reclamation	V2 Does not maintain or improve overall reliability	It is hard to imagine any vegetation encroachment that would not be exempted by this standard. Overall the exemptions appear to be inconsistent with the language in the respective requirements.
National Grid	V2 Does not maintain or improve overall reliability	National Grid disagrees that V2 will improve reliability for 3 reasons: 1) National Grid believes eliminating Clearance 1 will be detrimental to reliability. The determination of Clearance 1 is an important exercise for the TO to better understand the dynamics of conductor movement and vegetative growth. This required analysis should lead to development of a more informed vegetation management program. Clearance 1 also gives the TO leverage with landowners and local regulators to achieve the necessary operational clearances. If the only required clearance is the R4 Minimum Vegetation Clearance Distance (MVCD), landowners and local regulators will push the utility to maintain a clearance close to the MVCD. 2) National Grid believes eliminating the reporting of Category 3 sustained outages will lead to less effort by the TO's to mitigate danger tree exposure where the TO's property rights allow. This will lead to diminished reliability. 3) Removing the qualifications requirement from the standard will likely lead to TO's employing less qualified employees and contractors. The Utility Vegetation Management (UVM) industry, through development of ANSI Standards and industry Best Practices, and the International Society of Arboriculture certification programs, has worked to raise the level of professionalism in the UVM industry. National Grid believes that raising professional standards leads to better quality work and improved reliability.
Orange and Rockland Utilities, Inc.	V2 Does not maintain or improve overall reliability	ORU disagrees that V2 will improve reliability for 3 reasons: 1) ORU believes eliminating Clearance 1 will be detrimental to reliability. The determination of Clearance 1 is an important exercise for the TO to better understand the dynamics of conductor movement and vegetative growth. This required analysis should lead to development of a more informed vegetation management program. Clearance 1 also gives the TO leverage with landowners and local regulators to achieve the necessary operational clearances. If the only required clearance is the R4 Minimum Vegetation Clearance Distance (MCVD), landowners and local regulators will push the utility to maintain a clearance close to the MVCD. 2) ORU believe eliminating the reporting of Category 3 sustained outages will lead to less effort by the TO's to mitigate danger tree exposure where the TO's property rights allow. This will lead to diminished reliability. 3) Removing the qualifications requirement from the standard will likely lead to TO's employing less qualified employees and contractors. The Utility Vegetation Management (UVM) industry, through development of ANSI Standards, and the International Society of Arboriculture certification programs have worked to raise the level of professionalism in the UVM industry. We believe that raising professional standards leads to better quality work and improved reliability. ORU believes that the Standard

Organization	Does or Does Not	Question 17 Comment
		does help maintain or improve overall reliability since the requirements for a TVMP are clearly addressed including inspection cycles, responses to imminent threats, and documentation requirements. Also, the fact that real time encroachments are considered violations will make utilities more likely to use LIDAR and other technology without the fear of discovery of an encroachment violation of a condition that has not occurred. This will result in earlier detection of potential problems and will increase reliability. Even though the Clearance 1 value is being eliminated from the Standard, operating specifications will still govern the way a utility handles its clearances as is currently done. We do agree, however, that landowners and local regulators may want utilities to reduce operational clearance levels based on the MVCD listed in the Standard but the utility must properly communicate the reasoning behind achieving greater clearances as per their TVMP. We do not believe that eliminating the reporting of Category 3 sustained outages will lead to less effort to mitigate danger tree exposure since all transmission outages are sensitive to a Transmission Owner and must be addressed appropriately at multiple levels within the company as well as with other regulatory agencies in some cases. Removing the qualifications requirement may initially lead to Transmission Owners employing less qualified employees and contractors but there needs to be some level of flexibility that will allow for a larger candidate pool or temporary support since individuals with specialized training are not always readily available. The Transmission Owner should be solely responsible for determining the abilities and training needs of their employees and ensure that capable individuals perform their vegetation management functions.
PacifiCorp	V2 Does not maintain or improve overall reliability	PacifiCorp disagrees that FAC-003-02 will improve reliability because the standard lacks a requirement to adhere to best management practices, it does not mandate that programs be managed by qualified individuals, and it has no clearance 1.
Arizona Public Service	V2 Does not maintain or improve overall reliability	Removing the following sections from FAC-003 version 1 does not improve or maintain reliability; R1.2.1, R1.3. APS has responded in the section above.
Puget Sound Energy	V2 Does not maintain or improve overall reliability	The elimination of Clearance 1 from the current standard, and the close distance to the wire in the proposed Table 1 will create more difficulty with agencies and reluctant landowners. A closer distance to the MVCD will be pushed by some. This revised standard gives Transmission Owner no leverage for maintaining Utiltiy Vegetation management Best Management Practices (BMP). If BMP's were utilitzed consistently, there would be minimum outages.
Salt River Project	V2 Does not maintain or improve overall	The proposed MVCD values are less than SRP has defined in the current standard for Clearance 2 values and would not provide adequate clearance. Also see comments stated in question #4

Organization	Does or Does Not	Question 17 Comment
	reliability	regarding concern regarding the method used to determine the MVCD values.
Utility Arborist Association	V2 Does not maintain or improve overall reliability	The Utility Arborist Association thinks version 2 does not improve reliability over version 1 for two reasons. It does not have a qualification requirement, and it does not contain a requirement for utilities to conform to ANSI A300.First, the UAA considers removal of the qualification requirement from the standard to detract from reliability compared to FAC-003-01. Appropriate qualifications are every bit as critical for vegetation management as they are for other areas of expertise necessary to operate the electric grid. For example, no utility would assign engineering responsibilities to anyone without engineering training and experience, as the electric grid would quickly fail. Yet, it is common for utilities to assign vegetation management oversight to employees without the appropriate knowledge and background to succeed. Consider that none of the three North American blackouts in the past fifteen years occurred solely due to engineering deficiencies. Rather, they were initiated by tree contacts. More effective vegetation management programs would have prevented every one of them. Clearly vegetation management expertise is critical, as the consequences of vegetation management deficiencies have resulted in three catastrophic grid failures. It cannot be left to people with improper or inadequate competencies. The standard should say as much.The Utility Arborist Association recognizes that the qualification requirement has been removed due to industry reaction to unreasonable and overbearing demands for proof of qualifications on the part of some auditors. For example, several utilities complained that auditors required resumes of everyone in the program, including ground workers. Clearly, that goes well beyond what was intended in the FAC-003-01, which was that vegetation management oversight for a transmission operator be in the hands of knowledgeable and competent managers. Arguably, demands for resumes of everyone remotely involved detracts from an effective program by occupying managers with irrelevant paper work, rather than addressing the demands of protecting their systems. On the other hand, poor judgment on the part of some auditors doesn't reduce the need for programs to be designed and implemented by qualified utility arborists. The Utility Arborist Association understands the need to address deficiencies in aptitude among vegetation management auditors, and is responding by developing training programs for them. Our objective is to raise the level of understanding among vegetation management auditors to a level necessary for consistent, fair and reasonable compliance oversight that will contribute to, rather than detract from, electric reliability.Secondly, the Utility Arborist Association considers limiting a reference to ANSI A300 to a footnote to insufficiently emphasize it's criticality to overall electric reliability. The UAA strongly urges adding language to R1.1 and M1.6, and hold utilities accountable for using best management practices. The Utility Arborist Association has worked hard to incorporate sufficient flexibility into integrated vegetation management best management practices to account for the array of environmental, political and technical challenges that might confront vegetation managers anywhere they practice. The Utility Arborist Association is confident that adding them as

Organization	Does or Does Not	Question 17 Comment
		requirements to the standard will improve reliability by raising professionalism and leading to more effective results.
Northern Indiana Public Service Company	V2 Does not maintain or improve overall reliability	There are many instances where V2 contains requirements and/or measures are weaker or less stringent than V1. Examples:1. Elimination of Clearance 1 requirements which have been so instrumental in improving T.O. vegetation maintenance activities on R.O.W.'s (see my comments from Draft 1 of FAC-003-2).2. Elimination of requirement for personnel responsible for design and implementation of TVMPs to hold appropriate qualifications to do so.3. Limitation of Corrective Action Process or Mitigation Measures to instances of temporary constraints to planned work rather than all constraints to planned work.4. Nesting the provision for T.O.'s to develop minimum vegetation to conductor clearances that ensure MVCDs are never violated within a general requirement to specify maintenance strategies. This needs to be a clear stand alone clearance requirement similar to the existing Clearance 2.
BC Transmission Corporation	V2 Does not maintain or improve overall reliability	This is a vegetation outage standard not a vegetation management standard. It will do nothing to improve the quality of vegetation maangement programs in North America
Northeast Power Coordinating Council--RSC	V2 Does not maintain or improve overall reliability	V2 will not improve reliability for the following reasons. Eliminating Clearance 1 will be detrimental to reliability. The determination of Clearance 1 is an important exercise for the TO to better understand the dynamics of conductor movement and vegetative growth. This required analysis should lead to development of a more informed vegetation management program. Clearance 1 also gives the TO leverage with landowners and local regulators to achieve the necessary operational clearances. If the only required clearance is the R4 Minimum Vegetation Clearance Distance (MCVD), landowners and local regulators will push the utility to maintain a clearance close to the MVCD. This will lead to diminished reliability. In some respects the Standard does help maintain or improve overall reliability since the requirements for a TVMP are clearly addressed including inspection cycles, responses to imminent threats, and documentation requirements. Also, the fact that real time encroachments are considered violations will make utilities more likely to use LIDAR (radar) and other technology without the fear of discovery of an encroachment violation of a condition that has not occurred. This will result in earlier detection of potential problems and will increase reliability. Even though the Clearance 1 value is being eliminated from the Standard, operating specifications will still govern the way a utility handles its clearances as is currently done. We do agree, however, that landowners and local regulators may want utilities to reduce operational clearance levels based on the MVCD listed in the Standard, but the utility must properly communicate the reasoning behind achieving greater clearances as per their TVMP. We do not believe that eliminating the reporting of Category 3 sustained outages will lead to less effort to

Organization	Does or Does Not	Question 17 Comment
		mitigate danger tree exposure since all transmission outages are sensitive to a Transmission Owner and must be addressed appropriately at multiple levels within the company as well as with other regulatory agencies in some cases. Removing the qualifications requirement may initially lead to Transmission Owners employing less qualified employees and contractors but there needs to be some level of flexibility that will allow for a larger candidate pool or temporary support since individuals with specialized training are not always readily available. The Transmission Owner should be solely responsible for determining the abilities and training needs of its employees and ensure that capable individuals perform their vegetation management functions.
Independent Electricity System Operator	V2 Does not maintain or improve overall reliability	V2 will not improve reliability for the following reasons. Eliminating Clearance 1 will be detrimental to reliability. The determination of Clearance 1 is an important exercise for the TO to better understand the dynamics of conductor movement and vegetative growth. This required analysis should lead to development of a more informed vegetation management program. Clearance 1 also gives the TO leverage with landowners and local regulators to achieve the necessary operational clearances. If the only required clearance is the R4 Minimum Vegetation Clearance Distance (MCVD), landowners and local regulators will push the utility to maintain a clearance close to the MVCD. This will lead to diminished reliability. The Standard does help maintain or improve overall reliability since the requirements for a TVMP are clearly addressed including inspection cycles, responses to imminent threats, and documentation requirements. Also, the fact that real time encroachments are considered violations will make utilities more likely to use LIDAR (radar) and other technology without the fear of discovery of an encroachment violation of a condition that has not occurred. Hydro One Networks inc.	V2 Does not maintain or improve overall reliability	V2 will not necessarily improve reliability for the following reasons: 1) eliminating Clearance 1 will be detrimental to reliability. The determination of Clearance 1 is an important exercise for the TO to better understand the dynamics of conductor movement and vegetative growth. This required analysis should lead to development of a more informed vegetation management program. Clearance 1 also gives the TO leverage with landowners and local regulators to achieve the necessary operational clearances. If the only required clearance is the R4 Minimum Vegetation Clearance Distance (MCVD), landowners and local regulators will push the utility to maintain a clearance close to the MVCD. 2) Eliminating the reporting of Category 3 sustained outages will lead to less effort by the TOs to mitigate danger tree exposure where the TOs property rights allow. This might lead to diminished reliability.
ISO/RTO Council	V2 Does not maintain or improve overall reliability	The SRC believes the change from Reliability Coordinator to Planning Coordinator and the inclusion of specific sub 200kv facilities maintains but does not improve the reliability effectiveness of this standard over Version 1. The removal of the subrequirements R10.1 and R10.2 in Version 1 and the

Organization	Does or Does Not	Question 17 Comment
		new R10 applicable to PCs is appropriate.

18. Besides the comments you have already provided for the preceding questions, do you have further suggestions for improving this standard? If so, please elaborate.

Organization	Question 18 Comment
Salt River Project	- R4: Recommend changing the word “Minimum” in “Minimum Vegetation Clearance Distances” to “Critical” (same with M4) - Footnote #4 (page 5 of 15): Recommend adding “microburst” (after storm) - Footnote #5 (page 5 of 15): Recommend addi
Xcel Energy	(a) The comments made above regarding the Requirement Sections of FAC-003-2 would need to be followed through in the Measure Sections of the standard.(b) Compliance Section 1.5 â— 1b, the word “but” needs to be replaced with the word “which.” (c) Attachment 1 needs to be renamed “Critical Clearance Distances” as discussed above in number 4.(d) We understand the drafting team’s intent, when referring to “applicable lines”, is to encompass all 3 items under Facilities in the Applicability section. Yet it is not clear as presently worded. Please clarify this in the next draft.(e) In version 1 of FAC-003, a sustained outage caused by vegetation within the ROW likely results in a single violation. However, the latest draft of version 2 is written such that the same sustained outage would result in the violation of at least 2, if not 3, requirements. This could quickly ratchet up the penalty amount by 3-4 times. We do not feel that this is reasonable, and recommend that modifications be made to remove double or triple jeopardy circumstances.
Hydro One Networks inc.	(a) The inclusion of a detailed description of ANSI A300 contains a level of detail greater than what should be included in the standard. A simple reference to the ANSI standard would be more than sufficient to provide an example of what may be included in a TVMP, without appearing to dictate specific vegetation management practices that may or may not be available or practical for all Transmission Owners across North America.(b) In the applicability Section, Facilities (4.2.1 in the clean version) we suggest to explicitly indicate that the standard applies to BES facilities only, to read as follows:BES transmission lines (“applicable lines”) operated at 200 kV or higher, and BES transmission lines operated below 200 kV designated by the Planning Coordinator as being subject to this standard including but not limited to those that cross lands owned by federal, state, provincial, public, private, or tribal entities.
FirstEnergy Corp	1. Applicability of the standard with regard to Line Ratings - Regarding the phrase "throughout its operating range under rated conditions" in Req. R1, and also regarding the phrase "operating between no-load and their Rating" in Req. R4, R5, and R6, we feel that "rated conditions" and "Rating" is ambiguous. FE interprets the intent to reflect the maximum conductor thermal rating used in determining maximum sag conditions. We ask the SDT to confirm or clarify our interpretation. 2. Related to our comments in Question 10, section 4.2.2 should be revised to state that sub-200kV lines designated by the PC are subject to this standard 12 months after the Transmission Owner HAS RECEIVED the list from the PC.3. Changes may be needed to the Technical Ref. document based on changes to the standard per our previous comments. Also, on pg. 32 of the ref. document it shows a "high" VRF for Req. R6, but this should be "Medium". Lastly, on pg. 39 of the ref. document it references Part 11.3 which should say 1.1.3.4. Correct the misspelled word "Federal" in section 4.2.1.5. Compliance section 1.5 regarding

Organization	Question 18 Comment
	Categories, "Category 4" should be "Category 3". The footnote 7 is not needed and we suggest the team simply renumber the category list to be 1A, 1B, 2 and 3. Or, FE would support a renumbering of 1, 2, 3 and 4. The list should not skip or omit a category number.6. FE recommends that the SDT reconsider use of the term ‘applicable lines’ in the revised draft Standard. While applicability of the standard is already described, use of this term in specific requirements could suggest that there may be lines that are otherwise subject to requirements of the standard and only ‘applicable lines’ are addressed in some requirements. Therefore, we suggest removing the repeated use of the term "applicable lines" throughout the standard because it should be understood as those addressed in the "Applicability" section A4.2.. 7. Presently, the draft FAC-003-2 text includes a footnote stating that ANSI A300 standard for tree care operations is considered an industry best practice. FE recommends that this reference should not be included in the Standard. Since the ANSI standard would not provide certain obligations or requirements, it is not necessary to be included in the NERC Standard (See definition of Reliability Standard, Standards Development Procedure, p. 6). Rather, it should be included in a supporting document as a reference, as provided by the Standards Development Procedure (p. 34).
Entergy Services, Inc	A) The definition of Active Transmission Line Right of Way in the White Paper contains several examples of “inactive or unused” portions of corridors which are not contained in the definition in the standard. We suggest the examples contained in the White Paper are also included in the definition contained in the standard. Examples of something, the “corridor” in this case, helps clarify one’s understanding of “corridor”. The method is used in every dictionary. Therefore, we suggest adding the following to the definition in the standard:”Examples of inactive or unused portions of corridors include:1) The portions of the right of way acquired to accommodate future facilities. Power plant exits are examples where large rights of way are obtained for maximum corridor utilization and may currently have fewer lines constructed.2) The portion of the right of way where corridor edge zones (i.e., buffer zones) are provided for vegetation to exist.3) The portions of the right of way where double-circuit structures are installed but only one circuit is currently strung with conductors.4) Portions of the right of way with deactivated transmission lines that are unavailable for service.”B) Section 4.2 Facilities contains 3 subparts describing the facilities to which this standard applies. We suggest adding a fourth subpart from the White Paper which describes facilities to which this standard does not apply. Adding this fourth subpart will eliminate the need for future Interpretations and/or revisions to this standard. Please add to section 4.2 Facilities the following from the last paragraph of page 8 of the White Paper:”4.2.4 This standard does not apply to line sections inside the electric station or substation fence, other boundary of an electric station or substation, or underground lines.”C) The terms “imminent threat” and “vegetation imminent threat” are used in the standard. We suggest “vegetation imminent threat” be used in all locations of the standard.D) Standard R1.6 uses the term “never violated” which we believe requires 100% compliance and is too rigid a requirement given the propensity of hurricanes, tornados, and other weather conditions that cause debris to possibly broach the clearances contained in Table 1 Attachment 1. We suggest replacing “never violated” with “not violated during rated operating conditions and normal weather conditions.”E) R5, R6 and R8 contain 2 bullet items while the second bullet item in those requirements is not contained in R7. We suggest adding the second bullet item to R7:”Sustained Outages of applicable lines that result from human or animal activity.5”
MRO NERC Standards Review	A. In FAC-003-1 a self reportable violation could occur at any time vegetation was within, had previously been, or had passed through (fall in) the Clearance 2 zone. In FAC-003-2, this is reportable only if observed in real time. Under FAC-003-1, a tree

Organization	Question 18 Comment
Subcommittee	that was causing instantaneous operations of the line either through wind or loading would be a reportable violation of the Clearance 2 zone when found later during a patrol, even though the clearance now was well outside of the Clearance 2 zone. In FAC-003-2, a self reportable violation would be required only if the tree was observed, in real time, to be in the MVCD.B. Perhaps there should be a statement in FAC-003-2 that is explicit that the TO will manage its ROW to its "full and legal rights".C. The comments made above regarding the Requirement Sections of FAC-003-2 would need to be followed through in the Measure Sections of the standard.D. Compliance Section 1.5 Category 1B(“Grow-ins: Sustained Outages caused by vegetation growing into applicable lines but are not identified as an element of an IROL (or Major WECC Transfer Path) by vegetation inside and/or outside of the Active Transmission Line ROW”), the word “but” needs to be replaced with the word “which.” E. Attachment 1 needs to be renamed “Critical Clearance Distances” as discussed above in Question 4b.F. General comment to entire standard: Remove the repeated use of the term “applicable lines” throughout the revised standard. It should be understood as those addressed in the “Applicability” section A4.2.G. In version 1 of FAC-003, a sustained outage caused by vegetation within the ROW likely results in a single violation. However, the latest draft of version 2 is written such that the same sustained outage would result in the violation of at least 2, if not 3, requirements. This could quickly ratchet up the penalty amount by 3-4 times. We do not feel that this is reasonable, and recommend that modifications be made to remove double or triple jeopardy circumstances.
Utility Arborist Association	As the industry’s leading science and educational organization, the UAA urges the standards drafting team to incorporate provisions that will encourage and compel all utilities to utilize proven vegetation management techniques and practices. We advocate for adequate and appropriate training, adherence to applicable A300 standards, and a clear, consistent, science-based approach to effective vegetation management across North America. ANSI A300 has the flexibility to adjust to local conditions, so there is no reason to not require it’s implementation. We also feel that it is appropriate to expect each utility to have a qualified person on staff (or in a full or part time contracted position) who fully understands proper utlity vegetation maangment. We believe the requirements of qualified people, and adherence to best practices, should be a part of this standard. Further, it is important to recognize the impacts of not directly referencing qualifications and best management standards (A300, etc) in this standard. Now that clearance 1 (in FAC-003 version 1) has been removed, there will likely be more incidents where land agencies, local governments or individuals will attempt to force their own interpretation of what is correct on the utility. In these cases the utility should be able to point to specific references in the proposed standard which will clearly identify what needs to be done (such as the practices described in A300). The utilities should also be able to point to specific references in the standard that establish them as the true authority on the required scope of work (particularly when they are liable for any failure). A specific reference to qualified employees and adherence to A300 will enable the utilities to better control their own ROW’s and should be included in this version of FAC-003.Finally, we believe that the regulators, and other entities who shall be overseeing compliance with this standard, should have an equal understanding of utility vegetation management and compliance as the utilities charged with complying with FAC-003-02. In order to raise the understanding of vegetation managment on the part of vegetation management auditors, the UAA is developing training specifically for them. Our intent is to offer a program that will be available to utilities and compliance auditors that will lead to a consistent and informed understanding of vegetation management and its legal and regulatory requirements. Thank you for the opportunity to

Organization	Question 18 Comment
	comment on this very important regulation and the UAA stands ready to assist the standards drafting team in any way we can.
Consolidated Edison Company of New York Inc.	CECONY recommends that stricter language be used in the Standard specifically requiring the industry to remove incompatible species on Active ROWs. This should reduce the number of outages resulting from vegetation grow-ins and vegetation fall-ins and help maintain a higher level of reliability. This is currently done at the state level (in New York) and the revised wording in the Federal Standard would ensure consistency industry-wide and avoid confusion. A standard definition for the term incompatible would be required to avoid misuse of the term as well.
Edison Electric Institute	EEI has two additional recommendations for consideration by the SDT. First, the draft revised Standard stated purpose is to 'avoid vegetation related outages that could lead to Cascading.' To better align the Standard with the direction provided by Order No. 693 as well as the content of the revised draft Standard, EEI recommends that the SDT consider revising the purpose statement to read: 'To avoid vegetation-related Sustained Outages of transmission lines.'Second, EEI agrees with the intent of including events that would define exceptions for requirements to comply with FAC-003. To assist in reducing ambiguity and as an alternative to the approach in the draft Standard of using footnotes, EEI recommends that the SDT consider adding a generic exceptions statement in the applicability section more specifically stating that companies will not be subject to compliance requirements to the extent that events or circumstances beyond their control limit or prevent their abilities to perform. Here's one example:Compliance with this Standard will not apply should there exist an occurrence, non-occurrence, or other set of circumstances that are beyond the reasonable control of a Registered Entity subject to this Reliability Standard, and are not caused by the fault or negligence of the Registered Entity, including acts of God, strike, flood, drought, earthquake, storm, fire, hurricane, tornado, landslides, logging activities, animals severing trees, lightning, epidemic, war, riot, civil disturbance, sabotage, vandalism, terrorism, or action or inaction by any Governmental Authority or individual that restricts or prevents performance to comply with this Reliability Standard. Should the SDT choose to not add a specific exceptions statement, EEI encourages additional specificity in the footnotes.
Transmission Owner	FPL is in support of the changes made to the Purpose Statement. The purpose should be further clarified. FPL Suggests the following wording:To improve the reliability of applicable electric transmission facilities by preventing those vegetation related outages within active ROW that could lead to Cascading.FPL agrees with the changes in R9 and indicated that in Question 9, however, FPL sees a need for an exemption due to disasters (natural or manmade). During the hurricane seasons of 2004 and 2005 most utilities in the east and southeast were either directly or indirectly affected by the hurricanes occurring in that time period (including named storms. It was in the National interest that those not directly effected respond to requests for mutual aid from those utilities that were. Conversely, those affected had to restore their systems. Annual Work Plans were delayed or changed. An exemption or mechanism needs to be in place to allow utilities to respond with out violating the standard.
American Transmission Company	General comment to entire standard: Remove the repeated use of the term "applicable lines" throughout the revised standard. It should be understood as those addressed in the "Applicability" section A4.2.Also, ATC supports the deletion of footnote #2 to R1.1 regarding ANSI A300. Since the ANSI standard would not provide certain obligations or requirements, it is not necessary to be included in the NERC Standard. (See definition of Reliability Standard, Standards Development Procedure, p. 6) Rather,

Organization	Question 18 Comment
	it should be included in a supporting document as a reference, as provided by the Standards Development Procedure (p. 34)
Oncor Electric Delivery	Having a binary system for R4, 5, 6, 7, and 8 creates a one size fits all approach. The SDT should consider allowing for some normalizing of events / sustained outages per metric considering the number of applicable miles to allow a range of VSL's to be applied.
CenterPoint Energy	Improvements to Standard1. Revise the Purpose statement to "preventing vegetation related outages" and delete "that could lead to Cascading" since Cascading is not referenced anywhere else within the Standard.2. Within R1.6, substitute "practices" for "strategies" as a more actionable word.3. R1.2 and R3 should use the same wording when referring to the frequency of Vegetation Inspections.4. Within M1.6, substitute "practices" for "strategies" as a more actionable word.Improvements to Technical Reference 1. Revise the statement on page 9 to read as follows, "It is not intended to prevent customer outages from occurring due to tree contact with all transmission lines and voltages; however, the Standard is not intended to dissuade best utility practice regarding vegetation management for transmission lines that fall outside the Standard." The Technical Reference is a public document, and thus should be careful to mention best management practices, public safety, and hazard avoidance whenever applicable. Allowing trees to grow near transmission lines at any voltage is a public safety hazard.2. In the Wire-Border Zone section on page 15, CenterPoint Energy recommends revising this sentence as follows, "The wire zone is the section of a utility transmission right of way directly under the wires and extending outward a sufficient distance to allow for movement of the conductors", which deletes the phrase "about 10 feet on each side". The specific 10' distance is misleading where rights of way are purchased without ownership of a border zone, and it may be misleading to the public. CenterPoint Energy has not historically purchased a border zone, and the wire zone equates to the legal limits of our rights of way.The paragraphs on page 15 that start, "One way...", and "In areas where...", should be deleted because they may mislead the public by not taking into account all the needs to remove trees such as access below the lines and possible reconductoring or rebuilding of lines that change the transmission line profile and thus impact the need to remove tall trees in any instance. The prior statement that starts, "Although the wire-border zone..." is sufficient to introduce flexibility in practices.3. In the Selecting a Maintenance Strategy section on page 25, CenterPoint Energy recommends deleting the paragraph that starts, "If faced with...". It should be deleted because it may mislead the public to believing that granting exceptions for trees is a common practice and should be pursued. It does not take into account all the needs to remove trees such as access below the lines and possible reconductoring or rebuilding of lines that change the transmission line profile and thus impact the need to remove tall trees in any instance. It is also not necessary to the example.4. The third bullet under R4 on page 30 has an extra word, "Brief", that is not in the Standard itself.5. R6 quoted on page 32 has an incorrect Violation Risk Factor of "High" instead of "Medium".
Idaho Power Company	In the definition of terms remove 'intended for other facilities' from the definition for Active Transmission Line Right of Way. In the definition of Vegetation, remove ' considering the current location of the conductor and other possible locations of the conductor due to sag and sway for rated conditions' since this is covered in the Standards section.In the measures section, remove 'neighboring Planning Coordinators' from M10 since a neighbor may have different views as to which sub-200kV lines

Organization	Question 18 Comment
	are subject to Standard R10
SCE&G	N/A
WECC RC	NO
National Grid	No additional comments.
American Electric Power	No additional questions at this time.
PacifiCorp	None
NRECA - National Rural Electric Cooperative Association	NRECA on behalf of its members would like to thank the drafting team for its efforts in addressing cooperative concerns from the previous draft of FAC-003-2. In addition, it is important for the drafting team to incorporate the recommendations of the Generator Requirements at the Transmission Interface Ad Hoc Group (GOTO Team) regarding the implications of this standard for the transmission facilities designated as Generator Interconnection Facilities (GIFs). The specific recommendations NRECA supports are; the sole use of GIFs should not cause the registration of entities as Transmission Owners and Transmission Operators, clarifying requirements for GIFs, adding new requirements to make expectations clear for these facility types and working with the GOTO Team to incorporate any new definitions in the NERC Glossary of terms to clarify requirements of this standard.
Orange and Rockland Utilities, Inc.	ORU recommends that stricter language be used in the Standard specifically requiring the industry to remove incompatible species on Active ROWs. This should reduce the number of outages resulting from vegetation grow-ins and vegetation fall-ins and help maintain a higher level of reliability. This is currently done at the state level (in NY) and the revised wording in the Federal Standard would ensure consistency industry-wide and avoid confusion. A standard definition for the term incompatible would be required to avoid misuse of the term as well.
Associated Electric Cooperative, Inc.	Paragraph A.4.2.1 - Associated Electric Cooperative Inc assumes the Standard Drafting Team's intent is for the standard to apply, without exception, to all transmission lines operated at 200 kV or higher and to all transmission lines operated below 200 kV designated by the Planning Coordinator as being subject to the standard. To this end, AECI believes the list of land ownerships included in A.4.2.1 detracts from, rather than adds to, the clarity of the paragraph. It is suggested the paragraph be revised to something like, “All transmission lines (“applicable lines”) operated at 200 kV or higher, and all transmission lines operated below 200 kV designated by the Planning Coordinator as being subject to this standard.”Paragraph D.1.5 - This paragraph clearly requires Transmission Owners to provide periodic reports to the Regional Entity of Sustained Outages occurring on applicable lines that are caused by vegetation. As such, it should be included in the Requirements section of the standard. Associated Electric Cooperative Inc. does not disagree with the intent of the paragraph, only its location within the

Organization	Question 18 Comment
	standard.
Progress Energy Carolinas, Inc.	PEC recommends that the ANSI A300 footnote #2 to R1.1 be removed and included in supporting documentation (the Technical Reference document - “White Paper”).
Southern California Edison Company	SCE appreciates the great amount of time and effort expended by the Drafting Team on the FAC-003-2 Reliability Standard.
Entegra Power Group LLC	See Question 14 comments
Florida Municipal Power Agency, and its Member Cities, Lakeland Electric and Kissimmee Utility Authority	Specify an interim corrective action process for use when theTransmission Owner is temporarily constrained from performingvegetation maintenance as planned.
Vegetation Management Team	The “methods ... to control” in R1.1, the annual work plan in R1.3, and the “maintenance strategies” in R1.6 seem to refer to the same actions but require the TO to address them separately in the TVMP. This needs to be clarified or consolidated.
Central Maine Power an Energy East Company	The clearance 2 defined in FAC 003 1 was a useful tool for transmission owners to manage rights of ways to a robust standard rather than a minimum standard. This language should be included in the TVMP requirement (R1). Suggested language "The TVMP must define a clearance two". The standard would only require this distance be included as part of each T.O's plan, and would eliminate the fill in the blank concept.Suggest that standard note that qualif1ed vegetation managers are recommended to manage the V.M. program.FAC 003 2 should retain the reference to ANSI A300.
Hydro-Quebec TransEnergie (HQT)	The inclusion of a detailed description of ANSI A300 contains a level of detail greater than what should be included in the standard. A simple reference to the ANSI standard would be more than sufficient to provide an example of what may be included in a TVMP, without appearing to dictate specific vegetation management practices that may or may not be available or practical for all Transmission Owners across North America.It is recommended that stricter language be used in the Standard, specifically requiring the industry to remove incompatible species on Active ROWs. This should reduce the number of outages resulting from vegetation grow-ins and vegetation fall-ins and help maintain a higher level of reliability. This is currently done at the state level (in New York), and the revised wording in the Federal Standard would ensure consistency industry-wide and avoid confusion. A standard definition for the term incompatible would be required to avoid misuse of the term as well. Editorial comments--the “1” after “federal” in the first bullet under “Facilities” in the “Applicability” section should be a superscript to indicate the footnote. The text that a footnote refers to should appear at the bottom of the page it is used on, or at a common location, not on different pages.We reiterate the need to change the language used in the purpose of the Standard as per our answer to Q10; if not, we would appreciate to know the SDT rational.

Organization	Question 18 Comment
Independent Electricity System Operator	The inclusion of a detailed description of ANSI A300 contains a level of detail greater than what should be included in the standard. Organization	Question 18 Comment
Southern Company	The new format for the standard moves some requirements from the compliance section (i.e. outage reporting) to additional compliance information. Does this remove the outage reporting requirement from the CMEP? If not, how will it be monitored?
ReliabilityFirst Corporation	The only comment I have is in Facilities section, in the first bullet. I do not see need for adding all the verbiage (including but not limited to those that cross lands owned by federal1, state, provincial, public, private, or tribal entities) after “designated by the Planning Coordinator”.
Superintendent Transmission Maintenance	The white paper could further explain the process by which the planning coordinator and utilities identify sub-200kV lines to be included in the standard. Clarify the definition of an active transmission ROW.
Manitoba Hydro	the wording of requirement 1.5, last word should be changed from "planned" to "required" as one could change the plan based on land deal negotiations for example, or site specific engineering calculations, but at least the minimum requirements to maintain the vegetation must be met.In version 1 of FAC-003, a sustained outage caused by vegetation within the ROW likely results in a single violation. However, the latest draft of version 2 is written such that the same sustained outage would result in the violation of at least 2, if not 3, requirements. This could quickly ratchet up the penalty amount by 3-4 times. We do not feel that this is reasonable, and recommend that modifications be made to remove double or triple jeopardy circumstances.
SERC Vegetation Managment Sub-committee (VMS)	There are certain lines, not owned by Transmission Owners (TO’s) that should be covered by this standard. These include facilities owned by DP’s and GO’s that are not registered as TO’s. This should be addressed via the Standard’s applicability section and not via registration.
Bonneville Power Administration	There are several inconsistencies throughout the document regarding the way Attachments are referred to. The lines are referred to in many different ways - real-time, no load, etc. ??? Standard is a little difficult to follow. The term “sway” is not a technical term, suggest using “swing” or “blow out”.
North Carolina Electric Membership Corporation	Yes. There are certain facilities, not owned by Transmission Owners (TO’s) that should be covered by this standard. These include facilities owned by Distribution Provider’s (DP’s) and Generation Owner’s (GO’s) that are NOT registered as TO’s. In the last draft, several entities provided comments to the SDT about GO’s and DP’s who own such interconnection facilities to connect their generation and load to the transmission system. We make a plea to the SDT to reconsider those comments such as those provided by SERC Compliance Staff. As the standard currently exists today, it forces entities that have such interconnection facilities to be registered as a TO’s regardless of the length of the facility used for interconnection (50 feet, 0.50 miles or 50 miles). These additional facilities should be captured via the Standard’s applicability section and not via registration, thus making the entity subject only to the FAC-003 standard and not to all TO standards. Also, we respectfully request that the SDT provide additional guidance in the standard about length of interconnection facilities before the standard is applicable to such facilities. One suggestion has been offered in the GOTO Team forum ad we repeat here for the benefit of the SDT: Only those Generator Interconnection Facilities above 200kv which extend more than one mile from the Generator

Organization	Question 18 Comment
	Owner property boundary should be assigned applicability for FAC-003-1. A clarification may be needed to provide that those Generator Interconnection Facilities which are located entirely on Generator Owner property should not be applicable.We would also suggest the same guidance be provided for tap lines and radials owned by DPs when these taps or radial are short distances and are within DP property where there would be no gaps. Without this guidance or clarification, then it is left to each Regional Entity to apply their own opinion which may result in inconsistency in enforcing the standard.

NERC
NORTH AMERICAN ELECTRIC
RELIABILITY CORPORATION

Summary Considerations FAC-003-2
Second Industry Comment Period (9/10/09 to 10/24/09)

Background:
On January 14, 2010, the NERC Standards Committee endorsed the use of Project 2007-07 Vegetation Management as the prototype for the proof-of-concept for using the results-based criteria for developing a reliability standard. The results-based initiative is intended to focus the collective effort of NERC and industry participants on improving the clarity and quality of NERC reliability standards by developing performance, risk and competency-based requirements that accomplish a reliability objective through a defense-in-depth strategy, while eliminating documentation-driven requirements that do not have an impact on bulk power system reliability.

The Standards Committee directed the Vegetation Management SDT to stop work in refining its second draft of the Vegetation Management standard but to inform stakeholders on how the team had used stakeholder comments to refine the technical requirements carried over into draft 3 of the standard.

This report provides a copy of each of the questions that was posted for stakeholder comment with the second draft of FAC-003-2, and a summary indicating how the drafting team used stakeholder comments submitted in response to that question. The questions included in the second comment form provided explicit references to either background information provided in the comment form or to specific requirements or other elements in the standard and have been paraphrased here.

All questions asked and all comments provided by stakeholders have been posted at the following site:

http://www.nerc.com/filez/standards/Vegetation-Management_Project_2007-7.html

Index to Questions and Summary Responses:

Question 1

In response to industry comments, the Requirement for documentation of a TVMP was revised to clarify that the objective of the TVMP is to improve reliability by preventing Sustained Outages due to vegetation. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.
Second draft of proposed R1:

R1. Each Transmission Owner shall have a documented transmission vegetation management program that describes how it conducts work on its Active Transmission Line Rights of Way to prevent Sustained Outages due to vegetation, considering all possible locations the conductor may occupy under the effects of sag and sway throughout its operating range under rated conditions. The transmission vegetation management program shall: *[Violation Risk Factor – Lower][Time Horizon – Long-term planning]*

- **1.1.** Specify the methods that the Transmission Owner may use to control vegetation.[1]
- **1.2.** Specify a Vegetation Inspection frequency of at least once per calendar year that takes into account local[2] and environmental factors.
- **1.3.** Require an annual work plan. An annual work plan shall:
  - **1.3.1.** Identify the applicable lines to be maintained
  - **1.3.2.** Identify the work to be performed and methods to be used
  - **1.3.3.** Be flexible to adjust to changing conditions and to findings from Vegetation Inspections. Adjustments to the plan within the year are permissible.
  - **1.3.4.** Take into consideration permitting and scheduling requirements from landowners or regulatory authorities.
- **1.4.** Require a process or procedure for response to an imminent threat of a vegetation-related Sustained Outage. The process or procedure shall specify actions which shall include communication of the threat to the responsible control center.
- **1.5.** Specify an interim corrective action process for use when the Transmission Owner is temporarily constrained from performing vegetation maintenance as planned.
- **1.6.** Specify the maintenance strategies used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that Table 1 clearances in Attachment 1 are never violated. The maintenance strategies shall consider the sag and sway of the conductor throughout its operating range under rated conditions.

Summary Consideration: The vast majority of comments for this Question related to the Annual Vegetation Inspection frequency. Those commenters believed that a once/year mandate was too prescriptive and preferred to let the Transmission Owner choose a frequency.

[1] ANSI A300, Tree Care Operations – Tree, Shrub, and Other Woody Plant Maintenance – Standard Practices, while not a requirement of this standard, is considered to be an industry best practice.

[2] Local factors include items such as treatment cycle, extent and type of treatment, and their relationship to the normal growth rate.

After reviewing Order 693 in its entirety, the SDT set the frequency at once/year to avoid a fill-in-the-blank requirement and establish a reasonable frequency for most regions. However, the SDT also made it explicitly clear that this Vegetation Inspection can be combined with other line inspections to allow maximum flexibility in meeting this requirement. The vast majority of other comments dealt with specific wording in the Draft 2, Requirement 1. In an effort to be less prescriptive, the new Draft has removed most of the text that commenters wanted changed.

Question 2

In response to industry comments, the Requirement for implementation of Imminent Threat process/procedure was revised. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

Second draft of proposed R2:

R2. Each Transmission Owner shall implement its imminent threat process or procedure when the Transmission Owner has actual knowledge of such a threat, obtained through normal operating practices. *[Violation Risk Factor – Medium][Time Horizon – Real Time]*

Summary Consideration: Ninety percent of respondents agreed with Requirement 2 (Implementation of the Imminent Threat Process). No major themes of disagreement surfaced. Two respondents expressed confusion between the NERC defined term "Operating Process" and the language "operating practices" used in R2. Two respondents preferred more specificity in the requirement for audit purposes, one respondent suggested changing "actual knowledge" to "confirmed" and one respondent expressed concerns about proving a negative. Two other respondents had comments that were more appropriate for questions 1 & 4 and are answered there.

The SDT considered all comments and essentially retained all the previous language in the new draft. Of note, the term "actual knowledge" was changed to "verified knowledge" based on the guidelines for Requirements with the new standard format. This change still retains its meaning that the Transmission Owner "confirmed" the potential threat prior to initiating the Imminent Threat process.

Proposed requirement in Draft 3 of FAC-003-2:

R5. Each Transmission Owner shall take interim corrective action when it is temporarily constrained from performing planned vegetation work, where a Transmission Line is put at potential risk due to the constraint.

Question 3

In response to industry comments, the Requirement for conducting Vegetation Inspections was revised. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

Second draft of proposed R3:

R3. Each Transmission Owner shall conduct Vegetation Inspections of all applicable lines (as measured in line miles) in accordance with the frequency specified in its transmission vegetation management program, unless constrained by natural disasters. When constrained by a natural disaster, the Transmission Owner shall conduct the Vegetation Inspection(s) within six months or a period agreed to by its Regional Entity, whichever is greater. *[Violation Risk Factor – Medium][Time Horizon – Operations Planning]*

Summary Consideration: Eight commenters perceived an inconsistency in the inspection frequency required between Requirement 1.2 and Requirement R3. Eleven (11)respondents felt an inspection frequency of longer than once per calendar year should be acceptable, the required frequency for inspection was unclear, or that the requirement should simply state an inspection interval of once per calendar year. Five comments (5) noted that the Requirement R3 exception for non performance due to natural disasters should be expanded, re-organized, or re-worded to be more clear or include a number of additional situations including disease or species epidemics. Several entities (6) expressed a concern over the use of the term "line miles" in the performance measures for this requirement. Finally, a few comments (2) were received that suggested the phrase "all applicable lines" be removed from the requirement.

With this new Draft, the Standards Drafting Team has removed 1.2 which eliminates any perceived confusion. After reviewing Order 693 in its entirety, the SDT re-established the frequency at once/year to avoid a fill-in-the-blank requirement and establish a reasonable frequency for most regions. However, the SDT also made it explicitly clear that this Vegetation Inspection can be combined with other line inspections to allow maximum flexibility in meeting this requirement. The FAC-003-2 Draft 3 includes a general, and more inclusive, Force Majeure section which applies to the entire Standard. The Standards Drafting Team responded to industry comments about the term "line miles". There is now more explanation of this term in the VSL for R6."

Question 4

In response to industry comments, the Requirement for preventing vegetation encroachments was revised. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

Second draft of proposed R4:

R4. Each Transmission Owner shall prevent encroachment of vegetation into the Minimum Vegetation Clearance Distances (MVCD) listed in FAC-003-2 - Attachment 1 for its applicable lines as observed in real-time operating between no-load and their Rating, with the following exceptions: *[Violation Risk Factor – Medium][Time Horizon – Real Time]*

- Encroachment into the MVCD listed in FAC-003-2-Attachment 1 resulting from natural disasters.[3]
- Encroachment into the MVCD listed in FAC-003-2-Attachment 1 resulting from human or animal activity.[4]
- Encroachment into the MVCD listed in FAC-003-2-Attachment 1 resulting from falling vegetation.

Summary Consideration: Fifty-two percent (32 of 62) of the respondents disagreed with various aspects of Requirement 4 (Preventing Vegetation Encroachments). A major theme from 19 responses requested clarification on the fall-in tree exemption particularly when a fall-in tree may be lodged in another tree. The following six minor themes were identified:

- Requested the use of the word “critical” rather than “minimum” to aide with public perception (7 responses)
- Clarification on operating beyond emergency ratings (7 responses)
- Clarification on what is meant by “observed in real-time”(6 responses)
- Requested a force majeure exemption be added (5 responses)
- Requested observations be done by qualified observers (4 responses)
- Requested to eliminate R4 (4 responses).
- Requested an interpolation in the clearance tables for altitude(2 responses)
- Identified “Double Jeopardy” concern between Requirement 4 and the outage Requirements(1 response)

The SDT considered all comments and determined that two of these were significant enough to change the standard - the SDT combined the outage requirements (R5, R6, R7 and R8) with the encroachment requirement (R4). The SDT determined the other comments could be adequately addressed as modifications for clarity to the Technical Reference Document.

[3] Examples include, but are not limited to, earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods.

[4] Examples include, but are not limited to, logging, animal severing tree, vehicle contact with tree, arboricultural activities or horticultural or agricultural activities, or removal or digging of vegetation.

Question 5

In response to industry comments, the Requirement for preventing Sustained Outages due to grow-ins on IROL or Major WECC Transfer Paths was developed. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

Second draft of proposed R5:

R5. Each Transmission Owner shall prevent Sustained Outages[5] of applicable lines that are identified as an element of an Interconnection Reliability Operating Limit (IROL) (or Major WECC Transfer Path) due to vegetation growing into a conductor operating between no-load and its Rating, with the following exceptions: *[Violation Risk Factor – High][Time Horizon – Real Time]*

- Sustained Outages of applicable lines that result from natural disasters.
- Sustained Outages of applicable lines that result from human or animal activity.

Summary Consideration: Commenters generally agreed with R5 in draft 2. The most significant issues that the SDT needed to consider were: the addition of other exclusionary conditions, the prima facie double jeopardy that exists with this requirement and R4, the lack of robust VSLs, and the need for further clarity on terms and concepts (e.g. rating, minimum).

Finally, a few commenters noted that this requirement is structured unlike other conventional NERC standard requirements in that it does not say what must be accomplished for reliability (and compliance) but rather says what must NOT be done.

The SDT considered these comments and determined that two of these were significant enough to change the standard - the SDT combined the outage requirements (R5, R6, R7 and R8) with the encroachment requirement (R4), with one combined Requirement for IROLs/Major WECC Transfer Paths and another combined Requirement for all other lines. A broadened Force Majeure section was added to the applicability section of the standard. Additionally, the new R1 and R2 in this Draft were reworded to describe what must be done.

[5] Multiple Sustained Outages on an individual line, if caused by the same vegetation, shall be considered as one outage regardless of the actual number of outages within a 24-hour period.

Question 6

In response to industry comments, the Requirement for preventing Sustained Outages due to grow-ins on non-IROL or Major WECC Transfer Paths was developed. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

Second draft of proposed R6:

R6. Each Transmission Owner shall prevent Sustained Outages of applicable lines that are not an element of an IROL (or major WECC Transfer Path) due to vegetation growing into a conductor operating between no-load and its Rating, with the following exceptions: *[Violation Risk Factor – Medium][Time Horizon – Real Time]*

- Sustained Outages of applicable lines that result from natural disasters.
- Sustained Outages of applicable lines that result from human or animal activity.

Summary Consideration: Commenters generally agreed with R6 in draft 2. The most significant issues that the SDT needed to consider were: the addition of other exclusionary conditions, the prima facie double jeopardy that exists with this requirement and R4, the lack of robust VSLs, and the need for further clarity on terms and concepts (e.g. rating, minimum).

Finally, a few commenters noted that this requirement is structured unlike other conventional NERC standard requirements in that it does not say what must be accomplished for reliability (and compliance) but rather says what must NOT be done.

The SDT considered these comments and determined that two of these were significant enough to change the standard and have combined the outage requirements (R5, R6, R7 and R8) with this encroachment requirement (R4), with one combined Requirement for IROLs/Major WECC Transfer Paths and another combined Requirement for all other lines. A broadened Force Majeure section was added to the applicability section of the standard. Additionally, the new R1 and R2 in this Draft were reworded to describe what must be done.

Question 7

In response to industry comments, the Requirement for preventing Sustained Outages due to blowing together of vegetation and transmission line conductors was developed. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

Second draft of proposed R7:

R7. Each Transmission Owner shall prevent Sustained Outages of applicable lines due to the blowing together of vegetation and a conductor within an Active Transmission Line Right of Way (operating within design blow-out conditions) with the following exception: *[Violation Risk Factor – Medium][Time Horizon – Real Time]*

- Sustained Outages of applicable lines that result from natural disasters or wind-blown debris.

Summary Consideration: Approximately 70% of the respondents agreed with Requirement R7. Among the commenters who disagreed, a major comment issue pertains to the definition of the Active Transmission Line ROW which is further split into two sub issues.

- The first sub issue relates to a desire for a more descriptive definition of Active ROW.
- The other sub issue suggests the elimination of Active ROW.

A minority comment area pertains to altering the requirement to become more performance based with a graduated set of VSLs.

The SDT believes that the definition of "active transmission right-of-way" is appropriate for meeting the objectives of the Standard. This topic is addressed in the ***Guideline and Technical Basis*** section of this of FAC-003-2 Draft 3. The SDT considered the other comments and determined that two of these were significant enough to change the standard - the SDT combined the outage requirements (R5, R6, R7 and R8) with this encroachment requirement (R4), with one combined Requirement for IROLs/Major WECC Transfer Paths and another combined Requirement for all other lines. A broadened Force Majeure section was added to the applicability section of the standard. Additionally, the new R1 and R2 in this Draft were reworded to describe what must be done.

Question 8

In response to industry comments, the Requirement for preventing Sustained Outages due to fall-ins of vegetation was developed. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

Second draft of proposed R8:

R8. Each Transmission Owner shall prevent Sustained Outages of applicable lines due to vegetation falling into a conductor from within an Active Transmission Line Right of Way with the following exceptions: *[Violation Risk Factor – Medium] [Time Horizon – Real Time]*

- Sustained Outages of applicable lines that result from natural disasters or wind-blown debris.
- Sustained Outages of applicable lines that result from human or animal activity.

Summary Consideration: Approximately 78% of the respondents agreed with the Requirement R8. Among the commenters who disagree, a major comment pertains to the definition of Active Transmission Line ROW which is further split up into two sub issues.

- The first sub issue relates to a desire for a more descriptive/quantitative definition of the Active Transmission Line ROW.
- The other sub issue suggests the elimination of Active Transmission Line ROW.

A minority comment area pertains to altering the requirement to become more performance based with a graduated set of VSL's.

The SDT believes that the definition of "active transmission right-of-way" is appropriate for meeting the objectives of the Standard. This topic is addressed in the ***Guideline and Technical Basis*** section of FAC-003-2 Draft 3. The SDT considered the other comments and determined that two of these were significant enough to change the standard and have combined the outage requirements (R5, R6, R7 and R8) with this encroachment requirement (R4), with one combined Requirement for IROLs/Major WECC Transfer Paths and another combined Requirement for all other lines. A broadened Force Majeure section was added to the applicability section of the standard. Additionally, the new R1 and R2 in this Draft were reworded to describe what must be done.

Question 9

In response to industry comments, the Requirement for implementation of annual work plan was developed. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

Second draft of proposed R9:

R9. Each Transmission Owner shall implement its annual work plan for vegetation management to accomplish the purpose of this standard. *[Violation Risk Factor – Medium] [Time Horizon – Operations Planning]*

Summary Consideration: A majority of commenters requested the restoration of the phrase "subject to legal rights," citing that doing so would improve the ability of TO's in expediting approvals for access. A few comments objected to the phrase "to accomplish the purpose of the standard" citing it was superfluous. A minority of comments pertained to the extent and effect of the phrase "within the year". Commenters pointed out that carryover work into the next year is not possible with the requirement 1.3 as written.

In response to overwhelming industry comments from the first posting of the draft standard, the SDT removed the words "within the extent of its easements and/or legal rights". The concern expressed by the first commenters pertained to avoiding the situation where the expectation is for the transmission Owner to exercise its fullest legal rights when not needed. The SDT did remove the two phrases for clarity and in keeping with the guidelines for this new form of standard development. And sections 1.3.3 and 1.3.4 which were subject to misinterpretation have been removed.

Question 10

In response to industry comments, the Requirement for the preparation of list for sub 200kV transmission lines by the Planning Coordinator was developed. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

Second draft of proposed R10:

R10. Each Planning Coordinator shall prepare and review annually, a list of lines that are operated below 200kV, if any, which are subject to this standard. Each Planning Coordinator shall consult with its Transmission Owner(s) and neighboring Planning Coordinators to obtain input to develop the list. *[Violation Risk Factor – Lower] [Time Horizon – Long-term Planning]*

Summary Consideration: An overwhelming majority of respondents agreed with this requirement as found in the second draft. For those commenters that disagreed with the requirement, three concepts arose. First, some commenters note that a similar identification of important circuit exists in FAC-014 and as such this requirement is unnecessary. The second issue expressed involves the interaction between the TO and the PC. There was concern that the word “consult” was ambiguous and that the mere preparation of the list did not ensure that the TO would be provided the list. The last group opined that this requirement for the actual preparation of the list could be combined with the requirement to establish a methodology (R11) since either one is toothless without the other.

After reviewing these comments as well as a complete analysis of Draft 2 with respect to the guidelines for this new results-based standard development process, the Requirements dealing with the Planning Coordinator have been removed. For sub-200 kV lines, the applicability will derive from identification of Transmission Lines associated with IROLs or as Major WECC Transfer Paths - analysis already exists for both of these.

Question 11

In response to industry comments, the Requirement for the Planning Coordinator to document method for identification of applicable sub-200kV transmission lines was developed. Additionally the SDT assigned Time Horizons, Violation Risk Factors, and Violation Severity Levels. Do you agree? If not, please explain and propose an alternative.

Second draft of proposed R11:

R11. Each Planning Coordinator shall develop and document its method for assessing the reliability significance of sub-200kV transmission lines whose loss would place the grid at an unacceptable risk of instability, separation, or cascading failures. *[Violation Risk Factor – Lower] [Time Horizon – Long-term Planning]*

Summary Consideration: An overwhelming majority of respondents agreed with this requirement as found in the second draft. For those commenters that disagreed with the requirement the most common concern was that a similar identification of important circuit exists in FAC-014 and as such this requirement is unnecessary or duplicative. Two minor opinions also arose, one that all lines should be included in this standard, regardless of voltage, the other that no lines operating at voltage less than 200kV should be included.

After reviewing these comments as well as a complete analysis of Draft 2 with respect to the guidelines for this new results-based standard development process, the Requirements dealing with the Planning Coordinator have been removed. For sub-200 kV lines, the applicability will derive from identification of Transmission Lines associated with IROLs or as Major WECC Transfer Paths - analysis already exists for both of these.

Question 12

The SDT received suggestions from commenters to re-sequence the requirements contained in the standard to improve the logical flow of this document. The SDT submits for consideration a proposed alternative sequence. Do you agree with the proposed alternative sequencing? If not, please recommend a suggested sequence.

Summary Consideration: With only one exception, every commenter agreed that some re-sequencing was logical and appropriate. All others that disagreed with the SDT proposal included alternative sequences.

The SDT has rewritten the Requirements and re-sequenced those remaining by Results-based -type requirements, i.e., competency-based, risk-based, or performance-based.

Question 13
The Implementation Plan proposes an effective date that gives entities at least a year to become fully compliant. Do you agree with this implementation plan? If not, please indicate what should be changed and indicate why.

Summary Consideration: Most commenters felt that the proposed implementation was acceptable. However, a sizable number found this proposed Revision to be far superior to the current in-force standard and would like the SDT to consider options to expedite the implementation. One commenter indicated they would need more time.

The SDT has chosen to retain the implementation plan, rather than attempt an expedited schedule, with FAC-003-2 Draft 3.

Question 14

Do you have further questions about the standard that the Technical Reference document (White Paper) does not clear up? If so, please elaborate and propose additions.

Summary Consideration: The most prevalent comment requested revisions to the Diagrams to eliminate trees in impermissible areas. Another popular comment dealt with a change to the Active Transmission Line Right of Way. Some commenters wanted the SDT to address the Generator Interconnection Facility (GIF) issue. And finally, a few commenters wanted a change in the phrase “operating range” and in an expanded Force Majeure section.

The SDT will modify the Drawings as requested and they will be provided in the Technical Reference Document which is planned to be posted on March 23rd 2010.

The SDT slightly modified the definition of Active Transmission Line Right of Way as shown:

Active Transmission Line Right of Way — A strip or corridor of land that is occupied by active Transmission facilities. This corridor does not include the parts of the Right-of-Way that are unused or intended for other facilities.

The SDT is aware of the GIF issue, i.e. 200 kV, and above, circuits owned by Generator Owners which have in some instances been considered Transmission Lines. NERC created a team to address this issue for all NERC standards. The product of that team was a report of suggested changes that will be addressed by a NERC drafting team. As such this draft of FAC-003 does not include any of those recommendations as they may apply to this standard.

The phrase “operating range” has been re-written to use all NERC terms and a general Force Majeure section has been added to the applicability section of the standard.

Question 15

In response to industry comments, the applicability section is revised to replace Reliability Coordinator with Planning Coordinator. Do you agree with these changes? If not, please explain and propose an alternative.

Summary Consideration: The vast majority of commenters agreed the Planning Coordinator was the appropriate entity. A common concern of those who disagreed was that the Planning Coordinator role is not defined, not well defined, or duplicated in practice. (The SDT believes that this is registration/Functional Model problem not suited for resolution in this standard.) Only one commenter suggested the Reliability Coordinator was more appropriate for technical reasons, opining that the Reliability Coordinator was better suited to determine the importance of lines.

After reviewing these comments as well as a complete analysis of Draft 2 with respect to the guidelines for this new results-based standard development process, the Requirements dealing with the Planning Coordinator have been removed. For sub-200 kV lines, the applicability will derive from identification of Transmission Lines associated with IROLs or as Major WECC Transfer Paths - analysis already exists for both of these.

Question 16

In response to industry comments, changes were made to the definitions. Do you agree with these changes? If not, please explain and propose an alternative.
Definitions proposed with FAC-003-2 Draft 2:

> **Active Transmission Line Right of Way** — A strip of land that is occupied by active transmission facilities. This corridor does not include the inactive or unused part of the Right of Way intended for other facilities.
>
> **Vegetation Inspection** — The systematic examination of vegetation conditions on an Active Transmission Line Right of Way. This inspection may be combined with a general line inspection. The inspection includes the documentation of any vegetation that may pose a threat to reliability prior to the next planned inspection or maintenance work, considering the current location of the conductor and other possible locations of the conductor due to sag and sway for rated conditions.

Summary Consideration: A majority of commenters expressed a concern with the Active Transmission Line ROW definition ranging from unnecessary to requiring modification. Those who recommended modification cited an issue with the phrase "intended for other facilities". The belief is this phrase might preclude certain parts of a ROW from being considered inactive. A minority comment pertains to the concern of abuse in the application of the concept of Active Transmission Line ROW.

The SDT has revised the definition to attempt to address some of the concerns and in keeping with the guidelines for this new results-based standard development process.

> **Active Transmission Line Right-of-Way**
> A strip or corridor of land that is occupied by active transmission facilities. This corridor does not include the parts of the Right-of-Way that are unused or intended for other facilities.

The majority of commenters held concern with two aspects of Vegetation Inspection definition. One concern relates to the phrase "poses a threat" and offered the alternative phrase "poses an unacceptable risk" in its place. The other concern questions the necessity of the last sentence of the definition which contains "requirement-like" text about documentation. The SDT changed the definition as shown below:

> **Vegetation Inspection**
> The systematic examination of vegetation conditions on an Active Transmission Line Right-of-Way and may be combined with a general line inspection.

Question 17

When compared to Version 1, does this proposed Version 2 of the standard either maintain or improve overall electric reliability? Please provide a technical basis for your response?

Summary Consideration: The majority of the commenters agreed that Draft 2 improved reliability. Of those who disagreed, the primary objection was the elimination of Clearance 1 and removal of the qualification requirement. The commenters cited a reduce leverage with landowners in the rationale for disagreement. A majority comment insists that the standard ought to require the application of best management practices. A majority comment insists that the standard ought to require the application of best management practices.

The SDT thanks the commenters for their support. With this new Draft, the essential concepts in Draft 2 are retained with wording better suited to the new Results-based standards development process. The SDT believes that the qualification issue is better left to a SAR team for PER standards. The SDT considered requiring ANSI A300 as part of this standard but opted to include it in the ***Guideline and Technical Basis*** section.

Question 18

Besides the comments you have already provided for the preceding questions, do you have further suggestions for improving this standard? If so, please elaborate.

Summary Consideration: Many commenters repeated concerns expressed in other sections. The most cited items were: the purpose statement, the definition of applicable lines, double jeopardy for encroachments and outages, the GO/GOP/DP line issue, the necessity for a general force majeure statement, and the reference to ANSI A300.

The SDT has replaced the purpose statement with an Objective statement retaining the same concept.

The Applicability section has been revised to address commenters concerns, except relating to Generator Interconnection Facilities. (Please see response to Question 14.)

The Double Jeopardy concerns were addressed by combining requirements to produce the new Draft R1 and R2.

A general Force Majeure section was added to the applicability section of the standard that covers all Requirements. The reference to ANSI 300 has been added to the ***Guideline and Technical Basis*** section.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed

1. SC approved SAR for initial posting (January 11, 2007).
2. SAR posted for comment (January 15–February 14, 2007).
3. SAR posted for comment (April 10–May 9, 2007).
4. SC authorized moving the SAR forward to standard development (June 27, 2007).

Proposed Action Plan and Description of Current Draft
This is the first posting of the proposed revisions to the standard in accordance with Results-Based Criteria. The drafting team requests posting for a 30-day informal comment period.

Future Development Plan

Anticipated Actions	Anticipated Date
Drafting team considers comments, makes conforming changes, posts for 30-day informal comment period.	April 2010
Drafting team considers comments, makes conforming changes, and requests SC approval to proceed to formal comment and ballot.	June 2010
Recirculation ballot of standards.	August 2010
Receive BOT approval	September 2010

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Active Transmission Line Right-of-Way
A strip or corridor of land that is occupied by active transmission facilities. This corridor does not include the parts of the Right-of-Way that are unused or intended for other facilities.

Examples of active portions of corridors include:
The width of any Active Transmission Line Right-of-Way (ROW) is the portion of the ROW that has been cleared of vegetation to meet design clearance requirements such as National Electrical Safety Code or other design criteria, for the reliable operation of active facilities.

Examples of inactive portions of corridors include:

1) The portions of the ROW acquired to accommodate future Facilities. Power plant exits are examples where large ROWs are obtained for maximum corridor utilization and may currently have fewer circuits constructed.
2) The portion of the ROW where corridor edge zones are designated by regulatory bodies for vegetation to exist.
3) The portions of the ROW where double-circuit structures are installed but only one circuit is currently strung with conductors.

Vegetation Inspection
The systematic examination of vegetation conditions on an Active Transmission Line Right-of-Way which may be combined with a general line inspection.

The current glossary definition of this NERC term is modified to allow both maintenance inspections and vegetation inspections to be performed concurrently.

Current definition of Vegetation Inspection: The systematic examination of a transmission corridor to document vegetation conditions.

1. First calendar day of the first calendar quarter one year after applicable regulatory authority approval for all requirements
2. First calendar day of the first calendar quarter one year following Board of Trustees adoption unless governmental authority withholds approval
3. First calendar day of the first calendar quarter that is at least one year following Board of Trustees adoption

Exceptions:

Lines operated below 200kV, designated by the Planning Coordinator as an element of an IROL or as a Major WECC transfer path, become subject to this standard 12 months after the date the Planning Coordinator or WECC initially designates the lines as being subject to this standard.

An existing transmission line operated at 200kV or higher that is newly acquired by an asset owner and was not previously subject to this standard, becomes subject to this standard 12 months after the acquisition date of the line(s).

Version History

Version	Date	Action	Change Tracking
1	TBA	1. Added “Standard Development Roadmap.” 2. Changed “60” to “Sixty” in section A, 5.2. 3. Added “Proposed Effective Date: April 7, 2006” to footer. 4. Added “Draft 3: November 17, 2005” to footer.	01/20/06
1	April 4, 2007	Regulatory Approval — Effective Date	New
2			

Introduction

1. **Title:** Transmission Vegetation Management

2. **Number:** FAC-003-2

3. **Objectives:** To improve the reliability of the electric Transmission system by preventing those vegetation related outages that could lead to Cascading.

4. **Applicability**

 4.1. Functional Entities:

  4.1.1 Transmission Owners

 4.2. Facilities: Defined below, including but not limited to those that cross lands owned by federal[1], state, provincial, public, private, or tribal entities:

  4.2.1. Overhead transmission lines operated at 200kV or higher.

  4.2.2. Overhead transmission lines operated below 200kV having been identified as elements of an Interconnection Reliability Operating Limit (IROL).

  4.2.3. Overhead transmission lines operated below 200 kV having been identified as included in the definition of one of the *Major WECC Transfer Paths in the Bulk Electric System*.

  4.2.4. This Standard does not apply to Facilities identified above (4.2.1 through 4.2.3) located in the fenced area of a switchyard, station or substation.

 4.3. Other:

  4.3.1. This Standard does not apply to any occurrence, non-occurrence, or other set of circumstances that are beyond the reasonable control of a Transmission Owner subject to this Reliability Standard, and are not caused by the fault or negligence of the Transmission Owner, including acts of God, flood, drought, earthquake, major storms, fire, hurricane, tornado, landslides, logging activities, animals severing trees, lightning, epidemic, strike, war, riot, civil disturbance, sabotage, vandalism, terrorism, wind shear, or fresh gales that restricts or prevents performance to comply with this reliability standard's requirements.

5. **Background**

This NERC Vegetation Management Standard ("Standard") uses a defense-in-depth approach to improve the reliability of the electric Transmission System by preventing those vegetation related outages that could lead to Cascading. This Standard is not intended to address non-preventable outages such as those due to vegetation fall-ins from outside the Active Transmission Line Right-of-Way, vandalism, human errors

[1] EPAct 2005 section 1211c: *"Access approvals by Federal agencies"*.

and acts of nature. Operating experience indicates that trees that have grown out of specification have contributed to Cascading, especially under heavy electrical loading conditions.

Major outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations. Adherence to the Standard requirements for applicable lines on any kind of land or easement, whether they are Federal Lands, state or provincial lands, public or private lands, franchises, easements or lands owned in fee, will reduce and manage this risk. For the purpose of the Standard the term “public lands” includes municipal lands, village lands, city lands, and a host of other governmental entities.

This Standard addresses vegetation management along applicable overhead lines that serve to connect one electric station to another. However, this Standard does not apply to underground lines or to line sections inside an electric station boundary.

This Standard focuses on transmission lines to prevent those vegetation related outages that could lead to Cascading. It is not intended to prevent customer outages due to tree contact with lower voltage distribution system lines. For example, localized customer service might be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. However, this Standard is not written to address such isolated situations which have little impact on the overall Bulk Electric System.

Since vegetation growth is constant and always present, unmanaged vegetation poses an increased outage risk, especially when numerous transmission lines are operating at or near their Rating. This can present a significant risk of multiple line failures and Cascading. Conversely, most other outage causes (such as trees falling into lines, lightning, animals, motor vehicles, etc.) are statistically intermittent. These events are not any more likely to occur during heavy system loads than any other time. There is no cause-effect relationship which creates the probability of simultaneous occurrence of other such events. Therefore these types of events are highly unlikely to cause large-scale grid failures. Thus, this Standard’s emphasis is on vegetation grow-ins.

Requirements and Measures

R1. Each Transmission Owner shall prevent vegetation from encroaching within the Minimum Vegetation Clearance Distance (MVCD) of each line conductor that is identified as an element of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions) to avoid a Sustained Outage.

Rationale
The MVCD is a calculated minimum distance stated in feet (meters) to prevent spark-over between conductors and vegetation, for various altitudes and operating voltages. The distances in Table 2 were derived using a proven transmission design method.

M1. Evidence of violation of Requirement R1 is limited to**:**

- Real-time observation of encroachment into the MVCD, or
- A vegetation-related Sustained Outage due to a fall-in from inside the Active Transmission Line ROW, or
- A vegetation-related Sustained Outage due to blowing together of applicable lines and vegetation located inside the Active Transmission Line ROW, or
- A vegetation-related Sustained Outage due to a grow-in.

Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period.

R2. Each Transmission Owner shall prevent vegetation from encroaching within the MVCD of each applicable line conductor, which are not elements of an IROL and are not a Major WECC transfer path, (operating within Rating and Rated Electrical Operating Conditions) to avoid a Sustained Outage.

Rationale
The MVCD is a calculated minimum distance stated in feet (meters) to prevent spark-over between conductors and vegetation, for various altitudes and operating voltages. The distances in Table 2 were derived using a proven Transmission design method.

M2. Evidence of violation of Requirement R2 is limited to**:**

- Real-time observation of encroachment into the MVCD, or
- A vegetation-related Sustained Outage due to a fall-in from inside the Active Transmission Line ROW, or
- A vegetation-related Sustained Outage due to blowing together of applicable lines and vegetation located inside the Active Transmission Line ROW, or
- A vegetation-related Sustained Outage due to a grow-in.

Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period.

R3. Each Transmission Owner shall have a documented transmission vegetation management program that describes how it conducts work on its Active Transmission Line ROWs to avoid Sustained Outages due to vegetation, considering all possible locations the conductor may occupy assuming operation within Rating and Rated Electrical Operating Conditions.

M3. Each Transmission Owner has a documented transmission vegetation management program that describes how it conducts work on its Active Transmission Line ROW to avoid Sustained Outages due to vegetation, considering all possible locations the conductor may occupy assuming operation within Rating and Rated Electrical Operating Conditions.

Rationale

Provide a basis for evaluation on the intent and competency of the Transmission Owner in maintaining vegetation. There may be many acceptable approaches to maintain clearances. However, the Transmission Owner should be able to state what its approach is and how it conducts work to maintain clearances. See Figure 1 for an illustration of possible conductor locations.

R4. Each Transmission Owner shall notify the responsible control center when it has verified knowledge of a vegetation imminent threat condition. A vegetation imminent threat condition is one which is likely to cause a Sustained Outage at any moment.

M4. Each Transmission Owner that has experienced a verified vegetation imminent threat will have evidence that it notified the responsible control center.

Rationale

To ensure rapid notification of the correct personnel when an occurrence of a critical situation is observed. Verified knowledge includes observations by journeyman lineman, utility arborist, or other qualified personnel, or a report verified by these personnel.

R5. Each Transmission Owner shall take interim corrective action when it is temporarily constrained from performing planned vegetation work, where a transmission line is put at potential risk due to the constraint.

M5. Each Transmission Owner has evidence of the interim corrective action taken for each temporary constraint where a transmission line was put at potential risk. Examples of acceptable forms of evidence may include work orders, invoices, or inspection records.

Rationale

Legal actions and other events may occur which result in constraints that prevent the Transmission Owner from performing planned vegetation maintenance work. When this event occurs and the work is essential to avoid risk to the transmission line the Transmission Owner must establish and act on a plan to prevent an imminent threat. This is not intended to address situations where a planned work methodology cannot be performed but an alternate work methodology can be used.

R6. Each Transmission Owner shall perform a Vegetation Inspection of all applicable transmission lines at least once per calendar year.

M6. Each Transmission Owner has evidence that it conducted Vegetation Inspections at least once per calendar year for applicable transmission lines. Examples of acceptable forms of evidence may include work orders, invoices, or inspection records.

Rationale

The requirement is for once per calendar year because that seems to be reasonable length of time for a majority of situations. Transmission Owners should consider local and environmental factors that could warrant more frequent inspections that may affect reliability.

R7. Each Transmission Owner shall execute a flexible annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD.

M7. Each Transmission Owner has evidence that it executed a flexible annual vegetation work plan. Examples of acceptable forms of evidence may include work orders, invoices, or inspection records.

Rationale

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. A flexible annual vegetation work plan allows for work to be deferred into the following calendar year provided it does not have the potential to become an imminent threat.

Compliance

Compliance Enforcement Authority

- Regional Entity

Compliance Monitoring and Enforcement Processes:

- Compliance Audits
- Self-Certifications
- Spot Checking
- Compliance Violation Investigations
- Self-Reporting
- Complaints

Evidence Retention

The Transmission Owner retains data or evidence of Requirements R1 through R7, Measures M1 through M7 for three years to show compliance unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

If a Transmission Owner is found non-compliant, it shall keep information related to the non-compliance until found compliant.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

Additional Compliance Information
(See Administrative Procedure)

Time Horizons, Violation Risk Factors, and Violation Severity Levels

Table 1

R#	Time Horizon	VRF	Violation Severity Level			
			Lower	Moderate	High	Severe
R1	Real-time	High	The Transmission Owner failed to prevent vegetation from encroaching within the MVCD of a transmission line as described in R1.	The Transmission Owner incurred a Sustained Outage due to vegetation falling into a transmission line as described in R1 from within the Active Transmission Line ROW.	The Transmission Owner incurred a Sustained Outage due to the blowing together of vegetation and a transmission line as described in R1 from within the Active Transmission Line ROW.	The Transmission Owner incurred a Sustained Outage due to vegetation growing into a transmission line as described in R1.
R2	Real-time	Medium	The Transmission Owner failed to prevent vegetation from encroaching within the MVCD of a transmission line as described in R2.	The Transmission Owner incurred a Sustained Outage due to vegetation falling into a transmission line as described in R2 from within the Active Transmission Line ROW.	The Transmission Owner incurred a Sustained Outage due to the blowing together of vegetation and a transmission line as described in R2 from within the Active Transmission Line ROW.	The Transmission Owner incurred a Sustained Outage due to vegetation growing into a transmission line as described in R2.
R3	Long-Term Planning	Lower		The Transmission Owner has a documented transmission vegetation management program, but the transmission vegetation management program does not describe how work is conducted on the Active Transmission Line ROWs to avoid Sustained Outages due to vegetation.	The Transmission Owner has a documented transmission vegetation management program, but the transmission vegetation management program does not consider all possible locations the conductor may occupy assuming operation within Rating and Rated Electrical Operating Conditions	The Transmission Owner does not have a documented transmission vegetation management program.

R4	Real-time	Medium				The Transmission Owner had verified knowledge of a vegetation imminent threat condition and did not notify the responsible control center.
R5	Operations Planning	Medium				The Transmission Owner did not take interim corrective action when it was temporarily constrained from performing planned vegetation work where an applicable transmission line was put at potential risk.
R6	Operations Planning	High	The Transmission Owner inspected greater than 95% but less than 100% of the ROW as measured by applicable-line miles (kilometers) (based on units of choice: circuit, pole line, ROW, etc.).	The Transmission Owner inspected greater than 90% but less than or equal to 95% of the ROW as measured by applicable-line miles (kilometers) (based on units of choice: circuit, pole line, ROW, etc.).	The Transmission Owner inspected greater than 85% but less than or equal to 90% of the ROW as measured by applicable-line miles (kilometers) (based on units of choice: circuit, pole line, ROW, etc.).	The Transmission Owner inspected less than or equal to 85% of the ROW as measured by applicable-line miles (kilometers) (based on units of choice: circuit, pole line, ROW, etc.).
R7	Operations Planning	High	The Transmission Owner executed greater than 95% but less than 100% of its annual work plan as adjusted.	The Transmission Owner executed greater than 90% but less than or equal to 95% of its annual work plan as adjusted.	The Transmission Owner executed greater than 85% but less than or equal to 90% of its annual work plan as adjusted.	The Transmission Owner executed less than or equal to 85% of its annual work plan as adjusted.

Administrative Procedure

The Transmission Owner will submit a quarterly report to its Regional Entity, or the Regional Entity's designee, identifying all Sustained Outages of transmission lines determined by the Transmission Owner to have been caused by vegetation that includes, as a minimum, the following:.

- The name of the circuit(s), the date, time and duration of the outage; the voltage of the circuit; a description of the cause of the outage; the category associated with the Sustained Outage; other pertinent comments; and any countermeasures taken by the Transmission Owner.

A Sustained Outage is to be categorized as one of the following:

- Category 1A — Grow-ins: Sustained Outages caused by vegetation growing into applicable transmission lines, that are identified as an element of an IROL or Major WECC Transfer Path, by vegetation inside and/or outside of the Active Transmission Line ROW;
- Category 1B — Grow-ins: Sustained Outages caused by vegetation growing into applicable transmission lines, but are not identified as an element of an IROL or Major WECC Transfer Path, by vegetation inside and/or outside of the Active Transmission Line ROW;
- Category 2 — Fall-ins: Sustained Outages caused by vegetation falling into applicable transmission lines from within the Active Transmission Line ROW;
- Category[2] 4 — Blowing together: Sustained Outages caused by vegetation and applicable transmission lines blowing together from within the Active Transmission Line ROW.

The Regional Entity will report the outage information provided by Transmission Owners, as per the above, quarterly to NERC, as well as any actions taken by the Regional Entity as a result of any of the reported Sustained Outages.

Variances

None.

Interpretations

None.

[2] Category 3 reporting is eliminated.

Guideline and Technical Basis

Requirements R1 and R2:
Requirements R1 and R2 state that if a Transmission Owner observes vegetation within the distances prescribed in FAC-003 - Table 2 it is in violation of this Standard. The MVCD table contains the distances which are required to ensure that spark-over will not occur; the distances are based on the Gallet equations. Requirements R1 and R2 refer to observation in “real time”. This means an actual field observation or measurement of the conductor-to-vegetation distance and not a calculated determination of relative positions.

The MVCD is a calculated minimum distance stated in feet (or meters) to prevent spark-over, for various altitudes and operating voltages that is used in the design of Transmission Facilities. Keeping vegetation from entering this space will help prevent transmission outages. The movement of the transmission line conductor and the MVCD is illustrated in Figure 1 below.

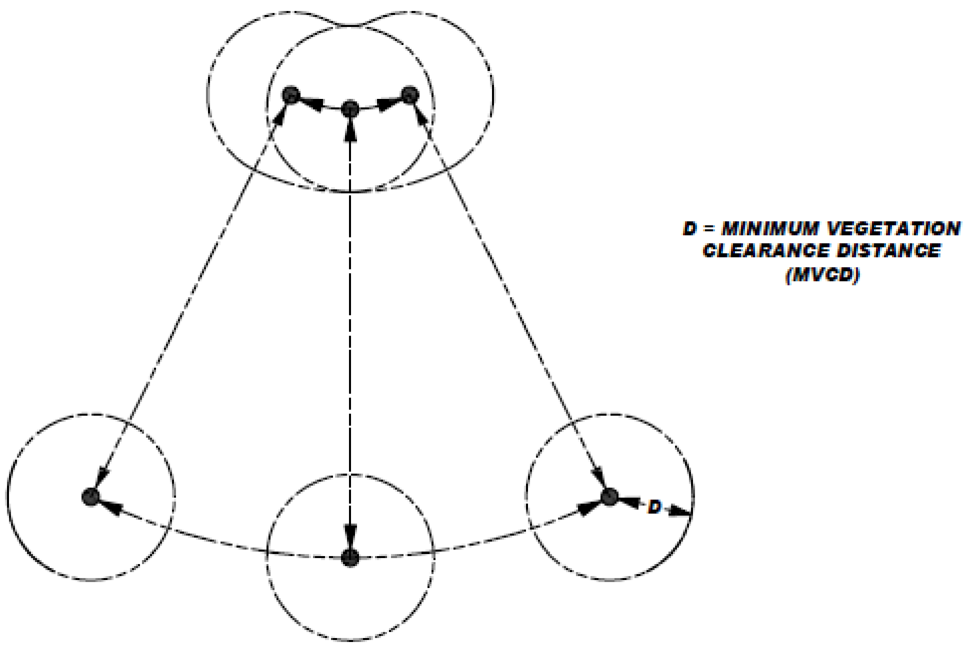

Figure 1
Cross-section view of a single conductor at a given point along the span showing six possible conductor positions due to movement resulting from thermal and mechanical loading.

By complying with encroachment-prevention Requirements R1 and R2, together with the competency-based Requirement R3 (for a documented transmission vegetation management program), the Transmission Owner will have a cohesive vegetation management program for managing vegetation in such a manner as to maintain separation between conductors and vegetation. Additionally, an effective imminent threat process and interim corrective action plan strategies should be executed to be successful in meeting these requirements. The Transmission Owner’s maintenance approach should result in vegetation never approaching the distances listed in the MVCD Table. However, brief encroachments by falling vegetation are not considered to be a violation.

In addition, the Transmission Owner should maintain detailed records of the findings of its planned inspections. This documentation constitutes evidence that the Transmission Owner had no encroachments into the MVCD Table distances.

These requirements assume that transmission lines are operating within their Rating. If a line conductor is intentionally or inadvertently operated beyond its rating (potentially in violation of other standards), the occurrence of a clearance encroachment is not be a violation of this Standard. Conductor position, and the associated vegetation distance, that result from operation of a transmission line beyond its Rating (for example emergency actions taken by a TOP or RC to protect an Interconnection) is beyond the scope of this Standard.

Requirement R3:
An adequate transmission vegetation management program formally establishes the guidelines that are used by the Transmission Owner to plan and perform vegetation work that is necessary to prevent transmission outages and minimize risk to the Transmission System.

There may be many acceptable approaches to maintain clearances. However, the Transmission Owner should be able to state what its approach is and how it conducts work to maintain clearances. See Figure 1 for illustration of possible conductor locations.

Requirement R4:
The term "verified knowledge" implies reliable confirmation that an imminent threat actually exists due to vegetation. Verification could be that the initial call-in came from a trained employee able to identify such a threat or it could be verified by sending out such a trained person to confirm a call-in from a citizen.

Two key elements of an acceptable imminent threat procedure are outlined below:

- Specify the vegetation-related conditions that warrant a response:

  Examples of these vegetation-related conditions include vegetation that is near or encroaching into the MVCD (growth issue) or vegetation that presents an imminent danger of falling into the transmission conductor (fall-in issue)

- Notify the appropriate operating authority:

  The Transmission Owner has the responsibility to ensure the proper communication between field personnel and the operating authority to allow the operating authority to take the appropriate action until the threat is relieved. Appropriate actions may include a temporary reduction in the line loading or switching the line out of service.

  The protocol for contacting the operating authority should be defined. Some Transmission Owners' processes may require a call directly to the operating authority, while other Transmission Owners may require a call to a supervisor or field forester who will in turn notify the proper operating authority.

> The term "responsible control center" refers to personnel with direct responsibility for operating the transmission lines, such as the Transmission Owner's control center, an Independent System Operator, or other operating entity. In the case where the operating authority is not the Transmission Operator the communication between the Transmission Operator and the operating authority will occur by the normal policies that govern their relationship.

The imminent threat process should be implemented in terms of minutes or hours as opposed to a longer time frame for interim corrective action plans (see R5).

All serious growth or fall-in vegetation-related conditions are not necessarily considered imminent threats under this Standard. For example, some Transmission Owners may have a danger tree identification program that identifies for removal trees with the potential to fall near the line. These trees are not necessarily considered imminent threats under the Standard unless they pose an immediate fall-in threat.

There can be situations involving vegetation that are not considered vegetation-related imminent threats under this Standard. For example, a logging operation on or near the Active Transmission Line ROW can pose an immediate threat of a sustained outage and result in the initiation of an imminent threat process in the same manner as the presence of a nearby crane or the notification of a hot-spot on a conductor connector. Although the logging threat in this example tangentially involves vegetation, it is not considered a vegetation-related imminent threat under the Standard.

Requirement R5:
The intent of this requirement is to deal with situations that prevent the Transmission Owner from performing planned vegetation management work and, as a result, have the potential to put the transmission line at risk. Constraints to performing vegetation maintenance work as planned could result from legal injunctions filed by property owners, the discovery of easement stipulations which limit the Transmission Owner's rights, or other circumstances.

This requirement is not intended to address situations where the transmission line is not at immediate risk and the work event can be rescheduled or re-planned using an alternate work methodology. For example, a land owner may prevent the planned use of chemicals on non-threatening, low growth vegetation but agree to the use of mechanical clearing. In this case the Transmission Owner is not under any immediate time constraint for achieving the management objective, can easily reschedule work using an alternate approach, and therefore does not need to take interim corrective action.

However, in situations where transmission line reliability is potentially at risk due to a constraint, the Transmission Owner is required to take an interim corrective action to mitigate the potential risk to the transmission line. A wide range of actions can be taken to address various situations. General considerations include:

- Identifying locations where the Transmission Owner is constrained from performing planned vegetation maintenance work which potentially leaves the transmission line at risk.
- Developing the specific action to immediately mitigate any potential risk associated with not performing the vegetation maintenance work as planned.
- Documenting and tracking the specific action taken for each location.

In developing the specific action to mitigate the potential risk to the transmission line the Transmission Owner could consider location specific measures such as modifying the inspection and/or maintenance intervals. Where a legal constraint would not allow any vegetation work, the interim corrective action could include limiting the loading on the transmission line.
The Transmission Owner should document and track the specific corrective action taken at each location. This location may be indicated as one span, one tree or a combination of spans on one property where the constraint is considered to be temporary.

Requirement R6:
This requirement sets a minimum time period for the Vegetation Inspections. More frequent inspections may be needed to maintain reliability levels, depending upon such factors as anticipated growth rates of the local vegetation, length of the growing season for the geographical area, limited Active Transmission ROW width, and rainfall amounts. Therefore some lines may be designated with a higher frequency of inspections.

The VSL for Requirement R6 has VSL categories ranked by the percentage of the required ROW inspections completed. To calculate the percentage of inspection completion the Transmission Owner lines may choose units such as: line miles or kilometers, circuit miles or kilometers, pole line miles, ROW miles, etc.

If a Transmission Owner operates 2,000 miles of 230 kV transmission lines this Transmission Owner will be responsible for inspecting all 2,000 miles of 230 kV transmission at least once line during the calendar year. If one of the included lines was 100 miles long, and if it was not inspected during the year, then the amount inspected would be 1900/2000 = 0.95 or 95%. The "Lower VSL" for R6 would apply in this example.

The standard allows Vegetation Inspections to be performed in conjunction with general line inspections as per the definition.

Requirement R7:
Documentation or other evidence of the work performed typically consists of signed-off work orders, signed contracts, printouts from work management systems, spreadsheets of planned versus completed work, timesheets, work inspection reports, or paid invoices. Other evidence may include photographs, work inspection reports and walk-through reports.

Documentation is required when the annual work plan is adjusted or not completely implemented as originally planned. The reasons for the deferrals or changes and the expected completion date of postponed work should be documented.

The flexibility to adjust the annual work plan must always ensure the reliability of the electric Transmission system. Flexibility is meant to address changing conditions of the vegetation on the Active Transmission Line ROW, emergencies, and other significant changing conditions.

This standard requires that the annual work plan be flexible to allow the Transmission Owner to change priorities during the year as conditions or situations dictate. For example, weather conditions (drought) could make herbicide application ineffective during the plan year. Another situational variance could be a major storm that redirects local resources away from planned maintenance. This situation may also include complying with mutual assistance agreements by moving resources off the Transmission Owner’s system to work on another system. Examples of documented adjustments may include deferrals or additions to the annual work plan.

The work plan is not intended to be a “span-by-span” detailed description of all work to be performed. It is intended to require the Transmission Owner to annually plan and schedule vegetation work to prevent encroachment into the MVCD.

The Transmission Owner is required to implement the annual work plan for vegetation management to accomplish the purpose of this standard. This means that vegetation maintenance ought to be performed to the extent of the Transmission Owner’s easement, fee simple and other legal rights. It is intended to address the importance of maintaining all locations on the Active Transmission Line ROWs for reliability purposes in lieu of making special exceptions.

- Property owners and other interested parties occasionally request special considerations to leave undesirable vegetation conditions. Such considerations must never be allowed to impact reliability.
- These undesirable vegetation conditions require more frequent work or inspections than other locations with similar vegetation threats and similar easement rights which are not subject to the special property owner requests.
- The Transmission Owner's vegetation maintenance work necessary to implement the annual work plan is most effective when performed to the maximum extent allowed by any easement, fee simple and other legal rights.
- The Transmission Owner should, therefore, endeavor to maintain its Active Transmission Line ROW to the full extent of its legal rights at all times and in all cases.

A comprehensive approach that exercises the full extent of legal rights is superior to incremental management in the long term because it reduces overall encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient at all locations on the Active Transmission Line ROW .

When developing the annual work plan the Transmission Owner should allow time for procedural requirements to obtain permits to work on federal, state, provincial, public, tribal lands. In some cases the lead time for obtaining permits may necessitate preparing work plans more than a year prior to work start dates. Transmission Owners may also need to consider those special landowner requirements as documented in easement instruments.

The following conditions may result in adjustments to the annual work plan: abnormal weather such as drought, major storms, excessive rainfall, other environmental conditions such as infestation, disease, fire, etc. These conditions may be found as part of a special or scheduled

Vegetation Inspection. Examples of annual work plan adjustments that are permitted may include revising the work plan priorities, rescheduling work to another time or selecting alternate vegetation control methods. Changes in land usage made by a property owner, such as timber clearing, may be another condition that warrants an adjustment.

FAC-003 — TABLE 2 — Minimum Vegetation Clearance Distances (MVCD)[3]

For **Alternating Current** Voltages

(AC) Nominal System Voltage (kV)	**(AC) Maximum System Voltage (kV)**	**MVCD feet (meters) sea level**	**MVCD feet (meters) 3,000ft (914.4m)**	**MVCD feet (meters) 4,000ft (1219.2m)**	**MVCD feet (meters) 5,000ft (1524m)**	**MVCD feet (meters) 6,000ft (1828.8m)**	**MVCD feet (meters) 7,000ft (2133.6m)**	**MVCD feet (meters) 8,000ft (2438.4m)**	**MVCD feet (meters) 9,000ft (2743.2m)**	**MVCD feet (meters) 10,000ft (3048m)**	**MVCD feet (meters) 11,000ft (3352.8m)**

RELIABILITY CORPORATION

Implementation Plan for FAC-003-2

Prerequisite Approvals

There are no other Reliability Standards or Standard Authorization Requests (SARs), in progress or approved, that must be implemented before this standard can be implemented.

FAC-003-2 — Vegetation Management

Revision to Sections of Approved Standards and Definitions

There are no proposed revisions to requirements in other already approved standards.
When FAC-003-2 is approved, a new definition for Active Transmission Line Right-of-Way and a revised definition for Vegetation Inspection should become effective.

The original definition of Vegetation Inspection should be retired when the new definition becomes effective.

FAC-003-1 will be retired when FAC-003-2 becomes effective.

Compliance with Standard

The standard applies to Transmission Owners.

Effective Date

The effective date is the date entities are expected to meet the performance identified in this standard. The effective date allows entities time to make revisions to their existing transmission vegetation management programs to comply with the new requirements.

Requirement	Jurisdiction									
	Alberta	British Columbia	Manitoba	New Brunswick	Newfound-land	Nova Scotia	Ontario	Quebec	Saskatch-ewan	USA

R7	1	1	1	3	TBD	TBD	2	TBD	1	1

1. First calendar day of the first calendar quarter one year after applicable regulatory authority approval for all requirements
2. First calendar day of the first calendar quarter one year following Board of Trustees adoption unless governmental authority withholds approval
3. First calendar day of the first calendar quarter that is at least one year following Board of Trustees adoption

Exceptions:

Lines operated below 200kV, designated by the Planning Coordinator as an element of an IROL or as a Major WECC Transfer Path, become subject to this standard 12 months after the date the Planning Coordinator or WECC initially designates the lines as being subject to this standard.

An existing transmission line operated at 200kV or higher that is newly acquired by an asset owner and was not previously subject to this standard, becomes subject to this standard 12 months after the acquisition date of the line(s).

including but not limited to those that cross lands owned by federal , state, provincial, public, private, or tribal entities. 4.2.2. Transmission lines operated below 200kV designated by the Planning Coordinator as being subject to this standard become subject to this standard 12 months after the date the Planning Coordinator initially designates the transmission line as being subject to this standard. 4.2.3. Existing transmission line(s) operated at 200kV or higher that is newly acquired by a Transmission Owner and was not previously subject to this standard, become subject to this standard 12 months after the acquisition date of the transmission line(s).		**4.2.4.** This Standard does not apply to Facilities identified above (4.2.1 through 4.2.3) located in the fenced area of a switchyard, station or substation. **4.3.** Other: **4.3.1** This Standard does not apply to any occurrence, non-occurrence, or other set of circumstances that are beyond the reasonable control of a Transmission Owner subject to this Reliability Standard, and are not caused by the fault or negligence of the Transmission Owner, including acts of God, flood, drought, earthquake, major storms, fire, hurricane, tornado, landslides, logging activities, animals severing trees, lightning, epidemic, strike, war, riot, civil disturbance, sabotage, vandalism, terrorism, wind shear, or fresh gales that restricts or prevents performance to comply with this reliability standard's requirements.
	Added new section titled, "Background" per SCPSC format.	**5. Background** This NERC Vegetation Management Standard ("Standard") uses a defense-in-depth approach to improve the reliability of the electric Transmission system by preventing those vegetation related outages that could lead to Cascading. This Standard is…
R1. Each Transmission Owner shall have a documented transmission vegetation management program that describes how it conducts work on its Active Transmission Line Rights of Way to avoid Sustained Outages due to vegetation,	Modified R1. by removing prescriptive text in sub parts 1.1 through 1.6. and focused on desired result of requiring competency on the part of	**R3.** Each Transmission Owner shall have a documented transmission vegetation management program that describes how it conducts work on its Active Transmission Line Rights of Way to avoid Sustained Outages due to vegetation, considering all possible locations the conductor may occupy assuming operation within Rating and Rated Electrical Operating Conditions. **R5.** Each Transmission Owner shall take interim corrective action when it is

Mapping of FAC-003-2 Draft 2 to FAC-003-2 Draft 3 (Results-based Standard)

Standard FAC-003-2 Draft 2	Comment	Proposed Standard FAC-003-2 RBS (Draft 3)
considering all possible locations the conductor may occupy under the effects of sag and sway throughout its operating range under rated conditions. The transmission vegetation management program shall: [Violation Risk Factor: Lower][Time Horizon: Long-term planning] 1.1. Specify the methodologies that the Transmission Owner uses to control vegetation. 1.2. Specify a Vegetation Inspection frequency of at least once per calendar year that takes into account local and environmental factors. 1.3. Require an annual work plan that identifies the applicable lines to be maintained and associated work to be performed during the year. It shall be flexible to adjust to changing conditions and to findings from Vegetation Inspections. Adjustments to the plan within the year are permissible. The plan shall take into consideration permitting and scheduling requirements from landowners or regulatory authorities. It shall support the objectives of the transmission vegetation management program and utilize the methodologies outlined in the transmission vegetation management program. 1.4. Require a process or procedure for response to imminent threats of a vegetation-related Sustained Outage. The process or procedure shall specify actions which shall include immediate communication of the threat to the Transmission Operator or proper operating authority. The process or	Transmission Owner. Elevated interim corrective actions to a standalone requirement to focus on desired result of working around impediments. Moved VRF and Time Horizon.	temporarily constrained from performing planned vegetation work, where a transmission line is put at potential risk due to the constraint.

Standard FAC-003-2 Draft 2	Comment	Proposed Standard FAC-003-2 RBS (Draft 3)
procedure shall specify what conditions warrant a response. 1.5. Specify an interim corrective action process for use when the Transmission Owner is constrained from performing vegetation maintenance as planned. 1.6. Specify the maintenance approach used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that Table 1 clearances are never violated. The maintenance approach shall consider the sag and sway of the conductor throughout its operating range under rated conditions.		
R2. Each Transmission Owner shall implement its imminent threat process or procedure when the Transmission Owner has actual knowledge of such a threat, obtained through normal operating practices.	Revised to focus on desired result to notify of imminent threats. Moved VRF and Time Horizon.	**R4.** Each Transmission Owner shall notify the responsible control center when it has verified knowledge of a vegetation imminent threat condition. A vegetation imminent threat condition is one which is likely to cause a Sustained Outage at any moment.
R3. Each Transmission Owner shall conduct Vegetation Inspections of all applicable lines (as measured in line miles) in accordance with the frequency specified in its transmission vegetation management program, unless constrained by natural disasters. When constrained by a natural disaster, the Transmission Owner shall conduct the Vegetation Inspection(s) within six months or a period agreed to by its Regional Entity, whichever is greater.	Revised to focus on desired result of inspecting for vegetation annually and to eliminate prescriptive text. Moved VRF and Time Horizon.	**R6.** Each Transmission Owner shall perform a Vegetation Inspection of all applicable lines once per calendar year, at a minimum.

Mapping of FAC-003-2 Draft 2 to FAC-003-2 Draft 3 (Results-based Standard)

Standard FAC-003-2 Draft 2	Comment	Proposed Standard FAC-003-2 RBS (Draft 3)
R4. Each Transmission Owner shall prevent encroachment of vegetation into the Minimum Vegetation Clearance Distances (MVCD) listed in FAC-003-2 - Attachment 1 for its applicable lines as observed in real-time operating between no-load and their Rating, with the following exceptions: *[Violation Risk Factor — Medium][Time Horizon — Real Time]* Encroachment into the MVCD listed in FAC-003-2-Attachment 1 resulting from natural disasters.[2] Encroachment into the MVCD listed in FAC-003-2-Attachment 1 resulting from human or animal activity.[3] Encroachment into the MVCD listed in FAC-003-2-Attachment 1 resulting from falling vegetation. **R5.** Each Transmission Owner shall prevent Sustained Outages[4] of applicable lines that are identified as an element of an Interconnection Reliability Operating Limit (IROL) (or Major WECC Transfer Path) due to vegetation growing into a conductor operating between no-load and its Rating, with the following exceptions: *[Violation Risk Factor — High][Time Horizon — Real Time]* • Sustained Outages of applicable	Revised to focus on desired result of keeping vegetation out of a minimum clearance distance from transmission lines and to improve clarity. Combined R4, R4, R6, R7, and R8 into two standalone requirements. Moved VRFs and Time Horizons.	**R1.** Each Transmission Owner shall prevent vegetation from encroaching within the Minimum Vegetation Clearance Distance (MVCD) of line conductors that are identified as an element of an IROL or Major WECC Transfer Path (operating within Rating and Rated Electrical Operating Conditions) to avoid a Sustained Outage. **R2.** Each Transmission Owner shall prevent vegetation from encroaching within the Minimum Vegetation Clearance Distance (MVCD) of applicable line conductors, which are not elements of an IROL and are not a Major WECC Transfer Path, (operating within Rating and Rated Electrical Operating Conditions) to avoid a Sustained Outage.

[2] Examples include, but are not limited to, earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods.

[3] Examples include, but are not limited to, logging, animal severing tree, vehicle contact with tree, arboricultural activities or horticultural or agricultural activities, or removal or digging of vegetation.

[4] Multiple Sustained Outages on an individual line, if caused by the same vegetation, shall be considered as one outage regardless of the actual number of outages within a 24-hour period.

Standard FAC-003-2 Draft 2	Comment	Proposed Standard FAC-003-2 RBS (Draft 3)
lines that result from natural disasters. • Sustained Outages of applicable lines that result from human or animal activity. **R6.** Each Transmission Owner shall prevent Sustained Outages of applicable lines that are not an element of an IROL (or major WECC Transfer Path) due to vegetation growing into a conductor operating between no-load and its Rating, with the following exceptions: *[Violation Risk Factor — Medium][Time Horizon — Real Time]* • Sustained Outages of applicable lines that result from natural disasters. • Sustained Outages of applicable lines that result from human or animal activity. **R7.** Each Transmission Owner shall prevent Sustained Outages of applicable lines due to the blowing together of vegetation and a conductor within an Active Transmission Line Right of Way (operating within design blow-out conditions) with the following exception: *[Violation Risk Factor — Medium][Time Horizon — Real Time]* Sustained Outages of applicable lines that result from natural disasters or wind-blown debris. **R8.** Each Transmission Owner shall prevent Sustained Outages of applicable lines due to vegetation falling into a conductor from within an Active Transmission Line Right of Way with the following exceptions: *[Violation Risk Factor —*		

Standard FAC-003-2 Draft 2	Comment	Proposed Standard FAC-003-2 RBS (Draft 3)
Medium] [Time Horizon — Real Time] • Sustained Outages of applicable lines that result from natural disasters or wind-blown debris. • Sustained Outages of applicable lines that result from human or animal activity.		
R9. Each Transmission Owner shall implement its annual work plan for vegetation management to accomplish the purpose of this standard.	Moved VRF and Time Horizon.	**R7.** Each Transmission Owner shall execute a flexible annual vegetation work plan to ensure no encroachments within the MVCD.
R10. Each Planning Coordinator shall prepare and review annually, a list of lines that are operated below 200kV, if any, which are subject to this standard. Each Planning Coordinator shall consult with its Transmission Owner(s) and neighboring Planning Coordinators to obtain input to develop the list.	Revised to add applicability sections 4.3.2 and 4.3.3 and eliminated this requirement.	**4.3.2.** Overhead transmission lines operated below 200kV having been identified as elements of an IROL. **4.3.3.** Overhead transmission lines operated below 200 kV having been included in the definition of one of the Major WECC Transfer Paths in the Bulk Electric System.
R11. Each Planning Coordinator shall develop and document its method for assessing the reliability significance of sub-200kV transmission lines whose loss would place the grid at an unacceptable risk of instability, separation, or cascading failures.	Revised to add applicability sections 4.3.2 and 4.3.3 and eliminated this requirement.	**4.3.2.** Overhead transmission lines operated below 200kV having been identified as elements of an IROL. **4.3.3.** Overhead transmission lines operated below 200 kV having been included in the definition of one of the Major WECC Transfer Paths in the Bulk Electric System.

Unofficial Comment Form for 3rd Draft of FAC-003-2 Transmission Vegetation Management — Part of Project 2007-07 Vegetation Management

Please **DO NOT** use this form to submit comments. Please use the electronic form located at the site below to submit comments on the 3rd Draft of FAC-003-2 Transmission Vegetation Management. Comments must be submitted by **March 31, 2010**

If you have questions please contact Harry Tom at Harry.Tom@nerc.net or by telephone at (860) 550-4157.

Background Information

The purpose of Project 2007-07 Vegetation Management is to:

- Assist in providing an adequate level of reliability for the North American electric Transmission System by verifying that the FAC-003-2 Transmission Vegetation Management standard is complete and that its requirements are set at an appropriate level to ensure reliability.
- Incorporate other general improvements described in the Standard Review Guidelines to bring FAC-003-2 Transmission Vegetation Management into conformance with the latest version of the Reliability Standards Development Procedure and the ERO Sanctions Guidelines.
- Consider comments received from ERO regulatory authorities and stakeholders on FAC-003-1 Transmission Vegetation Management as noted in the NERC Standards Issues Database.
- Satisfy the requirement for review of FAC-003-2 Transmission Vegetation Management within five-year review cycle.

In addition, on January 14, 2010, the NERC Standards Committee endorsed the use of Project 2007-07 Vegetation Management as the prototype for the proof-of-concept for using the results-based criteria for developing a reliability standard. The results-based initiative is intended to focus the collective effort of NERC and industry participants on improving the clarity and quality of NERC reliability standards by developing performance-based, risk-based and competency-based requirements that accomplish a reliability objective through a defense-in-depth strategy, while eliminating documentation-driven requirements that do not have an impact on bulk power system reliability.

The Standards Committee also directed the standard drafting team for Project 2007-07 Vegetation Management to do so with a target for final industry ballot of draft FAC-003-2 Transmission Vegetation Management by August 31, 2010.

The criteria for developing a results-based reliability standard include:

1. Strive to achieve a portfolio of performance-based, risk-based, and competency-based mandatory reliability requirements that provide an effective defense-in-depth strategy for achieving an adequate level of reliability of the bulk power system.
    a) **Performance-based** — defines a particular reliability objective or outcome to be achieved. In its simplest form, a results-based requirement has four

components: *who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome*?

b) **Risk-based** — preventive requirements to reduce the risks of failure to acceptable tolerance levels. A risk-based reliability requirement should be framed as: *who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome* *that reduces a stated risk to the reliability of the bulk power system?*

c) **Competency-based** — defines a minimum capability an entity needs to have to demonstrate it is able to perform its designated reliability functions.

2. The defense-in-depth strategy for reliability standards development should recognize that each requirement in a NERC reliability standard has a role in preventing system failures, and that these roles are complementary and reinforcing. Reliability standards should not be viewed as a body of unrelated requirements, but rather should be viewed as part of a portfolio of requirements designed to achieve an overall defense-in-depth strategy and comport with the quality objectives of a reliability standard.
3. Each requirement should identify a clear and measurable expected outcome, such as: i) a stated level of reliability performance, ii) a reduction in a specified reliability risk, or iii) a necessary competency.
4. Strive to minimize prescriptive, administrative (document something), and commercial requirements within the set of NERC reliability standards (i.e., these types of requirements are permissible in standards but should be the exception rather then the rule).
5. A requirement should not prescribe commercial business practices which do not contribute directly to reliability.

The Vegetation Management Standard Drafting Team worked with Ivy Hooks of Compliance Automation, Inc. to apply the “results-based” approach to developing requirements that are clear and enforceable. Ivy is the CEO of Compliance Automation and has shared a wealth of knowledge and expertise with the drafting team. The “look and feel” of the proposed standard contains much more information than we have been including in previous standards, thus the look and feel of the draft FAC-003-2 Transmission Vegetation Management standard is quite different from the look of our existing standards. One of the more obvious changes is the addition of information to aid end users in reading the requirements from a common understanding of the standard’s objective and the rationale for including each requirement. During the Three-year Performance Assessment, stakeholders indicated that they wanted more information to assist in applying standards – and the additional details provided in the proposed Vegetation Management standard provide an example of one way to fill that void.

On February 11, 2010 the Standards Committee authorized the standard drafting team for Project 2007-07 Vegetation Management to take the following actions relative to the development of draft FAC-003-2 Transmission Vegetation Management:

- Discontinue work in developing a complete Consideration of Comments Report for the comments received in response to the posting of the second draft of the draft FAC-003-2 Transmission Vegetation Management standard that was posted in August 2009; however, post the comments received along with a summary of the actions taken by the team in response to those comments but without an individual response to each comment provided.

- Use informal comment periods to collect comments on future "drafts" of the standard, post the comments received during the informal comment periods along with a summary of how the team used the comments received and a redline version of the standard showing the changes made based on the comments received.
- Conduct a 45-day formal comment period in parallel with the formation of the ballot pool and the initial ballot of the standard; post the comments from the formal comment period as they are received for at least the first 30 days of the comment period.
- Use a standard template that is different from the template stipulated in the Reliability Standard Development Procedure as provided by the Standards Committee's Process Subcommittee.

With respect to the first bullet above regarding stakeholder comments submitted in response to the posting of the second draft of the proposed standard, the SDT has posted a general summary response to the comments on the draft which was posted in August, 2009. However, the limited response does not mean that the SDT ignored the comments received in August 2009. The SDT carefully considered those comments and made modifications to the standard based on the comments received. A summary of the SDT considerations has been posted on the NERC website in lieu of a full Consideration of Comments Report.

A subset of comments received during the August 2009 posting suggested that the STD for this project (Project 2007-07 Vegetation Management) address the recommendations in the Final Report from the Ad Hoc Group for Generator Requirements at the Transmission Interface that pertain to FAC-003-1 Transmission Vegetation Management. The SDT for this project respectfully declined to address the referenced recommendations primarily for the following reasons:

- Project 2010-07 Transmission Requirements at the Generator Interface has been established to address the recommendations in the Final Report from the Ad Hoc Group for Generator Requirements at the Transmission Interface.
- The referenced recommendations are outside the scope of the Standard Authorization Request for this project (Project 2007-07 Vegetation Management).
- The appointed SDT does not have the proper representation to address the referenced recommendations.

Significant modifications incorporated into this draft of FAC-003-2 Transmission Vegetation Management include:

- Two new sections have been added: Background and Guideline and Technical Basis. While the titles are self-evident, the SDT would like to point out that this information was previously included for review in the Technical Reference (aka, White Paper).
- A "global" Force Majeure statement was added to the Applicability section of the standard in response to comments received. This statement is included at the front of the standard and thus is applicable to all Requirements. This "exclusion language" was included in a footnote in the prior version of the standard.
- The wording relating to expected conductor positions was modified. The previous draft of the standard referred to "operating within Rating under normal conditions" and/or "sag and sway". With this draft, and in response to comments received on this issue, the wording was changed, to state "operating within Rating under Rated Electrical Operating Conditions". This modification uses standard NERC glossary

terms to indicate the expectation that vegetation management should account for line operation as designed but not, for example, for overloaded conditions or excessive wind speeds.

With respect to the format of the draft FAC-003-2 Transmission Vegetation Management standard currently posted for informal comment, the NERC Standards Committee's Process Subcommittee (SCPS) has developed a proposed standard template for use by the standard drafting team for Project 2007-07 Vegetation Management. The proposed template is intended to meet the following key objectives:

1. Depicting the basic criteria for writing standard requirements that meet the Results-Based Reliability Standards concepts;
2. Having one Section that contains only the reliability requirements and associated measures;
3. Moving the administrative and compliance information that is not required for reliability into different sections so that there are "homes" for these materials;

In addition, the new template contains the following features/changes:

1. Allowing insertion of explanatory text to help readers better understand the basis of the definitions and requirements;
2. Moving the standard development timeline (previously called roadmap), revision history and effective date(s) up front before the Introduction Section;
3. Grouping Requirements and their corresponding Measures together;
4. Grouping VRFs, Time Horizons and VSLs - all of which are used only in the determination of a penalty or sanction - together in a table while leaving the requirements and measures free of any of the compliance elements.

The following questions will assist the SDT in finalizing the development of FAC-003-2 Transmission Vegetation Management and will also assist the Standards Committee's Process Subcommittee in refining the proposed standard template. For questions where you agree with indicated statement, please state that you agree and if able, please provide supporting documentation. If you disagree with the statement, please explain why you disagree and provide a rationale to support your position. We would appreciate responses to as many of the following questions as possible.

1. In response to comments received regarding potential for "double jeopardy" and to provide differentiation between transmission lines designated as having IROLs and Major WECC transfer paths from those that are not, the SDT consolidated requirements R4 though R8 found in the August 2009 draft of FAC-003-2 into two requirements in the latest draft of FAC-003-2 (new requirements R1 and R2). Do you agree? Please explain.

   ☐ Yes

   ☐ No

   Comments:

2. The results-based reliability standard criteria focus on striving to achieve a portfolio of performance-based, risk-based, and competency-based mandatory reliability requirements that provide an effective defense-in-depth strategy for achieving an

adequate level of reliability of the bulk power system in lieu of prescriptive requirements. Consequently, the SDT revised R1 and its subparts found in the August 2009 draft of FAC-003-2 in favor of the text in the latest draft of FAC-003-2 (new requirement R3). Do you agree? Please explain.

☐ Yes

☐ No

Comments:

3. Do you agree with the overall layout of the proposed template? If not, please suggest an alternative layout.

☐ Yes

☐ No

Comments:

4. Do you agree with grouping the standard development timeline (previously called roadmap) with the revision history, and the effective date(s) and putting this administrative information up front before the Introduction Section? Please explain.

☐ Yes

☐ No

Comments:

5. Do you agree with grouping the Requirements and Measures together, in one Section now called Requirements and Measures? Please explain.

☐ Yes

☐ No

Comments:

6. Do you agree with grouping VRFs, Time Horizons and VSLs together, and putting them in a table separate from the Requirements and Measures Section? Please explain.

☐ Yes

☐ No

Comments:

7. Do you agree with the insertion of text boxes, where necessary, to help readers better understand the basis of the Definitions and Requirements? Please explain.

☐ Yes

☐ No

Comments:

8. Do you agree with the addition of a Guideline and Technical Basis Section to place technical materials and other related information that assists entities in understanding

how to comply with the standard but does not contain mandatory actions/activities? Please explain.

☐ Yes

☐ No

Comments:

9. Do you prefer putting URL links to reference materials in the Guideline and Technical Basis Section, or do you prefer putting the additional technical/information materials in appendices, where needed, to supplement the Guideline and Technical Basis Sections? Please explain.

☐ Prefer the inclusion of URL links

☐ Prefer appendices

Comments:

10. Do you agree with the addition of the Background Section to allow provision of background information, and to elaborate on the reliability-related drivers for the standard/change? Please explain.

☐ Yes

☐ No

Comments:

11. Do you agree with the addition of an Administrative Procedure Section to place administrative/procedural requirements that are contained in the existing standards but which do not meet the results-based or risk-based criteria? Please explain.

☐ Yes

☐ No

Comments:

12. Is there any other information that should be included in the standard document? If so, please explain why you feel that this information should be included.

☐ Yes

☐ No

Comments:

13. Do you have any other comment regarding the draft FAC-003-2 Transmission Vegetation Management standard that have not been addressed above? If yes, please provide a reference to the section, requirement, or subrequirement that you believe should be changed, added or deleted and the rationale for your proposal.

☐ Yes

☐ No

Introduction

This document is intended to provide supplemental information and guidance for complying with the requirements of Reliability Standard FAC-003-2.

The purpose of the Standard is to improve the reliability of the electric transmission system by preventing those vegetation related outages that could lead to Cascading.

Compliance with the Standard is mandatory and enforceable.

Special Note: The Application of Results-Based Approach to FAC-003-2

In its three-year assessment as the ERO, NERC acknowledged stakeholder comments and committed to:

i) addressing quality issues to ensure each reliability standard has a clear statement of purpose, and has outcome-focused requirements that are clear and measurable; and

ii) eliminating requirements that do not have an impact on bulk power system reliability.

In 2010, the Standards Committee approved a recommendation to use Project 2007-07 Vegetation Management as a first proof of concept for developing results-based standards.

The Standard Drafting Team (SDT) employed a defense-in-depth[1] strategy for FAC-003-2, where each requirement has a role in preventing those vegetation related outages that could lead to Cascading. This portfolio of requirements was designed to achieve an overall defense-in-depth strategy and to comply with the quality objectives identified in the *Acceptance Criteria of a Reliability Standard* document.

The SDT developed a portfolio of performance, risk, and competency-based mandatory reliability requirements to support an effective defense-in-depth strategy. Each Requirement was developed using one of the following requirement types:

a. Performance-based - defines a particular reliability objective or outcome to be achieved. In its simplest form, a results-based requirement has four components: who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome?

b. Risk-based - preventive requirements to reduce the risks of failure to acceptable tolerance levels. A risk-based reliability requirement should be framed as: who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome that reduces a stated risk to the reliability of the bulk power system?

c. Competency-based - defines a minimum set of capabilities an entity needs to have to demonstrate it is able to perform its designated reliability functions. A competency-based reliability requirement should be framed as: who, under what conditions (if any), shall have what capability, to achieve what particular result or outcome to perform an action to achieve a result or outcome or to reduce a risk to the reliability of the bulk power system?

[1] A defense-in-depth strategy for reliability standards recognizes that each requirement in the NERC standards has a role in preventing system failures, and that these roles are complementary and reinforcing. These prevention measures should be arranged in a series of defensive layers or walls. No single defensive layer provides complete protection from failure by itself. But taken together, with well-designed layers including performance, risk, and competency-based, requirements, a defense-in-depth approach can be very effective in preventing future large scale power system failures.

The drafting team reviewed and edited version 1 of FAC-003-1 to remove prescriptive and administrative language in order to distill the technical requirements down to their essential reliability content. Text that is explanatory in nature is placed in a special section of the standard entitled Guideline and Technical Basis to aid in the understanding of the requirements. Furthermore, Rationale text boxes are inserted alongside each requirement to communicate the foundation for the requirement.

Disclaimer

This supporting document is supplemental to the reliability standard FAC-003-2 — Transmission Vegetation Management and does not contain mandatory requirements subject to compliance review.

Definition of Terms

Active Transmission Line Right of Way* — A strip or corridor of land that is occupied by active transmission facilities. This corridor does not include the parts of the Right-of-Way that are unused or intended for other facilities.

Examples of active portions of corridors include:

1) The width of any Active Transmission Line Right-of-Way (ROW) is the portion of the ROW that has been cleared of vegetation to meet design clearance requirements such as National Electrical Safety Code or other design criteria, for the reliable operation of active facilities.

Examples of inactive portions of corridors include:

2) The portions of the right of way acquired to accommodate future facilities. Power plant exits are examples where large rights-of-way are obtained for maximum corridor utilization and may currently have fewer structures constructed.
3) The portion of the ROW where corridor edge zones are designated by regulatory bodies for vegetation to exist.
4) The portions of the ROW where double-circuit structures are installed but only one circuit is currently strung with conductors.

Vegetation Inspection** — The systematic examination of vegetation conditions on an Active Transmission Line Right-of-Way which may be combined with a general line inspection.

The inspection includes the identification of any vegetation that may pose a threat to reliability prior to the next planned inspection or maintenance work, considering the current location of the conductor and other possible locations of the conductor due to sag and sway for rated conditions.

This definition allows both maintenance inspections and vegetation inspections to be performed concurrently.

*To be added to the NERC glossary of terms with final approval of this standard revision
** This is a modification to a defined term in the NERC glossary.

Applicability of the Standard

4. Applicability

4.1. Functional Entities:

4.1.1 Transmission Owners

4.2. Facilities: Defined below, including but not limited to those that cross lands owned by federal[1], state, provincial, public, private, or tribal entities:

4.2.1 Overhead transmission lines operated at 200kV or higher.

4.2.2 Overhead transmission lines operated below 200kV having been identified as elements of an Interconnection Reliability Operating Limit (IROL).

4.2.3 Overhead transmission lines operated below 200 kV having been identified as included in the definition of one of the Major WECC Transfer Paths in the Bulk Electric System.

4.2.4 This Standard does not apply to Facilities identified above (4.2.1 through 4.2.3) located in the fenced area of a switchyard, station or substation.

4.3. Other:

4.3.1 This Standard does not apply to any occurrence, non-occurrence, or other set of circumstances that are beyond the reasonable control of a Transmission Owner subject to this Reliability Standard, and are not caused by the fault or negligence of the Transmission Owner, including acts of God, flood, drought, earthquake, major storms, fire, hurricane, tornado, landslides, logging activities, animals severing trees, lightning, epidemic, strike, war, riot, civil disturbance, sabotage, vandalism, terrorism, wind shear, or fresh gales that restricts or prevents performance to comply with this reliability standard's requirements.

In Order 693, FERC discussed the 200 kV bright-line test of applicability. While FERC did not change the 200 kV bright line, the Commission remained concerned that there may be some transmission lines operating at lesser voltages that could have significant impact on the Bulk Electric System that should therefore be subject to this standard.

NERC Standard FAC-014 has the stated purpose, "*To ensure that System Operating Limits (SOLs) used in the reliable planning and operation of the Bulk Electric System (BES) are determined based on an established methodology or methodologies.*" FAC-014 requires Reliability Coordinators, Planning Coordinators, and Transmission Planners to have a methodology to identify all lines that might comprise an IROL. Thus, these entities would identify sub-200 kV lines that qualify as part of an IROL and should be subject to FAC-003-2.

Although all three entities may prepare the list of elements, FAC-003-2 presently does not specify that it is the list from the Planning Coordinator that should be used by Transmission Owners for FAC-003. However, the Time Horizon needed to plan vegetation management work does not lend itself to the operating horizon of a Reliability Coordinator. Additionally, the Planning Coordinator has a wider-area view than the Transmission Planner and could thus identify any elements of importance to a sub-set of its area that might be missed by a Transmission Planner.

Transmission Owners, who do not already get the list of circuits included in the definition of an IROL, can get them from the Planning Coordinator. Specifically R5 of FAC-014 specifies that "*The Reliability Coordinator, Planning Authority (Coordinator) and Transmission Planner shall each provide its SOLs and IROLs to those entities that have a reliability-related need for those limits and provide a written request that includes a schedule for delivery of those limits"*

Vegetation-related Sustained Outages that occur due to natural disasters are beyond the control of the Transmission Owner. These events are not classified as vegetation-related Sustained Outages and are therefore exempt from the Standard. Transmission lines are not designed to withstand the impacts of natural disasters such as tornadoes, hurricanes, severe ice loads, landslides, etc. In the aftermath of catastrophic system damage from natural disasters the Transmission Owner's focus is on electric system restoration for public safety and critical support infrastructure.

Sustained Outages due to human or animal activity are beyond the control of the Transmission Owner. These outages are not classified as vegetation-related Sustained Outages and are therefore exempt from the Standard. Examples of these events may include new plantings by outside parties of tall vegetation under the transmission line planted since the last Vegetation Inspection, tree contacts with line initiated by vehicles, logging activities, etc.

The foregoing exemptions are addressed in a new subsection, <u>4.3 Other,</u> of the Applicability section. Referred to collectively as force majeure events and activities, this section applies to all requirements in FAC-003-2.

The reliability objective of this NERC Vegetation Management Standard ("Standard") is to prevent vegetation-related outages which could lead to Cascading by effective vegetation maintenance while recognizing that certain outages such as those due to vandalism, human errors and acts of nature are not preventable. Operating experience clearly indicates that trees that have grown out of specification could contribute to a cascading grid failure, especially under heavy electrical loading conditions.

Serious outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations. To properly reduce and manage this risk, it is necessary to apply the Standard to applicable lines on any kind of land or easement, whether they are Federal Lands, state or provincial lands, public or private lands, franchises, easements or lands owned in fee. For the purposes of the Standard and this technical paper, the term "public lands" includes municipal lands, village lands, city lands, and land owned by a host of other governmental entities.

The Standard addresses vegetation management along applicable overhead lines that serve to connect one electric station to another. However, it is not intended to be applied to lines sections inside the electric station fence or other boundary of an electric station or underground lines.

The Standard is intended to reduce the risk of Cascading involving vegetation. It is not intended to prevent customer outages from occurring due to tree contact with all transmission lines and voltages. For example, localized customer service might be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. However, this Standard is not written to address such isolated situations which have little impact on the overall Bulk Electric System. In fact, the inclusion of such a transmission line (which does not lead to the undesirable conditions listed in Requirement R10) on the Planning Coordinator's list of sub-200kV lines may constitute a violation of Requirement R10.

Vegetation growth is constant and always present. Unmanaged vegetation poses an increased outage risk when numerous transmission lines are operating at or near their Rating. This poses a significant risk of multiple line failures and Cascading. On the other hand, most other outage causes (such as trees falling into lines, lightning, animals, motor vehicles, etc.) are statistically intermittent. The probability of occurrence of these events is not dependent on heavy loads. There is no cause-effect relationship which creates the probability of simultaneous occurrence of other such events. Therefore these types of events are highly unlikely to cause large-scale grid failures.

In preparing the original vegetation management standard in 2005, industry stakeholders set the threshold for applicability of the standard at 200kV. This was because an unexpected loss of lines operating at above 200kV has a higher probability of initiating a widespread blackout or cascading outages compared with lines operating at less than 200kV.

The NERC vegetation management standard FAC-003-1 also allowed for application of the standard to "critical" circuits (critical from the perspective of initiating widespread blackouts or cascading outages) operating below 200kV. While the percentage of these circuits is relatively low, it remains a fact that there are sub-200kV circuits whose loss could contribute to a widespread outage. Given the very limited exposure and unlikelihood of a major event related to these lower-voltage lines, it would be an imprudent use of resources to apply the Standard to all sub-200kV lines. The drafting team, after evaluating several alternatives, selected the IROL and WECC Major Transfer Path criteria to determine applicable lines below 200 kV that are subject to this standard.

Requirements R1 and R2

> **Rationale**
> The MVCD is a calculated minimum distance stated in feet (meters) to prevent spark-over between conductors and vegetation, for various altitudes and operating voltages. The distances in Table 2 were derived using a proven transmission design method.

R1. *Each Transmission Owner shall prevent vegetation from encroaching within the Minimum Vegetation Clearance Distance (MVCD) of each line conductor that is identified as an element of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions) to avoid a Sustained Outage.*

R2. *Each Transmission Owner shall prevent vegetation from encroaching within the MVCD of each applicable line conductor, which are not elements of an IROL and are not a Major WECC transfer path, (operating within Rating and Rated Electrical Operating Conditions) to avoid a Sustained Outage.*

M1. *Evidence of violation of Requirement R1 is limited to:*

- *Real-time observation of encroachment into the MVCD, or*
- *A vegetation-related Sustained Outage due to a fall-in from inside the Active Transmission Line ROW, or*
- *A vegetation-related Sustained Outage due to blowing together of applicable lines and vegetation located inside the Active Transmission Line ROW, or*
- *A vegetation-related Sustained Outage due to a grow-in.*

Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period.

M2. *Evidence of violation of Requirement R2 is limited to:*

- *Real-time observation of encroachment into the MVCD, or*
- *A vegetation-related Sustained Outage due to a fall-in from inside the Active Transmission Line ROW, or*
- *A vegetation-related Sustained Outage due to blowing together of applicable lines and vegetation located inside the Active Transmission Line ROW, or*
- *A vegetation-related Sustained Outage due to a grow-in.*

Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period.

R1 and R2 are performance-based requirements. The reliability objective or outcome to be achieved is the prevention of vegetation encroachments within a minimum distance of transmission lines. Content-wise, R1 and R2 are the same requirements, however, they apply to different Facilities. Both R1 and R2 require each Transmission Owner to prevent vegetation from encroaching within the Minimum Vegetation Clearance Distance of transmission lines. R1 is applicable to lines “identified as an element of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions) to avoid a Sustained Outage”. R2 applies to all other applicable lines that are not an element of an IROL or Major WECC Transfer Path.

The separation of applicability (between R1 and R2) recognizes that an encroachment into the MVCD of an IROL or Major WECC Transfer Path transmission line is a greater risk to the electric transmission system. Applicable lines that are not an element of an IROL or Major WECC Transfer Path are required to be clear of vegetation but these lines are comparatively less operationally significant. As a reflection of this difference in risk impact, the Violation Risk Factors (VRFs) are assigned as High for R1 and Medium for R2.

These requirements (R1 and R2) state that if vegetation encroaches within the distances prescribed in Table 1 in Appendix 1 of this Technical Reference document, it is in violation of the standard. Table 1 delineates the distances necessary to prevent spark-over based on the Gallet equations as described more fully in Appendix 1.

This requirement assumes that transmission lines and their conductors are operating within their Rating. If a line conductor is intentionally or inadvertently operated beyond its rating (potentially in violation of other standards), the occurrence of a clearance encroachment may not be a violation of this Standard. Conductor position, and the associated vegetation distance, that result from operation of a transmission line beyond its recognized Rating (for example emergency actions taken by a TOP or RC to protect an Interconnection) is beyond the scope of this standard.

Evidence of violation of Requirement R1 and R2 is limited to a real-time observation of encroachment into the MVCD, or a vegetation-related Sustained Outage due to a fall-in from inside the Active Transmission Line ROW, or a vegetation-related Sustained Outage due to blowing together of applicable lines and vegetation located inside the Active Transmission Line ROW, or a vegetation-related Sustained Outage due to a grow-in.

It is also important to note that Multiple Sustained Outages on an individual line can be caused by the same vegetation. Such events are considered to be a single vegetation-related Sustained Outage under the Standard where the Sustained Outages occur within a 24 hour period.

Requirement R3

R3. *Each Transmission Owner shall have a documented transmission vegetation management program that describes how it conducts work on its Active Transmission Line ROWs to avoid Sustained Outages due to vegetation, considering all possible locations the conductor may occupy assuming operation within Rating and Rated Electrical Operating Conditions.*

Rationale
Provide a basis for evaluation on the intent and competency of the Transmission Owner in maintaining vegetation. There may be many acceptable approaches to maintain clearances. However, the Transmission Owner should be able to state what its approach is and how it conducts work to maintain clearances. See Figure 1 for an illustration of possible conductor locations.

M3. *Each Transmission Owner has a documented transmission vegetation management program that describes how it conducts work on its Active Transmission Line ROW to avoid Sustained Outages due to vegetation, considering all possible locations the conductor may occupy assuming operation within Rating and Rated Electrical Operating Conditions.*

Whitepaper for section R3: (Competency Based Requirement)

Requirement R3 is a competency based requirement concerned with the content of the TVMP and supporting documentation.

An adequate transmission vegetation management program formally establishes the approach the Transmission Owner uses to plan and perform vegetation work that is necessary to prevent transmission Sustained Outages and minimize risk to the Transmission System.
This approach provides the basis for evaluating the intent, allocation of appropriate resources and the competency of the Transmission Owner in managing vegetation. There are many acceptable approaches to manage vegetation and avoid sustained outages. However, the Transmission Owner must be able to state what its approach is and how it conducts work to maintain clearances.

An example of one approach commonly used by industry is ANSI Standard A300, part 7. However, regardless of the approach a utility uses to manage vegetation, any approach a Transmission Owner chooses to use will generally contain the following elements:

1. *the maintenance strategy used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that MVCD clearances are never violated.*
2. *the work methods that the Transmission Owner uses to control vegetation*
3. *a stated Vegetation Inspection frequency*
4. *an annual work plan*

Conductor Dynamics
In order for a Transmission Owner to develop a specific maintenance approach, it is important to understand the dynamics of a line conductor's movement. This paper will first address the

complexities inherent in observing and predicting conductor movement, particularly for field personnel. It will then present some examples of maintenance approaches which Transmission Owners may consider that take into account these complexities, while resulting in practical approaches for field personnel.

Additionally, it is important the Transmission Owner consider all conductor locations, the MVCD, and vegetation growth between maintenance activities when developing a maintenance approach.

Understanding Conductor Position and Movement

The conductor's position in space at any point in time is continuously changing as a reaction to a number of different loading variables. Changes in vertical and horizontal conductor positioning are the result of thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation. Physical loading applied to the conductor affects sag and sway by combining physical factors such as ice and wind loading.

As a consequence of these loading variables, the conductor's position in space is dynamic and moving. When calculating the range of conductor positions, the Transmission Owner should use the same design criteria and assumptions that the Transmission Owner uses when establishing Ratings and SOL, as described in other standards. Typically, the greatest conductor movement would be at mid-span. As the conductor moves through various positions, a spark-over zone surrounding the conductor moves with it. The radius of the spark-over zone may be found by referring to Table 1 ("Minimum Vegetation Clearance Distances") in the standard. For illustrations of this zone and conductor movements, Figures 4 through 6 below demonstrate these concepts. At the time of making a field observation, however, it is very difficult to precisely know where the conductor is in relation to its wide range of all possible positions. Therefore, Transmission Owners must adopt maintenance approaches that account for this dynamic situation.

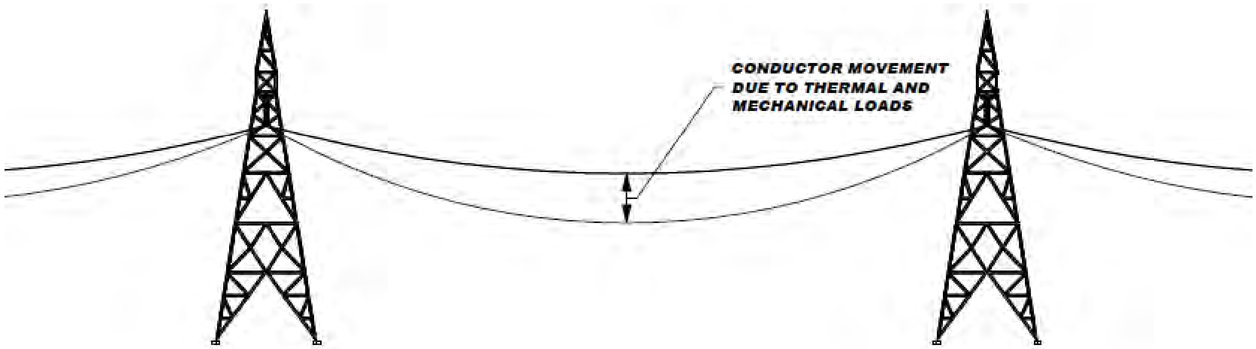

Figure 4

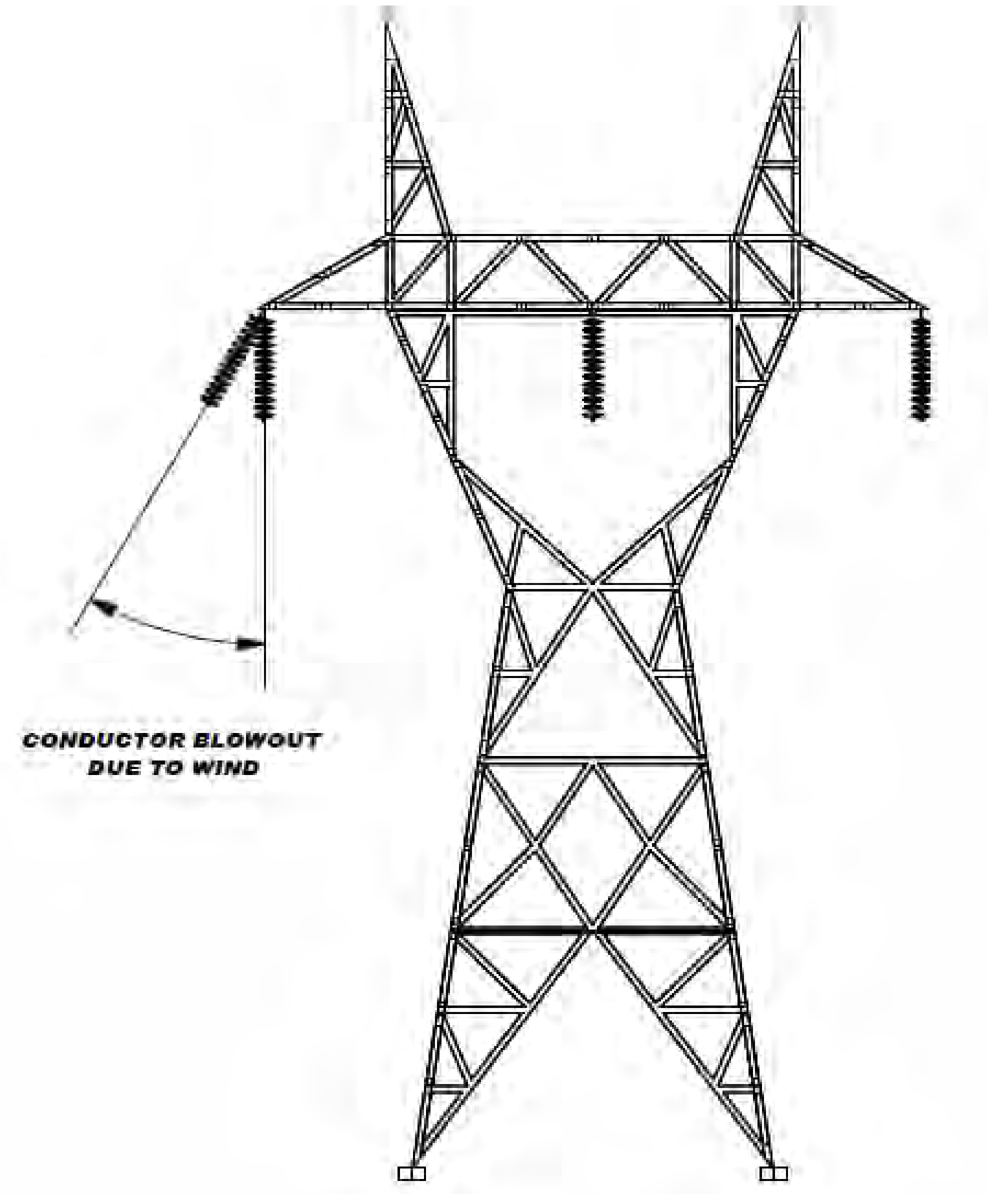

Figure 5

At a Given Point Along The Span
Showing Six Possible Conductor Positions Due to Movement
Resulting From Thermal and Mechanical Loading
For Consideration in Developing a Maintenance Approach

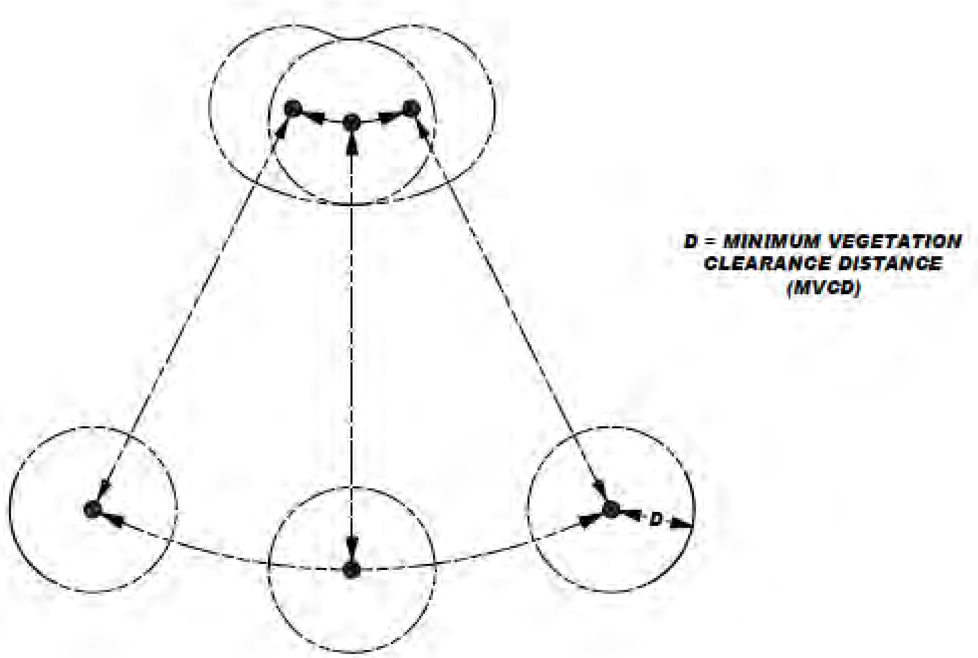

Figure 6

Selecting a Maintenance Approach

In order to maintain adequate separation between vegetation and transmission line conductors, the Transmission Owner must craft a maintenance strategy that keeps vegetation well away from the spark-over zone mentioned above. In fact, it is generally necessary to incorporate a variety of maintenance strategies. For example, one Transmission Owner may utilize a combination of routine cycles, traditional IVM techniques and long-term planning. Another Transmission Owner may place a higher reliance on frequent inspections and quick remediation as opposed to a cyclical approach. This variation of approaches is further warranted when factors, such as terrain, legal and other constraints, vegetation types, and climates, are considered in developing a Transmission Owner's specific approach to satisfying this requirement.

The following is a sample description of one combination of strategies which may be utilized by a Transmission Owner.

A Transmission Owner's basic maintenance approach could be to remove all incompatible vegetation from the right of way if it has the right to do so and has no constraints. In mountainous terrain, however, this strategy could change to one where the Transmission Owner manages vegetation based on vegetation-to-conductor clearances, since it might not be necessary to remove vegetation in a valley that is far below.

If faced with constraints and assuming a line design with sufficient ground clearance, the Transmission Owner 's approach could then be to allow vegetation such as fruit trees, but perhaps only up to a given height at maturity (perhaps 10 feet from the ground). If constraints cannot be overcome and if design clearances are sufficient, an exception to the Transmission Owner's 10-foot guideline might be made. Finally, if the Transmission Owner has chosen to utilize vegetation-to-conductor clearance distance methods, the Transmission Owner could have an inspection regimen in place to regularly ensure that any impending clearance problems are identified early for rectification.

ANSI A300 – Best Management Practices for Tree Care Operations

A description of ANSI A-300, part 7, is offered below to illustrate another maintenance approach that could be used in developing a comprehensive transmission vegetation management program.

Introduction

Integrated Vegetation Management (IVM) is a best management practice conveyed in the American National Standard for Tree Care Operations, Part 7 (ANSI 2006) and the International Society of Arboriculture Best Management Practices: Integrated Vegetation Management (Miller 2007). IVM is consistent with the requirements in FAC-003-02, and it provides practitioners with what industry experts consider to be appropriate techniques to apply to electric right-of-way projects in order to meet or exceed the Standard.

IVM is a system of managing plant communities whereby managers set objectives; identify compatible and incompatible vegetation; consider action thresholds; and evaluate, select and implement the most appropriate control method or methods to achieve set objectives. The choice of control method or methods should be based on the environmental impact and anticipated effectiveness; along with site characteristics, security, economics, current land use and other factors.

Planning and Implementation
Best management practices provide a systematic way of planning and implementing a vegetation management program. While designed primarily with transmission systems in mind, it is also applicable to distribution projects. As presented in ANSI A300 part 7 and the ISA best management practices, IVM consists of 6 elements:

1) Set Objectives
2) Evaluate the Site
3) Define Action Thresholds
4) Evaluate and Select Control Methods
5) Implement IVM
6) Monitor Treatment and Quality Assurance

The setting of objectives, defining action thresholds, and evaluating and selecting control methods all require decisions. The planning and implementation process is cyclical and continuous, because vegetation is dynamic and managers must have the flexibility to adjust their plans. Adjustments may be made at each stage as new information becomes available and circumstances evolve.

Set Objectives
Objectives should be clearly defined and documented. Examples of objectives can include promoting safety, preventing sustained outages caused by vegetation growing into electric facilities, maintaining regulatory compliance, protecting structures and security, restoring electric service during emergencies, maintaining access and clear lines of sight, protecting the environment, and facilitating cost effectiveness.

Objectives should be based on site factors, such as workload and vegetation type, in addition to human, equipment and financial resources. They will vary from utility to utility and project to project, depending on line voltage and criticality, as well as topographical, environmental, fiscal and political considerations. However, where it is appropriate, the overriding focus should be on environmentally-sound, cost effective control of species that potentially conflict with the electric facility, while promoting compatible, early successional, sustainable plant communities.

Work Load Evaluations
Work-load evaluations are inventories of vegetation that could have a bearing on management objectives. Work load assessments can capture a variety of vegetation characteristics, such as location, height, species, size and condition, hazard status, density and clearance from conductors. Assessments should be conducted considering voltage, conductor sag from ambient temperatures and loading, and the potential influence of wind on line sway.

Evaluate and Select Control Methods

Control methods are the process through which managers achieve objectives. The most suitable control method best achieves management objectives at a particular site. Many cases call for a combination of methods. Managers have a variety of controls from which to choose, including manual, mechanical, herbicide and tree growth regulators, biological, and cultural options.

Manual Control Methods

Manual methods employ workers with hand-carried tools, including chainsaws, handsaws, pruning shears and other devices to control incompatible vegetation. The advantage of manual techniques is that they are selective and can be used where others may not be. On the other hand, manual techniques can be inefficient and expensive compared to other methods.

Mechanical Control Methods

Mechanical controls are done with machines. They are efficient and cost effective, particularly for clearing dense vegetation during initial establishment, or reclaiming neglected or overgrown right of way. On the other hand, mechanical control methods can be non-selective and disturb sensitive sites.

Tree Growth Regulator and Herbicide Control Methods

Tree growth regulators and herbicides can be effective for vegetation management. Tree growth regulators (TGRs) are designed to reduce growth rates by interfering with natural plant processes. TGRs can be helpful where removals are prohibited or impractical by reducing the growth rates of some fast-growing species.

Herbicides control plants by interfering with specific botanical biochemical pathways. Herbicide use can control individual plants that are prone to re-sprout or sucker after removal. When trees that re-sprout or sucker are removed without herbicide treatment, dense thickets develop, impeding access, swelling workloads, increasing costs, blocking lines-of-site, and deteriorating wildlife habitat. Treating suckering plants allows early successional, compatible species to dominate the right-of-way and out-compete incompatible species, ultimately reducing work.

Cultural Control Methods

Cultural methods modify habitat to discourage incompatible vegetation and establish and manage desirable, early successional plant communities. Cultural methods take advantage of seed banks of native, compatible species lying dormant on site. In the long run, cultural control is the most desirable method where it is applicable.

A cultural control known as cover-type conversion provides a competitive advantage to short-growing, early successional plants, allowing them to thrive and eventually out-compete unwanted tree species for sunlight, essential elements and water. The early successional plant community is relatively stable, tree-resistant and reduces the amount of work, including herbicide application, with each successive treatment.

Wire-Border Zone

The wire-border zone technique is a management philosophy that can be applied through cultural control. W.C. Bramble and W.R. Byrnes developed it in the mid-1980s out of research begun in 1952 on a transmission right-of-way in the Pennsylvania State Game Lands 33 Research and Demonstration project (Yahner and Hutnik (2004).

The wire zone is the section of a utility transmission right-of-way directly under the wires and extending outward about 10 feet on each side. The wire zone is managed to promote a low-growing plant community dominated by grasses, herbs and small shrubs (under 3 feet in height at maturity). The border zone is the remainder of the right-of-way. It is managed to establish small trees and tall shrubs (under 25 feet in height at maturity). When properly managed, diverse, tree-resistant plant communities develop in wire and border zones. The communities not only protect the electric facility and reduce long-term maintenance, but also enhance wildlife habitat, forest ecology and aesthetic values.

Although the wire-border zone is a best practice in many instances, it is not necessarily universally suitable. For example, standard wire-border zone prescriptions may be unnecessary where lines are high off the ground, such as across low valleys or canyons, so the technique can be modified without sacrificing reliability.

One way to accommodate variances in topography is to establish different regions based on wire height. For example, over canyon bottoms or other areas where conductors are 100 feet or more above the ground, only a few trees are likely to be tall enough to conflict with the lines. In those cases, trees that potentially interfere with the transmission lines can be removed selectively on a case-by-case basis.

In areas where the wire is lower, perhaps between 50-100 feet from the ground, a border zone community can be developed throughout the right-of-way. Note that in many cases, conductor attachment points are more than 50 feet off the ground, so a border zone community can be cultivated near structures. Where the line is less than 50 feet off the ground, managers could apply a full wire-border zone prescription.

An environmental advantage of this type of modification is stream protection. Streams often course through the valleys and canyons where lines are likely to be elevated. Leaving timber or border zone communities in canyon bottoms helps shelter this valuable habitat, enabling managers to achieve environmentally sensitive objectives.

Implement IVM

All laws and regulations governing IVM practices and specifications written by qualified vegetation managers must be followed. Integrated vegetation management control methods should be implemented on regular work schedules, which are based on established objectives and completed assessments. Work should progress systematically, using control measures determined to be best for varying conditions at specific locations along a right-of-way. Some considerations used in developing schedules include the importance and type of line, vegetation clearances, work loads, growth rate of predominant vegetation, geography, accessibility, and in some cases, time lapsed since the last scheduled work.

Clearances Following Work
Clearances following work should be sufficient to meet management objectives, including preventing trees from entering the Minimum Vegetation Clearance Distance, electric safety risks, service-reliability threats and cost.

Monitor Treatment and Quality Assurance
An effective program includes documented processes to evaluate results. Evaluations can involve quality assurance while work is underway and after it is completed. Monitoring for quality assurance should begin early to correct any possible miscommunication or misunderstanding on the part of crewmembers. Early and consistent observation and evaluation also provides an opportunity to modify the plan, if need be, in time for a successful outcome.

Utility vegetation management programs should have systems and procedures in place for documenting and verifying that vegetation management work was completed to specifications. Post-control reviews can be comprehensive or based on a statistically representative sample. This final review points back to the first step and the planning process begins again.

Summary of A-300 example
Integrated Vegetation Management offers among others, a systematic way of planning and implementing a vegetation management program as presented in ANSI A300 Part 7. This methodology enables a program to comply with the NERC *Transmission Vegetation Management Program* standard (FAC-003-2). Managers should select control options to best promote management objectives.

Vegetation Inspections
As with the ANSI A-300 example, The Transmission Owner's transmission vegetation management program (TVMP) establishes the frequency of vegetation inspections based upon many factors. Such local and environmental factors may include anticipated growth rates of the local vegetation, length of the growing season for the geographical area, limited Active Transmission Rights of Way width, rainfall amounts, etc.

Annual Work Plan
Requirement R7 of the Standard addresses the execution of the annual work plan. A comprehensive approach that exercises the full extent of legal rights is superior to incremental management in the long term because it reduces overall encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient at all locations on the Active Transmission Line Right of Way. Removal is superior to pruning. Removal minimizes the possibility of conflicts between energized conductors and vegetation. Since this is not always possible, the Transmission Owner's approach should be to use its prescribed vegetation maintenance methods to work towards or achieve the maximum use of the Active Transmission Line Right of Way.

Requirement R4

R4. *Each Transmission Owner shall notify the responsible control center when it has verified knowledge of a vegetation imminent threat condition. A vegetation imminent threat condition is one which is likely to cause a Sustained Outage at any moment.*

The term "imminent threat" refers to a vegetation condition which is likely to cause a Sustained Outage at any moment. An imminent threat requires immediate action by the Transmission Owner to prevent the occurrence of a Sustained Outage.

> **Rationale**
> To ensure rapid notification of the correct personnel when an occurrence of a critical situation is observed. Verified knowledge includes observations by journeyman lineman, utility arborist, or other qualified personnel, or a report verified by these personnel.

M4. *Each Transmission Owner that has experienced a verified vegetation imminent threat will have evidence that it notified the responsible control center.*

R4 is a risk-based requirement type. It focuses upon preventative actions to be taken by the Transmission Owner for the mitigation of Sustained Outage risk when a vegetation imminent threat is verified. R4 involves the expeditious notification to the responsible control center of potentially threatening vegetation conditions to transmission lines.

The term "verified knowledge" implies reliable confirmation that an imminent threat actually exists due to vegetation. Verification could be that the initial call-in came from a trained employee able to identify such a threat or it could be verified by sending out such a trained person to confirm a call-in from a citizen or an untrained employee.

Vegetation-related conditions that warrant a response include vegetation that is near or encroaching into the MVCD (a grow-in issue) or vegetation that presents an imminent danger of falling into the transmission conductor (a fall-in issue). A knowledgeable verification of the risk would include an assessment of the possible sag or movement of the conductor operating between no-load and its rating.

The term "responsible control center" refers to personnel with direct responsibility for operating the transmission lines, such as the Transmission Owner's local control center, Transmission Operator, Independent System Operator, or other operating entity. In the case where the responsible control center is not the Transmission Operator, the communication between the responsible control center and the Transmission Operator will occur by the normal policies that govern their relationship.

The Transmission Owner has the responsibility to ensure the proper communication between field personnel and the responsible control center to allow the responsible control center to take the appropriate action until the threat is relieved. Appropriate actions may include a temporary reduction in the line loading, switching the line out of service or positioning the system in recognition of the increasing risk of outage on that circuit.

The imminent threat notification should be communicated in terms of minutes or hours as opposed to a longer time frame for interim corrective action plans (see R5).
All potential grow-in or fall-in vegetation-related conditions are not necessarily considered imminent threats under this Standard. For example, some Transmission Owners may have a danger tree identification program that identifies tree for removal with the potential to fall near the line. These trees are not necessarily considered imminent threats under the Standard unless they pose an immediate fall-in threat.

Requirement R5

R5. *Each Transmission Owner shall take interim corrective action when it is temporarily constrained from performing planned vegetation work, where a transmission line is put at potential risk due to the constraint.*

M5. *Each Transmission Owner has evidence of the interim corrective action taken for each temporary constraint where a transmission line was put at potential risk. Examples of acceptable forms of evidence may include work orders, invoices, or inspection records.*

Rationale
Legal actions and other events may occur which result in constraints that prevent the Transmission Owner from performing planned vegetation maintenance work. When this event occurs and the work is essential to avoid risk to the transmission line the Transmission Owner must establish and act on a plan to prevent an imminent threat. This is not intended to address situations where a planned work methodology cannot be performed but an alternate work methodology can be used.

R5 is a risk-based requirement type. It focuses upon preventative actions to be taken by the Transmission Owner for the mitigation of Sustained Outage risk when temporarily constrained from performing vegetation maintenance. The intent of this requirement is to deal with situations that prevent the Transmission Owner from performing planned vegetation management work and, as a result, have the potential to put the transmission line at risk. Constraints to performing vegetation maintenance work as planned could result from legal injunctions filed by property owners, the discovery of easement stipulations which limit the Transmission Owner's rights, or other circumstances.

This requirement is not intended to address situations where the transmission line is not at immediate risk and the work event can be rescheduled or re-planned using an alternate work methodology. For example, a land owner may prevent the planned use of chemicals on non-threatening, low growth vegetation but agree to the use of mechanical clearing. In this case the Transmission Owner is not under any immediate time constraint for achieving the management objective, can easily reschedule work using an alternate approach, and therefore does not need to take interim corrective action.

However, in situations where transmission line reliability is potentially at risk due to a constraint, the Transmission Owner is required to take an interim corrective action to mitigate the potential risk to the transmission line. A wide range of actions can be taken to address various situations. General considerations include:

- Identifying locations where the Transmission Owner is constrained from performing planned vegetation maintenance work which potentially leaves the transmission line at risk.
- Developing the specific action to mitigate any potential risk associated with not performing the vegetation maintenance work as planned.
- Documenting and tracking the specific action taken for each location.
- In developing the specific action to mitigate the potential risk to the transmission line the Transmission Owner could consider location specific measures such as modifying

the inspection and/or maintenance intervals. Where a legal constraint would not allow any vegetation work, the interim corrective action could include limiting the loading on the transmission line.

- The Transmission Owner should document and track the specific corrective action taken at each location. This location may be indicated as one span, one tree or a combination of spans on one property where the constraint is considered to be temporary.

Requirement R6

R6. *Each Transmission Owner shall perform a Vegetation Inspection of all applicable transmission lines at least once per calendar year*

M6. *Each Transmission Owner has evidence that it conducted Vegetation Inspections at least once per calendar year for applicable transmission lines. Examples of acceptable forms of evidence may include work orders, invoices, or inspection records.*

Rationale
The requirement is for once per calendar year because that seems to be reasonable length of time for a majority of situations. Transmission Owners should consider local and environmental factors that could warrant more frequent inspections that may affect reliability.

R6 is a risk-based requirement type. It focuses upon the preventative action of vegetation inspections to be conducted by the Transmission Owner for the mitigation of Sustained Outage risk. This requirement sets a minimum vegetation inspection frequency of once per calendar year. A once per calendar year frequency is reasonable based upon average growth rates across North America and common utility practice. Transmission Owners should consider local and environmental factors that could warrant more frequent inspections that may affect reliability.

This requirement sets a minimum time period for the Vegetation Inspections. More frequent inspections may be needed to maintain reliability levels, depending upon such factors as anticipated growth rates of the local vegetation, length of the growing season for the geographical area, limited Active Transmission ROW width, and rainfall amounts. Therefore some lines may be designated with a higher frequency of inspections.

The VSL for Requirement R6 has VSL categories ranked by the percentage of the required ROW inspections completed. To calculate the percentage of inspection completion, the Transmission Owner lines may choose units such as: line miles or kilometers, circuit miles or kilometers, pole line miles, ROW miles, etc.

For example, when a Transmission Owner operates 2,000 miles of 230 kV transmission lines this Transmission Owner will be responsible for inspecting all 2,000 miles of 230 kV transmission lines at least once during the calendar year. If one of the included lines was 100 miles long, and if it was not inspected during the year, then the amount inspected would be 1900/2000 = 0.95 or 95%. The “Lower VSL” for R6 would apply in this example.

The standard allows Vegetation Inspections to be performed in conjunction with general line inspections as per the definition.

Requirement R7

R7. *Each Transmission Owner shall execute a flexible annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD.*

M7. *Each Transmission Owner has evidence that it executed a flexible annual vegetation work plan. Examples of acceptable forms of evidence may include work orders, invoices, or inspection records.*

Rationale
This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. A flexible annual vegetation work plan allows for work to be deferred into the following calendar year provided it does not have the potential to become an imminent threat.

This is a risk-based requirement type. R7 focuses upon implementation of the annual vegetation work plan to diminish risk of vegetation encroachments within the MVCD. This requirement sets the expectation that the work identified in the annual vegetation work plan will be completed as planned.

The flexibility to adjust the annual vegetation work plan must always ensure the reliability of the electric Transmission system. Flexibility is meant to address changing conditions of the vegetation on the Active Transmission Line ROW, emergencies, and other significant changing conditions.

This standard requires that the annual vegetation work plan be flexible to allow the Transmission Owner to change priorities during the year as conditions or situations dictate. For example, weather conditions (drought) could make herbicide application ineffective during the plan year. Other conditions may also result in adjustments to the annual vegetation work plan:

- Environmental conditions such as excessive rainfall, infestation, disease, fire, etc.
- Work-management related conditions such as revised work plan priorities, rescheduled work to another time or selection of an alternative vegetation control method.
- Changes in land usage made by a property owner, such as timber clearing.
- Redirection of local resources away from planned maintenance to render assistance due to major storms, i.e., complying with mutual assistance agreements.

The work plan is not intended to be a “span-by-span” detailed description of all work to be performed. It is intended to require the Transmission Owner to annually plan and schedule vegetation work to prevent encroachment into the MVCD.

The Transmission Owner is required to implement the annual vegetation work plan to accomplish the purpose of this standard. This means that maintenance should be performed to the extent of the Transmission Owner’s easement, fee simple or other legal right. A comprehensive approach that exercises the full extent of legal rights is superior to incremental management in the long term by reducing overall encroachments. This approach emphasizes the importance of maintaining all locations on the Active Transmission Line ROWs for reliability purposes in lieu of making special exceptions.

Property owners, agencies and other interested parties occasionally request special considerations to leave undesirable vegetation conditions. Historically, such special considerations have led to outages (some of which became Cascading events) and can lead to violations of the standard.

Documentation or other evidence of the work performed typically consists of signed off work orders, signed contracts, printouts from work management systems, spreadsheets of planned versus completed work, timesheets, work inspection reports, or paid invoices. Other evidence may include photographs, work inspection reports and walk-through reports.

When the annual vegetation work plan is adjusted or otherwise not completely implemented as originally planned, the Transmission Owner is encouraged to document the change. The reasons for the deferrals or changes and the expected completion date of postponed work should also be documented.

When developing the annual vegetation work plan the Transmission Owner should allow time for procedural requirements to obtain permits to work on federal, state, provincial, public, tribal lands. In some cases the lead time for obtaining permits may necessitate preparing work plans more than a year prior to work start dates. Transmission Owners may also need to consider those special landowner requirements as documented in easement instruments.

Appendix One: Clearance Distance Derivation by the Gallet Equation

The Gallet Equation is a well-known method of computing the required strike distance for proper insulation coordination, and has the ability to take into account various air gap geometries, as well as non-standard atmospheric conditions. When the Gallet Equation and conservative probabilistic methods are combined, i.e. deterministic design, sparkover probabilities of 10^{-6} or less are achieved. This approach is well known for its conservatism and was used to design the first 500 kV and 765 kV lines in North America [1]. Thus, the deterministic design approach using the Gallet Equation is used for the standard to compute the minimum strike distance between transmission lines and the vegetation that may be present in or along the transmission corridor.

Method Explanation (Gallet Equation)

In 1975 G. Gallet published a benchmark paper that provided a method to compute the critical flashover voltage (CFO) of various air gap geometries [4]. The Gallet Equation uses various “gap factors” to take into account various air gap geometries. Various gap factor values are provided in [1]. If the vegetation in a transmission corridor, e.g. a tree, is assumed electrically to be a large structure then the CFO of such an air gap geometry can be computed for dry or wet conditions using a well established equation proposed by Gallet [1],[2],[4],

$$CFO_A = k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} \tag{1}$$

Where:

k_w is defined as the factor that takes into account wet or dry conditions (dry = 1.0 and wet = 0.96) and phase arrangement (multiply by 1.08 for outside phase), e.g. outside phase and wet conditions = (0.96)(1.08) = 1.037

k_g is defined as the gap factor (1.3 for conductor to large structure)

D is the strike distance (m)

CFO_A is the CFO for the relative air density (kV)

δ is defined as the relative air density and is approximately equal to (2) where A is the altitude in km

$$\delta = e^{-\frac{A}{8.6}} \tag{2}$$

$$m = 1.25G_0\left(G_0 - 0.2\right) \tag{3}$$

$$G_0 = \frac{CFO_s}{500 \cdot D} \tag{4}$$

$$CFO_s = k_w \cdot k_g \cdot \frac{3400}{1+\frac{8}{D}} \tag{5}$$

where CFO_S is the CFO for standard atmospheric conditions (kV). Using (1)-(5), the required CFO_A can be computed using an iterative process.

Once the CFO_A is known, deterministic methods can be used to determine the required clearance distance. If we let the maximum switching overvoltage be equal to the withstand voltage of the air gap (CFO_A - 3σ) then the CFO_A can be written as (6).

$$CFO_A = \frac{V_m}{1-3\left(\frac{\sigma}{CFO_A}\right)} \tag{6}$$

Where:

V_m is equal to the maximum switching overvoltage, i.e. the value that has a 0.135% chance of being exceeded

σ is the standard deviation of the air gap insulation

CFO_A is the critical flashover voltage of the air gap insulation under non-standard atmospheric conditions

The ratio of σ to the CFO_A given in (6) can be assumed to be 0.05 (5%) [1]. Thus, (6) can be written as (7).

$$CFO_A = \frac{V_m}{0.85} \tag{7}$$

Substituting (7) into (1) we arrive at (8).

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} \tag{8}$$

Equation 8 relates the maximum transient overvoltage, V_m, to the air gap distance, D. Using (8) to compute the required clearance distance for the specified air gap geometry (conductor to large structure) results in a probability of flashover in the range of 10^{-6}.

Transient Overvoltage

In general, the worst case transient overvoltages occurring on a transmission line are caused by energizing or re-energizing the line with the latter being the extreme case if trapped charge is present. The intent of FAC-003 is to keep a transmission line that is *in service* from becoming de-energized (i.e. tripped out) due to sparkover from the line conductor to nearby vegetation. Thus, the worst case scenarios that are typically analyzed for insulation coordination purposes (e.g. line energization and re-energization) can be ignored. For the purposes of FAC-003-2, the worst case transient overvoltage then becomes the maximum value that can occur with the line energized. Determining a realistic value of transient overvoltage for this situation is difficult because the maximum transient overvoltage factors listed in the literature are based on a

switching operation of the line in question. In other words, these maximum overvoltage values (e.g. the values listed in [2], [3] and [5]) are based on the assumption that the subject line is being energized, re-energized or de-energized. These operations, by their very nature, will create the largest transient overvoltages. Typical values of transient overvoltages of in-service lines, as such, are not readily available in the literature because the resulting level of overvoltage is negligible compared with the maximum (e.g. re-energizing a transmission line with trapped charge). A conservative value for the maximum transient overvoltage that can occur anywhere along the length of an in-service ac line is approximately 2.0 p.u.[2]. This value is a conservative estimate of the transient overvoltage that is created at the point of application (e.g. a substation) by switching a capacitor bank without a pre-insertion device (e.g. closing resistors). At voltage levels where capacitor banks are not very common (e.g. 362 kV), the maximum transient overvoltage of an “in-service” ac line are created by fault initiation on adjacent ac lines and shunt reactor bank switching. These transient voltages are usually 1.5 p.u. or less [2]. It is well known that these theoretical transient overvoltages will not be experienced at locations remote from the bus at which they were created; however, in order to be conservative, it will be assumed that all nearby ac lines are subjected to this same level of overvoltage. Thus, a maximum transient overvoltage factor of 2.0 p.u. for 242 kV and below and 1.4 p.u. for ac transmission lines 362 kV and above is used to compute the required clearance distances for vegetation management purposes.

The overvoltage characteristics of dc transmission lines vary somewhat from their ac counterparts. The referenced empirically derived transient overvoltage factor used to calculate the minimum clearance distances from dc transmission lines to vegetation for the purpose of FAC-003-2 will be 1.8 p.u.[3].

Example Calculation

An example calculation is presented below using the proposed method of computing the vegetation clearance distances. It is assumed that the line in question has a maximum operating voltage of 550 kV_{rms} line-to-line. Using a per unit transient overvoltage factor of 1.4, the result is a peak transient voltage of 629 kV_{crest}. It is further assumed that the line in question operates at a maximum altitude of 7000 feet (2.134 km) above sea level.

The required withstand voltage of the air gap must be equal to or greater than 629 kV_{crest}. Since the altitude is above sea level, (1) - (5) have to be iterated on to achieve the desired result. Equation (9) can be used as an initial guess for the clearance distance.

$$D_i = \frac{8}{\dfrac{3400 \cdot k_w \cdot k_g}{\left(\dfrac{V_m}{0.85}\right)} - 1} \tag{9}$$

For our case here, V_m is equal to 629 kV, k_w = 1.037 and k_g = 1.3. Thus,

$$D_i = \frac{8}{\dfrac{3400 \cdot k_w \cdot k_g}{\left(\dfrac{V_m}{0.85}\right)} - 1} = \frac{8}{\dfrac{3400 \cdot 1.037 \cdot 1.3}{\left(\dfrac{629}{0.85}\right)} - 1} = 1.535m \tag{10}$$

Using (2)-(5) and (8) the withstand voltage of the air gap is next computed. This value will then be compared to the maximum transient overvoltage.

$$CFO_S = k_w \cdot k_g \cdot \frac{3400}{1+\frac{8}{D}} = 1.037 \cdot 1.3 \cdot \frac{3400}{1+\frac{8}{1.535}} = 737.7kV \qquad (11)$$

$$\delta = e^{-\frac{A}{8.6}} = e^{-\frac{2.134}{8.6}} = 0.78 \qquad (12)$$

$$G_O = \frac{CFO_S}{500 \cdot D} = \frac{737.7}{(500)\cdot(1.535)} = 0.961 \qquad (13)$$

$$m = 1.25 \cdot G_O (G_O - 0.2) = 1.25 \cdot 0.961(0.961 - 0.2) = 0.915 \qquad (14)$$

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} = (0.85)(1.037)(1.3)(0.78)^{0.915}\left(\frac{3400}{1+\frac{8}{1.535}}\right) = 499.8kV \qquad (15)$$

The calculated V_m is less than 629 kV; thus, the clearance distance must be increased. A few iterations using (2)-(5) and (8) are required until the computed $V_m \geq 629$ kV. For this case it was found that D = 1.978 m (6.49 feet) yielded V_m = 629.3 kV. Using this clearance distance the following values were computed for the final iteration.

$$CFO_S = k_w \cdot k_g \cdot \frac{3400}{1+\frac{8}{D}} = 1.037 \cdot 1.3 \cdot \frac{3400}{1+\frac{8}{1.978}} = 908.5kV \qquad (16)$$

$$\delta = e^{-\frac{A}{8.6}} = e^{-\frac{2.134}{8.6}} = 0.78 \qquad (17)$$

$$G_O = \frac{CFO_S}{500 \cdot D} = \frac{908.5}{(500)\cdot(1.978)} = 0.919 \qquad (18)$$

$$m = 1.25 \cdot G_O (G_O - 0.2) = 1.25 \cdot 0.919(0.919 - 0.2) = 0.825 \qquad (19)$$

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} = (0.85)(1.037)(1.3)(0.78)^{0.825}\left(\frac{3400}{1+\frac{8}{1.978}}\right) = 629.3kV \qquad (20)$$

Therefore, the minimum vegetation clearance distance for a maximum line to line ac operating voltage of 550 kV at 7000 feet above sea level is 1.978 m (6.49 feet). Table 1 provides calculated distances for various altitudes and maximum system operating ac voltages.

Project 2007-07: Transmission Vegetation Management

The Transmission Vegetation Management Standard Drafting Team is seeking comments on the following documents **until 8 p.m. Eastern on March 31, 2010**:

- FAC-003-2 — Transmission Vegetation Management Program
- Mapping document (comparing this draft to previous)
- Implementation plan

Special Notes for this Project

On January 14, 2010, the NERC Standards Committee endorsed the selection of FAC-003 as the proof-of-concept for using “results-based” criteria for developing a reliability standard, and the drafting team has been working with a consultant to apply a results-based approach to draft standard FAC-003-2. The overall approach includes considerably more emphasis on the “concepts and assumptions” underlying the development of requirements and goes beyond the steps most drafting teams use when developing a standard. Accordingly, the “look and feel” of the vegetation management standard is quite different than NERC’s existing standards. However, at the core is a set of mandatory and enforceable requirements with useful guidance supporting these requirements, an approach NERC’s legal counsel has reviewed and finds acceptable.

In addition to the format changes, the Standards Committee authorized the drafting team to discontinue work in developing a complete consideration of comments report for the comments received in response to the posting of the second draft of FAC-003-2 (August 2009). Instead of posting an individual response to each comment, the team has posted the comments along with a summary of the actions taken by the team in response to those comments. The Standards Committee also authorized this approach going forward for this project, so this and future postings will be considered informal comment periods. Please see the “Next Steps” section below and the comment form for more information.

Instructions

Please use this electronic form to submit comments. If you experience any difficulties in using the electronic form, please contact Lauren Koller at Lauren.Koller@nerc.net. An off-line, unofficial copy of the comment form is posted on the project page:
http://www.nerc.com/filez/standards/Vegetation-Management_Project_2007-7.html

Next Steps

Since this is an informal comment period, the drafting team will post 1) the comments received, 2) a summary of how the team used the comments, and 3) a redline version of the standard showing the changes made based on the comments. More information about the scheduling for this project is available in the comment form for this posting.

Project Background

The project is an update to FAC-003-1, which was approved in 2006. The items identified for revision include the incorporation of FERC Order 693 comments related to applicability, procedural repairs to conform to the current standards format and development procedure, technical updates and guidance to address stakeholder suggestions, and the elimination of “fill-in-the-blank” components. More information is available on the project page:
http://www.nerc.com/filez/standards/Vegetation-Management_Project_2007-7.html

As mentioned, the NERC Standards Committee endorsed the use of Project 2007-07 Vegetation Management as the prototype for the proof-of-concept for using the “results-based” criteria for developing a reliability standard. More information about results-based standards can be found at:
http://www.nerc.com/filez/standards/Project2010-06_Results-based_Reliability_Standards.html

Applicability of Standards in Project

Transmission Owner
Specific facilities (see proposed standard for more information)

Standards Development Process

The Reliability Standards Development Procedure contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

For more information or assistance,
please contact Shaun Streeter at shaun.streeter@nerc.net or at 609.452.8060.

Consideration of Comments on 3rd Draft of FAC-003-2 Transmission Vegetation Management — Part of Project 2007-07 Vegetation Management

The Vegetation Management Standard Drafting Team thanks all commenters who submitted comments on the 3rd Draft of FAC-003-2 Transmission Vegetation Management. These standards were posted for a 30-day public comment period from March 1, 2010 through March 31, 2010. The stakeholders were asked to provide feedback on the standards through a special Electronic Comment Form. There were 55 sets of comments, including comments from more than 100 different people from over 60 companies representing 8 of the 10 Industry Segments as shown in the table on the following pages.

http://www.nerc.com/filez/standards/Vegetation-Management_Project_2007-7.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Gerry Adamski, at 609-452-8060 or at gerry.adamski@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

Index to Questions, Comments, and Responses

The Industry Segments are:

1 — Transmission Owners
2 — RTOs, ISOs
3 — Load-serving Entities
4 — Transmission-dependent Utilities
5 — Electric Generators
6 — Electricity Brokers, Aggregators, and Marketers
7 — Large Electricity End Users
8 — Small Electricity End Users
9 — Federal, State, Provincial Regulatory or other Government Entities
10 — Regional Reliability Organizations, Regional Entities

1. In response to comments received regarding potential for "double jeopardy" and to provide differentiation between transmission lines designated as having IROLs and Major WECC transfer paths from those that are not, the SDT consolidated requirements R4 though R8 found in the August 2009 draft of FAC-003-2 into two requirements in the latest draft of FAC-003-2 (new requirements R1 and R2). Do you agree? Please explain.

Summary Consideration:

Organization	Yes or No	Question 1 Comment
ERCOT ISO		
Exelon		
North Carolina EMC		
Westchester County Board of Legislators		Do not have enough knowledge on this to provide response.
Response:		
Nebraska Public Power District	No	Although it does provide some flexibility to the TO, it will be difficult to determine an encroachment into the MVCD. It would easier to implement if R1 and R2 were only applicable when there was an outage on the transmission system.
Response:		
Dominion	No	Dominion does not agree with the inclusion of facilities that WECC designates as 'major transfer paths' in a continent-wide standard. We suggest that, if the SDT wishes to include such reference and these facilities are meant to be treated or synonymous with either IROL or SOL, that the SDT add a proposal to adopt and define a suitable term for inclusion into the Glossary of Terms
Response:		
Cleco	No	Encroachment into the MCVD should require the owner to take immediate corrective action to mitigate the threat. Such an encroachment should not be reportable as a violation. Owners may be hesitant to

Organization	Yes or No	Question 1 Comment
		communicate possible vegetation threat conditions to the TOP or proper authority if they believe it will be reported as a violation. We recommend the SDT consider modifying the measure for R1 and R2 to be applicable only in the interruption of the transmission facility.
Response:		
NERC Staff (12 staff members)	No	NERC Staff does not see a need to have two requirements (R1 and R2) which differentiation between transmission lines designated as having IROLs and Major WECC transfer paths from those that are not with two different Violation Risk Factors. The standard as drafted applies to all 200kv and above lines. The Violation Risk Factor for all 200 kV and above lines should be "High". R2 should be deleted and R1 should be rewritten to be:R1. The Transmission Owner shall prevent vegetation from encroaching within the Minimum Vegetation Clearance Distance (MVCD) of applicable Transmission line conductors to avoid a Sustained Outage.
Response:		
Xcel Energy	No	Requirements 1 & 2 are identical except for their applicability (R1 for IROL elements and elements in the WECC Transfer Paths; R2 for all other lines =>200 KV). It is not readily apparent as to why there is a need to distinguish between the two. Referencing the Table 2 "VRF" and "VSL" matrix indicates that R1 has a "High" VRF and R2 has a "Medium" VRF. If this is the only reason, then consider adding, at a minimum, a "Rationale" box explaining that reasoning.Also, the definition of MVCD needs to be a defined term or included in R 1 & 2, e.g., "Minimum Vegetation Clearance Distance is the calculated minimum distanced stated in feet (meters) to prevent spark-over between conductors and vegetation for various altitudes and operating voltages as set forth in Table 2." See comments to # 7 and # 13.
Response:		
Arizona Public Service Company	No	This is a reliability standard for 230 kV and above and those lower voltages designated by the RRO. An outage is an outage and the utility should be held accountable no matter if they are or are not designated.
Response:		
SERC OC Standards Review Group	No	While we agree with the development of a second requirement to provide for the distinction between line segments that are critical for reliability, in R1, a regional distinction should not be embedded in a national standard. We also strongly disagree that perfect compliance with R2, as stated, would improve reliability. If a line is operated to avoid projected post contingent overloads, then the tripping thereof due to any cause has

Organization	Yes or No	Question 1 Comment
		no effect on BES reliability. A more prudent approach for the lines covered by R2 could be the requirement to achieve 3 sigma or 4 sigma performance over a year's time. Requirement 2, as stated, is not cost effective, and may produce an unjust and unreasonable outcome to rate payers.While this draft clarifies (from version FAC-003-1) that sustained outages are compliance violations and eliminates the "double jeopardy" which was errantly introduced in the last draft of FAC-003-2 (when sustained outages were clearly defined as compliance violations), we suggest that the team adjust R2 as previously mentioned. This draft provides a mechanism to address the difference in outages that have impact to grid reliability from those that have an impact only to local lines and associated customer reliability. The use of observed MVCD as a violation and in the violation severity level matrix: o drives the right behaviors for improving reliability (by proactively identifying and removing vegetation before it can become an imminent threat or cause an outage) o eliminates the need to perform detail engineering/surveying/theoretical calculations before cutting vegetation, o formalizes the informal interpretations that have resulted from FAC-003-1 enforcement and o allows the vegetation field operations to focus on facts and remain practical rather than theoretical.
Response:		
American Transmission Company	Yes	
Bonneville Power Administration	Yes	
Central Maine Power, Iberdrola USA	Yes	
City of Tallahassee (TAL)	Yes	
Consumers Energy	Yes	
Duke Energy	Yes	
Florida Municipal Power Agency (FMPA) and Some Members	Yes	
FRCC Manager of Operations	Yes	

Organization	Yes or No	Question 1 Comment
Ga Transmission Corp	Yes	
GCPD	Yes	
ITC Holding	Yes	
Manitoba Hydro	Yes	
Omaha Public Power District	Yes	
Pepco Holdings, Inc. - Affiliates	Yes	
PPL Electric Utilities Corporation (NCR00884)	Yes	
South Carolina Electric and Gas	Yes	
Southen Company	Yes	
TO/TOP	Yes	
Tucson Electric Power Co.	Yes	
Utility Risk Management Corporation	Yes	
MRO's NERC Standards Review Subcommittee	Yes	1. NSRS agrees with the revisions that the drafting team has made and agrees with the combining of four requirements into two. NSRS prefers the MVCD methodology to the minimum clearance distance methodology due to the fact that there is only one measurement to contend with versus two.2. If a company has a line with a standing IROL could they be found in violation of both the requirements R1 and R2? If so, the NSRS recommends combining R1 and R2.3. Please clarify the need for R1 and R2. Why were lines with IROL separated out from lines without IROLs?
Response:		

Organization	Yes or No	Question 1 Comment
American Electric Power (AEP)	Yes	American Electric Power agrees with this change.
Response:		
IRC Standards Review Committee	Yes	Because real-time observation in Measurement 1 would require an actual measurement for comparison to Table 2 to be defendable as a violation, the SRC suggests replacing observation with measurement. The SRC would suggest deleting the phrase "to avoid a sustained outage" as that phrase does not add any clarity to either of the two requirements. There do not seem to be any encroachments that the SDT will allow. If there are encroachments that are considered allowable, who is responsible for making that consideration? And what would be considered a "sustained" outage?Minimum Vegetation Clearance Distance (MVCD) is a capitalized term used in Requirements 1, 2 and 7 but is not defined in the NERC Glossary of Terms Used in Reliability Standards nor is a definition proposed in this standards action. Either a definition should be proposed or the capitalization should be removed.
Response:		
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG, CNE & CENG)	Yes	BGE agrees with the consolidation of R4 through R8 into two requirements in the FAC-003-2 draft.
Response:		
Ameren	Yes	Creating two specific requirements removes the potential for double jeopardy.
Response:		
Southern California Edison Company	Yes	SCE agrees that the consolidation of Requirements R4-R* resolves the "double jeopardy" issue.
Response:		
Tampa Electric Company	Yes	The change in the draft serves to consolidate, clarify and remove the “double jeopardy” as stated above. This is an improvement in the standard.
Response:		

Organization	Yes or No	Question 1 Comment
CenterPoint Energy	Yes	The differentiation in the Violation Risk Factor for R1 versus R2 seems appropriate.
Response:		
Consolidated Edison Company of New York, Inc.	Yes	The elements that comprise IROLs must be clearly communicated to each Transmission Owner and must be consistent across North America.
Orange and Rockland Utilities, Inc.	Yes	The elements that comprise IROLs must be clearly communicated to each Transmission Owner and must be consistent across North America.
Response:		
Northeast Power Coordinating Council	Yes	The most recent draft of the standard consolidated R4-R8 results in clearer requirements that meet the results based criteria and addresses the “double jeopardy” issue. However, there is concern with the differentiation of lines designated as having IROLs and Major WECC transfer paths from those that are not, as is proposed in the Applicability section 4.2 and subsequently in requirements R1 and R2. As stated in the background section: “This Standard focuses on transmission lines to prevent those vegetation related outages that could lead to Cascading. It is not intended to prevent customer outages due to tree contact with lower voltage distribution system lines. For example, localized customer service might be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. However, this Standard is not written to address such isolated situations which have little impact on the overall Bulk Electric System.” It must be recognized that in some systems, outages on lines operated at voltages greater than 69 kV, 200 kV for example, have localized impact only and do not lead to Cascading. Concurring with the background, a line should be subject to this standard only if a vegetation related outage “could lead to Cascading”, or could have a “significant impact” on the system. It does not depend on whether it is an IROL line or not.A performance based methodology is used in NPCC to determine if an outage on a line can cause a “significant impact” on the system. The lines identified by this methodology are not identified according to their voltages, but rather by their impact on the system, regardless of the voltage.The introduction of “two” subcategories of BES - an IROL and a non-IROL - appears to just differentiate between high VRF and medium VRF. Furthermore, in the Applicability section, the IROL “variable” is mentioned only for lines operated below 200 kV. What about lines operated at or above 200 kV lines? Why not have a single Application item stating: overhead transmission lines operated at any voltage whose outages have a significant impact on the system? A Table could define what is considered “significant”.There are standards for vegetation management on the distribution system, and there are standards for higher voltage systems. This standard should focus on lines with high impact on the system when a vegetation outage occurs.Utilities will not let the vegetation encroach on other lines, but an importance will be given to vegetation management

Organization	Yes or No	Question 1 Comment
		on "critical" lines for the reliability of the whole system. On other lines, if an outage occurs, it will have localized impact.A "Results-Based Reliability Standard" should first focus on the "critical" lines.If it is the intent of NERC or the industry to ensure that a vegetation outage causes no more than a fixed level of load loss, it should say so in a requirement.If the IROL "variable" is retained, identification of the transmission elements that comprise IROLs must be officially communicated to the Transmission Owners. This must be done either through a requirement in this, or another standard.
Response:		
Progress Energy Carolinas	Yes	The previous version (FAC-003-1) was not developed with individual outages listed as a requirement or a violation. The previous drafts of version 2 (FAC-003-2) have improved on FAC-003-1 by defining sustained outages from within the Right-of-Way as violations. However, the recent drafts of FAC-003-2 also introduced a potential for 'double jeopardy' when clarifying that sustained outages and MVCD encroachments were ('binary') requirements/violations. This latest draft clarifies the expected performance into two concise requirements that provide for differentiation in severity levels and risk factors, eliminating the unintended 'double jeopardy'. The inclusion of the use of observed MVCD as a violation of R1/R2 and in the violation severity level matrix drives the right behaviors for improving reliability (by proactively identifying and removing vegetation before it can become an imminent threat or cause an outage) , eliminates the need to perform detail engineering/surveying/theoretical calculations before cutting vegetation, formalizes the informal interpretations that have resulted from FAC-003-1 and allows the vegetation field operations to focus on facts (and remain practical rather than theoretical). Progress Energy believes that the R1 and R2 changes to this draft are a significant improvement over FAC-003-1. This version draft: clarifies real-time MVCD and sustained outages as a requirement; provides for differentiation between grid impacting outage events and outage events to lines primarily associated with customer reliability; introduces a performance barrier/defense that is fact based - eliminating the need to determine compliance through theoretical calculations that rely on design assumptions (e.g., mechanical behavior of aged conductor), prior design criteria/code versions (i.e., code clearances in effect at time of design) and detail site measurements (e.g., "survey" quality measurements and local environmental conditions at time of measurement/event).
Response:		
JEA	Yes	The simplification and clarification improves the ability of Registered Entities to comply thereby enhancing reliability.
Response:		

Organization	Yes or No	Question 1 Comment
Independent Electricity System Operator	Yes	This change addresses the perceived “double jeopardy” risk.
Response:		
Oncor Electric Delivery	Yes	This does not reduce the Standards effectiveness on the cascading issue or discount any outage on applicable lines subject to this Standard in the electric Transmission system.
Response:		
East Kentucky Power Cooperative, Inc.	Yes	This draft adequately addresses the "double jepoardy" issue. The use of the Minimum Vegetation Clearance Distances simplifies recommended maintenance process for field personnel and eliminates the need to perform costly and time consuming engineering studies prior to trimming or removing vegetation.
Response:		
SERC Vegetation Management Sub-committee	Yes	This draft clarifies (from version FAC-003-1) that sustained outages are compliance violations and eliminates the “double jeopardy” which was errantly introduced in the last draft of FAC-003-2 (when sustained outages were clearly defined as compliance violations). This draft provides a mechanism to address the difference in outages that have impact to grid reliability from those that have an impact only to local lines and associated customer reliability. The use of observed MVCD as a violation and in the violation severity level matrix: o drives the right behaviors for improving reliability (by proactively identifying and removing vegetation before it can become an imminent threat or cause an outage) o eliminates the need to perform detail engineering/surveying/theoretical calculations before cutting vegetation, o formalizes the informal interpretations that have resulted from FAC-003-1 enforcement and o allows the vegetation field operations to focus on facts and remain practical rather than theoretical.
Response:		
Western Area Power Administrtaion	Yes	This is a very efficient and logical consolidation of requirements.
Response:		
Western Area Power	Yes	This is not a critical issue for the WAPA - UGPR.

Organization	Yes or No	Question 1 Comment
Administration - Upper Great Plains Region		
Response:		
Tennessee Valley Authority	Yes	This method effectively recognizes the difference in reliabilty risks among various lines based on their value to the transmission grid.
Response:		
Entergy Services	Yes	We agree that R1 and R2 are beneficial, but believe that they should be explained in greater detail for much greater clarity to reflect their intent. Our understanding is that R1 applies to ALL IROL's and ALL Major WECC Transfer Path lines, regardless of voltage, and R2 is centered around ALL lines operated at voltages 200 kV and above but are not classified as IROL/WECC lines. Our understanding of the term "applicable line conductor" in R2 refers back to the facilities defined in Facilities - Section 4.2 and as modified by the phrase in R2: "which are not elements of an IROL and are not a Major WECC transfer path, (operating within Rating and Rated Electrical Operating Conditions)". However the appropriateness of our assumed reference back to Section 4.2 and the modification contained in R2 is not clear. It also is not clear that the term "applicable line conductor" in R2 is the same as "applicable line conductor" in R6. We suggest the term "applicable line conductor" be specifically defined as that term is intended to be applied in R2, and the term "applicable line conductor" be defined as that term is intended to be applied in R6.
Response:		
FirstEnergy	Yes	We agree that the new R1 and R2 alleviate the potential double jeopardy issue as well as differentiate the high and medium risk factor transmission lines. However, we offer the following comments and suggestions for improvement:It is not clear how the Transmission Owner (TO) will determine which lines are associated with IROLs. Upon reviewing standard FAC-014 Req. R5, which requires the communication of SOLs and IROLs, the required communication of IROLs to the TO is not specified. There needs to be a tie between this standard and the FAC-014 standard, which will require a revision to FAC-014. Unfortunately, this issue will create a gap if FAC-014 is not revised and submitted to FERC in parallel with the submittal of FAC-003-2 to FERC. This may require immediate action such as an urgent action SAR or other appropriate actions.If our suggestion to revise FAC-014 is not possible at the present time, then we suggest an alternative course of action to include language in R1 of FAC-003 to aid the TO in obtaining the information regarding lines associated with IROLs. We propose adding the following sentence to R1: "The Transmission Owner can request information regarding transmission lines associated with an IROL from its Planning Coordinator."

Organization	Yes or No	Question 1 Comment
Response:		
Ad Hoc Group subteam formed to review draft standard	Yes	We understand the differentiation to be around the intent that those transmission lines designated as having IROLs and Major WECC transfer paths pose a more significant threat to the reliability of the BES and that encroachment of the MVCD in these cases are relatively more significant. We suggest that this be clarified in the rationale.
Response:		
KCPL	No	The measures for R1 and R2 are zero tolerance for encroachments into the MVCD that did not result in a "contact" with the transmission facility. Considering the substantial number of miles of transmission involved, the complexities in anticipation of vegetation growth with numerous growth variables, vegetation management limitations imposed by other regulations or requirements, and unexpected transmission events that require substantial efforts regarding physical restoration, it is not reasonable or practical for the measures here to include encroachments that do not result in an interruption of transmission service. Recommend the SDT consider modifying the measures for R1 and R2 to be applicable only in the interruption of a transmission facility.
Response:		

2. The results-based reliability standard criteria focus on striving to achieve a portfolio of performance-based, risk-based, and competency-based mandatory reliability requirements that provide an effective defense-in-depth strategy for achieving an adequate level of reliability of the bulk power system in lieu of prescriptive requirements. Consequently, the SDT revised R1 and its subparts found in the August 2009 draft of FAC-003-2 in favor of the text in the latest draft of FAC-003-2 (new requirement R3). Do you agree? Please explain.

Summary Consideration:

Organization	Yes or No	Question 2 Comment
American Transmission Company		
East Kentucky Power Cooperative, Inc.		
ERCOT ISO		
Westchester County Board of Legislators		
Tampa Electric Company	No	A more in-depth technical review of this requirement is required. Our response is predicated upon the following quote from the draft standard; "...considering all possible locations the conductor may occupy assuming operation within Rating and Rated Electrical Operating Conditions."
Response:		
NERC Staff (12 staff members)	No	As written, R3 does not provide enough clarity as to what should be included in a documented transmission vegetation management program. R3 should be expanded to include what should be included in the transmission plan. Such as:R3. Each Transmission Owner shall have a documented transmission vegetation management program that describes how it conducts work on its Active Transmission Line Rights of Way to avoid Sustained Outages due to vegetation, considering all possible locations the conductor may occupy assuming operation within Rating and Rated Electrical Operating Conditions. The transmission vegetation management program shall:3.1 Specify the methodologies that the Transmission Owner uses to control vegetation.[1] 3.2 Specify a Vegetation Inspection frequency of at least once per calendar year that takes into account local[2] and environmental factors. 3.3 Require an annual work plan that identifies the

Organization	Yes or No	Question 2 Comment
		applicable lines to be maintained and associated work to be performed during the year. It shall be flexible to adjust to changing conditions and to findings from Vegetation Inspections. Adjustments to the plan within the year are permissible. The plan shall take into consideration permitting and scheduling requirements from landowners or regulatory authorities. It shall support the objectives of the transmission vegetation management program and utilize the methodologies outlined in the transmission vegetation management program. 3.4 Require a process or procedure for response to imminent threats[3] of a vegetation-related Sustained Outage. The process or procedure shall specify actions which shall include immediate communication of the threat to the Transmission Operator or proper operating authority. The process or procedure shall specify what conditions warrant a response.3.5 Specify an interim corrective action process for use when the Transmission Owner is constrained from performing vegetation maintenance as planned. 3.6 Specify the maintenance approach used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that Table 1 clearances in Attachment 1 are never violated. The maintenance approach shall consider the sag and sway of the conductor throughout its operating range under rated conditions.[1] ANSI A300, Tree Care Operations - Tree, Shrub, and Other Woody Plant Maintenance - Standard Practices, while not a requirement of this standard, is considered to be an industry best practice.[2] Local factors include treatment cycle, extent and type of treatment, and their relationship to the normal growth rate.[3] The term “imminent threat” refers to a vegetation condition which is placing the transmission line at a significant risk of a Sustained Outage. Refer to Technical Reference for examples of imminent threat procedures and conditions for implementation.
Response:		
Consumers Energy	No	Consumers Energy strongly disagrees with the MVCD as presented in this version of the standard. These distances do not provide an adequate safeguard to prevent outages since the conductor position relative to the vegetation is sensitive to electric load and wind at any particular moment while vegetation height is not. Measurements M1 and M2 require real-time observation of a violation of MVCD to be reportable. As presented, vegetation growing beneath the conductor with a clearance of MVCD + 1 foot is not reportable. However, this same conductor may sag due to load increase or move due to wind displacement within hours of the real-time observation. If great enough, the sag or displacement may move the conductor in contact with the vegetation resulting in an outage just hours after being deemed compliant.At a minimum the MVCD should be designed to provide the Gallet clearance distance at maximum sag or wind displacement (whichever is greater) at all times. No matter when the line is cleared of vegetation or inspected for vegetative conditions, if the enhanced MVCD is being met an outage cannot occur until further vegetative growth occurs. Furthermore, for line clearing operations, tree crews do not and cannot determine in the field the maximum potential sag or wind displacement to know how much vegetation to clear. They require much clearer instructions with a set amount of clearing distance to obtain at the time of work. This distance must

Organization	Yes or No	Question 2 Comment
		account for maximum sag, wind displacement and the Gallet distance at a minimum.
Response:		
Cleco	No	Encroachment into the MCVD should require the owner to take immediate corrective action to mitigate the threat. Such an encroachment should not be reportable as a violation. Owners may be hesitant to communicate possible vegetation threat conditions to the TOP or proper authority if they believe it will be reported as a violation. We recommend the SDT consider modifying the measure for R1 and R2 to be applicable only in the interruption of the transmission facility.
Response:		
GCPD	No	Grant believes that R1 and R2 should be the entire standard and the rest of the requirements should be in guidelines and supplementary materials to assist in meeting the two results based requirements. We understand that some risk-based and competency based requirements are necessary for some standards. Not this one. No grow-in caused outages is the objective. Requiring a specific plan does not show competency, it just shows you have a plan. Feels very much like the existing standards. "Show us your Documentation".
Response:		
Northeast Power Coordinating Council	No	R3 specifies "...considering all possible locations the conductor may occupy assuming operation within Rating and Rated Electrical Operating Conditions." Although both "Rating" and "Rated Electrical Operating Conditions" appear in the NERC Glossary, inspection of these definitions shows that they are very vague, and "Rated Electrical Operating Conditions" uses the word "reasonably", a term FERC has previously indicated as being unacceptable. From a practical standpoint this seems to allow too much latitude to an entity to do the least amount of trimming and not consider the extra sag and swing caused by some of the more extreme operating conditions that "may" occur, such as loading to an STE or DAL limit during a higher velocity wind than normal, coupled with a higher ambient temperature. An entity could potentially claim that vegetation was trimmed to normal load levels, normal facility loading sag, and minimum velocity wind speed swings, and be within the tolerance of the standard as we interpret it. The Drafting Team should clarify what the expectation is with regard to line loading, sag, and swing due to wind speed and the types of operating conditions it deems to be justified to create a more exact requirement.
Response:		

Organization	Yes or No	Question 2 Comment
Nebraska Public Power District	No	same concern as item 1.
Response:		
Central Maine Power, Iberdrola USA	No	The TVMP must include clearances bewteen trees and conductors at time of vegetation management work.Suggest that the TVMP require the use of qualified personnel to manage this program.
Response:		
Arizona Public Service Company	No	This standard lacks accountability and transparency. This is a reliability standard and the industry is to prevent outages within the active ROW. It doesn't matter if the vegetation grows-in, blows-in or falls into the conductor these are all outages. One is no less of an outage than the other one. They should be treated equally and the utility should be held accountable for lack of maintaining the transmission system.
Response:		
FirstEnergy	No	We agree that the previous R1 was too prescriptive and are in favor of the new Requirement R3. However, we do not agree with all the wording of R3 as well as the Rationale box for R3. 1. Requirement R3 - The phrase "considering all possible locations the conductor may occupy assuming operation within Rating and Rated Electrical Operating Conditions" is confusing. We like the wording from the previous (Draft 2) of FAC-003-2 and suggest the following rewording of this phrase: "considering all possible locations the conductor may occupy throughout its operating range under all rated conditions."2. Rationale box for Req. R3 - We suggest removing the first sentence in the Rationale box for R3. The need to provide a basis on the intent and competency of the TO in maintaining vegetation is not explicitly stated in the requirement. Also, we are not sure what is meant by "competency". If it is referring to minimum required competencies for personnel performing vegetation management, that is outside the scope of this standard.
Response:

MRO's NERC Standards Review Subcommittee	Yes	1. NSRS agrees with the revisions to R3. With regard to operations within Ratings and Rated Conditions, are operations after a contingency considered to be within Ratings and Rated Conditions?2. Could wording be added to R3 to specify rated conditions include National Electric Safety Code conditions or assumptions?
Response:		
Florida Municipal Power Agency (FMPA) and Some Members	Yes	Although FMPA agrees with the intent of the Measures, FMPA is concerned that the measures M1 and M2 may not meet the purpose of the measures as stated in the latest draft version of the Standard Processes Manual, which states that that a Measure "(p)rovides identification of the evidence or types of evidence needed to demonstrate compliance with the associated requirement." Instead, M1 and M2 provide examples of evidence that would be used to determine non-compliance, not used to determine compliance.
Response:		
American Electric Power (AEP)	Yes	American Electric Power agrees with this change.
Response:		
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG, CNE & CENG)	Yes	BGE agrees with the R3 text in the latest draft of FAC-003-2.
Response:		
Dominion	Yes	Dominion agrees and finds this approach superior to existing which sometimes appears to be more administratively focused.
Response:		
JEA	Yes	Given the basic performance required in R1 and R2 of this version, I agree that specifics about what is

Organization	Yes or No	Question 2 Comment
		included in the plan are not needed. Each entity should be encouraged to write their plan so that the occasional human errors and failures that are inevitable still lead to compliance with the performance aspects of this standard. The team should be sure that the measures do not require unfailing perfect execution of this procedure so that entities are encouraged to minimize this document.
Response:		
ITC Holding	Yes	ITC feels that this draft is an improvement by clarifying the action expected by this requirement (“competency-based” program specific methodology documentation) and separating other implementing (“risk based”) actions from FAC-003-1 as new requirements within this draft version. ITC also agrees with results-based reliability, a standard principle that is driven by relevant reliability requirements and measureable results rather than prescriptive requirements driven by documentation.The term “bulk power system” should not be used in the comment form or any other documentation associated with FAC-003-2.
Response:		
Independent Electricity System Operator	Yes	Old Requirement R1 has been distilled down to its essential elements with the removal of the detailed sub-requirements that were previously included. This places the onus of developing an effective transmission vegetation management program (TVMP) on the asset owners where it ought to be, since they have the requisite expertise. Guidance is however provided in the Technical Reference document to assist Transmission Owners in developing a TVMP that in their view works for them, and achieves the overall objective of preventing those vegetation related outages that could lead to Cascading. By specifying the “what” appropriately and leaving the “how” to the entity, the entity is now in the best position to determine the most effective deployment of its resources for meeting the goals of the standard.
Response:		
CenterPoint Energy	Yes	R3 focuses on its intended impact on Sustained Outages without being overly prescriptive.
Response:		
Southern California Edison Company	Yes	SCE prefers the results-based approach to crafting reliability standards because it provides utilities with the necessary flexibility to develop internal criteria based on widely accepted best practices and industry innovations.
Response:		

Organization	Yes or No	Question 2 Comment
Western Area Power Administrtaion	Yes	The old Draft 2 version of R1 was developed to give the regulatory entities substantial and tangible information from which to judge the adequacy of a TO's overall approach to program management. The old Draft 2 version of R1 was purposely crafted in this detailed manner as an alternative to attempting to manage the problematic CCZ concepts contained in Draft 1. Industry strongly rejected the CCZ management concepts contained in Draft 1 in the first comment period. It appears that the current Draft 3 version of R3 has lost some of the content needed to fully substitute for the management of Draft 1 CCZ concepts. The addition of an implementation requirement intended to measure the full execution and success of the overall management approach identified by a TO in response to the new R3 may help to address this shortcoming. As currently worded, the requirement to simply execute a flexible annual work under the new R7 in Draft 3 does appear extensive enough to fulfill this need.
Response:		
Oncor Electric Delivery	Yes	The RBS defense-in-depth strategy for this Standard does provide an adequate level of reliability. The Standards purpose statement refers to the electric Transmission system and corresponding applicable lines not the BPS or BES as currently defined in the NERC glossary or being proposed (NOPR) RM09-18-000. Removing prescriptive requirements allows utilities flexibility to document their program and perform their vegetation management to achieve the goal of no outages that lead to cascading.
Response:		
IRC Standards Review Committee	Yes	The SRC agrees with the intent of R3, but questions the need for inspection postponements to be limited to natural "disasters". A well-planned inspection may be delayed by a common lighting storm. While there is a need to conduct the inspections and those inspections could be done anytime within the TO's own plans - the SDT may want to modify the exception to be natural disasters or other conditions that are reported within 5 business days and agreed to as an excused condition by the Regional Reliability Organization.
Response:		
Southen Company	Yes	The term “bulk power system” should not be used in the comment form or any other documentation associated with FAC-003-2.
Response:		
Progress Energy Carolinas	Yes	This separates implementing actions such as inspections, annual plans and imminent threat procedures from TVMP methodology (which proves competency of the program).This draft is an improvement by clarifying the

Organization	Yes or No	Question 2 Comment
		action expected by this requirement ("competency-based" program specific methodology documentation) and separating other implementing ("risk based") actions from FAC-003-1 as new requirements within this draft version.
Response:		
SERC OC Standards Review Group	Yes	This separates implementing actions such as vegetation inspections, performing annual work plans and responding to imminent threats from the required documentation of the TVMP methodology (which proves competency of the program).This draft is an improvement by clarifying the action expected by this requirement (program specific methodology documentation requirement) and separating other implementing actions from FAC-003-1 as new requirements in this draft version.
SERC Vegetation Management Sub-committee	Yes	This separates implementing actions such as vegetation inspections, performing annual work plans and responding to imminent threats from the required documentation of the TVMP methodology (which proves competency of the program).This draft is an improvement by clarifying the action expected by this requirement (program specific methodology documentation requirement) and separating other implementing actions from FAC-003-1 as new requirements in this draft version.
Response:		
Western Area Power Administration - Upper Great Plains Region	Yes	WAPA - UGPR agrees with a reliability based standard. In the plains states, we have fewer trees than many utilities, so having prescriptive requirements that assume we have lines running through forested areas seems to mandate an excessive amount of detail. We prefer to keep our program very simple -- perform periodic inspections to identify vegetation problems and then direct applicable resources in to take care of the problem. Our hope is that a results-based reliability standard will provide some flexibility for those utilities with smaller scale vegetation encroachments.
Response:		
Ad Hoc Group subteam formed to review draft standard	Yes	While the new R3 is less prescriptive than the old R1, it appears to stray from criteria #4 for developing results-based standards, as described in this comment form. It appears to require only the development of a document. We understand that in some cases this cannot be avoided. We believe that this is one of those cases where the reliability objective of building competency in considering all possible locations the conductor may occupy and assuming operation within Rating and Rated Electrical Operating Conditions over-rides our reluctance in requiring a registered entity to produce a document rather than a result. We suggest that in a future revision to standard that this can be combined with R7 to create a comprehensive requirement that the

Organization	Yes or No	Question 2 Comment
		entity have a vegetation management program that demonstrates it is able to perform those actions necessary to keep vegetation out of the MVCD.
Response:		
KCPL	No	The measures for R1 and R2 are zero tolerance for encroachments into the MVCD that did not result in a “contact” with the transmission facility. Considering the substantial number of miles of transmission involved, the complexities in anticipation of vegetation growth with numerous growth variables, vegetation management limitations imposed by other regulations or requirements, and unexpected transmission events that require substantial efforts regarding physical restoration, it is not reasonable or practical for the measures here to include encroachments that do not result in an interruption of transmission service. Recommend the SDT consider modifying the measures for R1 and R2 to be applicable only in the interruption of a transmission facility.
Response:		

3. Do you agree with the overall layout of the proposed template? If not, please suggest an alternative layout.

Summary Consideration:

Organization	Yes or No	Question 3 Comment
TO/TOP		
Westchester County Board of Legislators		
American Transmission Company	No	a.) ATC believes that the “Guideline and Technical Basis” section does not belong within the NERC Standard. ATC feels there are parts of this section that appear to obligate the TO with additional mandatory requirements. (please refer to additional details in Question #8 below) b.) ATC believes the “Measures” section immediately following the Requirement is helpful and placement is appropriate, however, the introductory statement in R1 and R2 is poorly worded. For example, M1 currently states: “ Evidence of violation of Requirement R1 is limited to:” ATC feels this is a negative approach and recommends that it be stated in a positive manner such as”” Evidence of compliance to R1 would be to: o Not have any vegetation-related Sustained Outages due to a grow-in.” c.) ATC would like to clarify whether the “Rational” boxes remain within the final standard. It seems appropriate to have this information but that it would be better to have this information appear in the “Guideline and Technical Basis” section.
Response:		
GCPD	No	Don't need all the extra requirements beyond R2.
Response:		
Florida Municipal Power Agency (FMPA) and Some Members	No	FMPA appreciates the improvements and has additional suggestions. Please see responses to the remainder of the questions, and below, for suggestions:The evidence retention should be grouped with the Measures for ease of creating a records retention schedule for the standards and requirements.Do we really need a “Compliance Monitoring and Enforcement Processes” section of the standards? Are there any standards that don’t have all of these activities?
Response:		

Organization	Yes or No	Question 3 Comment
City of Tallahassee (TAL)	No	I would delete the Rationale in favor of keeping the Guideline and Technical Basis. The Guideline appears to be more in-depth than the Rationale. This makes the Rationale unnecessary.
Response:		
Northeast Power Coordinating Council	No	NPCC participating members want to thank the drafting team for the hard work devoted to developing this standard, and recognize the difficult issues of producing the first “results based” proof of concept standard and offer the following, not as criticism, but as helpful suggestions for their consideration based on a cross section of stakeholder reactions to the draft. 1) Measures are compliance related elements and should not appear immediately after the requirements. The older template had the compliance elements grouped together in a separate section, and we suggest this continues. In the past there have been instances of RSAW (Reliability Standards Audit Worksheets) not clearly matching the standard’s requirements or measures. We suggest that this initiative with a results based requirement consistently involve the development of the associated RSAWs to ensure coordination, and also that the requirement results in a performance based, competency, or risk based reliability criterion. 2) Effective dates have become a complex issue. We suggest that rather than having an effective date table in the standard, this type of information be restricted to the implementation plan and ultimately reside in a NERC relational database which is currently under discussion/development. NPCC participating members suggest that the “Effective Dates” section be replaced with “NERC BOT Adopted Date”. Due to their complexities, FERC and Provincial approvals are something best left to implementation plans and databases. 3) “Rationale” boxes appearing in the Requirements section are problematic. If a “Rationale” box is required to explain part of the requirement then the requirement needs to be revised. For example, in R7 the requirement states that a TO shall execute a flexible annual vegetation management plan. Flexible in this context could have many different interpretations, yet in the “Rationale” box the use of the word flexible is clearly delineated to mean work may be deferred if not an imminent threat. In general we believe these boxes add little value, and if the requirement can’t be understood without the “Rationale” then the requirement needs to be worded appropriately. Suggest these types of explanatory statements go into guidance documents, or supporting technical documents, and do not appear in the “Requirements” sections. 4) Also, there seems to be some confusion regarding the Administrative Procedure section. There seems to be requirements embedded within it, e.g. “The Transmission Owner will submit a quarterly report to its Regional Entity, or the Regional Entity’s designee, identifying all Sustained Outages of transmission lines determined by the Transmission Owner....” Is this an enforceable aspect of the standard? If so, are there any other documents such as the NERC Rules of Procedure “ROP” or compliance related documents such as the CMEP that have to be changed? NPCC participating members recognize that this is a results based standard. Administrative requirements should be removed from the standards, and dealt with elsewhere (such as the ROP). 5) The Guideline and Technical Basis section contains valuable information, but this adds to the volume of the document. The Drafting Team

Organization	Yes or No	Question 3 Comment
		should consider moving this to a separate document. In viewing the standards as a whole, the FAC-003 standard is relatively straightforward when compared to the developing of other standards such as the TPL standard. A similar approach, if applied to the TPL would result in a standard with potentially hundreds of pages. If the type of work appearing in this section is envisioned for other more complex standards such as TPL, the DT should consider separating out this section as a single supporting document. 6) Do FERC and the Provincial governmental authorities approve just the requirements in the Standard, or the whole package?
Response:		
FRCC Manager of Operations	No	See responses to #8, 10, 11 and 13.
Response:		
IRC Standards Review Committee	No	The proposal to move the time horizon and the VRF to a separate independent section is not useful. Take for example R1 and R2 of the proposed standard. A careful read of the two requirements and measurements would indicate that there is no difference between them and that it would be better to have one requirement for all conductors. It is not until the reader gets to the compliance section does the VRF difference show up. There is no savings to removing the previous format's parenthetical inclusion of time horizon and VRF at the end of the requirement. The Independent Section can contain all of the proposed information but don't remove it from the requirement. The format of the standard would not be an issue if NERC would develop a standards database. Then, the database could be queried in any format the user desires.
Response:		
ERCOT ISO	No	The Standard itself is several pages into the document. The VRFs/VSLs should be in the Requirements/Measures Section. The Background, Rationale, Administrative Procedures are additional information and should be located in an Appendix so it doesn't clutter the Standard.
Response:		
CenterPoint Energy	No	We suggest combining and moving the Rationale, Background, Guideline and Technical Basis, and Technical Reference to a consolidated appendix because there is much duplication in the wording within each of these sections, and independently they may be misinterpreted as being an integral part of the Requirements and Measurements which they are not. The Requirements and Measurements should stand clearly on their own. The appendix should contain examples of how to meet the requirements under various circumstances. The appendix should be supplementary and optional to the Standard.It is also not clear if the Administrative

Organization	Yes or No	Question 3 Comment
		Procedure is a mandatory activity. It would be helpful if the intent of this section was stated within the Standard.
Response:		
NERC Staff (12 staff members)	No	We suggest using two colors for explanatory information - yellow for information that is temporary - such as the information explaining the difference between the approved and proposed definitions of “Vegetation Inspection” - and using blue for all boxes that are intended to remain in the approved standard.We feel that the Standards Committee Process Subcommittee should pursue adding a statement from NERC’s legal department indicating which parts of the standard are enforceable. In the meantime, we suggest using the standard template in order to clearly define the enforceable parts of the standard. The section identified as “Guideline and Technical Basis” is not really a guideline (typically a proposed process for completing work) and is not really a “technical basis” (typically a summary of research or engineering judgment, etc. used to explain the reasoning for something). The information in this section is explaining how the drafting team expects compliance with the requirements to be measured. We suggest revising the heading to “Application Guidelines.” This is the term that was originally proposed by the Results-based team and is the heading identified in the proposed Standard Processes Manual.

JEA	Yes	Coupling the measures and rationale with each requirement make the standard easier to follow and to implement.
Response:		
Dominion	Yes	Dominion agrees, but suggests that reference(s) to figure(s) and table(s) contain links that can take reader to that section of the document. This is superior to having to scroll through document. If the reference(s) is external to this standard document, links may be harder to manage but should at least reference a common webpage(s) used by NERC for the posting of such documents.
Response:		
ITC Holding	Yes	ITC feels that the overall layout of the standard (a) improves readability, (b) clarifies expectations, (c) reduces confusion associated with referencing between pages, and (4) allows for background information and the SDT rationale to accompany the standards but we would suggest locating Guideline and Technical Basis after Requirements and Measures for better reference accessibility.
Response:		
MRO's NERC Standards Review Subcommittee	Yes	N/A
Tampa Electric Company	Yes	None
Western Area Power Administration - Upper Great Plains Region	Yes	None

Organization	Yes or No	Question 3 Comment
FirstEnergy	Yes	Overall, we like the layout of the standard, especially the Effective Date table in the front of the standard, the combination of Requirements and Measures, and the grouping of the VRF, Time Horizons, and VSL into one table. However, we would like to see a clearer delineation between the mandatory requirements and the guidance and rationale information. The standard should explicitly be clear as to what is mandatory and what is not, which may even require moving the "Rationale" text boxes out of the Requirements and Measures section. FE believes the information presented in the Rationale text boxes can be effectively covered in the "Guidelines and Technical Basis".
Response:		
Western Area Power Administrtaion	Yes	The format could be enhanced by moving the Guidelines and Technical Basis section forward to be included with the corresponding Requirement, Measure, and Rationale. This would be helpful because it is awkward flipping back and forth between these two sections when trying to fully understand a requirement.
Response:		
Pepco Holdings, Inc. - Affiliates	Yes	The general layout is quite effective. Still, it would be good to keep the VRFs and time horizons within the text of the requirement.
Response:		
Ga Transmission Corp	Yes	The layout is adequate but many things are needing further explanation such as the MVCD.
Response:		
Progress Energy Carolinas	Yes	The overall layout improves readability, clarifies expectations, reduces confusion associated with referencing between pages, and allows for background information and SDT rationale to accompany the standards (reducing the need for interpretation).
Response:		
SERC OC Standards Review Group	Yes	The overall layout improves readability, clarifies expectations, reduces confusing references between pages, and allows for background and rationale to accompany standards.
SERC Vegetation Management	Yes	The overall layout improves readability, clarifies expectations, reduces confusing references between pages,

Organization	Yes or No	Question 3 Comment
Sub-committee		and allows for background and rationale to accompany standards.
Response:		
East Kentucky Power Cooperative, Inc.	Yes	The overall layout is greatly improved. This draft is easier to read and understand and clarifies the expected actions required in the standard.
Response:		
American Electric Power (AEP)	Yes	The overall template layout is acceptable
Response:		
Tennessee Valley Authority	Yes	This aids the understanding of the standard.
Response:		
Ameren	Yes	This draft is much more user friendly and easier to follow; appreciate the follow up information.
Response:		
Consolidated Edison Company of New York, Inc.	Yes	We do believe the overall layout is effective but the SDT should consider putting the Background Section before the Applicability Section in the Introduction and also try to reduce any redundant verbiage in the Background Section and the Guideline and Technical Basis Section. A twenty-one page Standard is too lengthy and the supporting Technical Reference document properly addresses many of the issues mentioned in the Guideline and Technical Basis Section.
Response:		
KCPL	Yes	

4. Do you agree with grouping the standard development timeline (previously called roadmap) with the revision history, and the effective date(s) and putting this administrative information up front before the Introduction Section? Please explain.

Summary Consideration:

Organization	Yes or No	Question 4 Comment
FRCC Manager of Operations		
TO/TOP		
Westchester County Board of Legislators		
IRC Standards Review Committee	No	For this standard one must read through 7 pages before getting to the reason for the posting. The administrative information should be relegated to the end of the posting not the beginning.Under exceptions in the Effective Dates section of the standard, IROLs are referenced as only being created by the Planning Coordinator. Because Reliability Coordinators must also establish IROLs per FAC-011 and FAC-014, we suggest that reference to the Planning Coordinator should be redacted and IROLs should be discussed regardless of whether the Planning Coordinator or Reliability Coordinator creates them.
Response:		
Consolidated Edison Company of New York, Inc.	No	The only issue we have with the administrative information being before the Introduction Section is with the Definition of Terms Used in the Standard Section. We feel this should be part of the Introduction and not a stand alone section.
Orange and Rockland Utilities, Inc.	No	The only issue we have with the administrative information being before the Introduction Section is with the Definition of Terms Used in the Standard Section. We feel this should be part of the Introduction and not a stand alone section.
Response:		
ERCOT ISO	No	This information should be located at the end so that it doesn't distract from the main purpose of the Standard. It is cumbersome to read through several pages before getting to the actual language of the

Organization	Yes or No	Question 4 Comment
		Standard.
Response:		
Ad Hoc Group subteam formed to review draft standard	Yes	
American Transmission Company	Yes	
Arizona Public Service Company	Yes	
Bonneville Power Administration	Yes	
Central Maine Power, Iberdrola USA	Yes	
City of Tallahassee (TAL)	Yes	
Cleco	Yes	
Consumers Energy	Yes	
Duke Energy	Yes	
Exelon	Yes	
GCPD	Yes	
JEA	Yes	
Manitoba Hydro	Yes	
Nebraska Public Power District	Yes	

Organization	Yes or No	Question 4 Comment
NERC Staff (12 staff members)	Yes	
North Carolina EMC	Yes	
Omaha Public Power District	Yes	
Oncor Electric Delivery	Yes	
Pepco Holdings, Inc. - Affiliates	Yes	
PPL Electric Utilities Corporation (NCR00884)	Yes	
South Carolina Electric and Gas	Yes	
Southen Company	Yes	
Tennessee Valley Authority	Yes	
Tucson Electric Power Co.	Yes	
Utility Risk Management Corporation	Yes	
Western Area Power Administrtaion	Yes	
Ameren	Yes	Appreciate the ability to reference up front.
Response:		
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG, CNE & CENG)	Yes	BGE agrees with the proposed grouping and placement of these items.

Organization	Yes or No	Question 4 Comment
Response:		
Dominion	Yes	Dominion agrees that the new format is superior to the old. However, we suggest a table of contents be added to include at a minimum, sections for (1) Definitions of Terms Used in Standard (2) Effective dates, (3) Introduction, (4) requirements and measures (5) Compliance (6) Time Horizons, VRF and VSLs (7) Administrative (8+) guidelines, technical basis, tables or figures referenced in standard.
Response:		
Entergy Services	Yes	Easy to follow.
Response:		
Ga Transmission Corp	Yes	I do not see a problem with this change.
Response:		
Xcel Energy	Yes	It is acceptable to do so, however it is not clear as to how the effective date portion will be incorporated in a final version of the standard. Will there be some kind of cover page to at least indicate the standard or will it just be a small title bar at the top? (i.e. - what does page 1 of the standard look like?)
Response:		
ITC Holding	Yes	ITC agrees with locating the revision history and administrative information before the introduction. This alignment improves clarity and readability by providing a single location for this information.
Response:		
Florida Municipal Power Agency (FMPA) and Some Members	Yes	Just a question, when the standard becomes effective, how will it be posted? FMPA assumes that this section will move to the end of the standard instead of the front when approved.
Response:		
CenterPoint Energy	Yes	No preference.

Organization	Yes or No	Question 4 Comment
Tampa Electric Company	Yes	None
Northeast Power Coordinating Council	Yes	NPCC participating members believe this is acceptable. However our previous response to question 3 above still applies regarding the Effective Date section. It should be removed from the standard, and either appear in an implementation plan, or more effectively in a NERC relational database.
Response:		
Independent Electricity System Operator	Yes	Since in this case the effective dates of all requirements are all the same, we believe the effective dates table could be significantly condensed.
Response:		
East Kentucky Power Cooperative, Inc.	Yes	The format provides for better clarification and is easier to read and comprehend.
Response:		
MRO's NERC Standards Review Subcommittee	Yes	The NSRS likes the way the standards is now formatted and finds it more user friendly.
Response:		
American Electric Power (AEP)	Yes	These changes make sense to American Electric Power.
Response:		
SERC OC Standards Review Group	Yes	This format adds clarity and improves readability.
SERC Vegetation Management Sub-committee	Yes	This format adds clarity and improves readability.
Response:		

Organization	Yes or No	Question 4 Comment
Progress Energy Carolinas	Yes	This grouping improves clarity and readability by providing a single location for this information.
Response:		
Western Area Power Administration - Upper Great Plains Region	Yes	WAPA - UGPR is neutral on location of these items.
Response:		
Southern California Edison Company	Yes	We agree that grouping the administrative information up front is logical and makes for a cleaner presentation.
Response:		
FirstEnergy	Yes	We agree with having a detailed table showing the effective dates of each requirement. However, we would like to see NERC go back into the table and specify the dates of NERC and FERC effective dates once they are known. Having the statement "1st day of the 1st quarter one year after applicable regulatory approval" in the standard does not help the user of the standard when they are working towards compliance, and requires them to go elsewhere to find when the approvals took place. All this information should be in the standard when available and NERC staff should be afforded the latitude to do so even without needing to use its Errata process. Placing the dates directly within the standard is more convenient for the end user.
Response:		
KCPL	Yes	

5. Do you agree with grouping the Requirements and Measures together, in one Section now called Requirements and Measures? Please explain.

Summary Consideration:

Organization	Yes or No	Question 5 Comment
Westchester County Board of Legislators		
Xcel Energy		We are indifferent as to the placement of the Measures, however it does appear to create awkward shaped paragraphs when Requirements and Measures are place around Rationale boxes.
Response:		
Northeast Power Coordinating Council	No	As commented earlier in question 3, this is a compliance related issue and should be in the Compliance section. NPCC participating members believe clear concise requirements should be the focus, and inserting measures immediately after the requirements adds little value. In addition, RE compliance staffs who use the metrics find no value to moving it as well. This format would ease working with the document as a working draft, but should not be in an adopted document. Consider moving Measures back to the compliance section, and add a reference to a Measure's wording stating which requirement the measure refers to. Only adding a statement when the Requirement and Measure numbering don't line up could be considered.
Response:		
Bonneville Power Administration	Yes	
Cleco	Yes	
Duke Energy	Yes	
IRC Standards Review Committee	Yes	
Manitoba Hydro	Yes	

Organization	Yes or No	Question 5 Comment
Nebraska Public Power District	Yes	
NERC Staff (12 staff members)	Yes	
North Carolina EMC	Yes	
Omaha Public Power District	Yes	
Oncor Electric Delivery	Yes	
Pepco Holdings, Inc. - Affiliates	Yes	
PPL Electric Utilities Corporation (NCR00884)	Yes	
South Carolina Electric and Gas	Yes	
Southen Company	Yes	
Southern California Edison Company	Yes	
TO/TOP	Yes	
Tucson Electric Power Co.	Yes	
Utility Risk Management Corporation	Yes	
Western Area Power Administrtaion	Yes	
Central Maine Power, Iberdrola USA	Yes	Adds clarity between requirements and measures .

Organization	Yes or No	Question 5 Comment
Response:		
Arizona Public Service Company	Yes	APS doesn’t agree with all of the requirements.
Response:		
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG, CNE & CENG)	Yes	BGE agrees it makes sense to group these two sections together.
Response:		
JEA	Yes	Coupling the measures and rationale with each requirement make the standard easier to follow and to implement.
Response:		
Dominion	Yes	Dominion finds this format improved over the existing as reader can more easily correlate the requirement (process/procedures) to the measure (evidence).
Response:		
Exelon	Yes	Exelon agrees this is a good practice that will help ensure Requirements and Measures are aligned
Response:		
Florida Municipal Power Agency (FMPA) and Some Members	Yes	FMPA agrees that grouping the Requirements and Measures together in one section is a great idea; however, to realize even more benefit, we now have the opportunity to eliminate redundant wording, e.g., M3 can be shortened to: “A documented transmission vegetation management program” and eliminate the rest of the words that are redundant with R3.
Response:		
Entergy Services	Yes	Great addition and improvement!! Much clearer and easier to follow.

Organization	Yes or No	Question 5 Comment
Response:		
City of Tallahassee (TAL)	Yes	However, if you keep the Rationale text boxes, keep the Measures in the same column as the requirement. This will result in a more consistent “look and feel” to all the requirements (M3 for R3 is the example).
Response:		
FRCC Manager of Operations	Yes	In addition the DT could also eliminate redundant wording in the standard requirement, e.g., M3 can be shortened to: “A documented transmission vegetation management program” and eliminate the rest of the words that are redundant with R3 or use words in the measure that refer back "to the requirement above".
Response:		
ERCOT ISO	Yes	Including a specific measure with each requirement adds clarity; however, it isn’t clear whether each measure is exclusive to the requirement that it follows. Is it possible that some requirements will have multiple measures that are not listed immediately following the requirement?
Response:		
ITC Holding	Yes	ITC agrees with Requirements and Measures grouped together
Response:		
GCPD	Yes	Makes the standard template much easier to read and use.
Response:		
Consumers Energy	Yes	Much easier to follow in this format.
Response:		
Ameren	Yes	Much more user friendly to be able to see the requirement and the measurement together for clarification.
Response:		

Organization	Yes or No	Question 5 Comment
CenterPoint Energy	Yes	No preference.
MRO's NERC Standards Review Subcommittee	Yes	NSRS prefers to have the requirements, measures, VRFs, VSLs and Time Horizons together instead of referencing to another page or part of the standard.
Response:		
American Transmission Company	Yes	See ATC's comment on "Measures" in Question #3 above.
Response:		
Tennessee Valley Authority	Yes	This aides in understanding of the standard. Grouping the VSL and VRF for each requirement along with the measurement could be beneficial too.
Response:		
Ga Transmission Corp	Yes	This also is OK no problem with the layout.
Response:		
Progress Energy Carolinas	Yes	This change also improves readability and improves understanding of the requirement.
Response:		
SERC OC Standards Review Group	Yes	This format adds clarity and improves readability.
SERC Vegetation Management Sub-committee	Yes	This format adds clarity and improves readability.
Response:		
East Kentucky Power	Yes	This format provides for better readability and clarification.

Organization	Yes or No	Question 5 Comment
Cooperative, Inc.		
Response:		
Tampa Electric Company	Yes	This improves the clarity and understanding to the requirements.
Response:		
Independent Electricity System Operator	Yes	This is useful to avoid having to move back and forth between separate sections to find out what is needed to show that a requirement is met. We do not have a strong preference for this re-grouping however.
Response:		
Western Area Power Administration - Upper Great Plains Region	Yes	WAPA - UGPR believes this makes it easier to identify the requirement and what we need to provide to demonstrate with are in compliance with the requirement.
Response:		
FirstEnergy	Yes	We agree that grouping the Requirements and Measures together is convenient when utilizing the document for compliance.
Response:		
Consolidated Edison Company of New York, Inc.	Yes	We agree with grouping the Requirements and Measures together since it does add another level of clarifying description for our field forces who are ensuring compliance during vegetation management activities. The Measures for R1 and R2 describe evidence of violation while the Measures for the remaining Requirements R3 - R7 describe evidence of compliance. All Measures should be written consistently as either evidence of compliance or evidence of violation.
Response:		
Orange and Rockland Utilities, Inc.	Yes	We agree with grouping the Requirements and Measures together since it does add another level of clarifying description for our field forces who are ensuring compliance during vegetation management activities. The Measures for R1 and R2 describe evidence of violation while the Measures for the remaining Requirements R3 - R7 describe evidence of compliance. All Measures should be written consistently as either evidence of

Organization	Yes or No	Question 5 Comment
		compliance or evidence of violation.
Response:		
Ad Hoc Group subteam formed to review draft standard	Yes	We agree with the understanding that the specific requirements of the standard are the enforceable elements of the standard. The rationale and measures add clarity to support a results-based requirement.
Response:		
American Electric Power (AEP)	Yes	Yes, this is a more readable format.
Response:		
KCPL	Yes	

6. Do you agree with grouping VRFs, Time Horizons and VSLs together, and putting them in a table separate from the Requirements and Measures Section? Please explain.

Summary Consideration:

Organization	Yes or No	Question 6 Comment
Westchester County Board of Legislators		
Pepco Holdings, Inc. - Affiliates	No	Agree that the grouping of the subject material is appropriate, but it is not necessary to also remove the VRFs and time horizons from the requirement.
Response:		
JEA	No	I would prefer to have the VRF's and time horizons together with the requirements and measures section. The VSL's separate is appropriate as that is not information needed while complying, but only after a failure.
Response:		
Manitoba Hydro	No	If the VRF's Time Horizons and VSLs were listed in with each requirement and measure section, it would eliminate the need for cross referencing 2 sources of information.
Response:		
Oncor Electric Delivery	No	It would be nice to see the associated VRF's and Time Horizon with the requirements. No text, but referenced.
Response:		
ERCOT ISO	No	The associated VRFs/Time Horizons/VSLs should be identified alongside each Requirement so that all relevant criteria for a given Requirement are organized together.
Response:		

Organization	Yes or No	Question 6 Comment
IRC Standards Review Committee	No	While we agree that the grouping of the subject material is appropriate, it is not necessary to also remove the VRFs and time horizons from the requirement.
Response:		
Duke Energy	No	While we like grouping VRFs, Time Horizons and VSLs together in a table, we would also like to see each VRF and Time Horizon listed with its requirement. It's a small amount of information that we think adds value in both places.
Response:		
Ad Hoc Group subteam formed to review draft standard	Yes	
Ameren	Yes	
American Transmission Company	Yes	
Arizona Public Service Company	Yes	
Bonneville Power Administration	Yes	
Central Maine Power, Iberdrola USA	Yes	
Cleco	Yes	
Consolidated Edison Company of New York, Inc.	Yes	
Consumers Energy	Yes	
Dominion	Yes	

Organization	Yes or No	Question 6 Comment
East Kentucky Power Cooperative, Inc.	Yes	
Exelon	Yes	
FRCC Manager of Operations	Yes	
Independent Electricity System Operator	Yes	
Nebraska Public Power District	Yes	
North Carolina EMC	Yes	
Omaha Public Power District	Yes	
Orange and Rockland Utilities, Inc.	Yes	
PPL Electric Utilities Corporation (NCR00884)	Yes	
South Carolina Electric and Gas	Yes	
Southern California Edison Company	Yes	
TO/TOP	Yes	
Tucson Electric Power Co.	Yes	
Utility Risk Management Corporation	Yes	

Organization	Yes or No	Question 6 Comment
Western Area Power Administrtaion	Yes	
Xcel Energy	Yes	
MRO's NERC Standards Review Subcommittee	Yes	Again it is good to have this information together in place of referencing some other page or part of the Standard.
Response:		
Tennessee Valley Authority	Yes	Also please consider parsing out a copy of each VSL/VRF with in each individual requiremnt and measure part of the standard as mentioned in question 5 above.
Response:		
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG, CNE & CENG)	Yes	BGE supports grouping VRFs and VSLs together in a separate table.
Response:		
Southen Company	Yes	Consider putting the appropriate line from the table with each requirement in the body of the standard in addition to the table format. This does make the standard longer and does introduce some redundancy, but it would make each requirement easier to read and interpret on a “standalone” basis.
Response:		
City of Tallahassee (TAL)	Yes	I believe this makes it easier to follow the Requirements.
Response:		
ITC Holding	Yes	ITC Agree's
Response:		

Organization	Yes or No	Question 6 Comment
Florida Municipal Power Agency (FMPA) and Some Members	Yes	Much easier to find and understand
Response:		
CenterPoint Energy	Yes	No preference.
Entergy Services	Yes	This grouping helps to clarify the manner in which the violations will be ranked.
Response:		
Progress Energy Carolinas	Yes	This grouping improves the template used by previous versions by providing a single view of the impact and risk that has been associated with each requirement. Progress Energy believes that this change would also be improved if the applicable VRF/VSL/Time Horizon table rows were also listed with each requirement (consolidating pertinent info with the requirement). Another improvement would be including the penalty matrix (or including a URL link) to facilitate Transmission Owner discussions with property owners and other governmental agencies.
Response:		
SERC OC Standards Review Group	Yes	This improves the template used by previous versions by providing a single view of the impact consideration of each requirement. An improvement would be also listing the applicable table rows with each requirement which consolidates all pertinent info with the requirement. Also, adding the penalty matrix would facilitate discussions with property owners/agencies resisting maintenance activates.
Response:		
SERC Vegetation Management Sub-committee	Yes	This improves the template used by previous versions by providing a single view of the impact consideration of each requirement. An improvement would be also listing the applicable table rows with each requirement which consolidates all pertinent info with the requirement. Also, adding the penalty matrix would facilitate discussions with property owners/agencies resisting maintenance activates.
Response:		
GCPD	Yes	This is audit stuff that does need to stay together.

Organization	Yes or No	Question 6 Comment
Response:		
Northeast Power Coordinating Council	Yes	This is consistent with FERC's determination that these are compliance elements and not part of the standard requirements. It will also assist with compliance determinations.
Response:		
Western Area Power Administration - Upper Great Plains Region	Yes	WAPA - UGPR is neutral on location of these items.
Response:		
FirstEnergy	Yes	We agree with grouping these items together. It may also be beneficial to include links directly in the table to explanations of VRFs, Time Horizons, and VSLs so that someone unfamiliar with, for instance, what a "Long-Term Planning" horizon means, they could look it up.
Response:		
NERC Staff (12 staff members)	Yes	We agree with the idea behind the grouping. However, according to the Reliability Standard Development Procedure - Version 7, although a non-binding poll is taken of the VRFs and VSLs, it appears that the Time Horizons are part of the standard that is still subject to stakeholder ballot. The SDT should explain how this will be made clear to balloters. Is there intent to modify the standards process to remove the time horizons from the portions of the standard that are subject to ballot? This issue needs to be addressed by the Standards Committee Process Subcommittee.
Response:		
Tampa Electric Company	Yes	With all of the VRFs, Time Horizons and VSLs grouped together it facilitates the overall understanding of these factors as they relate to the standard.
Response:		
Ga Transmission Corp	Yes	Yes this was a good change.

Organization	Yes or No	Question 6 Comment
Response:		
American Electric Power (AEP)	Yes	Yes; this format is more user-friendly.
Response:		
KCPL	Yes	

7. **Do you agree with the insertion of text boxes, where necessary, to help readers better understand the basis of the Definitions and Requirements? Please explain.**

Summary Consideration:

Organization	Yes or No	Question 7 Comment
Westchester County Board of Legislators		
Exelon	No	Additional clarifications should be included in appendices or reference documents. Including them with the requirements and measures will cause confusion concerning what the compliance obligation is. This will introduce uncertainty to the compliance monitoring process.
Response:		
American Transmission Company	No	Although the test boxes provide some addition help, ATC believes that these text boxes should appear in the Guideline and Technical Basis section and that whole section should appear in a companion document to the standard but not be included as part of the standard. Also, see ATC's comment on Rational in Question #3 above.ATC believes that guidance information should not be reviewed and approved by FERC and the inclusion of such information within the standard opens this language up to FERC's oversight and approval.
Response:		
Northeast Power Coordinating Council	No	As stated in question 3 above, NPCC participating members believe crisp, clear results based requirements require no further explanation. Requirements must be written so they are clearly understood. Text boxes clutter up the standard. Questions could arise if these add "pseudo" requirements to the standards, and there is any inconsistency in what is stated about requirements. NPCC strongly suggests their removal in favor of clear, measurable, and high quality results based requirements.
Response:		
City of Tallahassee (TAL)	No	I would delete the Rationale in favor of keeping the Guideline and Technical Basis. The Guideline appears to be more in-depth than the Rationale. This makes the Rationale redundant and unnecessary.

Organization	Yes or No	Question 7 Comment
Response:		
CenterPoint Energy	No	It is not clear how the information in the text boxes will be used to determine compliance with the Requirements and Measures. It appears that in the Definition of Terms Used in Standard section that the text boxes add to the definitions or are footnotes to historical information. The Definitions should stand on their own and be robust enough to ensure they are helpful in determining compliance with the Requirements and Measures. In the Requirements and Measures section, the text boxes appear to contain partial information from the Guideline and Technical Basis, and Technical Reference. In all cases the information is not helpful and provides incomplete information. The text boxes should be deleted and pertinent information to compliance should be incorporated into the Definitions, Requirements, and Measures. Any explanatory text or examples should be moved to an appendix as supplementary and optional to the Standard.
Response:		
ERCOT ISO	No	It is not clear whether the information in the text boxes is “For Information Only.” While the additional information may be helpful, it appears to add sub-requirements within the Standard. This information could be included under a “Rationale” section in an Appendix. However, if the information clouds the purpose of the Requirements or dictates how to comply, then it should be eliminated completely.
Response:		
Consumers Energy	No	Not necessary given the “Guidelines and Technical Basis”.
Response:		
Nebraska Public Power District	No	Text boxes and other supporting information are a benefit to the reader as a clarification guide, but should be placed in something other than the Standard.
Response:		
IRC Standards Review Committee	No	The concept of text boxes needs further discussion. The idea of using text boxes for clarity and explanation is valuable, but is the material in the text box mandatory? If it includes mandatory material than it is not a good idea - all mandatory requirements must be in the requirement. If the text boxes are retained to explain how a phrase is being used (e.g. to make clear what compound actions apply to what compound time frames), then yes, this approach can be invaluable.

Organization	Yes or No	Question 7 Comment
Response:		
Cleco	No	The inclusion of the text implies additional requirements. Keep quidance to a separate paper.
Response:		
Arizona Public Service Company	Yes	
Bonneville Power Administration	Yes	
Consolidated Edison Company of New York, Inc.	Yes	
Duke Energy	Yes	
FRCC Manager of Operations	Yes	
Manitoba Hydro	Yes	
Omaha Public Power District	Yes	
Oncor Electric Delivery	Yes	
Orange and Rockland Utilities, Inc.	Yes	
Pepco Holdings, Inc. - Affiliates	Yes	
PPL Electric Utilities Corporation (NCR00884)	Yes	
Southen Company	Yes	
Tennessee Valley Authority	Yes	

Organization	Yes or No	Question 7 Comment
TO/TOP	Yes	
Tucson Electric Power Co.	Yes	
Utility Risk Management Corporation	Yes	
MRO's NERC Standards Review Subcommittee	Yes	1. We agree. The rationale boxes will cut down on interpretations. 2. Are the rationale boxes part of the approved standards for which registered entities will be audited. Are the rationale boxes federal law?3. Under R3, a reference to the National Electric Safety Code in the rationale box would be helpful. (The goal is to verify that utilities will not be held in violation of this standard when operating beyond the NESC conditions.)
Response:		
North Carolina EMC	Yes	Additional background in the test boxes is very helpful.
Response:		
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG, CNE & CENG)	Yes	BGE agrees this would help clarify the basis of the Definitions & Requirements.
Response:		
Dominion	Yes	Dominion agrees, but suggests that reference to figure(s) and table(s) contain links that can take reader to that section of the document. This is superior to having to scroll through document. If the reference(s) is external to this standard document, links may be harder to manage but should at least reference a common webpage(s) used by NERC for the posting of such documents.
Response:		
Xcel Energy	Yes	However, the boxes should be adding clarity, not "defining' terms or stipulating further requirements/criteria that must be met. See MVCD in R1 & R2 and the incorporated Table 2, and comments to #1 & #13 in this form. The standard should be able to convey the requirements without the text boxes or, if the text boxes are used, the purpose and legal import of such boxes should be clarified. Further, it should be clarifed that for

Organization	Yes or No	Question 7 Comment
		text boxes that provide examples (e.g., the boxes on page 2 in the definitions section), such boxes should clearly state that the examples are in no way limitations.
Response:		
Ga Transmission Corp	Yes	I do like the text boxes.
Response:		
ITC Holding	Yes	ITC agrees, but would like to suggest that the text boxes include additional pertinent information from the Technical Reference that would be helpful as reliability talking points to the public. Example: (R3): The following is a sample description of one combination of strategies which may be utilized by a Transmission Owner. A Transmission Owner's basic maintenance approach could be to remove all incompatible vegetation from the right of way if it has the right to do so and has no constraints
Response:		
Ameren	Yes	It's helpful to understand the SDT's logic for requirements, clarification is always appreciated.
Response:		
GCPD	Yes	May help in cutting down the volume of SAR interpretation requests.
Response:		
Central Maine Power, Iberdrola USA	Yes	R3 - this may be a good place to describe clearances at time of vegetation management work
Response:		
Florida Municipal Power Agency (FMPA) and Some Members	Yes	The clarification is important and will reduce the number of requests for interpretation if interpretation is already provided to some extent. Just a caution about how the text boxes will be used in the audit process, clarification concerning their use during compliance monitoring would be great.
Response:		

Organization	Yes or No	Question 7 Comment
NERC Staff (12 staff members)	Yes	The explanatory information posted with the proposed definitions, like the definitions, is only relevant to this standard, and some of the information is only relevant to the point where the definition becomes enforceable. What is the expectation for what will happen to this information in the future? We suggest that the text boxes associated with requirements include a reference to that requirement. (Change “Rationale” to “Rationale for R1”)
Response:		
Western Area Power Administrtaion	Yes	The format could be enhanced by moving the "Guidelines and Technical Basis" section forward to be included with the corresponding Requirement, Measure, and Rationale. Perhaps the "Guidelines and Technical Basis" could also be combined with the corresponding "Rationale" text box. This would be helpful because it is awkward flipping back and forth between these two sections when trying to fully understand a requirement.
Response:		
SERC OC Standards Review Group	Yes	This format adds clarity and improves readability.
SERC Vegetation Management Sub-committee	Yes	This format adds clarity and improves readability.
Response:		
East Kentucky Power Cooperative, Inc.	Yes	This format is simpler, easier to read, understand and implement.
Response:		
Progress Energy Carolinas	Yes	This format provides clarity and improves readability. Progress Energy believes that having SDT basis information for a requirement in the standard will reduce the need for interpretation and improve the interpretation process for a requirement, if necessary.
Response:		
Tampa Electric Company	Yes	This improves the clarity and understanding to the requirements.

Organization	Yes or No	Question 7 Comment
Response:		
American Electric Power (AEP)	Yes	This is a good change.
Response:		
JEA	Yes	This is extremely helpful in understanding the intent of the requirement
Response:		
Western Area Power Administration - Upper Great Plains Region	Yes	WAPA - UGPR believes that the expanations within the text boxes provided additional useful information.
Response:		
Entergy Services	Yes	We agree that text boxes being used for additional clarity is a benefit if used in a correct and clear manner. It needs to be specifically stated in the document that the text boxes are to be used for reference only, entities will not be required to specifically follow the language in the Rationale box, and that each utility should specify their own process for addressing each Requirement. For example....the Rationale box for R4 states that "Verified knowledge includes observations by journeyman lineman, utility arborist, or other qualified personnel.......". Our process will specify exactly who that qualified personnel is (Transmission Specialist or another qualified Entergy Employee in the Transmission Vegetation Group, for example). We will specify this in our internal processes.
Response:		
FirstEnergy	Yes	We agree that text boxes can be useful for requirements and definitions. However, the SDT may want to consider eliminating the text boxes since this information is already provided in the Guidance and Technical Basis section. Also, we have the following additional comments:General:1. With respect for the rationale text boxes for definitions, it is not clear if these boxes will be retained once the definitions are moved out of the standard and added to the NERC Glossary.2. The rationale text boxes can be beneficial for the requirements, but some of the text boxes in this current draft of FAC-003-2 seem to include prescriptiveness that is not found in the requirement. An example is in the text box for Req. R4, which implies timeliness of notification of an imminent threat with the use of the word "rapid". In the case of R4, the requirement should state that notification be carried out immediately (see our suggested rewording of R4 in Question 13). 3.

Organization	Yes or No	Question 7 Comment
		Although these text boxes are not enforceable for compliance, we are not convinced that an auditor will view this as simply guidance.Specific:1. Definition for Active Transmission Line ROW - Example 3 of Inactive ROW - Consider removing this example; situations where vegetation is left unmanaged on portions of the ROW where double-circuit structures exist with only one circuit strung with conductors poses an unnecessary increased risk for vegetation related outages. 2. Rationale box for Req. R3 - See our comments in Question 23. Rationale box for Req. R4 should be revised to state: "To ensure rapid notification of the responsible control center when an occurrence of an imminent threat condition is verified. Evidence of verified knowledge includes observations by journeyperson, lineperson, utility arborist, or other qualified personnel, or a report verified by these personnel. This notification allows the responsible control center to take the appropriate action until the threat is relieved. Appropriate actions may include a temporary reduction in the line loading or switching the line out of service."4. Rationale box for Req. R5 - (1) The last statement of this box seems incomplete. It should be revised to state: "This requirement is not intended to address situations where the transmission line is not at immediate risk and the work event can be rescheduled or re-planned using an alternate work methodology."; and (2) We suggest revising the first statement to "Legal actions filed by property owners, easement restrictions and other events...."
Response:		
Southern California Edison Company	Yes	We agree that the insertion of text boxes aids readers in understanding the basis for the Definitions and Requirements.
Response:		
Independent Electricity System Operator	Yes	We agree that the side-bars give useful contextual information that is not part of standard. This is good and avoids the reader's attention being completely redirected to a reference document when seeking clarification of the intent of a requirement. We believe however that these text boxes should be used sparingly and the content should also be brief to minimize possible distractions to the reader.It should also be made clear in the standard that these text boxes are not intended to impose additional requirements and in the event of any perceived conflict, the text of the requirement will take precedence.
Response:		
South Carolina Electric and Gas	Yes	We agree, however we would like clarification on whether entities can be held accountable for rationale portions of the standard as they are for interpretations that are added to a standard.
Response:		

Organization	Yes or No	Question 7 Comment
Ad Hoc Group subteam formed to review draft standard	Yes	We understand this question to refer to the “rationale” text boxes in this standard. Additional information such as this is useful to the entity in explaining and clarifying the understanding of the drafting team in articulating the requirement and thus supports a fuller understanding of the entity in achieving compliance with the requirement.
Response:		
KCPL	No	I like information that helps to “guide” and “provide guidance”, however, we already having trouble with information from FAQ’s, White Papers, and other guiding documents creeping into the requirements by auditing teams. The inclusion of “guiding information” in the text of the Standard itself may promote adding to requirements. Although helpful, I recommend removing this text from within the body of the Standard.
Response:		

8. Do you agree with the addition of a Guideline and Technical Basis Section to place technical materials and other related information that assists entities in understanding how to comply with the standard but does not contain mandatory actions/activities? Please explain.

Summary Consideration:

Organization	Yes or No	Question 8 Comment
Westchester County Board of Legislators		
Florida Municipal Power Agency (FMPA) and Some Members	No	Although FMPA agrees that a Guideline and Technical Basis document is important, FMPA has concerns about how this section might be used in compliance monitoring and enforcement. For instance, R4 has a time requirement somewhat embedded in the Guideline and Technical Basis that is not in the requirement in the standard: “The imminent threat process should be implemented in terms of minutes or hours as opposed to a longer time frame for interim corrective action plans”. How many minutes or hours? This adds ambiguity to the standard. If a time limit is desired, it should be in the requirement. There are other examples of items that could be interpreted as requirements in the Guidelines. It should be made clear what the purpose of the Guidelines is in compliance monitoring and enforcement. FMPA suggests publishing two documents in the same fashion that the Functional Model has two documents, one for the standards (e.g., the requirements), and another for technical guidance to the standards (e.g., the Guideline and Technical Basis section) to parallel the structure of the Functional Model and Functional Model Technical Document, which will help make the distinction between CMEP and guidance more distinct.
Response:		
American Transmission Company	No	ATC disagrees with the above statement that it only assists in understanding how to comply. ATC believes that parts of this section are written so they could be interpreted to contain mandatory actions/ activities. To demonstrate, see example on pg.15, R4, 2nd paragraph states...Two key elements of an acceptable imminent threat procedure are outlined below:..........) It should not be more than a preferred method for implementation or supporting how the TO can meet the standard. NERC needs to clarify how this section was intended to be used. (This as written could become part of a Compliance Audit process)Also, refer to ATC’s comment on this section in Question #3 above.
Response:		

Organization	Yes or No	Question 8 Comment
Bonneville Power Administration	No	Consider referencing ANSI A300 part 7 as best management practices for R3. It is currently referenced in the White Paper, and would lend more credibility to the standard if it was inserted in the text box for R3.
Response:		
ERCOT ISO	No	For the same reasons stated in the comments to Question 7, it should be expressly stated that this section is for information purposes only and is not part of the Standard Requirements. Compiling all of the "Information Only" materials into an Appendix would be the preferred method of organization.
Response:		
Northeast Power Coordinating Council	No	NPCC participating members do not believe that publishing more information as part of the standard is appropriate. For the same reasons as stated in the preceding response related to "Text Boxes" in question 7, any inconsistency may result in a conflict with a requirement. The information in the Guideline and Technical Basis section is valuable, however, and should be available to the industry in the form of guidelines. NPCC participating members suggest that NERC assemble a comprehensive set of "Guideline" documents into one bookmarked pdf publication to be updated as standards change. This will afford the industry a knowledge base that is not directly sanctionable for non-compliance, but a set of industry best practices, background, and reference for the standards development activities. Also, concern exists that FERC and Provincial governmental authorities will have jurisdiction over "Guidelines", and when the standard is approved it will become a mandatory "rule".
Response:		
Nebraska Public Power District	No	Same as item 7.
Response:		
CenterPoint Energy	No	See answer to Q3.
Response:		
GCPD	No	Should be separate documents. If located with the standard it will get used by the auditors as compliance issues. NO matter how much text you provide to the contrary it will become part of the standard over time.

Organization	Yes or No	Question 8 Comment
Response:		
Consolidated Edison Company of New York, Inc.	No	Since the SDT has developed a complete Technical Reference Document for this Standard, there seems to be redundancy with the Guideline and Technical Basis Section. This Standard has become too lengthy with all of the additional details and information that has been added. We prefer to have a shorter Standard and a more detailed stand alone supporting reference document.
Response:		
Orange and Rockland Utilities, Inc.	No	Since the SDT has developed a complete Technical Reference Document for this Standard, there seems to be redundancy with the Guideline and Technical Basis Section. This Standard has become too lengthy with all of the additional details and information that has been added. We prefer to have a shorter Standard and a more detailed stand alone supporting reference document.
Response:		
Cleco	No	The inclusion of the text implies additional requirements. Keep quidance to a separate paper.
Response:		
IRC Standards Review Committee	No	This change also requires some additional explanation. What level of importance will be given to such materials? If an SDT inserted a Best Practices document, does that allow auditors to refer to that document for purposes of holding an entity non-compliant? Are these materials there to help entities who do not know how to comply? If these materials are self-help guides, then it would be better to include them as URL references that are stored in the NERC library. That way there can be not confusion about whether the material is there as a self-help guide, or as a reference for auditors.
Response:		
FRCC Manager of Operations	No	We agree that this is valuable information and important to convey with the standard. This should be a separate companion document balloted, approved and posted with the standard but not be a part of the standard.
Response:		

Organization	Yes or No	Question 8 Comment
TO/TOP	No	We agree that this is valuable information and important to convey with the standard. This should be a separate companion document balloted, approved and posted with the standard but not as part of the standard.
Response:		
SERC OC Standards Review Group	No	We recommend that the text "grid reliability" be substituted for "Bulk Electric System" on page 6 of the draft.The inclusion of non-mandatory guidelines in a standard that will ultimately be approved by FERC gives undue credence to "guidelines" that will lead undoubtedly to mis-application by future compliance auditors. We suggest separation of this information from the mandatory reliability standard that will be filed at FERC. It could be held in a repository on the NERC website.
Response:		
Arizona Public Service Company	Yes	
Central Maine Power, Iberdrola USA	Yes	
Consumers Energy	Yes	
Duke Energy	Yes	
Exelon	Yes	
Manitoba Hydro	Yes	
North Carolina EMC	Yes	
Omaha Public Power District	Yes	
Oncor Electric Delivery	Yes	
Pepco Holdings, Inc. - Affiliates	Yes	

Organization	Yes or No	Question 8 Comment
PPL Electric Utilities Corporation (NCR00884)	Yes	
South Carolina Electric and Gas	Yes	
Tennessee Valley Authority	Yes	
Tucson Electric Power Co.	Yes	
Utility Risk Management Corporation	Yes	
Tampa Electric Company	Yes	Aids in improved understanding of FAC-003-2.
Response:		
FirstEnergy	Yes	Although we agree that guidelines are good to have and agree that having them in the body of the standards is convenient, we question how this section will be viewed from a compliance standpoint. We understand this section is not intended to be mandatory, but does that mean that regulatory authorities will only approve the other sections of the standard and not this section? Also, it should be clear and explicitly stated in the lead-in to this section that this is guidance which is not mandatory and enforceable. Additionally, terms such as "shall", "should", and "require" should not be used in the guidance section because the information presented in this section could be construed as mandatory by an auditor. An example of this is in the guidance information for Requirement R7 which states "Documentation is required when the annual work plan is adjusted...". This mandatory-type language should not be included in the Guidelines section.
Response:		
MRO's NERC Standards Review Subcommittee	Yes	Another good addition to the standard and will help clarify parts of the standard without referring to another document or set of guidelines.
Response:		
Southern California Edison Company	Yes	Assuming that the "Guideline and Technical Basis Section" will be retained and revised in future revisions to the standard, such information should prove very useful.

Organization	Yes or No	Question 8 Comment
Response:		
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG, CNE & CENG)	Yes	BGE agrees with the addition of a Guidance & Technical Basis section.
Response:		
JEA	Yes	Having the information in the same document makes the information more accessible to the entity attempting to comply with the standard.
Response:		
Ga Transmission Corp	Yes	I do however believe that each utility should have the flexibility to manage there program the way they feel is the most effective method. I do not want the technical basis section to limit options. Should this be in a white paper format?
Response:		
East Kentucky Power Cooperative, Inc.	Yes	I have no preference one way or the other on this issue.
Response:		
ITC Holding	Yes	ITC agrees with Guidelines and Technical Basis section, but recommend including useful Technical Reference actions and activities that would support defense-in-depth strategy. We also feel that to avoid any confusion with the applicability section and interpretations in the future, any references to the Bulk Electric System in the standard sections and guidance/technical reference document should be reviewed and changed.
Response:		
Entergy Services	Yes	Language should be added to the Guideline and Technical Basis Section to clarify or re-state that this section is for assisting entities in understanding how to comply with the standard but does not contain mandatory actions/activities, and a statement that entities are not required to use the information in the Guideline and

Organization	Yes or No	Question 8 Comment
		Technical Basis Section.
Response:		
Western Area Power Administrtaion	Yes	The format could be enhanced by moving the "Guidelines and Technical Basis" section forward to be included with the corresponding Requirement, Measure, and Rationale. Perhaps the "Guidelines and Technical Basis" could also be combined with the corresponding "Rationale" text box. This would be helpful because it is awkward flipping back and forth between these two sections when trying to fully understand a requirement.
Response:		
NERC Staff (12 staff members)	Yes	There is no language in the body of the standard to clarify that the information in the Guideline and Technical Basis Section of the standard is not subject to enforcement. We suggest revising the heading to “Application Guidelines.” This is the term that was originally proposed by the Results-based team and is the heading identified in the proposed Standard Processes Manual.
Response:		
SERC Vegetation Management Sub-committee	Yes	This format adds clarity and improves readability.
Response:		
Xcel Energy	Yes	This is all good information to add a depth of understanding for the user. It's not clear as to how modifications to the Guideline and Technical Basis would come about - it is the same as the standards revision process? Does this section replace the white paper? Will it actually be deemed to be part of the Standard? We are curious as to the legal weight if this is not part of the Standard and believe that key provisions are in this section. It seems it should be part of the Standard.
Response:		
Ameren	Yes	This is helpful information to have that does not clutter up the requirements and measurements. Under R6, the third paragraph, there is a typo: ..."230kv transmission lines at least once 'line' during the calendar year".
Response:		

Organization	Yes or No	Question 8 Comment
City of Tallahassee (TAL)	Yes	This is very useful information and will minimize misinterpretations by the entities and the compliance teams.
Response:		
Progress Energy Carolinas	Yes	This new section provides additional information and SDT rationale that is critical to understanding how to comply with the requirements in the standard and will also provide SDT intent/basis for the interpretation process when necessary. Progress Energy believes that any references to the Bulk Electric System in the standard sections and guidance/technical reference document should be reviewed and changed (e.g. “grid reliability”) to avoid confusion with the applicability section in this draft and avoid the potential for applicability interpretations once this version is adopted.
Response:		
Independent Electricity System Operator	Yes	This section should be placed in an appendix preceded by a statement that clearly states the purpose of the Section and indicates that the Guideline and Technical Basis Section does not in any way add to the requirements of the standard. Also, this section appears to be a summary of the Technical Reference Document but we could find no reference to the Technical Reference within the standard. This reference should be cited for the benefit of anyone seeking further detail.
Response:		
Western Area Power Administration - Upper Great Plains Region	Yes	WAPA - UGPR agrees with the concept of placing the background technical information in a separate section. We were a bit concerned with the Guideline for R7 because it seems to mandate many more items than were called for in the actual requirement in the body of the standard. Our belief is that the Guideline section should not infer or list any more requirements than the actual requirement dictates.
Response:		
Ad Hoc Group subteam formed to review draft standard	Yes	We agree with the additional material as an aide to entities to further understand the basis for the requirements. In this spirit the information should support compliant behavior and thus the reliability objectives of the standard.
Response:		
Dominion	Yes	While we agree that these can be useful, we are concerned about the ‘last minute’ change (March 24th) to the

Organization	Yes or No	Question 8 Comment
		technical reference document being used by those reviewing the materials for this project.
Response:		
Southen Company	Yes	Would it be better to have an official white paper associated with the standard rather than having this information in the standard? A white paper can be changed without seeking industry comments and approval from NERC, while information in the standard must go through the entire approval process. As it is structured now, information-only updates to the Technical Basis Section would require the entire standards approval process to be completed.
Response:		
American Electric Power (AEP)	Yes	Yes, although American Electric Power does question whether auditors will be able to avoid reading and applying such text.
Response:		
KCPL	No	I like information that helps to “guide” and “provide guidance”, however, we already having trouble with information from FAQ’s, White Papers, and other guiding documents creeping into the requirements by auditing teams. The inclusion of “guiding information” in the text of the Standard itself may promote adding to requirements. Although helpful, I recommend removing this text from within the body of the Standard.
Response:		

9. Do you prefer putting URL links to reference materials in the Guideline and Technical Basis Section, or do you prefer putting the additional technical/information materials in appendices, where needed, to supplement the Guideline and Technical Basis Sections? Please explain.

Summary Consideration:

Organization	Yes or No	Question 9 Comment
Central Maine Power, Iberdrola USA		
Westchester County Board of Legislators		
MRO's NERC Standards Review Subcommittee		If there is background information contained in a URL link pertaining to a particular Requirement, that link should be with the Requirement that it pertains to.
Response:		
Ad Hoc Group subteam formed to review draft standard		Judicious and correct use of citations should allow the proper documentation of references without the hazard of expired URLs or expansion from using appendices.
Response:		
Tennessee Valley Authority		No preference, either way will work.
Response:		
Consumers Energy	Prefer appendices	
Exelon	Prefer appendices	
PPL Electric Utilities Corporation (NCR00884)	Prefer appendices	

Organization	Yes or No	Question 9 Comment
South Carolina Electric and Gas	Prefer appendices	
TO/TOP	Prefer appendices	
Tucson Electric Power Co.	Prefer appendices	
Western Area Power Administrtaion	Prefer appendices	
Xcel Energy	Prefer appendices	
GCPD	Prefer appendices	Actually we prefer that they are separate from the standard entirely. See question 8.
Response:		
Cleco	Prefer appendices	An appendix ensures the information is available and original at the time the document it supports was prepared.
Response:		
ERCOT ISO	Prefer appendices	An Appendix would probably be easier to use, but either type of reference would suffice. Regardless of which is used, it should include a footnote that the information is “For Information Purposes Only” and are not a part of the Standard’s Requirements. If the information causes confusion, then it should be eliminated completely. Also, what types of materials are contemplated to be “reference materials”?
Response:		
Oncor Electric Delivery	Prefer appendices	Appendices would memorialize documents vs URL links to reference materials that may change over time. This Standard was crafted from “todays” point of view and background information. Reference material might change and the URL would point to material not validating the current form, logic, and background of the Standard.
Response:		

Organization	Yes or No	Question 9 Comment
Entergy Services	Prefer appendices	Appendices, or reference to a single site for all referenced material, would be the most helpful from the standpoint of keeping the information together and more readily available.
Response:		
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG, CNE & CENG)	Prefer appendices	BGE prefers that such materials be included in the appendices.
Response:		
NERC Staff (12 staff members)	Prefer appendices	It is not clear what part of the standard is being balloted and what part is not. In addition, it is not clear what process will be used to modify the guideline/technical basis section of the standard. This needs to be determined before this standard can be balloted.
Response:		
FRCC Manager of Operations	Prefer appendices	Links can get broken - official records (ie. standards) need to stand alone.
Response:		
City of Tallahassee (TAL)	Prefer appendices	The fewer places I have to navigate to the better I like it. I find too many “broken” URLs. This will also make it easier when I download a “complete set” of standards from the NERC website.
Response:		
Dominion	Prefer appendices	Unless a ‘failsafe’ process is developed to insure URL links are keep up-to-date, preference is to locate all referenced materials within the standard (same URL). However, there are a number of ways that URL linkage could be done. One would be to locate all Guideline and Technical Basis documents on a webpage dedicated to such documents. This would allow URL linkage at a higher level than if there is URL linkage for each Guideline or Technical Basis document. This is probably the easiest to maintain. Another would be to link each Guideline or Technical Basis document referenced in a standard to the same URL as that standard. Maintaining URL linkage is probably medium. Yet another is to have the URL link to a webpage created specifically for that Guideline or Technical Basis document. This is likely

Organization	Yes or No	Question 9 Comment
		to be the hardest (require most effort) to maintain.
Response:		
CenterPoint Energy	Prefer appendices	URL links tend to change over time due to administrative requirements. Moving them to the appendix will avoid revisions to the Standard. See also answer to Q3 regarding the Guideline and Technical Basis Section.
Response:		
Florida Municipal Power Agency (FMPA) and Some Members	Prefer appendices	URLs can break
Response:		
Nebraska Public Power District	Prefer appendices	URLs change periodically.
Response:		
North Carolina EMC	Prefer appendices	Will need to put something in place to make sure that the links get properly updated if they change.
Response:		
Ameren	Prefer the inclusion of URL links	
Arizona Public Service Company	Prefer the inclusion of URL links	
Bonneville Power Administration	Prefer the inclusion of URL links	
Consolidated Edison Company of New York, Inc.	Prefer the inclusion of URL links	

Organization	Yes or No	Question 9 Comment
Duke Energy	Prefer the inclusion of URL links	
Ga Transmission Corp	Prefer the inclusion of URL links	
IRC Standards Review Committee	Prefer the inclusion of URL links	
Manitoba Hydro	Prefer the inclusion of URL links	
Omaha Public Power District	Prefer the inclusion of URL links	
Pepco Holdings, Inc. - Affiliates	Prefer the inclusion of URL links	
Southern California Edison Company	Prefer the inclusion of URL links	
Utility Risk Management Corporation	Prefer the inclusion of URL links	
Progress Energy Carolinas	Prefer the inclusion of URL links	Additional reference documents provide additional information that may be needed to understand how to comply and the basis of requirements, but they should not be included as appendices. The use appendices could result in a SDT process/effort for minor revisions to the reference document.
Response:		
American Transmission Company	Prefer the inclusion of URL links	Also see ATC's comment on "Guideline and Technical Basis Section" in Question #3 above.
Response:		

Organization	Yes or No	Question 9 Comment
Independent Electricity System Operator	Prefer the inclusion of URL links	In general the additional reference materials may make the document extremely voluminous so we prefer URL links.
Response:		
Northeast Power Coordinating Council	Prefer the inclusion of URL links	Links are preferable to alleviate the concerns expressed in question 8 above, especially with respect to FERC approval.
Response:		
JEA	Prefer the inclusion of URL links	No strong preference.
Tampa Electric Company	Prefer the inclusion of URL links	None
Western Area Power Administration - Upper Great Plains Region	Prefer the inclusion of URL links	None
Orange and Rockland Utilities, Inc.	Prefer the inclusion of URL links	Prefer the inclusion of URL links
Response:		
East Kentucky Power Cooperative, Inc.	Prefer the inclusion of URL links	Provides for clarity and readability.
Response:		
Southen Company	Prefer the inclusion of URL links	See answer to number 8.
Response:		

Organization	Yes or No	Question 9 Comment
American Electric Power (AEP)	Prefer the inclusion of URL links	The use of URL links is probably most appropriate for an increasingly web-based reference repository.
Response:		
SERC OC Standards Review Group	Prefer the inclusion of URL links	This format adds clarity and improves readability.
Response:		
SERC Vegetation Management Sub-committee	Prefer the inclusion of URL links	This format adds clarity and improves readability.
Response:		
ITC Holding	Prefer the inclusion of URL links	URL links provide immediate access, are less cumbersome, and usually provide additional research material when accessed.
Response:		
FirstEnergy	Prefer the inclusion of URL links	We prefer URL links. Although, we are not clear what this question is asking regarding "additional technical/information materials". Is the team referring to "supplemental" reference documents such as the technical reference white paper that was recently posted for stakeholder review on March 24, 2010? If so, we agree that supplemental reference material be included through URL links, perhaps at the end of the "Guidelines and Technical Basis" section of the standard.
Response:		
KCPL	Prefer appendices	Although a good idea generally, too many times URL links change name or something else that makes the imbedded link unusable or takes you to the wrong place. Having an appendix ensures the information is available and original at the time the document it supports was prepared.
Response:		

10. Do you agree with the addition of the Background Section to allow provision of background information, and to elaborate on the reliability-related drivers for the standard/change? Please explain.

Summary Consideration:

Organization	Yes or No	Question 10 Comment
Westchester County Board of Legislators		
ERCOT ISO	No	Again, it is preferable to include this type of information in an Appendix as long as it is made clear that this is additional information and is not a part of the Standard's Requirements. However, if there is a chance that the additional information included in the Appendix is going to cloud the Requirements spelled out in the Standard, then our preference is to eliminate the additional information completely.
Response:		
SERC OC Standards Review Group	No	Inclusion of a background section in a document that will be approved wholly by FERC give undue credence and weight to statements which may be included that are not necessarily factual 100% of the time. For example, the first sentence of the last paragraph of the background section reads as follows: "Since vegetation growth is constant and always present, unmanaged vegetation poses an increased outage risk, especially when numerous transmission lines are operating at or near their Rating." Obviously, woody stems do not grow during the dormant season, yet the background asserts that it does. There are other areas in this sentence that are not completely factual and should not be in a reliability standard. We recommend that the text "grid reliability" be substituted for "Bulk Electric System" on page 6 of the draft.
Response:		
Consumers Energy	No	Not necessary.
Response:		
Northeast Power Coordinating Council	No	NPCC participating members believe this is more informational and appropriate on the individual standard's NERC Website "Under Development" page, in an announcement, cover letter, or to be distributed with the standard drafts.

Organization	Yes or No	Question 10 Comment
Response:		
Nebraska Public Power District	No	Same as item 7.
Response:		
CenterPoint Energy	No	See answer to Q3.
Response:		
Florida Municipal Power Agency (FMPA) and Some Members	No	The background belongs in the Guidelines and not as part of the standard.
Response:		
FRCC Manager of Operations	No	The background section should be re-named "Technical Basis". Trim content and leave only the first and last paragraphs. In addition, all 5 paragraphs of the section as written should be moved to the front of the Guidelines and Technical Basis document as a "Background" section of that separate document. NERC should limit its use of "background" information within the reliability standard itself.
Response:		
TO/TOP	No	The background section should be re-named "Technical Basis". Trim content and leave only the first and last paragraphs. In addition, all 5 paragraphs of the section as written should be moved to the front of the Guidelines and Technical Basis document as a "Background" section. NERC should limit its use of "background" information in reliability standards.
Response:		
Cleco	No	The inclusion of the text implies additional requirements. Keep quidance to a separate paper.
Response:		
Exelon	No	This information should be in appendices or reference documents available on the NERC standards site.

Organization	Yes or No	Question 10 Comment
Response:		
Ameren	Yes	
Arizona Public Service Company	Yes	
Bonneville Power Administration	Yes	
Central Maine Power, Iberdrola USA	Yes	
City of Tallahassee (TAL)	Yes	
Duke Energy	Yes	
East Kentucky Power Cooperative, Inc.	Yes	
Ga Transmission Corp	Yes	
JEA	Yes	
Manitoba Hydro	Yes	
MRO's NERC Standards Review Subcommittee	Yes	
North Carolina EMC	Yes	
Omaha Public Power District	Yes	
Oncor Electric Delivery	Yes	
Pepco Holdings, Inc. - Affiliates	Yes	

Organization	Yes or No	Question 10 Comment
PPL Electric Utilities Corporation (NCR00884)	Yes	
South Carolina Electric and Gas	Yes	
Southen Company	Yes	
Tennessee Valley Authority	Yes	
Tucson Electric Power Co.	Yes	
Utility Risk Management Corporation	Yes	
Western Area Power Administrtaion	Yes	
SERC Vegetation Management Sub-committee	Yes	Allows for a more informed interpretation of the standard.
Response:		
American Electric Power (AEP)	Yes	American Electric Power agrees with this change.
Response:		
American Transmission Company	Yes	ATC agrees that the Background Section is helpful; however, NERC should define its purpose and goal. What is currently written is more than necessary to be included in this standard.
Response:		
Dominion	Yes	Dominion agrees but suggests it be moved towards end (suggest between Administrative and Guideline/Technical basis sections).

Organization	Yes or No	Question 10 Comment
Response:		
Ad Hoc Group subteam formed to review draft standard	Yes	Great help in showing intent and reliability goal of the standard.
Response:		
Southern California Edison Company	Yes	Including a background section should prove useful for future editions. However, at some point such information could be made accessible through URL links.
Response:		
ITC Holding	Yes	ITC agrees with the addition of Background Section
Response:		
GCPD	Yes	May help in iterpretations and in explaining to stakeholders in our organizations.
Response:		
Tampa Electric Company	Yes	None
Western Area Power Administration - Upper Great Plains Region	Yes	None
Progress Energy Carolinas	Yes	Progress Energy agrees and believes that the background section will allow relevant background information that provided direction/guidance for the SDT to be readily available after the standard revision is adopted.
Response:		
Entergy Services	Yes	The Background Section is helpful, but the last sentence states....."Thus, this Standard's emphasis is on vegetation grow-ins.". This statement seems to conflict with the outage Category 2 "Fall In" classification, even though it is a fall in from within the ROW.

Organization	Yes or No	Question 10 Comment
Response:		
Xcel Energy	Yes	The Background section should be moved to the back, in front of the Guideline and Technical Basis.
Response:		
IRC Standards Review Committee	Yes	This background is important for insertion at the beginning of a SAR. But for a standard-posting, it is suggested that this section is redundant and better inserted after the requirement and measures with the other Administrative materials.
Response:		
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG, CNE & CENG)	Yes	This makes sense to BGE.
Response:		
NERC Staff (12 staff members)	Yes	This provides a context for the requirements and is very beneficial in understanding the intent of the standard.
Response:		
Independent Electricity System Operator	Yes	This section expands on the purpose statement and will promote a uniform understanding of the fundamental drivers for the standard and its requirements, as well as its philosophy and scope.
Response:		
Consolidated Edison Company of New York, Inc.	Yes	We agree but believe the Background Section should be situated before the Applicability Section in the revised Standard and redundant verbiage should be removed.
Response:		
Orange and Rockland Utilities, Inc.	Yes	We agree but believe the Background Section should be situated before the Applicability Section in the revised Standard and redundant verbiage should be removed.

Organization	Yes or No	Question 10 Comment
Response:		
FirstEnergy	Yes	We agree that a Background section is beneficial. However, we believe it may be more appropriate to move this information to the Guidelines section as a lead-in. Also, we suggest a rewording of the first sentence of the first paragraph on Pg. 2 which states: "Major outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations". We agree that vegetation can contribute to outages, but it cannot be the sole cause of major outages. Major outages can be prevented if other measures required by other NERC standards are implemented when vegetation causes a line or other equipment to malfunction. We suggest a rewording of this statement as follows: "Interference between vegetation and transmission lines located on many types of land have contributed to significant outages and operational challenges."
Response:		
KCPL	No	I like information that helps to “guide” and “provide guidance”, however, we already having trouble with information from FAQ’s, White Papers, and other guiding documents creeping into the requirements by auditing teams. The inclusion of “guiding information” in the text of the Standard itself may promote adding to requirements. Although helpful, I recommend removing this text from within the body of the Standard.
Response:		

11. Do you agree with the addition of an Administrative Procedure Section to place administrative/procedural requirements that are contained in the existing standards but which do not meet the results-based or risk-based criteria? Please explain.

Summary Consideration:

Organization	Yes or No	Question 11 Comment
ERCOT ISO		
North Carolina EMC		
Westchester County Board of Legislators		
Consumers Energy	No	
Nebraska Public Power District	No	Administrative requirements should not be included in the Standard, they may be construed unintentionally as a requirement.
Response:		
GCPD	No	Anything not directly associated with the compliance requirements or for help with interpretations should not be in the standard.
Response:		
Northeast Power Coordinating Council	No	As stated earlier, NPCC participating members don't understand if this section holds sanctionable requirements, and if so under what authority. Administrative items are best left to the ROP or Compliance documents. A results based standard's primary focus should be on the requirements, and the goal or reliability objective. Taking administrative requirements out of the formal requirements section, adding them to another section, and still deeming them to be requirements is of no value to reducing the administrative burden on the industry. This makes the implementation of the standard more burdensome due to the fact that these additional "requirements" now reside in different places in the standard document. NPCC participating members suggest if these are truly valid requirements they need to be together with the other requirements. If they do not meet the results based criteria, and were included in this "Administrative Procedure" section

Organization	Yes or No	Question 11 Comment
		strictly because of that, then they need to reside in another document. Their continued appearance in the document dilutes the integrity of the results based standard initiative.
Response:		
Exelon	No	Exelon is concerned this will raise questions concerning what criterion separates an administrative requirement from a results or risk based requirement. How are administrative requirements to be treated in the CMEP?
Response:		
CenterPoint Energy	No	It is not clear if the Administrative Procedure is a mandatory activity. It would be helpful if the intent of this section was stated within the Standard.Also, this section in not parallel with the Rating and Rated Electrical Operating Conditions exception contained in R1 and R2. We recommend the following parallel wording for the first paragraph of this section:"The Transmission Owner will submit a quarterly report to its Regional Entity, or the Regional Entity's designee, identifying certain Sustained Outages of the categories defined below, while operating within the Rating and Rated Electrical Operating Conditions, determined by the Transmission Owner to have been caused by vegetation that includes, as a minimum, the following:"Also, the categories listed in this section do not have parallel language to M1 and M2. We recommend that this section should adopt the wording in M1 and M2 for the Sustained Outages to be reported. Currently, Category 2 and Category 4 do not distinguish between an IROL and Major WECC Transfer Path. This may become a tracking problem since they have different Violation Risk Factors. If this is not important, then Category 1A and 1B can be combined.
Response:		
Consolidated Edison Company of New York, Inc.	No	It is somewhat confusing to have sanctionable requirements located in other sections of the Standard outside of 'Requirements and Measures.' The section title 'Administrative Procedure' is somewhat misleading; if it was renamed 'Administrative Requirements' we feel it would be clearer to the industry.
Orange and Rockland Utilities, Inc.	No	It is somewhat confusing to have sanctionable requirements located in other sections of the Standard outside of 'Requirements and Measures.' The section title 'Administrative Procedure' is somewhat misleading; if it was renamed 'Administrative Requirements' we feel it would be clearer to the industry.
Response:		

Organization	Yes or No	Question 11 Comment
SERC OC Standards Review Group	No	Reporting Outages is not a part of Vegetation Mgmt. Therefore, this reporting belongs in an Administrative Section or possibly via a NERC 1600 request. In no circumstance should it be a Requirement of the standard. In the last paragraph this section appears to place a requirement on a regional reliability entity: “The Regional Entity will report the outage information provided by Transmission Owners, as per the above, quarterly to NERC, as well as any actions taken by the Regional Entity as a result of any of the reported Sustained Outages.” Was this really intended? What if the RE fails to make a report?
Response:		
IRC Standards Review Committee	No	Some additional explanation is needed. If the requirement is to do inspections, and compliance is measured on that basis only then the Administrative Section is OK. If the entity is mandated to also meet the actions specified in the Administrative Section, then the change is not acceptable. This standard's example administrative section is introducing new requirements into the standard, and those requirements should be in the standard. In short, if there is a reliability requirement than that is what should be mandated. The idea of mandating administrative items that are often designed to make auditing (not operations or planning) simpler should not be mandated.
Response:		
FRCC Manager of Operations	No	The "Administrative" section needs to be streamlined - remove the first 2 paragraphs - quarterly reporting is no longer required and would be an administratively redundant process to the self-reporting of outages. Leave the outage categories to support consistent self-reports. Delete last paragraph - reporting by the Regional Entities to NERC is a delegated function that should be governed by the delegation agreements, rules of procedure or other internal ERO process, not within a reliability standard since REs and the EROs are not users, operators, etc of the BPS.
Response:		
TO/TOP	No	The "Administrative" section needs to be streamlined - remove the first 2 paragraphs - quarterly reporting is no longer required and would be an administratively redundant process to the self-reporting of outages. Leave the outage categories to support consistent self-reports. Delete last paragraph - reporting by the Regional Entities to NERC is a delegated function that should be governed by the delgation agreements, rules of procedure or other internal ERO process, not a reliability standard.
Response:		

Organization	Yes or No	Question 11 Comment
Ad Hoc Group subteam formed to review draft standard	No	The administrative procedure section is appropriate under results-based requirements. However, we believe that reporting requirements established under other methods, such as the CMEP, may be confused by including it. It is unclear how non-conformance with administrative procedures would be handled. Perhaps administrative procedures would be better handled under ROP Section 1600 data requests or other Rules.
Response:		
Cleco	No	The inclusion of the text implies additional requirements. Keep quidance to a separate paper.
Response:		
Florida Municipal Power Agency (FMPA) and Some Members	No	The reporting requirements really boil down to a self-reporting or self-certification process since the only items to report would be violations to the standard. If such quarterly reporting is desired, it is really a self-certification process and should be governed by that process and not through a separate Administrative Procedure.FMPA recommends deleting the last paragraph - reporting by the Regional Entities to NERC is a delegated function that should be governed by the delegation agreements, rules of procedure or other internal ERO process, not within a reliability standard since REs and the EROs are not users, operators, etc of the BPS, and are not designated in the Applicability section.
Response:

Xcel Energy	Yes	Are we to understand that the requirements listed in the Administrative section are not sanctionable from a NERC compliance perspective?

Organization	Yes or No	Question 11 Comment
Response:		
American Transmission Company	Yes	ATC feels this adds good will on the part of the entity to submit necessary reports, however, ATC requests clarification whether this section is subject to NERC violations. (Currently not listed in Table 1 Time Horizons, VRFs and VSLs)
Response:		
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG, CNE & CENG)	Yes	BGE agrees with addition of an Administrative Procedure section.
Response:		
Duke Energy	Yes	During the WEBINAR, a question was raised regarding how failure to meet an Administrative/Procedural requirement would be addressed by the Regional Entity. Can the Standard Drafting Team prepare a response to the question?
Response:		
JEA	Yes	However, it needs to be made clear whether this is subject to audit, and whether failure to meet the requirement is subject to the same or different enforcement procedures as the numbered requirements in the standard.
Response:		
East Kentucky Power Cooperative, Inc.	Yes	I do not believe that reporting of outages is a part of development and implementation of a Vegetation Management Plan. I fail to see how it brings value to the standard.
Response:		
ITC Holding	Yes	ITC agrees that the “administrative role” such as outage reporting; shouldn’t be a reliability requirement and are more appropriately defined as an administrative procedure. We would also like some clarification on whether this section of the standard is subject to NERC violations. Currently it’s not listed in Table 1 Time Horizons, VRFs and VSLs

Organization	Yes or No	Question 11 Comment
Response:		
Western Area Power Administration - Upper Great Plains Region	Yes	None
Tampa Electric Company	Yes	Not sure why separating 1.A & 1.B is preferred over 1,2,3,4?
Response:		
Progress Energy Carolinas	Yes	Progress Energy agrees that “Administrative” functions such as outage reporting should not be listed as a reliability requirement and are more appropriately defined as an administrative procedure. (Outage reporting is an administrative function that does not directly improve reliability which should be the focus of reliability standard requirements.)NERC has other formal information request procedures in place (such as a NERC 1600 request), if that becomes necessary to ensure outage reporting.
Response:		
SERC Vegetation Management Sub-committee	Yes	Reporting Outages is not a part of Vegetation Mgmt. Therefore, this reporting belongs in an Administrative Section or possibly via a NERC 1600 request. In no circumstance should it be a Requirement of the standard.
Response:		
Western Area Power Administrtaion	Yes	The Administrative Procedure section could be moved forward following the Background section to better introduce the general administrative overview for what would then become the following Requirements, Measures, etc. These general administrative and procedural requirements are more easily overlooked when they included at the back of the Standard.
Response:		
American Electric Power (AEP)	Yes	This addition is acceptable
Response:		
Independent Electricity System	Yes	This section imposes an additional reporting requirement but there is no associated VRF or VSL. Is this

Organization	Yes or No	Question 11 Comment
Operator		intentional? How will failure to report on time be treated? This is unclear as is the significance of any such Administrative "Requirements" within the standard, in general. Is the intention to establish separate procedures to govern the administrative and reporting obligations of registered entities under the Rules of Procedure?
Response:		
FirstEnergy	Yes	We agree with the Administrative Procedure Section. Monetary fines should not be imposed for noncompliance with administrative requirements.
Response:		
KCPL	No	It is too easy to unintentionally infer or introduce something that is not intended to be a requirement, but gets interpreted as a requirement in this section. Standards should be clear in what is a requirement and what is helpful information. If these are requirements, then propose them as requirements. If not, then remove to another guiding document.
Response:		

12. Is there any other information that should be included in the standard document? If so, please explain why you feel that this information should be included.

SERC OC Standards Review Group	Yes	As suggested in comment six, an improvement would be also listing the applicable table rows with each requirement which consolidates all pertinent info with the requirement. Also, adding the penalty matrix would facilitate discussions with property owners/agencies resisting maintenance activates. This standard indicates a lack of recognition that vegetation outages are not necessarily reliability events. In the quest for improved reliability, spending the money necessary to achieve perfect compliance with R2, as stated, either will increase customer rates unnecessarily or cause the misallocation of maintenance funding away from maintenance activities that have a substantially higher impact on reliability.
Response:		
SERC Vegetation Management Sub-committee	Yes	As suggested in comment six, an improvement would be also listing the applicable table rows with each requirement which consolidates all pertinent info with the requirement. Also, adding the penalty matrix would facilitate discussions with property owners/agencies resisting maintenance activates.
Response:		
Arizona Public Service Company	Yes	Clearance 1 needs to be put back into this requirement as written. This is a vegetation management standard and there needs to be clear direction on how the system is going to be maintain at the time of maintenance. This ensures a clear direction to the utility the system has to be maintained. ANSI A-300 part 1 and 7 needs to be a requirement within the standard. Following this consensus agreement within the Professional Utility Vegetation Management sector outlines a process for providing a reliable transmission system. At a minimum ANSI A-300 part 1 and 7 should be incorporated into the Guideline and Technical Basis Section as a resource for compliance with this standard. Prudence would dictate that it be adopted into this draft as the foundation of any transmission vegetation management program as it is the accepted standard for professionals who are responsible for managing vegetation for electric utilities.Personnel qualifications need to be included in the standard and should include minimum measures such that there is consistency across the industry. This ensures that personnel are qualified and will have ongoing training and education in utility vegetation management. For example: The person who manages the field operation should have at least 5

FirstEnergy	Yes	See our other comments.

Organization	Yes or No	Question 12 Comment
Response:		
Central Maine Power, Iberdrola USA	Yes	Table 2 expand footnote - State that table 2 is intended as a buiding block to develop clearance at time of vegetation management work. See TVMP for clearances.
Response:		
CenterPoint Energy	Yes	The detailed rationale for the required one year inspection cycle in R6 should be included in the Technical Reference. The explanation provided in the Rationale that it “seems to be reasonable” and in the Technical Reference that it is “reasonable based on upon average growth rates across North America and common utility practice” are unfounded and arbitrary without a specific reference to a North American study. The Technical Reference should contain an example diagram of “the portion of the ROW where the corridor edge zones are designated by regulatory bodies for vegetation to exist” taken from the examples in the Definition of Terms Used in Standard section. It is unclear how this example should be interpreted for compliance should a Sustained Outage occur from vegetation growing within this zone. It is common for regulatory bodies to push utilities to plant trees or maintain trees within transmission rights of way to “hide the lines”, and it is unclear if this example is attempting to encourage such practice by regulatory bodies at the sacrifice of reliability.In general, the Technical Reference should contain more specific examples of violations of the Requirements and highlight specific exceptions related to vegetation related outages.The background and basis for adding the term “Active Transmission Line Right-of-Way” should be added to the Technical Reference.The background and basis for 4.2.4 that excludes the Standard from applying to fenced substations should be added to the Technical Reference.Just as the force majeure statement (4.3.1) was moved to the Applicability section of the Standard, the exception for applicability beyond the Rating and Rated Electrical Operating Conditions should be included in the Applicability section as well. Currently, it is only included in R1 and R2. It should be made clear if the other Requirements and Measurements must consider conditions beyond the Rating and Rated Electrical Operating Condition.Within the Requirements and Measures section there should be subheadings for each type of Requirement, performance-based, risk based, and competency-based. This classification is only indicated in the Technical Reference.
Response:		
MRO's NERC Standards Review Subcommittee	Yes	The NSRS believes a section for definitions and abbreviated terms such as, Active ROW, MVCD, and WECC is needed. Also, See comment above in Question 9 on URL links.
Response:		

Organization	Yes or No	Question 12 Comment
Southen Company	Yes	We feel a definition of Category 3 outages (non reportable outages) should be included under the administrative procedures. Although these outages are not reportable, this would provide a mechanism for classifying these outages so the utility can maintain evidence of its investigation and the rationale for not reporting them.
Response:		
KCPL	No	

13. Do you have any other comment regarding the draft FAC-003-2 Transmission Vegetation Management standard that have not been addressed above? If yes, please provide a reference to the section, requirement, or subrequirement that you believe should be changed, added or deleted and the rationale for your proposal.

FRCC Manager of Operations	Yes	- Applicability Section 4.3 - use the term "Exemptions" instead of "Other" as it is more descriptive.- As noted earlier - Applicability Section 5 - use the term "Technical Basis" instead of "Background" and streamline by removing paragraphs 2, 3 and 4.- R
Response:		
American Transmission Company	Yes	(a) R1 and R2 (pg.7) - What is meant by “to avoid a Sustained Outage”. Could be argued that a grow-in that does not cause a Sustained Outage is acceptable. (Could this be a FERC issue?)(b) R5 (pg.9) - ATC believes the term “temporarily” should be stricken from the requirement. This leaves too much to interpretation and does not add to the requirement(c) R6 (pg.9) - The descriptive timeframe “at least once per calendar year” is used. What does this mean? Every 365 days or a 12 month period within a calendar year? NERC needs to define this.(d) R4 (pg.15 in the Guideline and Technical Basis) - The term “verified knowledge” is used which does not seem consistent with the definition of “Verified Knowledge” in R4 Rationale on pg.8.(e) R4 (pg.16 in the Guideline and Technical Basis) - The term “responsible control center” is used and further defined. ATC believes this is the Transmission Operator. This should either be moved to the “Definitions of Terms” section or to R4 of the standard where the term is used.

Organization	Yes or No	Question 13 Comment
Response:		
Western Area Power Administrtaion	Yes	1) It is suggested that the word "located" in the third bullet in Measure 1 and Measure 2 be replaced with the word "originating". As worded, M1 or M2 could be interpreted to mean that vegetation originating outside of the right-of-way which blows or sways into contact with conductors "located inside the ... right-of-way" would be evidence of a violation of R1 or R2. Utilities generally are very limited in their ability to manage vegetative conditions outside of their right-of-ways.2) Please reference the comments under Question 2 above regarding the incompleteness of requirements R3 and R7 in fully replacing the CCZ management concepts utilized in the Draft 1 version of the proposed FAC-003-2.3) The requirement R4 Guidelines and Technical Basis narrative is inconsistent with requirement R4. Specifically, in the Guidelines and Technical Basis section the second paragraph's introductory sentence identifies a requirement for an imminent threat procedure, and the second bullet in this paragraph identifies a need to identify vegetation related conditions that warrant a response. Neither of these items are a requirement of R4 as currently written. R4 only speaks to the notification of the responsible control center when it has verified knowledge of a vegetation imminent threat condition.4) The requirement R7 Guidelines and Technical Basis section is written with an inappropriate bias towards very extensive or time based vegetation maintenance programs. Comments received from previous draft standard reviews have revealed that there are many other effective program approaches being utilized by the industry. It is suggested that this section be revised to broaden its scope to incorporate these other program approaches.
Response:		
Ga Transmission Corp	Yes	1) I would like further examples of inactive portions of corridors. For example would a ten foot buffer strip that is in addition to a normal width to stay off a property line but is included in an easement plat but not cleared be considered inactive corridor or not? 2) The MVCD definition may not be realistic in its wording. Many utility companies may not be able to maintain these clearances at "design of Transmission Facility". This needs further definition maybe "NESC moderate wind". Many utilities in coastal areas will design lines for high sustained winds due to hurricanes these clearances may not be possible to maintain under these conditions however the line may be designed to with stand these winds.
Response:		
FirstEnergy	Yes	1. Requirements R1 and R2 - We do not agree with the "zero tolerance" for real-time observation of encroachments that do not cause an outage. When discovered, most Transmission Owners (TO) take immediate action to alleviate encroachments and it is not appropriate to be fined for taking immediate action when no outage has occurred. Therefore, a violation should only occur when the TO has not immediately alleviated the situation within 24 hours. We suggest the following change to the first bullet in Measures M1 and M2: "Real-time observation of encroachment into the MVCD that is not corrected within 24 hours."2. Measurement M1 and M2 - For additional clarity, we suggest

Organization	Yes or No	Question 13 Comment
		adding the following wording from Guideline and Technical Basis into M1 and M2 - "Brief encroachment by falling vegetation are not considered a violation."3. Requirement R4 - Since the intent of this requirement is the immediate notification of an imminent threat, we suggest adding the word "immediately" between "shall" and "notify".4. Requirement R5 - We suggest removing the term "temporarily" in the requirement. Some constraints faced by Transmission Owners are permanent and appropriate alternate action is permanently implemented. 5. Requirement R7 - Although we agree that the TO should be allowed to adjust the plan, the use of the term "flexible" is subjective. Additionally, the phrase "to ensure no vegetation encroachments occur within the MVCD" is redundant with the other requirements of the standard. Therefore, we suggest revising the wording of Requirement R7 to the following: "Each Transmission Owner shall implement an annual vegetation work plan. Adjustments to the work plan to defer work beyond the calendar year are acceptable and shall be documented."6. Coordination between Project 2007-07 and 2010-07 - Since the TO-GO interface team has identified the need for Generator Owner (GO) applicability in the FAC-003 standard, we believe that these two drafting teams should coordinate the addition of the GO into this Version 2 of FAC-003. It would not seem sensible to revise Version 1 of FAC-003 to include the GO while Version 2 is developed and approved without applicability to the GO.7. Compliance Section - Under "Additional Compliance Information", we suggest removing the parenthetical phrase "See Administrative Procedure" and replace with "None". Since the Administrative Procedure is not part of the requirements, it is not sanctionable and should not be included in the Compliance Section.
Response:		
MRO's NERC Standards Review Subcommittee	Yes	1. Need definition for the phrase “Major WECC Transfer Paths”.2. In question 2 of the comment form, it refers to the “bulk power system.” This standard does not cover the bulk power system, it covers lines above 200kV and certain ones below 200kV.
Response:		
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG, CNE & CENG)	Yes	4.2.4 States that the Standard is not applicable to “...to Facilities .... located inside the fenced area of a switchyard, station or substation”. This implies that anything within the fenced area of a switchyard, substation or power plant does not fall within the jurisdiction of FAC-003-2. Some fenced in areas could be very large and susceptible to vegetation encroachments issues.4.3.1 Suggest including in the Force Majeure government a phrase referencing government interference, such as “Federal, State or other regulatory interference, including legal or other legislative actions, that prevents performance to comply with this reliability standard.”M1 & M2 bullet: “Real-time observation of encroachment into the MVCD” implies that real-time observation of vegetation encroachment ensures reliable operation the Bulk Electric System. The reliability standard objective states;”To improve the reliability of the electric Transmission system by preventing those vegetation related outages that could lead to Cascading.”However, real time observation of current operating conditions provides no assurance that vegetation will not lead to outages. BGE recommends removing the language. If an inspector finds vegetation encroaching into the MVCD during a visual inspection he / she

Organization	Yes or No	Question 13 Comment
		should immediately initiate an Immediate Threat Notification. Therefore, this measure has no value.Disagree with R6. - Inspection Frequency. Very prescriptive. Please consider allowing TO's to select an annual frequency that best fits their requirements, such as calendar year, every growing season, every non-growing season, etc. BGE currently defines their inspection frequency as annually during the non-growing season, October 1 to May 1. BGE believes inspecting during the dormant season is a best practice due to the ability of the inspector to identify vegetation defects, especially off the ROW, which could be hidden during the growing season due to foliage, canopy cover, etc. Also, if a utility elects to leverage an advance technology, such as LiDAR, it provides the most effective results when LiDAR is utilize during the growing season, therefore allowing the results of the advance technology to enhance the fall to spring inspection cycle. All of the above comments are submitted on behalf of: - Baltimore Gas & Electric Company - Constellation Energy Group, Inc. - Constellation Power Source Generation, Inc. - Constellation Energy Commodities Group, Inc. - Constellation New Energy, Inc. - Constellation Energy Nuclear Group, Inc.
Response:		
Arizona Public Service Company	Yes	APS objects to number 3 Objectives statement. This is the only reliability standard that has at its Objective to prevent vegetation related outages that could lead to cascading. This is a reliability standard and its objective needs to be: "To improve the electric Transmission system by preventing vegetation related outages." Requirement 6: To ensure reliability the TO's are responsible for doing an annual inspection. You either do it or don't and if you don't finish it you should be held accountable. There shouldn't be a lower VSL because you didn't finish all of it. This is poor planning on the utilities part.Requirement R7: When developing the annual work plan the Transmission Owner should allow time for procedural requirements to obtain permits to work on federal, state, provincial, public, tribal lands. In some cases the lead time for obtaining permits may necessitate preparing work plans more than a year prior to work start dates. Transmission Owners may also need to consider those special landowner requirements as documented in easement instruments. There needs to be parameters for the TO to show they allowed time for procedural requirements. An example, some land agencies will give you permission to perform work in as little time as two weeks and others can take two years. Even within the same land agency the timing of approvals is a moving target. APS recommends the TO must show documentation it submitted their Vegetation Management Plan to the land agency at least 120 days prior to the required start date. If the land agency doesn't respond within this time frame and the utility can not perform the work they shouldn't be held responsible.
Response:		
JEA	Yes	Generally, I believe this document is a huge improvement. The requirements are much clearer and easier to implement than some versions from the past. I do not understand why R7 is still in this standard however. It appears to be a requirement whose purpose is only to dictate HOW an entity must document its implementation of its vegetation management program. Thus, I believe this requirement should be removed.

Organization	Yes or No	Question 13 Comment
Response:		
Consolidated Edison Company of New York, Inc.	Yes	In R5, the SDT should better define the phrase 'where a transmission line is put at potential risk due to the constraint.' This is rather vague and could lead to inconsistent practices between utilities. Con Edison defines all undesirable species on the full width of the ROW as 'potential risks to the transmission line' regardless of height or location at the time of vegetation management. Interim corrective action should only be required when the potential risk is approaching the imminent threat classification.
Response:		
Orange and Rockland Utilities, Inc.	Yes	In R5, the SDT should better define the phrase 'where a transmission line is put at potential risk due to the constraint.' This is rather vague and could lead to inconsistent practices between utilities. ORU defines all undesirable species on the full width of the ROW as 'potential risks to the transmission line' regardless of height or location at the time of vegetation management. Interim corrective action should only be required when the potential risk is approaching the imminent threat classification.
Response:		
Florida Municipal Power Agency (FMPA) and Some Members	Yes	In the Applicability section, the use of the term “Other” should be changed to another term, such as Force Majeure, since its purpose is not to include scope into the standard, but exclude scope from the standard.R4 uses the term “responsible control center”, which seems inappropriate. Consider using the term “responsible operating entity”. The M4 is simply a restatement of R4 without an example of types of evidence, e.g., such as voice recording, operator logs, etc.R5, consider using a different term than “constrained”, which has other transmission related connotations. Possibly “limited” or “hindered”.FMPA disagrees with a 3 year retention schedule for all of the Requirements and Measures. R4 and M4 would seem to be supported by operator logs, voice recordings and such and three year retention for such evidence is inconsistent with other standards.
Response:		
ITC Holding	Yes	In the previous draft the VRF’s R6 and R7 were listed as Medium; and in the latest revision they are listed as High VRF’s, what is the reason for this change or is this just a mistake?”Temporarily” should be removed from the requirement (R5 pg.9) this will be an interpretation issue and doesn’t add to the requirement.
Response:		

Organization	Yes or No	Question 13 Comment
Northeast Power Coordinating Council	Yes	NPCC participating members recognize the hard work the drafting team has done and appreciate the efforts to address the issues presented. An issue seems to be a recurring theme with the advent of the MVCD. Some believe that the eventual adoption of this standard with MVCD will result in the reduction of current trimming cycles and clearance distances. Opinions have been expressed that this may result in increased vegetation contacts and trips. After reviewing some of the MVCD distances, for example 3.12 feet at sea level for 345kV, some expressed the opinion that this is much less than what typical trim practices are today, and may actually “lower” the bar for trimming practices, and effectively allow a TO to trim less and reduce the margin of clearance.Requirement R1 discusses encroachment. M1 bullet 1 states one way to violate encroachment would be:”Real-time observation of encroachment into the MVCD...”From a practical standpoint what is meant here? Who would determine this and how would it be done? The intent is certainly to avoid a sustained outage. However, if a TO was in the process of trimming after an active growing season, and noticed a slight encroachment while trimming, would it be considered a reportable violation? How would the RE measure compliance with avoiding something, with the absence of a sustained outage reported? A statement should be added to the “Definition of Terms Used in Standard” section to indicate how terms defined in the NERC Glossary and used in the standard are identified (for example capitalizing the first letters of the term or using italics or bold font). To avoid confusion when a term might be used at the beginning of a sentence, bolding or italicizing the term should be considered. The Guideline and Technical Basis section should be a separate document, and not part of the standard (mentioned previously in question 8). It should be included in the Technical Reference Document.Applicability 4.2.4--A fenced area of a switchyard, station or substation can have vegetation that could present a potential risk to facilities. What is the reason for this exclusion, and the exclusion in Applicability Section 5--Background paragraph 3 “...this Standard does not apply...to line sections inside an electric station boundary.”Referring to our previous responses to questions 1 and 2 for Requirements R1, R2, and R3, what rating is used? It is possible to operate above a facility’s normal rating for a prescribed time (for example a transmission line may be operated above its normal rating but below its LTE rating for up to 4 hours). Operating at emergency ratings should be considered. During emergencies transmission lines might be loaded to their emergency ratings, thus increasing the sag, thus increasing the likelihood of a vegetation caused trip if the required clearances don’t take into account the increased loading. Especially in an emergency loading scenario, operating into an avoidable potential risk is very undesirable. Referring to FAC-003 - Table 2 - Minimum Vegetation Clearance Distances (MVCD), for 345kV (line to line), 3.12 foot (assuming to ground) clearance is required at sea level. IEEE Std 516-2003 IEEE Guide for Maintenance Methods on Energized Power Lines dated July 29, 2003, Table 5 (p. 20), lists the MAID (minimum air insulation distance) for 345kV phase to phase equipment at altitudes below 900 meters (2953 feet) to be 2.88 meters (9.45 feet) phase to ground. It is understood that MAID is “The shortest distance in air between an energized electrical apparatus and/or a line worker’s body at different potential...”, but the clearance differences at the various voltage levels seem very significant. If a figure is referenced in a requirement (R3), it would be preferable to have that figure positioned within that requirement. If that is not possible, it should be explicitly stated where the figure can be found. Requirement R5--Legal actions and other events that prevent vegetation maintenance work be included in the Introduction Section 4.3.1. What does “interim corrective action” mean specifically? The requirement as written needs to be made clearer. Without the Rationale box it loses its meaning (refer to the question 3 response).Interim

Organization	Yes or No	Question 13 Comment
		Corrective Actions are explained on page 28 of the separate Technical Reference Document, with examples such as modifying the inspection interval, or limiting the loading on the line (effectively changing its rating) to minimize sag. “Interim corrective action” should be defined and added to the Glossary.Are voltages referred to in the Standard (Applicability Section) line to line or line to ground for ac systems? (345kV line to line is 199kV line to ground, below the 200kV threshold in the standard). Are the voltages also applicable to DC equipment?
Response:		
Xcel Energy	Yes	On page 6, in paragraph 5 ("Background"), we suggest enhancing the 3rd paragraph by inserting the words "Active Transmission Right-of-Way", as follows: "...addresses vegetation management in the Active Transmission Right-of-Way along applicable overhead lines..." This change emphasizes that this does not apply to areas outside of the Active Transmission Right-of-Way. Comments to Requirments and Measures Section (pages 7 -9)The term Minimum Vegetation Clearance Distance (MVCD) should be explicitly defined as a new "definition" rather than explained in a "rationale" box. Additionally, formalizing the definition would give weight to how "Table 2" is supposed to be used. As it is currently drafted, the requirements of the standard don't refer to Table 2 at all. (i.e., - our understanding is that the rationale boxes are for clarification and the requirements should be able to convey what is necessary on their own.)MVCD - while we understand this as an 'engineering term', the terminology is difficult to convey since land owners tend to question the need to do anything more than the "minimum". We recommend revising the term to "Critical Clearance Distance (CCD)". M1 & M2 should be revised to insert the concept of "verified knowledge" (that is used in R4). This is because M1 & M2 do not clarify whose real-time obseration it is referencing. As such, we recommend stating "Real time verified knowledge of encroachement into the MVCD..." instead of just the term "observation" to make it clear that a trained, knowledgeable individual is making this determination. Also, it may make sense to turn "verified knowledge" into a defined term since it will be used in M1, M2 and R4. If it is not made a defined term, then the meaning in M1 & M2 must be clarified in those sections (maybe a cross refefrence to as defined in R4 and on page 15 will work). However, we think it is best to make it a defined term.R5: Rationale box: consider enhancing the second sentence by adding the word "significant", to read "...avoid significant risk..."R5: Requirement & Measure: consider adding exception language when the constraint is known to be longer than "temporary". e.g. - stand offs can occur on right of ways that cross federal and tribal lands and the entity cannot force the federal government to do do something.R6: Xcel Energy still believes the requirement in R6 that mandates an annual inspection is too onerous and is at odds with the results-based approach of these revisions. Xcel Energy urges the retention of the provision in the existing standard that allows the Transmission Owner to set the frequency of inspection. In some areas of the country, annual inspections may not be adequate. Yet in other areas, a longer inspection frequency may be perfectly reasonable and practical. Our point is that inspection frequency should not be treated as if it were “one size fits all”. If treated this way, we feel this could pose a risk to reliability and is not likely to be cost-effective. The Transmission Owner should be allowed some flexibility. However, if the drafting team disagrees and determines that an annual inspection is to be mandated, Xcel Energy believes that an exception to the annual inspection is appropriate when a non-subjective advanced technology such as LIDAR is utilized to achieve

Organization	Yes or No	Question 13 Comment
		actual clearance distances. This places the Transmission Owner in a situation where it can rationally determine that the objectively measured distances result in a situation where an inspection need not be performed within the next year. It is suggested that R6 be revised to read as follows: Each Transmission Owner shall perform a Vegetation Inspection of all applicable transmission lines at least once per calendar year, unless the Transmission Owner, based on a non-subjective advanced technology, such as LIDAR, determines that a longer inspection period is appropriate.R7: Revise the requirement to eliminate the superfulous language at the end of the sentence that says "... to ensure no vegetation encoachments occur wihtin the MVCD", i.e., R7 would read as "Each Transmission Owner shall execute a flexible annual vegetation work plan."
Response:		
Independent Electricity System Operator	Yes	Our comments to this point have focussed exclusively on the proof-of-concept for using the results-based criteria for developing a reliability standard. We have one comment on the specifics of Requirement R7 and its Measure M7. The rationale for M7 states that a flexible annual vegetation work plan allows for work to be deferred into the following calendar year provided it does not have the potential to become an imminent threat. This will evidently require some kind of assessment in each case. Will entities be expected to document those assessments as evidence in support of its view that the associated vegetation did not have the potential to become an imminent threat, or would it be sufficient to look at the outcomes of these decisions to defer items in the work plan - i.e. there were no imminent threats and sustained outages? Finally, we applaud the drafting team for its efforts in developing this draft. The industry has often commented about overly prescriptive requirements and I believe this draft has focused on the “what” of the requirements and left the “how” up to the appropriate entities. In our view this draft, with its succinctly stated requirements, represents an important first step in the right direction. Thank you.
Response:		
Ameren	Yes	Page 9, M7 - what are the limits of flexibility in executing "a flexible annual vegetation work plan"?
Response:		
Duke Energy	Yes	Please review the VRF Guideline because we believe that the VRF’s for R6 and R7 should possibly be changed to “Medium” instead of “High”. They were “Medium” in the last draft of FAC-003-2.
Response:		
Westchester County Board of Legislators	Yes	Please see e-mail sent to sar@nerc.com. Thank you.

Organization	Yes or No	Question 13 Comment
Response:		
Progress Energy Carolinas	Yes	Progress Energy believes that the VRFs for R6 and R7 should be returned to “medium” since no singular “risk-based” requirement in a defense in depth strategy should be depended upon to eliminate/prevent risk to grid reliability. In a defense in depth strategy, no one specific “risk-based” or “competency” requirement should be “high” unless failure to complete that singular requirement will result in an immediate “high” risk to grid reliability (if that is the case, then the standard is not truly employing a defense in depth approach). Also, R6 and R7 (which have a zero tolerance) have no differentiation between grid impacting facilities (IROL) and facilities primary impacting local customer reliability (i.e., radial lines to load, etc).
Response:		
North Carolina EMC	Yes	R4: The requirement to notify the responsible control center of an imminent threat may potentially result in confusion at the control center if the transmission lines in question are not part of the control center's actively monitored grid. As an example, NCEMC has a few short radial 230kV lines that fall under the requirements of this standard, but these lines are not shown on the BA's control center system because they are downstream from a protective device located at a tap off networked transmission lines. A vegetation-related outage on these lines would not result in any of the transmission elements continuously monitored by the control center being outaged, and the operator receiving a call notifying the imminent threat may not have any familiarity with the line section being identified, since it is not on their system. If prompt action to respond to any imminent threat is the intended goal, why not consider making it a significant part of the mitigating factors of an actual outage.
Response:		
City of Tallahassee (TAL)	Yes	Recommend deleting the “to avoid a Sustained Outage” in R1 and R2. Has a violation occurred if a momentary (successful reclose) outage occurs but the TO did not “observe(s) vegetation within the” MVCD? While it may not have to be reported on the quarterly report, Table 1 for the Lower VSL seems to suggest a violation of the MVCD has occurred, even if it was not “observed” as “required” in the Guideline and Technical Basis.In the Guideline and Technical Basis, the final paragraph for R1 and R2, line 3 contains an extra word “...encroachment is not be a violation...”In the Guideline and Technical Basis, the third paragraph for R6, line 2/3 contains an extra word “...230kV transmission at least once line during the calendar year.”
Response:		
Cleco	Yes	Requirement 4:Recommend the SDT consider modifying to make it clear the requirement applies to threats within the right of way (ROW).Requirement 4.3.1:Recommend adding human activities to the list of causes. Logging activities

Organization	Yes or No	Question 13 Comment
		are listed but other human activities such as private property owner tree care operations are not.
Response:		
Exelon	Yes	See R6. Exelon prefers “annual” to “calendar” but notes the requirement runs counter to the results based approach and could be interpreted to be inconsistent with R7.The Rationale for R6 is ambiguous and without justification suggests shorter but not longer cycles are acceptable. If local factors can shorten a cycle, they could also increase it. The Rational is in conflict with the prescriptive nature of the requirement.
Response:		
NERC Staff (12 staff members)	Yes	Standard Development TimelineThe Development Steps Completed section of the standard is incomplete. This section should include the dates of previous postings. Draft 1 of revised standard was posted for stakeholder comment from 10/27/08 - 11/25/08. Draft 2 of revised standard was posted for stakeholder comment from 09/10/09 - 10/24/09.Definitions of Terms Used in StandardThe definition of Active Transmission Right-of-Way is ambiguous and subject to interpretation. This definition need to be revised to add clarity. It is unclear what “active transmission facilities” are. In the gray box, the SDT should explain what “active portions of corridors” are, and how that is different than the “land that is occupied by active transmission facilities.” The terminology should be consistent. The example should state whether the width is the portion that has been cleared or should be cleared and if it was not maintained and should have been. The SDT should explain the reference to the National Electrical Safety Code in the gray box, and how it differs from the IEEE clearances. In addition, the team should explain why the Table 2 clearances set forth in the standard itself are not referenced. The examples in the “inactive portion” suggest that there are active transmission facilities (see references to conductors and circuits). The SDT should provide the rationale for excluded them from vegetation management. While vegetation is permitted to exist at the corridor edge, the SDT should address why there is no obligation to maintain it. The revised definition of Vegetation Inspection does not seem necessary. It appears that the SDT is using the definition to set an expectation for enforcement by adding “which may be combined with a general line inspection.” If both vegetation and general line inspections are to occur concurrently, there should be minimum background requirements to perform such inspections. We recommend that the last portion of the draft definition be moved to the Application Guideline section so the definition of Vegetation Inspection should be “The systematic examination of vegetation conditions on an Active Transmission Line Right of Way.”The team should consider making Minimum Vegetation Clearance Distance a defined term.Effective DatesThe effective date for Ontario needs to be tied to the effective date in the U.S.With respect to the second exception, the team should provide the rationale behind the exception for the effective date for “existing transmission line operated at 200kV or higher that is newly acquired by an asset owner and was not previously subject to this standard”. All existing transmission lines operated at 200 kV or higher are currently subject to vegetation management. Please explain why a new owner would get an exception for this.Based on the wording in the Exceptions section, it appears that some lines in the US could be brought into this standard prior to regulatory approval. (i.e. Lines operated below 200kV, designated by the Planning

Organization	Yes or No	Question 13 Comment
		Coordinator as an element of an IROL or as a Major WECC transfer path, become subject to this standard 12 months after the date the Planning Coordinator or WECC initially designates the lines as being subject to this standard. An existing transmission line operated at 200kV or higher that is newly acquired by an asset owner and was not previously subject to this standard, becomes subject to this standard 12 months after the acquisition date of the line(s))ObjectiveThe purpose of this standard should not be limited to outages that lead to Cascading, but prevention of all vegetation related outagesApplicabilityThis standard should apply to Generation Owners.The term Facilities is defined to exclude those in a fenced area of a switchyard, station or substation. The SDT should provide the basis for the exclusion.Footnote 1 needs to be clarified. It is too cursory.The “Other” section should not be included in this section. It is the expectation that the Compliance Enforcement Authority will not expect the Transmission Owner to prevent tree contacts that the TO could not prevent. This might be better suited in the Application Guideline section.In the “Other” section, the SDT should provide rationale for why the standard is not intended to address “human errors”.The SDT might consider rewording the “Other” section as:”This Standard shall not apply in circumstances where a requirement of this Standard was not complied with due to Acts of God, flood, drought, earthquake, major storms, fire, hurricane, tornado, landslides, logging activities, animals severing trees, lightning, epidemic, strike, war, riot, civil disturbance, sabotage, vandalism, terrorism, wind shear, or fresh gales that restricts or prevents performance to comply with this Reliability Standard's requirements, so long as the non-compliance was not caused by the fault or negligence of the Transmission Owner.”The team should provide justification for the applicability criteria they have selected; specifically why a 200 kV cutoff was chosen.The team should provide justification for eliminating fall-ins from outside the ROW.BackgroundAs a general comment, the background section seems repetitive.The fourth paragraph of the background section notes that this standard is not intended to prevent customer outages due to tree contact with lower voltage distribution systems. It is clear from the applicability section that this pertains to 200 kV and higher, although the standard contemplates that some lower voltage facilities could be subject to the standard. The SDT should address whether this paragraph also address customer outages due to tree contacts with respect to 200 kV or higher facilities.Requirements R1 and R2:R1If an auditor were to assess compliance with R1, they would need to have the list of conductors that were associated with an IROL or a Transfer Path. This list should be identified in the list of evidence that must be retained.R1 & R2 In the Rationale box, the term “a proven transmission design method” is used. Please describe what this refers to, and whether these refer to the IEEE minimum clearances. The SDT should state what the method was and what changes, if any, were made to it.The SDT should address why the requirements only reference line conductors and not transmission facilities or transmission lines (the VSLs refer to transmission lines).The word “encroaching” should be replaced with another word/phrase that clearly defines the concept for compliance purposes. The word, “encroach” could be interpreted differently by different people (how close can vegetation grow before it enters the MVCD and is it a violation of R1/R2 - is it 2”, 2’, 10”, 10’?), whereas the word “enter” is explicit.Guidance is offered in the Guideline section of the standard that implies that all TOs should retain this evidence, yet the evidence is not identified anywhere in the Measures or evidence retention sections of the standard.We suggest adding the phrase, “of its” to clarify that the TO is only responsible for facilities it owns. “In addition, the Transmission Owner should maintain detailed records of the findings of its planned inspections. This documentation constitutes evidence that the Transmission Owner had no encroachments into the MVCD Table

Organization	Yes or No	Question 13 Comment
		distances."Immediately after the phrase MVCD, we suggest including the text "as specified in FAC-003-2 Transmission Vegetation Management Table 2 - Minimum Vegetation Clearance Distances (MVCD). Table 2 is not referenced in any of the requirements. If you require entities to use the MVCD as stated in Table 2, then this should be referenced in at least R1 and R2.M1 & M2Overall, it appears that these measures are asking for evidence of non-compliance. The initial item under M1 & M2 (shown below) should be rephrased with the addition of the words "verbal or written report of a," otherwise the measure doesn't seem as though it could be used objectively. In addition, the words Real-time should be removed, as they ad confusion to the issue."Verbal or written report of a observation of encroachment into the MVCD, or"The phrase "Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period" should be changed to a footnote that reads "Consider Multiple Sustained Outages on an individual line, if caused by the same vegetation, as one outage regardless of the actual number of outages due to the same piece of vegetation"Momentary outages due to vegetation are also a violation of R1. Momentary outages from tree contacts may not result in a sustained outage but are evidence of a tree within the MVCD. The requirement should not be limited to only sustained outages. Consider this scenario: An entity self-reports a violation of the standard. Does that mean that if there is no actual "real-time observation" or a "Sustained Outage" there is no violation? Who must do the observing? Please explain.Requirement R3 Consider this scenario: A Sustained Outage occurs on a location that was not considered and therefore was not part of the TO's TVMP. Would this result in a violation simply because the location was not considered when the entity developed a TVMP?Requirement R4 Each requirement should identify "who shall do what under what conditions, for what reliability outcome." R4 has no identified reliability outcome. What is the reason for making a prompt notification? Is it to give the real-time system operator information on which to develop and implement an action plan if there is an outage on the line with the imminent threat? Then that should be stated in the requirement. R4 contains explanatory information. The sentence "A vegetation imminent threat condition is one which is likely to cause a Sustained Outage at any moment" should be moved to the blue box.Please explain what "verified knowledge" means. The Rationale section does not really address this. While this is in the Guidelines and Technical Basis section, it defines it as "implies reliable confirmation." This should be clarified and put in the measures section."Imminent threat" should be defined so that it does not evolve into an enforcement issue."Notify the responsible control center" should be clarified so that it does not evolve into an enforcement issue.Application Guideline for R4 should contain provisions in the imminent threat procedure for notification of the land owner.M4 should provide examples of acceptable evidence.Requirement R5 This requirement does not include a reliability outcome. The requirement should be rewritten to include a reliability outcome.Requirement R6 The Rationale for R6 is that one year "seems to be reasonable." The SDT should address how this relates to the practice in place now, and whether it is consistent with current practice or is more or less than current practice. If inconsistent, the SDT should provide an explanation.The Rationale states the TOs should consider other factors that could warrant more frequent inspections. If so, the SDT should explain whether we are requiring them to do so if such factors exist.This requirement does not include a reliability outcome. The requirement should be rewritten to include a reliability outcome.Requirement R7 R7 is ambiguous; it is not clear how this could be enforced objectively. The rationale for the "flexible" plan indicates that the owner can delay work as long as it will not pose an "imminent threat." The SDT

Organization	Yes or No	Question 13 Comment
		should explain what the Compliance Enforcement Authority would look at to determine that the work that was delayed was not causing an “imminent threat.” The SDT should address whether it would ever be acceptable to delay work on a critical line (covered under R1).In Requirement R7, please explain what “execute a work plan” means. Did the SDT mean implement a work plan? As drafted, it could be read to just have one in place. The SDT should explain what “flexible” means. Does it mean there will never be a FAC-003 violation if you fail to implement the plan? The Rationale says the work can be deferred if it does not have the potential to become an imminent threat. Please explain. Corresponding clarification changes should be made to the VSLs for this requirement.Either M7 or the evidence retention for M7 needs to include the annual work plan. Without that the Compliance Enforcement Authority can’t determine if the plan was executed. The VSLs for R7 imply that the entire annual plan will be accomplished. . . not a “flexible” amount of the plan - the VSLs don’t line up with the use of the word “flexible.”According to the VSL Guidelines the VSLs should be stated in language that identifies the degree of noncompliance in language that identifies the amount that was noncompliant, rather than the amount that was compliant. VSLs for R6 and R7 are stated in terms of the % of the required performance that was compliant and should be rephrased. GuidelinesThe following guidance is offered in the Guideline section of the standard:Documentation or other evidence of the work performed typically consists of signed-off work orders, signed contracts, printouts from work management systems, spreadsheets of planned versus completed work, timesheets, work inspection reports, or paid invoices. Other evidence may include photographs, work inspection reports and walk-through reports.Documentation is required when the annual work plan is adjusted or not completely implemented as originally planned. The reasons for the deferrals or changes and the expected completion date of postponed work should be documented.This implies that all TOs should retain this evidence, yet the evidence is not identified in nearly this level of detain in the Measures section of the standard. In addition, no part of the requirement or measure is clear in indicating that documentation is required to support the need for a work plan adjustment. Evidence Retention The evidence retention periods specified don’t reflect the guidance in the SDT Guidelines. Should the evidence retention be the later of three years or three years from the last audit? The second paragraph should be stricken because it seems to contradict the first paragraph retention period.VSLsThe SDT should verify that the VSLs for Requirement 3 are properly calibrated.Administrative ProcedureThe Administrative Procedure does not require prompt reporting of sustained outages; rather it requires only a quarterly report. This appears to be less stringent than the current requirements as employed today.The SDT should explain what “blowing together” means, and how this is different from a tree that grows into a line.FootnotesFootnote 1 should be deleted or modified. It is only relevant in explaining the proposed modifications to the standard. In footnote 4 the word, “substantially” adds ambiguity.Guideline and Technical BasisIn the Guidelines and Technical Basis section, it states “Requirements 1 and 2 state if the TO observes vegetation within the distances prescribed in FAC-003 - Table 2 it is in violation of this Standard.” This is actually in the Measures 1 and 2 and not the requirements.General commentsThere seems to be a lot of information not captured in the Requirements but rather are in various other sections. The SDT should clearly delineate whether these other sections are considered part of the Standard or just informational.With the next posting of the standard, the drafting team should include the following four points for stakeholder review:1. Justification for selection of the applicable lines. 2. Table listing each FERC directive and stakeholder issue (from the Issues Database) associated with the standard and identification of how the

Organization	Yes or No	Question 13 Comment
		team addressed each of these3. Table listing each VRF and identification of how the proposed VRF meets both NERC criteria for setting VRFs and FERC's five Guidelines for approving VRFs4. Document identifying how the proposed VSLs meet both NERC criteria for setting VSLs and FERC's four Guidelines for approving VSLs.There is a significant concern with the use of the Gallet equations in this standard. This standard eliminates Clearances 1 and 2 from the previous version and replaces it with a single Minimum Vegetation Clearance Distance (MVCD) based on the Gallet equations. This approach reflects the most basic lowest common denominator and significantly lowers the bar versus the performance expected from the existing standard. Further, it would not appear that responsible entities would use the Gallet equations as the basis for the development of the vegetation management program. Additionally, whereas the multiple clearance zones provide an indicator of proactive vegetation management, the current proposal does not provide an equivalent demonstration of proactive performance. This approach appears inconsistent with Order 693 and the presentation of NERC standards to provide a defense in depth strategy, which is a fundamental outcome of the results-based standards process. Order 693 states in P24 that the "reliability mandate of Section 215 of the Federal Power Act....contemplates the prevention of incidents, acts, and events that would interfere with the reliable operation of the Bulk Power System." The SDT should consider adding more clarification to the draft standard and white paper describing the building blocks for determining how much vegetation management (trimming) needs to be performed based upon growth rate of vegetation and the time between trimmings to reflect a proactive approach.The SDT should consider the impact of moving the reporting requirement in the existing standard to the compliance section of the new standard. The team should consider the reporting of this activity on an exception basis within a pre-defined timeframe following the event. This approach would provide more timely awareness to the Regional Entity and NERC of an event than the quarterly reporting expectation, and provide opportunities for identification and implementation of mitigating strategies in a more timely manner. While this approach removes an administrative type requirement from the standard that is believed to provide a deterrent to responsible entities, the increased timeliness of reporting in an exception basis would provide greater benefit to the effort to maintain reliability.Transmission Line is a defined term. The SDT should consider using this term in place of "transmission line."The report identified in the administrative section of draft 3 of FAC-003 is really a "Periodic Data Submittal" used to assess compliance and does not belong in an administrative section of the standard - it belongs in the compliance section of the standard. "Periodic Data Submittals" is one of eight different compliance monitoring and enforcement processes that may be used to monitor and assess compliance. The eight processes are identified in the Uniform Compliance Monitoring and Enforcement Program of the North American Electric Reliability Corporation and should not be mixed in with other processes or procedures. Each standard must list the appropriate processes in the compliance section of the standard so that there is a clear understanding of the purpose of the data submittal.As drafted, FAC-003-2 applies only to Transmission Owners. It also should apply to Generator Owners. The SDT should explain whether the issues brought forward in the GO/TO Report been considered and are addressed as part of this revision.Please update the mapping document so that it compares the last version of the approved standard to the latest proposed version of the standard so that it is easy to compare the proposed standard to the standard that is in force now.

Organization	Yes or No	Question 13 Comment
Response:		
Utility Risk Management Corporation	Yes	Suggested Improvements to M1. and M2.The purpose of Requirements R1 and R2 is to require the prevention of vegetation encroachments within the MVCD. As made clear in the background and remaining FAC 003-2 requirements, the overarching intent of FAC 003-2 is to prevent sustained outages caused by vegetation that could lead to cascading. However, both M1 and M2 include real-time observations of encroachment into the MVCD as an automatic violation of R1 or R2, respectively (even though the violations may not result in penalty or fine). This is inconsistent with the "defense in depth" goal sought by the committee, as a real time observation using new technologies may in fact demonstrate that the Transmission Owner is in fact aggressively managing vegetation to meet the MVDC requirements and is discovering new encroachments and remediating them quickly and effectively and thereby is not in violation of the standard.Similar to imminent threats, remediation procedures should be permitted for encroachments as well and serve to make clear the observation is not automatically a violation. Classifying a real-time observation of an encroachment automatically as a violation of R1 or R2 penalizes a Transmission Owner for identifying vegetation threats, which are less severe than imminent threats. Under Requirement R4, the transmission owner is permitted to take appropriate actions to alleviate an imminent threat through short term corrective actions upon observation of any vegetation that is near to or is encroaching into the MVCD. (See FAC-003-2 Guideline and Technical Basis, Requirement R4). Considering the allowance for remedial action under Requirement R4 when facing a condition that is "likely to cause a Sustained Outage at any moment," it seems excessive to qualify a real-time observation of an encroachment as a violation of R1 or R2. We suggest a better approach is to modify M1 and M2 to allow for remedial action. Or, in the alternative, the standard should clarify that observations of encroachments using software-enabled technology, such as LIDAR coupled with work order management systems, do not constitute a "real time observation of an encroachment." First, by modifying M1 and M2 to allow for remedial action as suggested below will deal with the concern we raise:M1. Evidence of violation of Requirement R1 is limited to: o Real-time observation of encroachment into the MVCD which is not mediated in accordance with R4. o ... M2. Evidence of violation of Requirement R1 is limited to: o Real-time observation of encroachment into the MVCD which is not mediated in accordance with R4. o ... In the Alternative, "Real-Time Observation" Should be Clarified. As noted above, a real-time observation of an encroachment is evidence of a violation of Requirements R1 and R2. Observations in real time mean "an actual field observation or measurement of the conductor-to-vegetation distance and not a calculated determination of relevant positions." (See FAC-003-2 Guidelines and Technical Basis, Requirements R1 and R2) Given the current definition, it is not clear observations using software-enabled LiDAR would trigger violations and thereby would discourage the Standard's emphasis on preventing sustained outages or Cascading due to grow-ins. This may result in penalties for registered entities that are engaged in good faith activities to prevent sustained outages. The meaning of "real-time observation" should be clarified as to remove any adverse incentives for vegetation inspection and management. To implement this suggestion as an alternative to allowing remediation to prevent an observation from being an automatic violation, the definition could be reworded to state:"Real-time observation" means an actual field observation or measurement of the conductor-to-vegetation distance which is not performed under the regular Vegetation Inspection of Requirement R6 or annual vegetation work plans in accordance

Organization	Yes or No	Question 13 Comment
		with Requirement R7. Such observations do not include calculated determinations of relative vegetation positions. Conclusion:Adopting one or both of these proposed changes would help R1 and R2 measures more fully meet the goal of preventing overgrown vegetation and systemic failures triggered by flash over, as stated in the background section on page 6 of FAC-003-2. The current M1 and M2 use of real-time observations conflicts with the expectation that utilities engage in "defense in depth" measures. As the guidelines conclude regarding Requirements R1 and R2, the Transmission Owner is expected to have a cohesive vegetation management program for managing vegetation in such a manner as to maintain separation between conductors and vegetation. This is to function in conjunction with the imminent threat procedure to facilitate interim corrective action. "However, brief encroachments by falling vegetation are not considered to be a violation." Making the changes suggested above - coupled with the existing requirement that the utility mitigate an observation in accordance with the utility TVMP through a response schedule - thereby advance the goals of the standard and take away an impediment to aggressive defense in depth.
Response:		
SERC OC Standards Review Group	Yes	The requirements (R6 and R7) for inspections and the performance of work plans are part of a defense-in-depth approach and as such the TO is not depending on singular requirements to prevent sustained outages, therefore, the VRF for R6 and R7 should remain medium not high. We applaud the attempt to improve the readability and ultimate comprehension of reliability standards by changing to this new template. We have included some comments also made by the SERC Vegetation Management Subcommittee (VMS)."The comments expressed herein represent a consensus of the views of the above named members of the SERC OC Standards Review group only and should not be construed as the position of SERC Reliability Corporation, its board or its officers."
Response:		
SERC Vegetation Management Sub-committee	Yes	The requirements (R6 and R7) for inspections and the performance of work plans are part of a defense-in-depth approach and as such the TO is not depending on singular requirements to prevent sustained outages, therefore, the VRF for R6 and R7 should remain medium not high.
Response:		
GCPD	Yes	The standard should include only R1, R2 and the Clearance Table. Everything else should be in guidelines as to how you might comply with the standard. If R3 thru R7 remain in the standard then it is virtually the same as it exists today, just put in a different order.
Response:		

Organization	Yes or No	Question 13 Comment
CenterPoint Energy	Yes	The term "Active Transmission Line Right-of-way" (ATLROW) is not defined in sufficient detail in the Definition of Terms Used in the Standard section to know how to apply it to the Requirements and Measures. The Technical Reference merely depicts the relative position of energized conductors, but it does not show a graphical determination of the limits of the ATLROW. The ATLROW is missing a definable and determinable width in its current definition within the Standard which makes it an arbitrary term and does not allow for a clear and measurable expected outcome of each requirement. In several sections, the Standard relies on the specific determination of the physical width of the ATLROW to determine applicability of the requirements. The Vegetation Inspection definition refers to “on” an ATLROW. The Background section refers to “outside” the ATLROW. Table 1 refers to “within” and “on” the ATLROW. M1 and M2 refer to “inside” the ATLROW. R3 and M3 refer to “on” the ATLROW. The Administrative Procedure refers to “inside and/or outside” and “within” the ATLROW. The Guideline and Technical Basis section refers to “on or near” the ATLROW and the “limited” ATLROW “width”. It also says that, “The Transmission Owner should, therefore, endeavor to maintain its ATLROW to the full extent of its legal rights at all times in all cases.” Since the Standard does not currently define how a Transmission Owner is to determine the specific boundaries of the ATLROW, it would appear that the Transmission Owner is to make that determination on a case by case basis at its discretion. Should that not be the intent, we recommend the definition for the ATLROW to be, “A strip or corridor of land or aerial space that is occupied by energized transmission conductors with its operational clearance limits defined by the Transmission Owner’s specific legal rights but in no case less confining than the MVCD applied to the movement of the conductors within their Rating and Rated Electrical Operating Conditions.” This definition contains sufficient detail to determine the physical limits of the ATLROW, and it allows for vegetation management to apply within the full extent of the legal rights of the Transmission Owner while requiring a minimum area for vegetation management in undefined ROW’s to ensure Sustained Outages are minimized.M1 contains a reference to “real-time observation of encroachment into the MVCD” but does not explain who is to make the observation and where it is to be documented. If this is to be done by the Transmission Owner, then perhaps it should be a Measurement under R6 and recorded under M6.The language in R6 refers to inspecting “transmission lines” and Table 1 for R6 refers to inspecting “ROW”. Both areas should use consistent terminology.M1 and M2 have the potential for double jeopardy when a Sustained Outage occurs because the Violation Severity Level has an entry for an MVCD encroachment (which causes the outage) and another sister entry for the type of Sustained Outage. Some additional clarity in the application of M1 and M2 is necessary.R5 should include the exception stated in the Rationale text box to add clarity to the Requirement. R5 should read, “Each Transmission Owner shall take interim corrective action when it is temporarily constrained from performing planned vegetation work, where a transmission line is put at potential risk due to a constraint, except where the risk is avoided by implementing an alternate work methodology.” In the Guideline and Technical Basis section for R1 and R2 (page 15), there is a reference to records of “planned inspections” and “evidence” for no encroachment into the MVCD. This reference should be moved to R6 where the inspections are required. If R6 is intended to provide evidence for M1, then that should be stated in R6.In the Guideline and Technical Basis section for R6, the reference to the VSL calculation units and the example units should be consistent-the example should use “line miles”, not just “miles”.Table 2 contains several “*” in the voltage column that are not defined.In the Technical Reference on page 21, the following sentence should be deleted, “If constraints cannot be

Organization	Yes or No	Question 13 Comment
		overcome and if design clearances are sufficient, an exception to the Transmission Owner's 10-foot guideline might be made." The Technical Reference should not provide examples of granting exceptions as they may be misinterpreted as an endorsement by NERC to increase the planting of trees near and under transmission lines without taking into account several other factors such as ROW access, changing design conditions, future line additions and rebuilds. The inclusion of modifications to the wire zone on page 24 regarding the wire-border zone model should be re-examined to be sure they are specific to an environmental conservancy requirement while allowing for construction and inspection access as needed.In the Technical Reference on page 22 under Planning and Implementation, delete the sentence, "While designed primarily with transmission systems in mind, t is also applicable to distribution projects." The Standard should not imply its applicability to distribution systems since it is intended only as a transmission standard.In the Technical Reference, the last sentence on page 26 starting with "Appropriate actions..." should be moved to R5 where it applies. In general, the proposed FAC-003-2 has gone FAR beyond what was contemplated by the Commission in FERC Order 693 and equates to a total re-writing of the Standard for no apparent reason. The Commission's determination dealt with the following areas: (1) applicability; (2) inspection cycles; and (3) minimum clearances on National Forest Service lands. For instance in Paragraph 729, the Commission states, "As proposed in the NOPR, the Commission approves Reliability Standard FAC-003-1 with no proposed modification on the issue of clearances. The Commission reaffirms its interpretation that FAC-003-1 requires sufficient clearances to prevent outages due to vegetation management practices under all applicable conditions...." Rewriting the minimum clearances introduced a new set of confusing definitions, and further burdens the Transmission Owners with new documentation requirements with little if any benefit when compared to the Clearance 2 concept in the existing Standard.A preferred approach would have been to incorporate the following few items into the existing Standard: (1) the RC versus the RRO; (2) the designation of a specific inspection frequency; (3) the Gallet equation; and (4) the applicability to National Forest Service lands.
Response:		
Ad Hoc Group subteam formed to review draft standard	Yes	The wording in R7 is troublesome. We believe that the process for developing the annual work plan is imbedded in R3. As discussed in question 2, demonstrating capability to actually perform those actions necessary to ensure no vegetation encroachments occur within the MVCD is the primary concern. Deferring such work into the next calendar year appears contrary to this concern and neutralizes the defense-in-depth concept by diminishing the imminent threat requirement of R4 to a primary means of defense. While we don't want to incent vague annual work-plans, we also don't want to remove the imperative that the work must be done.
Response:		
Nebraska Public Power District	Yes	Under section 4.3.1 add in ice storms as one of the force majeure events. This type of event may impact many TOs and should be included.

Organization	Yes or No	Question 13 Comment
Response:		
Oncor Electric Delivery	Yes	Use of the Gallet equation to determine the minimum gap between vegetation and conductor to prevent sparkover seems to be appropriate. No utility should be managing to this distance but developing a distance beyond this would be arbitrary. This is a reliability standard not a worker safety or vegetation management practices standard. As Federal agencies and other entities are interpreting the Standard to limit normal vegetation management efforts, the FERC should develop and adopt an overarching memo allowing utilities to maintain vegetation under any agency jurisdiction as a utility manages vegetation along the entire right-of-way corridor.
Response:		
Western Area Power Administration - Upper Great Plains Region	Yes	WAPA - UGPR would like to see "ice storms" specifically mentioned in Section 4.3.1. Having additional clarification as to what is considered a "major storm" would also be helpful.
Response:		
Bonneville Power Administration	Yes	We believe the minimum vegetation distances are very granular and nearly un-measurable in real life. When a person considers the table to be a list of minimums it seems that the regulated entities, or land owners would want the distances to be as close to the wire as possible. We would not want a non-technical manager to believe that any small distance outside of the noted distances is ok.
Response:		
Omaha Public Power District	Yes	We have concern over establishing proof an outage is exempt due to fresh gale. A fresh gale, or even a localized thunderstorm, can easily produce wind gusts that exceed the lines rated capacity for blow out. If an outage occurs under these conditions, the standard provides an exemption under Section 4.3.1, but there is often no way to empirically prove conditions exceeded the lines normal operating conditions. How should a utility handle these situations?
Response:		
Southen Company	Yes	We have concern over establishing proof an outage is exempt due to fresh gale. A fresh gale, or even a localized thunderstorm, can easily produce wind gusts that exceed the lines rated capacity for blow out. If an outage occurs under these conditions, the standard provides an exemption under Section 4.3.1, but there is often no way to empirically prove conditions exceeded the lines normal operating conditions. How should a utility handle these

Organization	Yes or No	Question 13 Comment
		situations? Please note there is a typographical error in the third paragraph on page 15, "...encroachment violation is not be a violation..."We would like to thank the Standard Drafting Team for their hard work. The time and effort they have put into developing this standard is obvious.
Response:		
Dominion	Yes	While not related solely to this standard, we suggest that no future standard be effective until approval has been granted by the applicable regulatory authority. Having an effective date that differs from the mandatory date is causing confusion/chaos on the part of the applicable registered entity(ies). With the current process, it is possible to have a standard that is mandatory conflict with a superseding newer version (or a new standard that contains requirements meant to supersede those in the mandatory standard). Applicable entity(ies) may not be able to comply with both when this is true, and may not be able to take steps necessary to transition from mandatory requirement to superseding requirement without becoming non-compliant.
Response:		
Westchester County Board of Legislators		1. Bulk Electricity System NOPR – FERC recently issued a notice of proposed rulemaking to revise the definition of "bulk electric system" (BES) to include all transmission facilities with a rating of 100 kV or above. 130 FERC ¶ 61,204 (Mar. 18, 2010). If approved, such revision might significantly increase the amount of transmission facilities subject to standard FAC-003. In areas with dense residential and commercial development, this revision will exacerbate existing conflicts between homeowners, municipalities, affected transmission owners (TOs), and regulating agencies. As described in comments below, compliance with the existing or perceived requirements in FAC-003 has produced numerous conflict in areas of dense development and narrow rights-of-way between homeowners, TOs, and regulating agencies because of economic, environmental, and aesthetic impacts. If FERC adopts the proposed BES definition, then the FAC-003 standard (current 001 and draft 002) should be extensively reviewed by the drafting team to evaluate the amount of affected facilities and the need for standard revision to avoid as far as possible further conflicts. 2. "Background" Section 5 – The draft adds a new section titled "Background" (Section 5). The existing standard FAC-003-1 does not include a similar section. This narrative section appears to provide interpretation on the rationale for a vegetation management reliability standard and to clarify the standard applicability. This discussion may be more appropriate in the accompanying technical reference, which describes and clarifies standard FAC-003. While identifying overgrown vegetation as cause of major outages and operational problems, this section fails to state that many other causes can lead to Cascading events. Indeed, of the many NERC reliability standards, only one, FAC-003, concerns vegetation management. While the August 2003 blackout was initiated by a tree contact, there were numerous other factors that caused this power outage to spread to over a dozen states. Section 5 should therefore be revised to clarify that FAC-003 is only one of many factors that can lead to a large-scale grid failure.

Organization	Yes or No	Question 13 Comment
		3. Standard Applicability Across Land Uses – Standard FAC-003-1 and the proposed draft do not vary in applicability, even though the types of land uses within and adjacent to transmission facilities vary widely. Among certain land uses, such as dense residential development, this can lead to substantial conflict between the TO and adjacent landowners, especially concerning environmental, aesthetic, and economic impacts. The Westchester County Board of Legislators identified such problems in its recent resolution, available at http://meetings.westchesterlegislators.com/Citizens/FileOpen.aspx?Type=4&ID=2828&AgencyName=WestchesterCounty . Notwithstanding the reliability imperative expressed by Congress in enacting Section 1211 of the 2005 Energy Policy Act, the implementation of reliability standard FAC-003 has produced significant challenges for all parties in suburban areas. In particular, surburban area homeowners, often on small parcels, that abut or are near to transmission rights-of-way have experienced dramatic impacts upon their properties and property values when TOs exercise their "full extent of legal rights at all times and in all cases", as stated on page 18 of the draft. Therefore, the development of standard FAC-003 must consider this backdrop and select requirements and accompanying text that provide some balancing of electric reliabilty with environmental and economic impacts. As presently written, the draft does not acknowledge such balance. 4. Varying Conditions – Requirement R1.2.1 of Standard FAC-003-1 identifies numerous local conditions that should be considered in determining appropriate clearance distances. This balanced evaluation of factors should be retained in FAC-003-2. 5. Full Legal Rights – The draft encourages TOs to exercise full legal rights at all times and in all cases. This language is not included in present standard FAC-003-1. As noted above, electric reliabilty and TO compliance with FAC-003 must not preclude other important societal factors. The language encouraging full exercise of legal rights should be removed from the draft.
Response:		
KCPL	Yes	**Requirement 4:** Recommend the SDT consider modifying R4 to make it clear the requirement applies to that which is within the Right Of Way (ROW) for the transmission facility. Obviously, the Transmission Owner has no authority or control beyond the ROW. This is also an audit concern regarding "triggering" this requirement on a subjective evaluation of "imminent threat". How does a Registered Entity, Regional Entity or Auditor determine what constitutes an "imminent threat"? This will be a matter of opinion and makes this a difficult requirement regarding compliance when a difference of opinion arises. In addition, as proposed, this requirement does not address the need to take immediate corrective actions to mitigate an imminent threat. The previous FAC-003 Standard included taking action to remove the "imminent threat" which is not included in this proposed version 2. What was the intention of the SDT in this regard? Recommend the SDT

Organization	Yes or No	Question 13 Comment
		consider language to include taking action to remove the imminent threat. **<u>In the “Guideline and Technical Basis” section:</u>** 1. Under R6: believe the word “per” is missing in the first sentence of the third paragraph between “once (per) line”. 2. Under R7: concerned regarding the use of words such as “never”, “at all times”, and “in all cases” in the bulleted items with paragraph 6 in this section as a guiding document. This is the kind of material that is creeping into compliance audits and recommend softening this language. **<u>Violation Severity Levels</u>** 1. Do not agree with the zero tolerance for encroachments that do not result in a service interruption for R1 and R2. 2. Not notifying the Control Center should be a HIGH and not removing the imminent threat should be a SEVERE.
Response:		

Consideration of Comments on 3rd Draft of FAC-003-2 Transmission Vegetation Management — Part of Project 2007-07 Vegetation Management

The Vegetation Management Standard Drafting Team and the Standards Committee's Process Subcommittee thank all those who submitted comments on the 3rd Draft of FAC-003-2 Transmission Vegetation Management. The standard was posted for a 30-day public comment period from March 1, 2010 through March 31, 2010. Stakeholders were asked to provide feedback on the standard and its proposed format through a special Electronic Comment Form. There were 13 questions posed, and most of the questions were developed to collect stakeholder feedback on the proposed "results-based format" for the standard. There were 55 sets of comments, including comments from more than 100 different people from over 60 companies representing 8 of the 10 Industry Segments as shown in the table on the following pages.

On January 14, 2010, the NERC Standards Committee endorsed the use of Project 2007-07 Vegetation Management as the prototype for the proof-of-concept for using the results-based criteria for developing a reliability standard. The results-based initiative is intended to focus the collective effort of NERC and industry participants on improving the clarity and quality of NERC reliability standards by developing performance, risk and competency-based requirements that accomplish a reliability objective through a defense-in-depth strategy, while eliminating documentation-driven requirements that do not have an impact on bulk power system reliability.

This report provides a copy of each of the questions that was posted for stakeholder comment with the third draft of FAC-003-2, a summary indicating how the drafting team or the Process Subcommittee used stakeholder comments submitted in response to that question, and the comments received. The comments may be viewed in their original format at the following site:

http://www.nerc.com/filez/standards/Vegetation-Management_Project_2007-7.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Gerry Adamski, at 609-452-8060 or at gerry.adamski@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

1. **In response to comments received regarding potential for "double jeopardy" and to provide differentiation between transmission lines designated as having IROLs and Major WECC transfer paths from those that are not, the SDT consolidated requirements R4 though R8 found in the August 2009 draft of FAC-003-2 into two requirements in the latest draft of FAC-003-2 (new requirements R1 and R2). Do you agree? Please explain.**

Summary Consideration: There were 43 comment forms indicating agreement with the proposed Requirement R1 and R2 and 8 comment forms indicating disagreement.

The major comment issues covered:

- The differentiation of IROL/WECC Major Transfer Path and other lines subject to this standard is defensible in the context of VRF. While vegetation outages to lines covered in R2 are preventable and as such violations, the practical impact to the BES is no different than an outage caused by other factors
- WECC Transfer Path criteria should not be included in a national standard.

The VMSDT considerations for the major comment issues are:

- The new R1 and R2 requirements have eliminated the double jeopardy problem. NERC's Standards don't allow two VRF's for the same requirement so the SDT created two requirements with different VRF's.
- The VM SDT believes that WECC criteria for Major Transfer Paths is not applicable in other RE's and assumed this to be common knowledge.

Some minor comment issues are:

- Encroachment of the MVCD should not be a violation. A sustained outage should be the grounds for a violation.
- MVCD should be defined.
- Lines which cannot impact the BES, regardless of voltage, should be exempted from the standard

The VM SDT considerations for the minor issues are:

- The team has concluded encroachment into the MVCD or 'spark-over' distance is a clear indication of improper or negligent vegetation management and further that such encroachment creates an imminent threat condition.
- MVCD is defined in both the Requirement and the Rationale.

FERC has directed the ERO to develop a methodology or test to designate "operationally significant" facilities in the March 18, 2010 Order 733. The test is intended for application in PRC-023-1; however it can be extended for FAC-003-2 use.

Organization	Yes or No	Question 1 Comment
Westchester County Board of Legislators		Do not have enough knowledge on this to provide response.

Organization	Yes or No	Question 1 Comment
Nebraska Public Power District	No	Although it does provide some flexibility to the TO, it will be difficult to determine an encroachment into the MVCD. It would easier to implement if R1 and R2 were only applicable when there was an outage on the transmission system.
Dominion	No	Dominion does not agree with the inclusion of facilities that WECC designates as 'major transfer paths' in a continent-wide standard. We suggest that, if the SDT wishes to include such reference and these facilities are meant to be treated or synonymous with either IROL or SOL, that the SDT add a proposal to adopt and define a suitable term for inclusion into the Glossary of Terms
Cleco	No	Encroachment into the MCVD should require the owner to take immediate corrective action to mitigate the threat. Such an encroachment should not be reportable as a violation. Owners may be hesitant to communicate possible vegetation threat conditions to the TOP or proper authority if they believe it will be reported as a violation. We recommend the SDT consider modifying the measure for R1 and R2 to be applicable only in the interruption of the transmission facility.
NERC Staff (12 staff members)	No	NERC Staff does not see a need to have two requirements (R1 and R2) which differentiation between transmission lines designated as having IROLs and Major WECC transfer paths from those that are not with two different Violation Risk Factors. The standard as drafted applies to all 200kv and above lines. The Violation Risk Factor for all 200 kV and above lines should be "High". R2 should be deleted and R1 should be rewritten to be:R1. The Transmission Owner shall prevent vegetation from encroaching within the Minimum Vegetation Clearance Distance (MVCD) of applicable Transmission line conductors to avoid a Sustained Outage.
Xcel Energy	No	Requirements 1 & 2 are identical except for their applicability (R1 for IROL elements and elements in the WECC Transfer Paths; R2 for all other lines =>200 KV). It is not readily apparent as to why there is a need to distinguish between the two. Referencing the Table 2 "VRF" and "VSL" matrix indicates that R1 has a "High" VRF and R2 has a "Medium" VRF. If this is the only reason, then consider adding, at a minimum, a "Rationale" box explaining that reasoning.Also, the definition of MVCD needs to be a defined term or included in R 1 & 2, e.g., "Minimum Vegetation Clearance Distance is the calculated minimum distanced stated in feet (meters) to prevent spark-over between conductors and vegetation for various altitudes and operating voltages as set forth in Table 2." See comments to # 7 and # 13.
Arizona Public Service Company	No	This is a reliability standard for 230 kV and above and those lower voltages designated by the RRO. An outage is an outage and the utility should be held accountable no matter if they are or are not designated.
SERC OC Standards Review	No	While we agree with the development of a second requirement to provide for the distinction between line segments that are critical for reliability, in R1, a regional distinction should not be embedded in a national

Organization	Yes or No	Question 1 Comment
Group		standard. We also strongly disagree that perfect compliance with R2, as stated, would improve reliability. If a line is operated to avoid projected post contingent overloads, then the tripping thereof due to any cause has no effect on BES reliability. A more prudent approach for the lines covered by R2 could be the requirement to achieve 3 sigma or 4 sigma performance over a year's time. Requirement 2, as stated, is not cost effective, and may produce an unjust and unreasonable outcome to rate payers.While this draft clarifies (from version FAC-003-1) that sustained outages are compliance violations and eliminates the "double jeopardy" which was errantly introduced in the last draft of FAC-003-2 (when sustained outages were clearly defined as compliance violations), we suggest that the team adjust R2 as previously mentioned. This draft provides a mechanism to address the difference in outages that have impact to grid reliability from those that have an impact only to local lines and associated customer reliability. The use of observed MVCD as a violation and in the violation severity level matrix: o drives the right behaviors for improving reliability (by proactively identifying and removing vegetation before it can become an imminent threat or cause an outage) o eliminates the need to perform detail engineering/surveying/theoretical calculations before cutting vegetation, o formalizes the informal interpretations that have resulted from FAC-003-1 enforcement and o allows the vegetation field operations to focus on facts and remain practical rather than theoretical.
KCPL	No	The measures for R1 and R2 are zero tolerance for encroachments into the MVCD that did not result in a "contact" with the transmission facility. Considering the substantial number of miles of transmission involved, the complexities in anticipation of vegetation growth with numerous growth variables, vegetation management limitations imposed by other regulations or requirements, and unexpected transmission events that require substantial efforts regarding physical restoration, it is not reasonable or practical for the measures here to include encroachments that do not result in an interruption of transmission service. Recommend the SDT consider modifying the measures for R1 and R2 to be applicable only in the interruption of a transmission facility.
American Transmission Company	Yes	
Bonneville Power Administration	Yes	
Central Maine Power, Iberdrola USA	Yes	
City of Tallahassee (TAL)	Yes	
Consumers Energy	Yes

MRO's NERC Standards Review Subcommittee	Yes	1. NSRS agrees with the revisions that the drafting team has made and agrees with the combining of four requirements into two. NSRS prefers the MVCD methodology to the minimum clearance distance

Organization	Yes or No	Question 1 Comment
		methodology due to the fact that there is only one measurement to contend with versus two.2. If a company has a line with a standing IROL could they be found in violation of both the requirements R1 and R2? If so, the NSRS recommends combining R1 and R2.3. Please clarify the need for R1 and R2. Why were lines with IROL separated out from lines without IROLs?
American Electric Power (AEP)	Yes	American Electric Power agrees with this change.
IRC Standards Review Committee	Yes	Because real-time observation in Measurement 1 would require an actual measurement for comparison to Table 2 to be defendable as a violation, the SRC suggests replacing observation with measurement. The SRC would suggest deleting the phrase "to avoid a sustained outage" as that phrase does not add any clarity to either of the two requirements. There do not seem to be any encroachments that the SDT will allow. If there are encroachments that are considered allowable, who is responsible for making that consideration? And what would be considered a "sustained" outage?Minimum Vegetation Clearance Distance (MVCD) is a capitalized term used in Requirements 1, 2 and 7 but is not defined in the NERC Glossary of Terms Used in Reliability Standards nor is a definition proposed in this standards action. Either a definition should be proposed or the capitalization should be removed.
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG, CNE & CENG)	Yes	BGE agrees with the consolidation of R4 through R8 into two requirements in the FAC-003-2 draft.
Ameren	Yes	Creating two specific requirements removes the potential for double jeopardy.
Southern California Edison Company	Yes	SCE agrees that the consolidation of Requirements R4-R* resolves the "double jeopardy" issue.
Tampa Electric Company	Yes	The change in the draft serves to consolidate, clarify and remove the “double jeopardy” as stated above. This is an improvement in the standard.
CenterPoint Energy	Yes	The differentiation in the Violation Risk Factor for R1 versus R2 seems appropriate.
Consolidated Edison Company of New York, Inc.	Yes	The elements that comprise IROLs must be clearly communicated to each Transmission Owner and must be consistent across North America.
Orange and Rockland Utilities, Inc.	Yes	The elements that comprise IROLs must be clearly communicated to each Transmission Owner and must be consistent across North America.

Organization	Yes or No	Question 1 Comment
Northeast Power Coordinating Council	Yes	The most recent draft of the standard consolidated R4-R8 results in clearer requirements that meet the results based criteria and addresses the “double jeopardy” issue. However, there is concern with the differentiation of lines designated as having IROLs and Major WECC transfer paths from those that are not, as is proposed in the Applicability section 4.2 and subsequently in requirements R1 and R2. As stated in the background section: “This Standard focuses on transmission lines to prevent those vegetation related outages that could lead to Cascading. It is not intended to prevent customer outages due to tree contact with lower voltage distribution system lines. For example, localized customer service might be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. However, this Standard is not written to address such isolated situations which have little impact on the overall Bulk Electric System.” It must be recognized that in some systems, outages on lines operated at voltages greater than 69 kV, 200 kV for example, have localized impact only and do not lead to Cascading. Concurring with the background, a line should be subject to this standard only if a vegetation related outage “could lead to Cascading”, or could have a “significant impact” on the system. It does not depend on whether it is an IROL line or not.A performance based methodology is used in NPCC to determine if an outage on a line can cause a “significant impact” on the system. The lines identified by this methodology are not identified according to their voltages, but rather by their impact on the system, regardless of the voltage.The introduction of “two” subcategories of BES - an IROL and a non-IROL - appears to just differentiate between high VRF and medium VRF. Furthermore, in the Applicability section, the IROL “variable” is mentioned only for lines operated below 200 kV. What about lines operated at or above 200 kV lines? Why not have a single Application item stating: overhead transmission lines operated at any voltage whose outages have a significant impact on the system? A Table could define what is considered “significant”.There are standards for vegetation management on the distribution system, and there are standards for higher voltage systems. This standard should focus on lines with high impact on the system when a vegetation outage occurs.Utilities will not let the vegetation encroach on other lines, but an importance will be given to vegetation management on “critical” lines for the reliability of the whole system. On other lines, if an outage occurs, it will have localized impact.A “Results-Based Reliability Standard” should first focus on the “critical” lines.If it is the intent of NERC or the industry to ensure that a vegetation outage causes no more than a fixed level of load loss, it should say so in a requirement.If the IROL “variable” is retained, identification of the transmission elements that comprise IROLs must be officially communicated to the Transmission Owners. This must be done either through a requirement in this, or another standard.
Progress Energy Carolinas	Yes	The previous version (FAC-003-1) was not developed with individual outages listed as a requirement or a violation. The previous drafts of version 2 (FAC-003-2) have improved on FAC-003-1 by defining sustained outages from within the Right-of-Way as violations. However, the recent drafts of FAC-003-2 also introduced a potential for ‘double jeopardy’ when clarifying that sustained outages and MVCD encroachments were (‘binary’) requirements/violations. This latest draft clarifies the expected performance into two concise requirements that provide for differentiation in severity levels and risk factors, eliminating the unintended

Organization	Yes or No	Question 1 Comment
		‘double jeopardy’. The inclusion of the use of observed MVCD as a violation of R1/R2 and in the violation severity level matrix drives the right behaviors for improving reliability (by proactively identifying and removing vegetation before it can become an imminent threat or cause an outage) , eliminates the need to perform detail engineering/surveying/theoretical calculations before cutting vegetation, formalizes the informal interpretations that have resulted from FAC-003-1 and allows the vegetation field operations to focus on facts (and remain practical rather than theoretical). Progress Energy believes that the R1 and R2 changes to this draft are a significant improvement over FAC-003-1. This version draft: clarifies real-time MVCD and sustained outages as a requirement; provides for differentiation between grid impacting outage events and outage events to lines primarily associated with customer reliability; introduces a performance barrier/defense that is fact based - eliminating the need to determine compliance through theoretical calculations that rely on design assumptions (e.g., mechanical behavior of aged conductor), prior design criteria/code versions (i.e., code clearances in effect at time of design) and detail site measurements (e.g., “survey” quality measurements and local environmental conditions at time of measurement/event).
JEA	Yes	The simplification and clarification improves the ability of Registered Entities to comply thereby enhancing reliability.
Independent Electricity System Operator	Yes	This change addresses the perceived “double jeopardy” risk.
Oncor Electric Delivery	Yes	This does not reduce the Standards effectiveness on the cascading issue or discount any outage on applicable lines subject to this Standard in the electric Transmission system.
East Kentucky Power Cooperative, Inc.	Yes	This draft adequately addresses the "double jepoardy" issue. The use of the Minimum Vegetation Clearance Distances simplifies recommended maintenance process for field personnel and eliminates the need to perform costly and time consuming engineering studies prior to trimming or removing vegetation.
SERC Vegetation Management Sub-committee	Yes	This draft clarifies (from version FAC-003-1) that sustained outages are compliance violations and eliminates the “double jeopardy” which was errantly introduced in the last draft of FAC-003-2 (when sustained outages were clearly defined as compliance violations). This draft provides a mechanism to address the difference in outages that have impact to grid reliability from those that have an impact only to local lines and associated customer reliability. The use of observed MVCD as a violation and in the violation severity level matrix: o drives the right behaviors for improving reliability (by proactively identifying and removing vegetation before it can become an imminent threat or cause an outage) o eliminates the need to perform detail engineering/surveying/theoretical calculations before cutting vegetation, o formalizes the informal interpretations that have resulted from FAC-003-1 enforcement and o allows the vegetation field operations to focus on facts and remain practical rather than theoretical.

Organization	Yes or No	Question 1 Comment
Western Area Power Administrtaion	Yes	This is a very efficient and logical consolidation of requirements.
Western Area Power Administration - Upper Great Plains Region	Yes	This is not a critical issue for the WAPA - UGPR.
Tennessee Valley Authority	Yes	This method effectively recognizes the difference in reliabilty risks among various lines based on their value to the transmission grid.
Entergy Services	Yes	We agree that R1 and R2 are beneficial, but believe that they should be explained in greater detail for much greater clarity to reflect their intent. Our understanding is that R1 applies to ALL IROL's and ALL Major WECC Transfer Path lines, regardless of voltage, and R2 is centered around ALL lines operated at voltages 200 kV and above but are not classified as IROL/WECC lines. Our understanding of the term "applicable line conductor" in R2 refers back to the facilities defined in Facilities - Section 4.2 and as modified by the phrase in R2: "which are not elements of an IROL and are not a Major WECC transfer path, (operating within Rating and Rated Electrical Operating Conditions)". However the appropriateness of our assumed reference back to Section 4.2 and the modification contained in R2 is not clear. It also is not clear that the term "applicable line conductor" in R2 is the same as "applicable line conductor" in R6. We suggest the term "applicable line conductor" be specifically defined as that term is intended to be applied in R2, and the term "applicable line conductor" be defined as that term is intended to be applied in R6.
FirstEnergy	Yes	We agree that the new R1 and R2 alleviate the potential double jeopardy issue as well as differentiate the high and medium risk factor transmission lines. However, we offer the following comments and suggestions for improvement:It is not clear how the Transmission Owner (TO) will determine which lines are associated with IROLs. Upon reviewing standard FAC-014 Req. R5, which requires the communication of SOLs and IROLs, the required communication of IROLs to the TO is not specified. There needs to be a tie between this standard and the FAC-014 standard, which will require a revision to FAC-014. Unfortunately, this issue will create a gap if FAC-014 is not revised and submitted to FERC in parallel with the submittal of FAC-003-2 to FERC. This may require immediate action such as an urgent action SAR or other appropriate actions.If our suggestion to revise FAC-014 is not possible at the present time, then we suggest an alternative course of action to include language in R1 of FAC-003 to aid the TO in obtaining the information regarding lines associated with IROLs. We propose adding the following sentence to R1: "The Transmission Owner can request information regarding transmission lines associated with an IROL from its Planning Coordinator."
Ad Hoc Group subteam formed to	Yes	We understand the differentiation to be around the intent that those transmission lines designated as having IROLs and Major WECC transfer paths pose a more significant threat to the reliability of the BES and that

Organization	Yes or No	Question 1 Comment
review draft standard		encroachment of the MVCD in these cases are relatively more significant. We suggest that this be clarified in the rationale.

2. **The results-based reliability standard criteria focus on striving to achieve a portfolio of performance-based, risk-based, and competency-based mandatory reliability requirements that provide an effective defense-in-depth strategy for achieving an adequate level of reliability of the bulk power system in lieu of prescriptive requirements. Consequently, the SDT revised R1 and its subparts found in the August 2009 draft of FAC-003-2 in favor of the text in the latest draft of FAC-003-2 (new requirement R3). Do you agree? Please explain.**

Summary Consideration: There were 41 comment forms that indicated agreement with revising Requirement R1 found in the August 2009 draft of FAC-003-2 in favor of the text in the latest draft (new requirement R3) and 12 forms indicating disagreement.

The major comment issues covered:

- Several respondents felt R3 lacked clarity and needed more definition. However there were a large number of commenters who specifically pointed out an appreciation for the requirement being less prescriptive and allowing the Transmission Owner flexibility in developing its program.
- Several respondents felt encroachment of the MVCD should not be a violation.
- There were several concerns raised with citing the Rating and Rated Conditions to describe the conditions the Transmission Owner should use to develop its clearances and avoid encroaching into the MVCD.
- The term “Bulk Power System” should not be used in this Requirement.

The VM SDT considerations for the major comment issues are:

- Due to the large number of respondents who expressed a positive opinion of eliminating prescriptive items in R3 using the Results-based approach the SDT felt R3 is appropriate as written.
- The team has concluded encroachment into the MVCD or ‘spark-over’ distance is a clear indication of improper or negligent vegetation management and further that such encroachment creates an imminent threat condition.
- The team has further described Rating and Rated Conditions in the Guideline and Technical Basis Section under Requirement R3.
- This term “Bulk Power System” has been removed from every instance in the Standard.

Some minor comment issues are:

- Make Standard dependant on R1 and R2 only. Remove all other requirements.
- Add NESC clearance requirements to R3.

The VMS SDT considerations for the minor comment issues are:

- One of the tenets of the Results-based framework is a set of building blocks which support each other. While R1 and R2 are the ultimate test of reliability they are an insufficient number of building blocks for an Results-based Standard.
- While adding NESC clearance requirements to R3 may clarify what is needed to develop the document, the SDT felt that Rating and Rated Conditions adequately cover this.

Organization	Yes or No	Question 2 Comment
Tampa Electric Company	No	A more in-depth technical review of this requirement is required. Our response is predicated upon the following quote from the draft standard; “...considering all possible locations the conductor may occupy assuming operation within Rating and Rated Electrical Operating Conditions.”
NERC Staff (12 staff members)	No	As written, R3 does not provide enough clarity as to what should be included in a documented transmission vegetation management program. R3 should be expanded to include what should be included in the transmission plan. Such as:R3. Each Transmission Owner shall have a documented transmission vegetation management program that describes how it conducts work on its Active Transmission Line Rights of Way to avoid Sustained Outages due to vegetation, considering all possible locations the conductor may occupy assuming operation within Rating and Rated Electrical Operating Conditions. The transmission vegetation management program shall:3.1 Specify the methodologies that the Transmission Owner uses to control vegetation.[1] 3.2 Specify a Vegetation Inspection frequency of at least once per calendar year that takes into account local[2] and environmental factors. 3.3 Require an annual work plan that identifies the applicable lines to be maintained and associated work to be performed during the year. It shall be flexible to adjust to changing conditions and to findings from Vegetation Inspections. Adjustments to the plan within the year are permissible. The plan shall take into consideration permitting and scheduling requirements from landowners or regulatory authorities. It shall support the objectives of the transmission vegetation management program and utilize the methodologies outlined in the transmission vegetation management program. 3.4 Require a process or procedure for response to imminent threats[3] of a vegetation-related Sustained Outage. The process or procedure shall specify actions which shall include immediate communication of the threat to the Transmission Operator or proper operating authority. The process or procedure shall specify what conditions warrant a response.3.5 Specify an interim corrective action process for use when the Transmission Owner is constrained from performing vegetation maintenance as planned. 3.6 Specify the maintenance approach used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that Table 1 clearances in Attachment 1 are never violated. The maintenance approach shall consider the sag and sway of the conductor throughout its operating range under rated conditions.[1] ANSI A300, Tree Care Operations - Tree, Shrub, and Other Woody Plant Maintenance - Standard Practices, while not a requirement of this standard, is considered to be an industry best practice.[2] Local factors include treatment cycle, extent and type of treatment, and their relationship to the normal growth rate.[3] The term “imminent threat” refers to a vegetation condition which is placing the transmission line at a significant risk of a Sustained Outage. Refer to Technical Reference for examples of imminent threat procedures and conditions for implementation.
Consumers Energy	No	Consumers Energy strongly disagrees with the MVCD as presented in this version of the standard. These distances do not provide an adequate safeguard to prevent outages since the conductor position relative to the vegetation is sensitive to electric load and wind at any particular moment while vegetation height is not. Measurements M1 and M2 require real-time observation of a violation of MVCD to be reportable. As

Organization	Yes or No	Question 2 Comment
		presented, vegetation growing beneath the conductor with a clearance of MVCD + 1 foot is not reportable. However, this same conductor may sag due to load increase or move due to wind displacement within hours of the real-time observation. If great enough, the sag or displacement may move the conductor in contact with the vegetation resulting in an outage just hours after being deemed compliant.At a minimum the MVCD should be designed to provide the Gallet clearance distance at maximum sag or wind displacement (whichever is greater) at all times. No matter when the line is cleared of vegetation or inspected for vegetative conditions, if the enhanced MVCD is being met an outage cannot occur until further vegetative growth occurs. Furthermore, for line clearing operations, tree crews do not and cannot determine in the field the maximum potential sag or wind displacement to know how much vegetation to clear. They require much clearer instructions with a set amount of clearing distance to obtain at the time of work. This distance must account for maximum sag, wind displacement and the Gallet distance at a minimum.
Cleco	No	Encroachment into the MCVD should require the owner to take immediate corrective action to mitigate the threat. Such an encroachment should not be reportable as a violation. Owners may be hesitant to communicate possible vegetation threat conditions to the TOP or proper authority if they believe it will be reported as a violation. We recommend the SDT consider modifying the measure for R1 and R2 to be applicable only in the interruption of the transmission facility.
GCPD	No	Grant believes that R1 and R2 should be the entire standard and the rest of the requirements should be in guidelines and supplementary materials to assist in meeting the two results based requirements. We understand that some risk-based and competency based requirements are necessary for some standards. Not this one. No grow-in caused outages is the objective. Requiring a specific plan does not show competency, it just shows you have a plan. Feels very much like the existing standards. "Show us your Documentation".
Northeast Power Coordinating Council	No	R3 specifies "...considering all possible locations the conductor may occupy assuming operation within Rating and Rated Electrical Operating Conditions." Although both "Rating" and "Rated Electrical Operating Conditions" appear in the NERC Glossary, inspection of these definitions shows that they are very vague, and "Rated Electrical Operating Conditions" uses the word "reasonably", a term FERC has previously indicated as being unacceptable. From a practical standpoint this seems to allow too much latitude to an entity to do the least amount of trimming and not consider the extra sag and swing caused by some of the more extreme operating conditions that "may" occur, such as loading to an STE or DAL limit during a higher velocity wind than normal, coupled with a higher ambient temperature. An entity could potentially claim that vegetation was trimmed to normal load levels, normal facility loading sag, and minimum velocity wind speed swings, and be within the tolerance of the standard as we interpret it. The Drafting Team should clarify what the expectation is with regard to line loading, sag, and swing due to wind speed and the types of operating conditions it deems to be justified to create a more exact requirement.

Organization	Yes or No	Question 2 Comment
Nebraska Public Power District	No	same concern as item 1.
Central Maine Power, Iberdrola USA	No	The TVMP must include clearances bewteen trees and conductors at time of vegetation management work.Suggest that the TVMP require the use of qualified personnel to manage this program.
Arizona Public Service Company	No	This standard lacks accountability and transparency. This is a reliability standard and the industry is to prevent outages within the active ROW. It doesn't matter if the vegetation grows-in, blows-in or falls into the conductor these are all outages. One is no less of an outage than the other one. They should be treated equally and the utility should be held accountable for lack of maintaining the transmission system.
FirstEnergy	No	We agree that the previous R1 was too prescriptive and are in favor of the new Requirement R3. However, we do not agree with all the wording of R3 as well as the Rationale box for R3. 1. Requirement R3 - The phrase "considering all possible locations the conductor may occupy assuming operation within Rating and Rated Electrical Operating Conditions" is confusing. We like the wording from the previous (Draft 2) of FAC-003-2 and suggest the following rewording of this phrase: "considering all possible locations the conductor may occupy throughout its operating range under all rated conditions."2. Rationale box for Req. R3 - We suggest removing the first sentence in the Rationale box for R3. The need to provide a basis on the intent and competency of the TO in maintaining vegetation is not explicitly stated in the requirement. Also, we are not sure what is meant by "competency". If it is referring to minimum required competencies for personnel performing vegetation management, that is outside the scope of this standard.
Ameren	Yes	
Bonneville Power Administration	Yes	
City of Tallahassee (TAL)	Yes	
Consolidated Edison Company of New York, Inc.	Yes	
Duke Energy	Yes	
Entergy Services	Yes	
Exelon	Yes

MRO's NERC Standards Review Subcommittee	Yes	1. NSRS agrees with the revisions to R3. With regard to operations within Ratings and Rated Conditions, are operations after a contingency considered to be within Ratings and Rated Conditions?2. Could wording be added to R3 to specify rated conditions include National Electric Safety Code conditions or assumptions?

Organization	Yes or No	Question 2 Comment
Florida Municipal Power Agency (FMPA) and Some Members	Yes	Although FMPA agrees with the intent of the Measures, FMPA is concerned that the measures M1 and M2 may not meet the purpose of the measures as stated in the latest draft version of the Standard Processes Manual, which states that that a Measure "(p)rovides identification of the evidence or types of evidence needed to demonstrate compliance with the associated requirement." Instead, M1 and M2 provide examples of evidence that would be used to determine non-compliance, not used to determine compliance.
American Electric Power (AEP)	Yes	American Electric Power agrees with this change.
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG, CNE & CENG)	Yes	BGE agrees with the R3 text in the latest draft of FAC-003-2.
Dominion	Yes	Dominion agrees and finds this approach superior to existing which sometimes appears to be more administratively focused.
JEA	Yes	Given the basic performance required in R1 and R2 of this version, I agree that specifics about what is included in the plan are not needed. Each entity should be encouraged to write their plan so that the occasional human errors and failures that are inevitable still lead to compliance with the performance aspects of this standard. The team should be sure that the measures do not require unfailing perfect execution of this procedure so that entities are encouraged to minimize this document.
ITC Holding	Yes	ITC feels that this draft is an improvement by clarifying the action expected by this requirement ("competency-based" program specific methodology documentation) and separating other implementing ("risk based") actions from FAC-003-1 as new requirements within this draft version. ITC also agrees with results-based reliability, a standard principle that is driven by relevant reliability requirements and measureable results rather than prescriptive requirements driven by documentation.The term "bulk power system" should not be used in the comment form or any other documentation associated with FAC-003-2.
Independent Electricity System Operator	Yes	Old Requirement R1 has been distilled down to its essential elements with the removal of the detailed sub-requirements that were previously included. This places the onus of developing an effective transmission vegetation management program (TVMP) on the asset owners where it ought to be, since they have the requisite expertise. Guidance is however provided in the Technical Reference document to assist Transmission Owners in developing a TVMP that in their view works for them, and achieves the overall objective of preventing those vegetation related outages that could lead to Cascading. By specifying the "what" appropriately and leaving the "how" to the entity, the entity is now in the best position to determine the most effective deployment of its resources for meeting the goals of the standard.

Organization	Yes or No	Question 2 Comment
CenterPoint Energy	Yes	R3 focuses on its intended impact on Sustained Outages without being overly prescriptive.
Southern California Edison Company	Yes	SCE prefers the results-based approach to crafting reliability standards because it provides utilities with the necessary flexibility to develop internal criteria based on widely accepted best practices and industry innovations.
Western Area Power Administrtaion	Yes	The old Draft 2 version of R1 was developed to give the regulatory entities substantial and tangible information from which to judge the adequacy of a TO's overall approach to program management. The old Draft 2 version of R1 was purposely crafted in this detailed manner as an alternative to attempting to manage the problematic CCZ concepts contained in Draft 1. Industry strongly rejected the CCZ management concepts contained in Draft 1 in the first comment period. It appears that the current Draft 3 version of R3 has lost some of the content needed to fully substitute for the management of Draft 1 CCZ concepts. The addition of an implementation requirement intended to measure the full execution and success of the overall management approach identified by a TO in response to the new R3 may help to address this shortcoming. As currently worded, the requirement to simply execute a flexible annual work under the new R7 in Draft 3 does appear extensive enough to fulfill this need.
Oncor Electric Delivery	Yes	The RBS defense-in-depth strategy for this Standard does provide an adequate level of reliability. The Standards purpose statement refers to the electric Transmission system and corresponding applicable lines not the BPS or BES as currently defined in the NERC glossary or being proposed (NOPR) RM09-18-000. Removing prescriptive requirements allows utilities flexibility to document their program and perform their vegetation management to achieve the goal of no outages that lead to cascading.
IRC Standards Review Committee	Yes	The SRC agrees with the intent of R3, but questions the need for inspection postponements to be limited to natural "disasters". A well-planned inspection may be delayed by a common lighting storm. While there is a need to conduct the inspections and those inspections could be done anytime within the TO's own plans - the SDT may want to modify the exception to be natural disasters or other conditions that are reported within 5 business days and agreed to as an excused condition by the Regional Reliability Organization.
Southen Company	Yes	The term “bulk power system” should not be used in the comment form or any other documentation associated with FAC-003-2.
Progress Energy Carolinas	Yes	This separates implementing actions such as inspections, annual plans and imminent threat procedures from TVMP methodology (which proves competency of the program).This draft is an improvement by clarifying the action expected by this requirement (“competency-based” program specific methodology documentation) and separating other implementing (“risk based”) actions from FAC-003-1 as new requirements within this draft

Organization	Yes or No	Question 2 Comment
		version.
SERC OC Standards Review Group	Yes	This separates implementing actions such as vegetation inspections, performing annual work plans and responding to imminent threats from the required documentation of the TVMP methodology (which proves competency of the program).This draft is an improvement by clarifying the action expected by this requirement (program specific methodology documentation requirement) and separating other implementing actions from FAC-003-1 as new requirements in this draft version.
SERC Vegetation Management Sub-committee	Yes	This separates implementing actions such as vegetation inspections, performing annual work plans and responding to imminent threats from the required documentation of the TVMP methodology (which proves competency of the program).This draft is an improvement by clarifying the action expected by this requirement (program specific methodology documentation requirement) and separating other implementing actions from FAC-003-1 as new requirements in this draft version.
Western Area Power Administration - Upper Great Plains Region	Yes	WAPA - UGPR agrees with a reliability based standard. In the plains states, we have fewer trees than many utilities, so having prescriptive requirements that assume we have lines running through forested areas seems to mandate an excessive amount of detail. We prefer to keep our program very simple -- perform periodic inspections to identify vegetation problems and then direct applicable resources in to take care of the problem. Our hope is that a results-based reliability standard will provide some flexibility for those utilities with smaller scale vegetation encroachments.
Ad Hoc Group subteam formed to review draft standard	Yes	While the new R3 is less prescriptive than the old R1, it appears to stray from criteria #4 for developing results-based standards, as described in this comment form. It appears to require only the development of a document. We understand that in some cases this cannot be avoided. We believe that this is one of those cases where the reliability objective of building competency in considering all possible locations the conductor may occupy and assuming operation within Rating and Rated Electrical Operating Conditions over-rides our reluctance in requiring a registered entity to produce a document rather than a result. We suggest that in a future revision to standard that this can be combined with R7 to create a comprehensive requirement that the entity have a vegetation management program that demonstrates it is able to perform those actions necessary to keep vegetation out of the MVCD.
KCPL	No	The measures for R1 and R2 are zero tolerance for encroachments into the MVCD that did not result in a “contact” with the transmission facility. Considering the substantial number of miles of transmission involved, the complexities in anticipation of vegetation growth with numerous growth variables, vegetation management limitations imposed by other regulations or requirements, and unexpected transmission events that require substantial efforts regarding physical restoration, it is not reasonable or practical for the measures here to include encroachments that do not result in an interruption of transmission service. Recommend the SDT

Organization	Yes or No	Question 2 Comment
		consider modifying the measures for R1 and R2 to be applicable only in the interruption of a transmission facility.

3. Do you agree with the overall layout of the proposed template? If not, please suggest an alternative layout.

Summary Consideration: Most comment forms (43 out of 53) indicated agreement with the overall layout of the proposed template. However, some expressed concerns over individual parts of the template. The Vegetation Management SDT and the Standards Committee Process Subcommittee (SCPS) appreciate the commenters' comments and suggestions.

Some commenters do not agree with grouping Measures and Requirements together on the basis that Measures are compliance related elements and hence should be grouped with the compliance elements. This suggestion was not adopted. The SCPS asked a specific question about putting the requirements and measures together, and 50 of the 52 comment forms indicated support for this change.

Some commenters proposed that the Text Boxes are not needed if standards are written clearly; others expressed a concern that the material in the text boxes may be taken as mandatory, or used by the auditors as guidelines for assessing compliance. Some suggested that it is necessary to have a clear declaration on which parts/elements in the standards are mandatory. While the rationale for a requirement may be clear to most people who are familiar with the topic addressed by the standard, as the industry grows and people unfamiliar with the industry try to understand each requirement, documenting the rationale for each requirement is expected to be useful. The Text Boxes that provide the "rationale" for each requirement and other explanatory information will remain in the body of the standard until it is balloted, but will be removed from the approved version of the standard. Their content will be moved to the Guideline and Technical Basis Section.

The subcommittee will ask that NERC's legal department to write a statement for addition to each standard to clarify which parts/elements of the standard are mandatory and enforceable and which are provided only as information.

Some commenters raised a concern over the administrative elements. Some are unsure whether or not these elements are mandatory and asked if they are mandatory, then why they are not included in the Requirement Section. These commenters suggested that if the administrative reporting is not mandatory, does it belong in the standard, or should the Rules of Procedure Section 1600 be used to collect the data or document.

Some suggested that the Guideline and Technical Basis Section does not belong to a standard; others suggested that the material in the Guideline and Technical Basis Section be moved to appendices. Some suggested that the materials in the text boxes can also be regarded as providing the 'technical basis' and as such, can also be moved to appendices. Some commenters suggested moving the Guideline and Technical Basis Section to immediately after the Requirements and Measures section for ease of reference and this suggestion was not adopted. The compliance elements of the standard include evidence retention as well as other information that is mandatory, and the SCPS believes this should appear before the elements of the standard that aren't mandatory.

Some commenters do not support moving VRFs and Time Horizons away from the Requirements to be grouped together with the VSLs. They expressed a desire to be able to see the VRF associated with each Requirement to know the violation impact. The SCPS will modify the format to put the information in both places – adjacent to the requirement and in a separate table.

Some commenters expressed a concern with putting the Development Plan, Definitions, Effective Dates and Revision History at the front end since the readers must screen through 4-5 pages before getting to the standard itself. Some commenters suggested that these housekeeping items be moved to the end, other commenters suggested putting the Background Section before the Applicability Section in the Introduction. The table with effective dates was removed as this will be challenging to keep up to date, however the other sections of the standard will remain where proposed with the exception that the Definitions Section will be moved ahead of the Background Section.

Some commenters indicated that there appears to be some redundant verbiage in the Background Section and the Guideline and Technical Basis Section. The SCPS will bring this to the attention of the VM SDT. These two sections were intended to have two distinctly different purposes – the Background Section identifies “why” the standard exists, and the Guideline and Technical Basis Section provides information that may be useful to entities in applying the standard.

Some commenters suggested using color code to differentiate between the information that is meant to be temporary and the information that is expected to stay with the standards. This suggestion was not adopted.

Organization	Yes or No	Question 3 Comment
American Transmission Company	No	a.) ATC believes that the “Guideline and Technical Basis” section does not belong within the NERC Standard. ATC feels there are parts of this section that appear to obligate the TO with additional mandatory requirements. (please refer to additional details in Question #8 below) b.) ATC believes the “Measures” section immediately following the Requirement is helpful and placement is appropriate, however, the introductory statement in R1 and R2 is poorly worded. For example, M1 currently states: “ Evidence of violation of Requirement R1 is limited to:” ATC feels this is a negative approach and recommends that it be stated in a positive manner such as”” Evidence of compliance to R1 would be to: o Not have any vegetation-related Sustained Outages due to a grow-in.” c.) ATC would like to clarify whether the “Rational” boxes remain within the final standard. It seems appropriate to have this information but that it would be better to have this information appear in the “Guideline and Technical Basis” section.
GCPD	No	Don't need all the extra requirements beyond R2.
Florida Municipal Power Agency (FMPA) and Some Members	No	FMPA appreciates the improvements and has additional suggestions. Please see responses to the remainder of the questions, and below, for suggestions:The evidence retention should be grouped with the Measures for ease of creating a records retention schedule for the standards and requirements.Do we really need a “Compliance Monitoring and Enforcement Processes” section of the standards? Are there any standards that don’t have all of these activities?
City of Tallahassee (TAL)	No	I would delete the Rationale in favor of keeping the Guideline and Technical Basis. The Guideline appears to be more in-depth than the Rationale. This makes the Rationale unnecessary.
Northeast Power Coordinating Council	No	NPCC participating members want to thank the drafting team for the hard work devoted to developing this standard, and recognize the difficult issues of producing the first “results based” proof of concept standard and offer the following, not as criticism, but as helpful suggestions for their consideration based on a cross section of stakeholder reactions to the draft. 1) Measures are compliance related elements and should not

Organization	Yes or No	Question 3 Comment
		appear immediately after the requirements. The older template had the compliance elements grouped together in a separate section, and we suggest this continues. In the past there have been instances of RSAW (Reliability Standards Audit Worksheets) not clearly matching the standard's requirements or measures. We suggest that this initiative with a results based requirement consistently involve the development of the associated RSAWs to ensure coordination, and also that the requirement results in a performance based, competency, or risk based reliability criterion. 2) Effective dates have become a complex issue. We suggest that rather than having an effective date table in the standard, this type of information be restricted to the implementation plan and ultimately reside in a NERC relational database which is currently under discussion/development. NPCC participating members suggest that the "Effective Dates" section be replaced with "NERC BOT Adopted Date". Due to their complexities, FERC and Provincial approvals are something best left to implementation plans and databases. 3) "Rationale" boxes appearing in the Requirements section are problematic. If a "Rationale" box is required to explain part of the requirement then the requirement needs to be revised. For example, in R7 the requirement states that a TO shall execute a flexible annual vegetation management plan. Flexible in this context could have many different interpretations, yet in the "Rationale" box the use of the word flexible is clearly delineated to mean work may be deferred if not an imminent threat. In general we believe these boxes add little value, and if the requirement can't be understood without the "Rationale" then the requirement needs to be worded appropriately. Suggest these types of explanatory statements go into guidance documents, or supporting technical documents, and do not appear in the "Requirements" sections. 4) Also, there seems to be some confusion regarding the Administrative Procedure section. There seems to be requirements embedded within it, e.g. "The Transmission Owner will submit a quarterly report to its Regional Entity, or the Regional Entity's designee, identifying all Sustained Outages of transmission lines determined by the Transmission Owner...." Is this an enforceable aspect of the standard? If so, are there any other documents such as the NERC Rules of Procedure "ROP" or compliance related documents such as the CMEP that have to be changed? NPCC participating members recognize that this is a results based standard. Administrative requirements should be removed from the standards, and dealt with elsewhere (such as the ROP). 5) The Guideline and Technical Basis section contains valuable information, but this adds to the volume of the document. The Drafting Team should consider moving this to a separate document. In viewing the standards as a whole, the FAC-003 standard is relatively straightforward when compared to the developing of other standards such as the TPL standard. A similar approach, if applied to the TPL would result in a standard with potentially hundreds of pages. If the type of work appearing in this section is envisioned for other more complex standards such as TPL, the DT should consider separating out this section as a single supporting document. 6) Do FERC and the Provincial governmental authorities approve just the requirements in the Standard, or the whole package?
FRCC Manager of Operations	No	See responses to #8, 10, 11 and 13.
IRC Standards Review	No	The proposal to move the time horizon and the VRF to a separate independent section is not useful. Take for example R1 and R2 of the proposed standard. A careful read of the two requirements and measurements

Organization	Yes or No	Question 3 Comment
Committee		would indicate that there is no difference between them and that it would be better to have one requirement for all conductors. It is not until the reader gets to the compliance section does the VRF difference show up. There is no savings to removing the previous format's parenthetical inclusion of time horizon and VRF at the end of the requirement. The Independent Section can contain all of the proposed information but don't remove it from the requirement. The format of the standard would not be an issue if NERC would develop a standards database. Then, the database could be queried in any format the user desires.
ERCOT ISO	No	The Standard itself is several pages into the document. The VRFs/VSLs should be in the Requirements/Measures Section. The Background, Rationale, Administrative Procedures are additional information and should be located in an Appendix so it doesn't clutter the Standard.
CenterPoint Energy	No	We suggest combining and moving the Rationale, Background, Guideline and Technical Basis, and Technical Reference to a consolidated appendix because there is much duplication in the wording within each of these sections, and independently they may be misinterpreted as being an integral part of the Requirements and Measurements which they are not. The Requirements and Measurements should stand clearly on their own. The appendix should contain examples of how to meet the requirements under various circumstances. The appendix should be supplementary and optional to the Standard.It is also not clear if the Administrative Procedure is a mandatory activity. It would be helpful if the intent of this section was stated within the Standard.
NERC Staff (12 staff members)	No	We suggest using two colors for explanatory information - yellow for information that is temporary - such as the information explaining the difference between the approved and proposed definitions of "Vegetation Inspection" - and using blue for all boxes that are intended to remain in the approved standard.We feel that the Standards Committee Process Subcommittee should pursue adding a statement from NERC's legal department indicating which parts of the standard are enforceable. In the meantime, we suggest using the standard template in order to clearly define the enforceable parts of the standard. The section identified as "Guideline and Technical Basis" is not really a guideline (typically a proposed process for completing work) and is not really a "technical basis" (typically a summary of research or engineering judgment, etc. used to explain the reasoning for something). The information in this section is explaining how the drafting team expects compliance with the requirements to be measured. We suggest revising the heading to "Application Guidelines." This is the term that was originally proposed by the Results-based team and is the heading identified in the proposed Standard Processes Manual.
Ad Hoc Group subteam formed to review draft standard	Yes	
Arizona Public Service Company	Yes	

Organization	Yes or No	Question 3 Comment
Bonneville Power Administration	Yes	
Central Maine Power, Iberdrola USA	Yes	
Cleco	Yes	
Consumers Energy	Yes	
Duke Energy	Yes	
Entergy Services	Yes	
Exelon	Yes	
Independent Electricity System Operator	Yes	
Manitoba Hydro	Yes	
Nebraska Public Power District	Yes	
North Carolina EMC	Yes	
Omaha Public Power District	Yes	
Oncor Electric Delivery	Yes	
Orange and Rockland Utilities, Inc.	Yes	
PPL Electric Utilities Corporation (NCR00884)	Yes	
South Carolina Electric and Gas	Yes	

Organization	Yes or No	Question 3 Comment
Southen Company	Yes	
Southern California Edison Company	Yes	
Tucson Electric Power Co.	Yes	
Utility Risk Management Corporation	Yes	
Xcel Energy	Yes	
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG, CNE & CENG)	Yes	BGE is supportive of the proposed template.
JEA	Yes	Coupling the measures and rationale with each requirement make the standard easier to follow and to implement.
Dominion	Yes	Dominion agrees, but suggests that reference(s) to figure(s) and table(s) contain links that can take reader to that section of the document. This is superior to having to scroll through document. If the reference(s) is external to this standard document, links may be harder to manage but should at least reference a common webpage(s) used by NERC for the posting of such documents.
ITC Holding	Yes	ITC feels that the overall layout of the standard (a) improves readability, (b) clarifies expectations, (c) reduces confusion associated with referencing between pages, and (4) allows for background information and the SDT rationale to accompany the standards but we would suggest locating Guideline and Technical Basis after Requirements and Measures for better reference accessibility.
MRO's NERC Standards Review Subcommittee	Yes	N/A
Tampa Electric Company	Yes	None
Western Area Power Administration - Upper Great	Yes	None

Organization	Yes or No	Question 3 Comment
Plains Region		
FirstEnergy	Yes	Overall, we like the layout of the standard, especially the Effective Date table in the front of the standard, the combination of Requirements and Measures, and the grouping of the VRF, Time Horizons, and VSL into one table. However, we would like to see a clearer delineation between the mandatory requirements and the guidance and rationale information. The standard should explicitly be clear as to what is mandatory and what is not, which may even require moving the "Rationale" text boxes out of the Requirements and Measures section. FE believes the information presented in the Rationale text boxes can be effectively covered in the "Guidelines and Technical Basis".
Western Area Power Administrtaion	Yes	The format could be enhanced by moving the Guidelines and Technical Basis section forward to be included with the corresponding Requirement, Measure, and Rationale. This would be helpful because it is awkward flipping back and forth between these two sections when trying to fully understand a requirement.
Pepco Holdings, Inc. - Affiliates	Yes	The general layout is quite effective. Still, it would be good to keep the VRFs and time horizons within the text of the requirement.
Ga Transmission Corp	Yes	The layout is adequate but many things are needing further explanation such as the MVCD.
Progress Energy Carolinas	Yes	The overall layout improves readability, clarifies expectations, reduces confusion associated with referencing between pages, and allows for background information and SDT rationale to accompany the standards (reducing the need for interpretation).
SERC OC Standards Review Group	Yes	The overall layout improves readability, clarifies expectations, reduces confusing references between pages, and allows for background and rationale to accompany standards.
SERC Vegetation Management Sub-committee	Yes	The overall layout improves readability, clarifies expectations, reduces confusing references between pages, and allows for background and rationale to accompany standards.
East Kentucky Power Cooperative, Inc.	Yes	The overall layout is greatly improved. This draft is easier to read and understand and clarifies the expected actions required in the standard.
American Electric Power (AEP)	Yes	The overall template layout is acceptable
Tennessee Valley Authority	Yes	This aids the understanding of the standard.

Organization	Yes or No	Question 3 Comment
Ameren	Yes	This draft is much more user friendly and easier to follow; appreciate the follow up information.
Consolidated Edison Company of New York, Inc.	Yes	We do believe the overall layout is effective but the SDT should consider putting the Background Section before the Applicability Section in the Introduction and also try to reduce any redundant verbiage in the Background Section and the Guideline and Technical Basis Section. A twenty-one page Standard is too lengthy and the supporting Technical Reference document properly addresses many of the issues mentioned in the Guideline and Technical Basis Section.
KCPL	Yes	

4. Do you agree with grouping the standard development timeline (previously called roadmap) with the revision history, and the effective date(s) and putting this administrative information up front before the Introduction Section? Please explain.

Summary Consideration: A vast majority of the comment forms (48 out of 52 who responded to this question) indicated support for grouping the Development Timeline, Revisions History and Effective Dates and putting them up front before the introduction Section.

Some commenters suggested moving this group of information to the end, other commenters suggested that the Definition Section be taken out of the group and placed just before Introduction. The SCPS does not think that moving the grouped information to the end will result in much improved readability. Readers can get to the beginning of a standard as quickly by scrolling or flipping through the pages.

The SCPS agrees with moving the Definition Section to just before the Introduction Section since Definitions are part of the balloted materials and the team adopted this suggestion. Note that after the standard is balloted, the definitions, if approved, are moved out of the standard and into the Glossary of Terms Used in Reliability Standards.

Some commenters suggested adding a table of contents. The SCPS will consider this in the next posting.

Organization	Yes or No	Question 4 Comment
IRC Standards Review Committee	No	For this standard one must read through 7 pages before getting to the reason for the posting. The administrative information should be relegated to the end of the posting not the beginning.Under exceptions in the Effective Dates section of the standard, IROLs are referenced as only being created by the Planning Coordinator. Because Reliability Coordinators must also establish IROLs per FAC-011 and FAC-014, we suggest that reference to the Planning Coordinator should be redacted and IROLs should be discussed regardless of whether the Planning Coordinator or Reliability Coordinator creates them.
Consolidated Edison Company of New York, Inc.	No	The only issue we have with the administrative information being before the Introduction Section is with the Definition of Terms Used in the Standard Section. We feel this should be part of the Introduction and not a stand alone section.
Orange and Rockland Utilities, Inc.	No	The only issue we have with the administrative information being before the Introduction Section is with the Definition of Terms Used in the Standard Section. We feel this should be part of the Introduction and not a stand alone section.
ERCOT ISO	No	This information should be located at the end so that it doesn't distract from the main purpose of the Standard. It is cumbersome to read through several pages before getting to the actual language of the Standard.
Ad Hoc Group subteam formed to	Yes	

Organization	Yes or No	Question 4 Comment
review draft standard		
American Transmission Company	Yes

Consumers Energy	Yes	
Duke Energy	Yes	
Exelon	Yes	
GCPD	Yes	
JEA	Yes	
Manitoba Hydro	Yes	
Nebraska Public Power District	Yes	
NERC Staff (12 staff members)	Yes	
North Carolina EMC	Yes	
Omaha Public Power District	Yes	

Organization	Yes or No	Question 4 Comment
Oncor Electric Delivery	Yes	
Pepco Holdings, Inc. - Affiliates	Yes	
PPL Electric Utilities Corporation (NCR00884)	Yes	
South Carolina Electric and Gas	Yes	
Southen Company	Yes	
Tennessee Valley Authority	Yes	
Tucson Electric Power Co.	Yes	
Utility Risk Management Corporation	Yes	
Western Area Power Administrtaion	Yes	
Ameren	Yes	Appreciate the ability to reference up front.
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG, CNE & CENG)	Yes	BGE agrees with the proposed grouping and placement of these items.
Dominion	Yes	Dominion agrees that the new format is superior to the old. However, we suggest a table of contents be added to include at a minimum, sections for (1) Definitions of Terms Used in Standard (2) Effective dates, (3) Introduction, (4) requirements and measures (5) Compliance (6) Time Horizons, VRF and VSLs (7) Administrative (8+) guidelines, technical basis, tables or figures referenced in standard.
Entergy Services	Yes	Easy to follow.
Ga Transmission Corp	Yes	I do not see a problem with this change.

Organization	Yes or No	Question 4 Comment
Xcel Energy	Yes	It is acceptable to do so, however it is not clear as to how the effective date portion will be incorporated in a final version of the standard. Will there be some kind of cover page to at least indicate the standard or will it just be a small title bar at the top? (i.e. - what does page 1 of the standard look like?)
ITC Holding	Yes	ITC agrees with locating the revision history and administrative information before the introduction. This alignment improves clarity and readability by providing a single location for this information.
Florida Municipal Power Agency (FMPA) and Some Members	Yes	Just a question, when the standard becomes effective, how will it be posted? FMPA assumes that this section will move to the end of the standard instead of the front when approved.
CenterPoint Energy	Yes	No preference.
Tampa Electric Company	Yes	None
Northeast Power Coordinating Council	Yes	NPCC participating members believe this is acceptable. However our previous response to question 3 above still applies regarding the Effective Date section. It should be removed from the standard, and either appear in an implementation plan, or more effectively in a NERC relational database.
Independent Electricity System Operator	Yes	Since in this case the effective dates of all requirements are all the same, we believe the effective dates table could be significantly condensed.
East Kentucky Power Cooperative, Inc.	Yes	The format provides for better clarification and is easier to read and comprehend.
MRO's NERC Standards Review Subcommittee	Yes	The NSRS likes the way the standards is now formatted and finds it more user friendly.
American Electric Power (AEP)	Yes	These changes make sense to American Electric Power.
SERC OC Standards Review Group	Yes	This format adds clarity and improves readability.
SERC Vegetation Management Sub-committee	Yes	This format adds clarity and improves readability.

Organization	Yes or No	Question 4 Comment
Progress Energy Carolinas	Yes	This grouping improves clarity and readability by providing a single location for this information.
Western Area Power Administration - Upper Great Plains Region	Yes	WAPA - UGPR is neutral on location of these items.
Southern California Edison Company	Yes	We agree that grouping the administrative information up front is logical and makes for a cleaner presentation.
FirstEnergy	Yes	We agree with having a detailed table showing the effective dates of each requirement. However, we would like to see NERC go back into the table and specify the dates of NERC and FERC effective dates once they are known. Having the statement "1st day of the 1st quarter one year after applicable regulatory approval" in the standard does not help the user of the standard when they are working towards compliance, and requires them to go elsewhere to find when the approvals took place. All this information should be in the standard when available and NERC staff should be afforded the latitude to do so even without needing to use its Errata process. Placing the dates directly within the standard is more convenient for the end user.
KCPL	Yes	

5. Do you agree with grouping the Requirements and Measures together, in one Section now called Requirements and Measures? Please explain.

Summary Consideration: A vast majority of the comment forms (50 out of 52) indicated support for grouping the Requirements and Measures in one Section.

Some commenters suggested moving the Measures back to the Compliance Section and adding a reference to each Measure stating which Requirement it refers to. The SCPS does not think that moving the Measures back to the Compliance Section will result in any improvement in readability. Keeping the Measures together with the Requirements provides readers with a clear and easy view of what evidence needs to be provided to demonstrate compliance with the Requirements.

Organization	Yes or No	Question 5 Comment
Xcel Energy		We are indifferent as to the placement of the Measures, however it does appear to create awkward shaped paragraphs when Requirements and Measures are place around Rationale boxes.
Northeast Power Coordinating Council	No	As commented earlier in question 3, this is a compliance related issue and should be in the Compliance section. NPCC participating members believe clear concise requirements should be the focus, and inserting measures immediately after the requirements adds little value. In addition, RE compliance staffs who use the metrics find no value to moving it as well. This format would ease working with the document as a working draft, but should not be in an adopted document. Consider moving Measures back to the compliance section, and add a reference to a Measure's wording stating which requirement the measure refers to. Only adding a statement when the Requirement and Measure numbering don't line up could be considered.
Bonneville Power Administration	Yes	
Cleco	Yes	
Duke Energy	Yes	
IRC Standards Review Committee	Yes	
Manitoba Hydro	Yes	
Nebraska Public Power District	Yes	
NERC Staff (12 staff members)	Yes	

Organization	Yes or No	Question 5 Comment
North Carolina EMC	Yes	
Omaha Public Power District	Yes	
Oncor Electric Delivery	Yes	
Pepco Holdings, Inc. - Affiliates	Yes	
PPL Electric Utilities Corporation (NCR00884)	Yes	
South Carolina Electric and Gas	Yes	
Southen Company	Yes	
Southern California Edison Company	Yes	
TO/TOP	Yes	
Tucson Electric Power Co.	Yes	
Utility Risk Management Corporation	Yes	
Western Area Power Administrtaion	Yes	
Central Maine Power, Iberdrola USA	Yes	Adds clarity between requirements and measures .
Arizona Public Service Company	Yes	APS doesn’t agree with all of the requirements.
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG,	Yes	BGE agrees it makes sense to group these two sections together.

Organization	Yes or No	Question 5 Comment
CNE & CENG)		
JEA	Yes	Coupling the measures and rationale with each requirement make the standard easier to follow and to implement.
Dominion	Yes	Dominion finds this format improved over the existing as reader can more easily correlate the requirement (process/procedures) to the measure (evidence).
Exelon	Yes	Exelon agrees this is a good practice that will help ensure Requirements and Measures are aligned
Florida Municipal Power Agency (FMPA) and Some Members	Yes	FMPA agrees that grouping the Requirements and Measures together in one section is a great idea; however, to realize even more benefit, we now have the opportunity to eliminate redundant wording, e.g., M3 can be shortened to: “A documented transmission vegetation management program” and eliminate the rest of the words that are redundant with R3.
Entergy Services	Yes	Great addition and improvement!! Much clearer and easier to follow.
City of Tallahassee (TAL)	Yes	However, if you keep the Rationale text boxes, keep the Measures in the same column as the requirement. This will result in a more consistent “look and feel” to all the requirements (M3 for R3 is the example).
FRCC Manager of Operations	Yes	In addition the DT could also eliminate redundant wording in the standard requirement, e.g., M3 can be shortened to: “A documented transmission vegetation management program” and eliminate the rest of the words that are redundant with R3 or use words in the measure that refer back "to the requirement above".
ERCOT ISO	Yes	Including a specific measure with each requirement adds clarity; however, it isn’t clear whether each measure is exclusive to the requirement that it follows. Is it possible that some requirements will have multiple measures that are not listed immediately following the requirement?
ITC Holding	Yes	ITC agrees with Requirements and Measures grouped together
GCPD	Yes	Makes the standard template much easier to read and use.
Consumers Energy	Yes	Much easier to follow in this format.
Ameren	Yes	Much more user friendly to be able to see the requirement and the measurement together for clarification.

Organization	Yes or No	Question 5 Comment
CenterPoint Energy	Yes	No preference.
MRO's NERC Standards Review Subcommittee	Yes	NSRS prefers to have the requirements, measures, VRFs, VSLs and Time Horizons together instead of referencing to another page or part of the standard.
American Transmission Company	Yes	See ATC's comment on "Measures" in Question #3 above.
Tennessee Valley Authority	Yes	This aides in understanding of the standard. Grouping the VSL and VRF for each requirement along with the measurement could be beneficial too.
Ga Transmission Corp	Yes	This also is OK no problem with the layout.
Progress Energy Carolinas	Yes	This change also improves readability and improves understanding of the requirement.
SERC OC Standards Review Group	Yes	This format adds clarity and improves readability.
SERC Vegetation Management Sub-committee	Yes	This format adds clarity and improves readability.
East Kentucky Power Cooperative, Inc.	Yes	This format provides for better readability and clarification.
Tampa Electric Company	Yes	This improves the clarity and understanding to the requirements.
Independent Electricity System Operator	Yes	This is useful to avoid having to move back and forth between separate sections to find out what is needed to show that a requirement is met. We do not have a strong preference for this re-grouping however.
Western Area Power Administration - Upper Great Plains Region	Yes	WAPA - UGPR believes this makes it easier to identify the requirement and what we need to provide to demonstrate with are in compliance with the requirement.
FirstEnergy	Yes	We agree that grouping the Requirements and Measures together is convenient when utilizing the document for compliance.

Organization	Yes or No	Question 5 Comment
Consolidated Edison Company of New York, Inc.	Yes	We agree with grouping the Requirements and Measures together since it does add another level of clarifying description for our field forces who are ensuring compliance during vegetation management activities. The Measures for R1 and R2 describe evidence of violation while the Measures for the remaining Requirements R3 - R7 describe evidence of compliance. All Measures should be written consistently as either evidence of compliance or evidence of violation.
Orange and Rockland Utilities, Inc.	Yes	We agree with grouping the Requirements and Measures together since it does add another level of clarifying description for our field forces who are ensuring compliance during vegetation management activities. The Measures for R1 and R2 describe evidence of violation while the Measures for the remaining Requirements R3 - R7 describe evidence of compliance. All Measures should be written consistently as either evidence of compliance or evidence of violation.
Ad Hoc Group subteam formed to review draft standard	Yes	We agree with the understanding that the specific requirements of the standard are the enforceable elements of the standard. The rationale and measures add clarity to support a results-based requirement.
American Electric Power (AEP)	Yes	Yes, this is a more readable format.
KCPL	Yes	

6. **Do you agree with grouping VRFs, Time Horizons and VSLs together, and putting them in a table separate from the Requirements and Measures Section? Please explain.**

Summary Consideration: A vast majority of the comment forms (47 out of 54) indicated support with grouping VRFs, Time Horizons and VSLs together.

Some commenters suggested moving the VERs and Time Horizon back to the Requirements.

Some commenters agree with grouping VRFs, VSLs and Time Horizons together, but expressed a desire to also see the VRFs and Time Horizons in the Requirements as well. The SCPS adopted this suggestion in the next posting.

Some commenters suggested listing the applicable table rows with each requirement to consolidate all pertinent information with the requirement. The SPCS believes that this will convolute the Requirements and Measures Section with little added value.

Some suggested adding the penalty matrix to facilitate discussions with property owners/agencies resisting maintenance activates. The SCPS does not believe the penalty matrix is a standard element or technical reference material. This suggestion was not adopted.

Some commenters indicated that although a non-binding poll is taken of the VRFs and VSLs, it appears that the Time Horizons are part of the standard that is still subject to stakeholder ballot. Commenters suggested that the SDT should explain how this will be made clear to balloters and asked if there is an intent to modify the standards process to remove the time horizons from the portions of the standard that are subject to ballot.

In response to the above suggestions, the SCPS will retain the grouping as proposed, but will also put Time Horizons and VRFs adjacent to their associated Requirements.

Organization	Yes or No	Question 6 Comment
Pepco Holdings, Inc. - Affiliates	No	Agree that the grouping of the subject material is appropriate, but it is not necessary to also remove the VRFs and time horizons from the requirement.
JEA	No	I would prefer to have the VRF’s and time horizons together with the requirements and measures section. The VSL’s separate is appropriate as that is not information needed while complying, but only after a failure.
Manitoba Hydro	No	If the VRF’s Time Horizons and VSLs were listed in with each requirement and measure section, it would eliminate the need for cross referencing 2 sources of information.
Oncor Electric Delivery	No	It would be nice to see the associated VRF’s and Time Horizon with the requirements. No text, but referenced.
ERCOT ISO	No	The associated VRFs/Time Horizons/VSLs should be identified alongside each Requirement so that all relevant criteria for a given Requirement are organized together.

Organization	Yes or No	Question 6 Comment
IRC Standards Review Committee	No	While we agree that the grouping of the subject material is appropriate, it is not necessary to also remove the VRFs and time horizons from the requirement.
Duke Energy	No	While we like grouping VRFs, Time Horizons and VSLs together in a table, we would also like to see each VRF and Time Horizon listed with its requirement. It's a small amount of information that we think adds value in both places.
Ad Hoc Group subteam formed to review draft standard	Yes	
Ameren	Yes	
American Transmission Company	Yes	
Arizona Public Service Company	Yes	
Bonneville Power Administration	Yes	
Central Maine Power, Iberdrola USA	Yes	
Cleco	Yes	
Consolidated Edison Company of New York, Inc.	Yes	
Consumers Energy	Yes

TO/TOP	Yes	
Tucson Electric Power Co.	Yes	
Utility Risk Management Corporation	Yes	
Western Area Power Administrtaion	Yes	
Xcel Energy	Yes	
MRO's NERC Standards Review	Yes	Again it is good to have this information together in place of referencing some other page or part of the

Organization	Yes or No	Question 6 Comment
Subcommittee		Standard.
Tennessee Valley Authority	Yes	Also please consider parsing out a copy of each VSL/VRF with in each individual requiremnt and measure part of the standard as mentioned in question 5 above.
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG, CNE & CENG)	Yes	BGE supports grouping VRFs and VSLs together in a separate table.
Southen Company	Yes	Consider putting the appropriate line from the table with each requirement in the body of the standard in addition to the table format. This does make the standard longer and does introduce some redundancy, but it would make each requirement easier to read and interpret on a “standalone” basis.
City of Tallahassee (TAL)	Yes	I believe this makes it easier to follow the Requirements.
ITC Holding	Yes	ITC Agree's
Florida Municipal Power Agency (FMPA) and Some Members	Yes	Much easier to find and understand
CenterPoint Energy	Yes	No preference.
Entergy Services	Yes	This grouping helps to clarify the manner in which the violations will be ranked.
Progress Energy Carolinas	Yes	This grouping improves the template used by previous versions by providing a single view of the impact and risk that has been associated with each requirement. Progress Energy believes that this change would also be improved if the applicable VRF/VSL/Time Horizon table rows were also listed with each requirement (consolidating pertinent info with the requirement). Another improvement would be including the penalty matrix (or including a URL link) to facilitate Transmission Owner discussions with property owners and other governmental agencies.
SERC OC Standards Review Group	Yes	This improves the template used by previous versions by providing a single view of the impact consideration of each requirement. An improvement would be also listing the applicable table rows with each requirement which consolidates all pertinent info with the requirement. Also, adding the penalty matrix would facilitate discussions with property owners/agencies resisting maintenance activates.

Organization	Yes or No	Question 6 Comment
SERC Vegetation Management Sub-committee	Yes	This improves the template used by previous versions by providing a single view of the impact consideration of each requirement. An improvement would be also listing the applicable table rows with each requirement which consolidates all pertinent info with the requirement. Also, adding the penalty matrix would facilitate discussions with property owners/agencies resisting maintenance activates.
GCPD	Yes	This is audit stuff that does need to stay together.
Northeast Power Coordinating Council	Yes	This is consistent with FERC's determination that these are compliance elements and not part of the standard requirements. It will also assist with compliance determinations.
Western Area Power Administration - Upper Great Plains Region	Yes	WAPA - UGPR is neutral on location of these items.
FirstEnergy	Yes	We agree with grouping these items together. It may also be beneficial to include links directly in the table to explanations of VRFs, Time Horizons, and VSLs so that someone unfamiliar with, for instance, what a "Long-Term Planning" horizon means, they could look it up.
NERC Staff (12 staff members)	Yes	We agree with the idea behind the grouping. However, according to the Reliability Standard Development Procedure - Version 7, although a non-binding poll is taken of the VRFs and VSLs, it appears that the Time Horizons are part of the standard that is still subject to stakeholder ballot. The SDT should explain how this will be made clear to balloters. Is there intent to modify the standards process to remove the time horizons from the portions of the standard that are subject to ballot? This issue needs to be addressed by the Standards Committee Process Subcommittee.
Tampa Electric Company	Yes	With all of the VRFs, Time Horizons and VSLs grouped together it facilitates the overall understanding of these factors as they relate to the standard.
Ga Transmission Corp	Yes	Yes this was a good change.
American Electric Power (AEP)	Yes	Yes; this format is more user-friendly.
KCPL	Yes	

7. **Do you agree with the insertion of text boxes, where necessary, to help readers better understand the basis of the Definitions and Requirements? Please explain.**

Summary Consideration: The majority of comment forms (43 out of 54) agree with the insertion of text boxes.

Some commenters disagree with the insertion as the material in the text boxes will be subject to FERC's review and approval.

Other commenters raised a concern that the materials may become pseudo requirements; others are concerned that the material in the text boxes is also mandatory, or may be used by auditors as guidelines to assess compliance.

Some believed that text boxes are not necessary given there is a Guideline and Technical Basis Section. Some suggested removing the text boxes and moving the material to the Guideline and Technical Basis Section.

Some commenters indicated that some text boxes can be temporary (for example, those associated with a definition). More clarity is needed to distinguish this type of text box in the drafting stage, with the expectation that they will be removed after a standard is approved and the definition becomes effective (and removed from the standard).

The SCPS appreciates these comments and the commenters' concerns. The SCPS agreed to post the text boxes with the working document but move the text boxes into the Guideline and Technical Basis Section to support the standard until it is balloted, but will be removed from the approved version of the standard before it is submitted for adoption and filing with regulatory and governmental authorities. Their content will be moved to the Guideline and Technical Basis Section. The material in the Guideline and Technical Basis Section is intended to provide guidance but is not intended to expand on any of the requirements and is not intended to include any mandatory performance. A legal statement will be added to the standard to make this clear.

Organization	Yes or No	Question 7 Comment
Exelon	No	Additional clarifications should be included in appendices or reference documents. Including them with the requirements and measures will cause confusion concerning what the compliance obligation is. This will introduce uncertainty to the compliance monitoring process.
American Transmission Company	No	Although the test boxes provide some addition help, ATC believes that these text boxes should appear in the Guideline and Technical Basis section and that whole section should appear in a companion document to the standard but not be included as part of the standard. Also, see ATC's comment on Rational in Question #3 above.ATC believes that guidance information should not be reviewed and approved by FERC and the inclusion of such information within the standard opens this language up to FERC's oversight and approval.
Northeast Power Coordinating Council	No	As stated in question 3 above, NPCC participating members believe crisp, clear results based requirements require no further explanation. Requirements must be written so they are clearly understood. Text boxes clutter up the standard. Questions could arise if these add "pseudo" requirements to the standards, and there is any inconsistency in what is stated about requirements. NPCC strongly suggests their removal in favor of

Organization	Yes or No	Question 7 Comment
		clear, measurable, and high quality results based requirements.
City of Tallahassee (TAL)	No	I would delete the Rationale in favor of keeping the Guideline and Technical Basis. The Guideline appears to be more in-depth than the Rationale. This makes the Rationale redundant and unnecessary.
CenterPoint Energy	No	It is not clear how the information in the text boxes will be used to determine compliance with the Requirements and Measures. It appears that in the Definition of Terms Used in Standard section that the text boxes add to the definitions or are footnotes to historical information. The Definitions should stand on their own and be robust enough to ensure they are helpful in determining compliance with the Requirements and Measures. In the Requirements and Measures section, the text boxes appear to contain partial information from the Guideline and Technical Basis, and Technical Reference. In all cases the information is not helpful and provides incomplete information. The text boxes should be deleted and pertinent information to compliance should be incorporated into the Definitions, Requirements, and Measures. Any explanatory text or examples should be moved to an appendix as supplementary and optional to the Standard.
ERCOT ISO	No	It is not clear whether the information in the text boxes is “For Information Only.” While the additional information may be helpful, it appears to add sub-requirements within the Standard. This information could be included under a “Rationale” section in an Appendix. However, if the information clouds the purpose of the Requirements or dictates how to comply, then it should be eliminated completely.
Consumers Energy	No	Not necessary given the “Guidelines and Technical Basis”.
Nebraska Public Power District	No	Text boxes and other supporting information are a benefit to the reader as a clarification guide, but should be placed in something other than the Standard.
IRC Standards Review Committee	No	The concept of text boxes needs further discussion. The idea of using text boxes for clarity and explanation is valuable, but is the material in the text box mandatory? If it includes mandatory material than it is not a good idea - all mandatory requirements must be in the requirement. If the text boxes are retained to explain how a phrase is being used (e.g. to make clear what compound actions apply to what compound time frames), then yes, this approach can be invaluable.
Cleco	No	The inclusion of the text implies additional requirements. Keep quidance to a separate paper.
Arizona Public Service Company	Yes	
Bonneville Power Administration	Yes	

Organization	Yes or No	Question 7 Comment
Consolidated Edison Company of New York, Inc.	Yes	
Duke Energy	Yes	
FRCC Manager of Operations	Yes	
Manitoba Hydro	Yes	
Omaha Public Power District	Yes	
Oncor Electric Delivery	Yes	
Orange and Rockland Utilities, Inc.	Yes	
Pepco Holdings, Inc. - Affiliates	Yes	
PPL Electric Utilities Corporation (NCR00884)	Yes	
Southen Company	Yes	
Tennessee Valley Authority	Yes	
TO/TOP	Yes	
Tucson Electric Power Co.	Yes	
Utility Risk Management Corporation	Yes	
MRO's NERC Standards Review Subcommittee	Yes	1. We agree. The rationale boxes will cut down on interpretations. 2. Are the rationale boxes part of the approved standards for which registered entities will be audited. Are the rationale boxes federal law?3. Under R3, a reference to the National Electric Safety Code in the rationale box would be helpful. (The goal is to

Organization	Yes or No	Question 7 Comment
		verify that utilities will not be held in violation of this standard when operating beyond the NESC conditions.)
North Carolina EMC	Yes	Additional background in the test boxes is very helpful.
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG, CNE & CENG)	Yes	BGE agrees this would help clarify the basis of the Definitions & Requirements.
Dominion	Yes	Dominion agrees, but suggests that reference to figure(s) and table(s) contain links that can take reader to that section of the document. This is superior to having to scroll through document. If the reference(s) is external to this standard document, links may be harder to manage but should at least reference a common webpage(s) used by NERC for the posting of such documents.
Xcel Energy	Yes	However, the boxes should be adding clarity, not "defining' terms or stipulating further requirements/criteria that must be met. See MVCD in R1 & R2 and the incorporated Table 2, and comments to #1 & #13 in this form. The standard should be able to convey the requirements without the text boxes or, if the text boxes are used, the purpose and legal import of such boxes should be clarified. Further, it should be clarifed that for text boxes that provide examples (e.g., the boxes on page 2 in the definitions section), such boxes should clearly state that the examples are in no way limitations.
Ga Transmission Corp	Yes	I do like the text boxes.
ITC Holding	Yes	ITC agrees, but would like to suggest that the text boxes include additional pertinent information from the Technical Reference that would be helpful as reliability talking points to the public. Example: (R3): The following is a sample description of one combination of strategies which may be utilized by a Transmission Owner. A Transmission Owner's basic maintenance approach could be to remove all incompatible vegetation from the right of way if it has the right to do so and has no constraints
Ameren	Yes	It's helpful to understand the SDT's logic for requirements, clarification is always appreciated.
GCPD	Yes	May help in cutting down the volume of SAR interpretation requests.
Central Maine Power, Iberdrola USA	Yes	R3 - this may be a good place to describe clearances at time of vegetation management work
Florida Municipal Power Agency	Yes	The clarification is important and will reduce the number of requests for interpretation if interpretation is already provided to some extent. Just a caution about how the text boxes will be used in the audit process,

Organization	Yes or No	Question 7 Comment
(FMPA) and Some Members		clarification concerning their use during compliance monitoring would be great.
NERC Staff (12 staff members)	Yes	The explanatory information posted with the proposed definitions, like the definitions, is only relevant to this standard, and some of the information is only relevant to the point where the definition becomes enforceable. What is the expectation for what will happen to this information in the future? We suggest that the text boxes associated with requirements include a reference to that requirement. (Change “Rationale” to “Rationale for R1”)
Western Area Power Administrtaion	Yes	The format could be enhanced by moving the "Guidelines and Technical Basis" section forward to be included with the corresponding Requirement, Measure, and Rationale. Perhaps the "Guidelines and Technical Basis" could also be combined with the corresponding "Rationale" text box. This would be helpful because it is awkward flipping back and forth between these two sections when trying to fully understand a requirement.
SERC OC Standards Review Group	Yes	This format adds clarity and improves readability.
SERC Vegetation Management Sub-committee	Yes	This format adds clarity and improves readability.
East Kentucky Power Cooperative, Inc.	Yes	This format is simpler, easier to read, understand and implement.
Progress Energy Carolinas	Yes	This format provides clarity and improves readability. Progress Energy believes that having SDT basis information for a requirement in the standard will reduce the need for interpretation and improve the interpretation process for a requirement, if necessary.
Tampa Electric Company	Yes	This improves the clarity and understanding to the requirements.
American Electric Power (AEP)	Yes	This is a good change.
JEA	Yes	This is extremely helpful in understanding the intent of the requirement
Western Area Power Administration - Upper Great Plains Region	Yes	WAPA - UGPR believes that the expanations within the text boxes provided additional useful information.

Organization	Yes or No	Question 7 Comment
Entergy Services	Yes	We agree that text boxes being used for additional clarity is a benefit if used in a correct and clear manner. It needs to be specifically stated in the document that the text boxes are to be used for reference only, entities will not be required to specifically follow the language in the Rationale box, and that each utility should specify their own process for addressing each Requirement. For example....the Rationale box for R4 states that "Verified knowledge includes observations by journeyman lineman, utility arborist, or other qualified personnel.......". Our process will specify exactly who that qualified personnel is (Transmission Specialist or another qualified Entergy Employee in the Transmission Vegetation Group, for example). We will specify this in our internal processes.
FirstEnergy	Yes	We agree that text boxes can be useful for requirements and definitions. However, the SDT may want to consider eliminating the text boxes since this information is already provided in the Guidance and Technical Basis section. Also, we have the following additional comments:General:1. With respect for the rationale text boxes for definitions, it is not clear if these boxes will be retained once the definitions are moved out of the standard and added to the NERC Glossary.2. The rationale text boxes can be beneficial for the requirements, but some of the text boxes in this current draft of FAC-003-2 seem to include prescriptiveness that is not found in the requirement. An example is in the text box for Req. R4, which implies timeliness of notification of an imminent threat with the use of the word "rapid". In the case of R4, the requirement should state that notification be carried out immediately (see our suggested rewording of R4 in Question 13). 3. Although these text boxes are not enforceable for compliance, we are not convinced that an auditor will view this as simply guidance.Specific:1. Definition for Active Transmission Line ROW - Example 3 of Inactive ROW - Consider removing this example; situations where vegetation is left unmanaged on portions of the ROW where double-circuit structures exist with only one circuit strung with conductors poses an unnecessary increased risk for vegetation related outages. 2. Rationale box for Req. R3 - See our comments in Question 23. Rationale box for Req. R4 should be revised to state: "To ensure rapid notification of the responsible control center when an occurrence of an imminent threat condition is verified. Evidence of verified knowledge includes observations by journeyperson, lineperson, utility arborist, or other qualified personnel, or a report verified by these personnel. This notification allows the responsible control center to take the appropriate action until the threat is relieved. Appropriate actions may include a temporary reduction in the line loading or switching the line out of service."4. Rationale box for Req. R5 - (1) The last statement of this box seems incomplete. It should be revised to state: "This requirement is not intended to address situations where the transmission line is not at immediate risk and the work event can be rescheduled or re-planned using an alternate work methodology."; and (2) We suggest revising the first statement to "Legal actions filed by property owners, easement restrictions and other events...."
Southern California Edison Company	Yes	We agree that the insertion of text boxes aids readers in understanding the basis for the Definitions and Requirements.

Organization	Yes or No	Question 7 Comment
Independent Electricity System Operator	Yes	We agree that the side-bars give useful contextual information that is not part of standard. This is good and avoids the reader’s attention being completely redirected to a reference document when seeking clarification of the intent of a requirement. We believe however that these text boxes should be used sparingly and the content should also be brief to minimize possible distractions to the reader.It should also be made clear in the standard that these text boxes are not intended to impose additional requirements and in the event of any perceived conflict, the text of the requirement will take precedence.
South Carolina Electric and Gas	Yes	We agree, however we would like clarification on whether entities can be held accountable for rationale portions of the standard as they are for interpretations that are added to a standard.
Ad Hoc Group subteam formed to review draft standard	Yes	We understand this question to refer to the “rationale” text boxes in this standard. Additional information such as this is useful to the entity in explaining and clarifying the understanding of the drafting team in articulating the requirement and thus supports a fuller understanding of the entity in achieving compliance with the requirement.
KCPL	No	I like information that helps to “guide” and “provide guidance”, however, we already having trouble with information from FAQ’s, White Papers, and other guiding documents creeping into the requirements by auditing teams. The inclusion of “guiding information” in the text of the Standard itself may promote adding to requirements. Although helpful, I recommend removing this text from within the body of the Standard.

8. **Do you agree with the addition of a Guideline and Technical Basis Section to place technical materials and other related information that assists entities in understanding how to comply with the standard but does not contain mandatory actions/activities? Please explain.**

Summary Consideration: Most of the comment forms (38 out of 54) indicated agreement with the addition of the Guideline and Technical Basis Section.

Some commenters expressed a concern over how the materials contained in this Section may be used in compliance monitoring and enforcement.

Some commenters suggested that it should be expressly stated that this section is for information purposes only and is not part of the Standard Requirements. They further suggested compiling all of the “Information Only” materials into an Appendix as a preferred alternative. Others suggested that guideline materials be moved into a separate document.

Some commenters suggested that while this Section contains useful materials, NERC should consider developing a separate set of Guideline documents to afford the industry a knowledge base that is not directly sanctionable for non-compliance.

Some commenters expressed a concern that being located within the standard, the Guideline Section will imply additional requirements for mandatory compliance, or get used by auditors as compliance issues.

The SCPS assesses that the industry likes the idea of having technical guidelines for standards. Guideline materials, whether they are put in a separate document or included in a standard, can be used by anyone to assess compliance with standards. Putting them outside of the standard does not eliminate this possibility.

The material in the Guideline and Technical Basis Section is intended to provide guidance but is not intended to expand on any of the requirements and is not intended to include any mandatory performance. A legal statement will be added to the standard to make this clear. The SCPS believes that as long as it is made clear that only the requirements and provision of evidence are mandatory, any supporting materials can be provided in a standard to aid readers better understand the standard without binding them to complying with the supporting materials. The intent of the description of the elements of a standard in the proposed Standard Processes Manual is to make it clear that there is a distinction between the enforceable sections of the standard and the compliance and supporting information sections of the standard.

Organization	Yes or No	Question 8 Comment
Florida Municipal Power Agency (FMPA) and Some Members	No	Although FMPA agrees that a Guideline and Technical Basis document is important, FMPA has concerns about how this section might be used in compliance monitoring and enforcement. For instance, R4 has a time requirement somewhat embedded in the Guideline and Technical Basis that is not in the requirement in the standard: “The imminent threat process should be implemented in terms of minutes or hours as opposed to a longer time frame for interim corrective action plans”. How many minutes or hours? This adds ambiguity to the standard. If a time limit is desired, it should be in the requirement. There are other examples of items that could be interpreted as requirements in the Guidelines. It should be made clear what the purpose of the Guidelines is in compliance monitoring and enforcement. FMPA suggests publishing two documents in the same fashion that the Functional Model has two documents, one for the standards (e.g., the requirements), and another for technical guidance to the standards (e.g., the Guideline and Technical Basis section) to

Organization	Yes or No	Question 8 Comment
		parallel the structure of the Functional Model and Functional Model Technical Document, which will help make the distinction between CMEP and guidance more distinct.
American Transmission Company	No	ATC disagrees with the above statement that it only assists in understanding how to comply. ATC believes that parts of this section are written so they could be interpreted to contain mandatory actions/ activities. To demonstrate, see example on pg.15, R4, 2nd paragraph states...Two key elements of an acceptable imminent threat procedure are outlined below:..........) It should not be more than a preferred method for implementation or supporting how the TO can meet the standard. NERC needs to clarify how this section was intended to be used. (This as written could become part of a Compliance Audit process)Also, refer to ATC's comment on this section in Question #3 above.
Bonneville Power Administration	No	Consider referencing ANSI A300 part 7 as best management practices for R3. It is currently referenced in the White Paper, and would lend more credibility to the standard if it was inserted in the text box for R3.
ERCOT ISO	No	For the same reasons stated in the comments to Question 7, it should be expressly stated that this section is for information purposes only and is not part of the Standard Requirements. Compiling all of the "Information Only" materials into an Appendix would be the preferred method of organization.
Northeast Power Coordinating Council	No	NPCC participating members do not believe that publishing more information as part of the standard is appropriate. For the same reasons as stated in the preceding response related to "Text Boxes" in question 7, any inconsistency may result in a conflict with a requirement. The information in the Guideline and Technical Basis section is valuable, however, and should be available to the industry in the form of guidelines. NPCC participating members suggest that NERC assemble a comprehensive set of "Guideline" documents into one bookmarked pdf publication to be updated as standards change. This will afford the industry a knowledge base that is not directly sanctionable for non-compliance, but a set of industry best practices, background, and reference for the standards development activities. Also, concern exists that FERC and Provincial governmental authorities will have jurisdiction over "Guidelines", and when the standard is approved it will become a mandatory "rule".
Nebraska Public Power District	No	Same as item 7.
CenterPoint Energy	No	See answer to Q3.
GCPD	No	Should be separate documents. If located with the standard it will get used by the auditors as compliance issues. NO matter how much text you provide to the contrary it will become part of the standard over time.

Organization	Yes or No	Question 8 Comment
Consolidated Edison Company of New York, Inc.	No	Since the SDT has developed a complete Technical Reference Document for this Standard, there seems to be redundancy with the Guideline and Technical Basis Section. This Standard has become too lengthy with all of the additional details and information that has been added. We prefer to have a shorter Standard and a more detailed stand alone supporting reference document.
Orange and Rockland Utilities, Inc.	No	Since the SDT has developed a complete Technical Reference Document for this Standard, there seems to be redundancy with the Guideline and Technical Basis Section. This Standard has become too lengthy with all of the additional details and information that has been added. We prefer to have a shorter Standard and a more detailed stand alone supporting reference document.
Cleco	No	The inclusion of the text implies additional requirements. Keep quidance to a separate paper.
IRC Standards Review Committee	No	This change also requires some additional explanation. What level of importance will be given to such materials? If an SDT inserted a Best Practices document, does that allow auditors to refer to that document for purposes of holding an entity non-compliant? Are these materials there to help entities who do not know how to comply? If these materials are self-help guides, then it would be better to include them as URL references that are stored in the NERC library. That way there can be not confusion about whether the material is there as a self-help guide, or as a reference for auditors.
FRCC Manager of Operations	No	We agree that this is valuable information and important to convey with the standard. This should be a separate companion document balloted, approved and posted with the standard but not be a part of the standard.
TO/TOP	No	We agree that this is valuable information and important to convey with the standard. This should be a separate companion document balloted, approved and posted with the standard but not as part of the standard.
SERC OC Standards Review Group	No	We recommend that the text “grid reliability” be substituted for “Bulk Electric System” on page 6 of the draft.The inclusion of non-mandatory guidelines in a standard that will ultimately be approved by FERC gives undue credence to “guidelines” that will lead undoubtedly to mis-application by future compliance auditors. We suggest separation of this information from the mandatory reliability standard that will be filed at FERC. It could be held in a repository on the NERC website.
Arizona Public Service Company	Yes	
Central Maine Power, Iberdrola	Yes	

Organization	Yes or No	Question 8 Comment
USA		
Consumers Energy	Yes	
Duke Energy	Yes	
Exelon	Yes	
Manitoba Hydro	Yes	
North Carolina EMC	Yes	
Omaha Public Power District	Yes	
Oncor Electric Delivery	Yes	
Pepco Holdings, Inc. - Affiliates	Yes	
PPL Electric Utilities Corporation (NCR00884)	Yes	
South Carolina Electric and Gas	Yes	
Tennessee Valley Authority	Yes	
Tucson Electric Power Co.	Yes	
Utility Risk Management Corporation	Yes	
Tampa Electric Company	Yes	Aids in improved understanding of FAC-003-2.
FirstEnergy	Yes	Although we agree that guidelines are good to have and agree that having them in the body of the standards is convenient, we question how this section will be viewed from a compliance standpoint. We understand this section is not intended to be mandatory, but does that mean that regulatory authorities will only approve the other sections of the standard and not this section? Also, it should be clear and explicitly stated in the lead-in

Organization	Yes or No	Question 8 Comment
		to this section that this is guidance which is not mandatory and enforceable. Additionally, terms such as "shall", "should", and "require" should not be used in the guidance section because the information presented in this section could be construed as mandatory by an auditor. An example of this is in the guidance information for Requirement R7 which states "Documentation is required when the annual work plan is adjusted...". This mandatory-type language should not be included in the Guidelines section.
MRO's NERC Standards Review Subcommittee	Yes	Another good addition to the standard and will help clarify parts of the standard without referring to another document or set of guidelines.
Southern California Edison Company	Yes	Assuming that the "Guideline and Technical Basis Section" will be retained and revised in future revisions to the standard, such information should prove very useful.
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG, CNE & CENG)	Yes	BGE agrees with the addition of a Guidance & Technical Basis section.
JEA	Yes	Having the information in the same document makes the information more accessible to the entity attempting to comply with the standard.
Ga Transmission Corp	Yes	I do however believe that each utility should have the flexibility to manage there program the way they feel is the most effective method. I do not want the technical basis section to limit options. Should this be in a white paper format?
East Kentucky Power Cooperative, Inc.	Yes	I have no preference one way or the other on this issue.
ITC Holding	Yes	ITC agrees with Guidelines and Technical Basis section, but recommend including useful Technical Reference actions and activities that would support defense-in-depth strategy. We also feel that to avoid any confusion with the applicability section and interpretations in the future, any references to the Bulk Electric System in the standard sections and guidance/technical reference document should be reviewed and changed.
Entergy Services	Yes	Language should be added to the Guideline and Technical Basis Section to clarify or re-state that this section is for assisting entities in understanding how to comply with the standard but does not contain mandatory actions/activities, and a statement that entities are not required to use the information in the Guideline and Technical Basis Section.

Organization	Yes or No	Question 8 Comment
Western Area Power Administrtaion	Yes	The format could be enhanced by moving the "Guidelines and Technical Basis" section forward to be included with the corresponding Requirement, Measure, and Rationale. Perhaps the "Guidelines and Technical Basis" could also be combined with the corresponding "Rationale" text box. This would be helpful because it is awkward flipping back and forth between these two sections when trying to fully understand a requirement.
NERC Staff (12 staff members)	Yes	There is no language in the body of the standard to clarify that the information in the Guideline and Technical Basis Section of the standard is not subject to enforcement. We suggest revising the heading to “Application Guidelines.” This is the term that was originally proposed by the Results-based team and is the heading identified in the proposed Standard Processes Manual.
SERC Vegetation Management Sub-committee	Yes	This format adds clarity and improves readability.
Xcel Energy	Yes	This is all good information to add a depth of understanding for the user. It's not clear as to how modifications to the Guideline and Technical Basis would come about - it is the same as the standards revision process? Does this section replace the white paper? Will it actually be deemed to be part of the Standard? We are curious as to the legal weight if this is not part of the Standard and believe that key provisions are in this section. It seems it should be part of the Standard.
Ameren	Yes	This is helpful information to have that does not clutter up the requirements and measurements. Under R6, the third paragraph, there is a typo: ..."230kv transmission lines at least once 'line' during the calendar year".
City of Tallahassee (TAL)	Yes	This is very useful information and will minimize misinterpretations by the entities and the compliance teams.
Progress Energy Carolinas	Yes	This new section provides additional information and SDT rationale that is critical to understanding how to comply with the requirements in the standard and will also provide SDT intent/basis for the interpretation process when necessary. Progress Energy believes that any references to the Bulk Electric System in the standard sections and guidance/technical reference document should be reviewed and changed (e.g. “grid reliability”) to avoid confusion with the applicability section in this draft and avoid the potential for applicability interpretations once this version is adopted.
Independent Electricity System Operator	Yes	This section should be placed in an appendix preceded by a statement that clearly states the purpose of the Section and indicates that the Guideline and Technical Basis Section does not in any way add to the requirements of the standard. Also, this section appears to be a summary of the Technical Reference Document but we could find no reference to the Technical Reference within the standard. This reference should be cited for the benefit of anyone seeking further detail.

Organization	Yes or No	Question 8 Comment
Western Area Power Administration - Upper Great Plains Region	Yes	WAPA - UGPR agrees with the concept of placing the background technical information in a separate section. We were a bit concerned with the Guideline for R7 because it seems to mandate many more items than were called for in the actual requirement in the body of the standard. Our belief is that the Guideline section should not infer or list any more requirements than the actual requirement dictates.
Ad Hoc Group subteam formed to review draft standard	Yes	We agree with the additional material as an aide to entities to further understand the basis for the requirements. In this spirit the information should support compliant behavior and thus the reliability objectives of the standard.
Dominion	Yes	While we agree that these can be useful, we are concerned about the 'last minute' change (March 24th) to the technical reference document being used by those reviewing the materials for this project.
Southen Company	Yes	Would it be better to have an official white paper associated with the standard rather than having this information in the standard? A white paper can be changed without seeking industry comments and approval from NERC, while information in the standard must go through the entire approval process. As it is structured now, information-only updates to the Technical Basis Section would require the entire standards approval process to be completed.
American Electric Power (AEP)	Yes	Yes, although American Electric Power does question whether auditors will be able to avoid reading and applying such text.
KCPL	No	I like information that helps to "guide" and "provide guidance", however, we already having trouble with information from FAQ's, White Papers, and other guiding documents creeping into the requirements by auditing teams. The inclusion of "guiding information" in the text of the Standard itself may promote adding to requirements. Although helpful, I recommend removing this text from within the body of the Standard.

9. Do you prefer putting URL links to reference materials in the Guideline and Technical Basis Section, or do you prefer putting the additional technical/information materials in appendices, where needed, to supplement the Guideline and Technical Basis Sections? Please explain.

Summary Consideration: Out of the 52 comment forms received, 28 forms indicated a preference for use of URLs, 22 indicated a preference for appendices and 5 indicated no preference. These results indicate that either approach would be acceptable. The SCPS agreed to put the information in an appendix rather than in a URL because it is difficult to maintain the accuracy of URLs over time, and because keeping the information in the body of the standard is less work for end users as all information would be in one place.

Organization	Yes or No	Question 9 Comment
MRO's NERC Standards Review Subcommittee		If there is background information contained in a URL link pertaining to a particular Requirement, that link should be with the Requirement that it pertains to.
Ad Hoc Group subteam formed to review draft standard		Judicious and correct use of citations should allow the proper documentation of references without the hazard of expired URLs or expansion from using appendices.
Tennessee Valley Authority		No preference, either way will work.
Consumers Energy	Prefer appendices	
Exelon	Prefer appendices	
PPL Electric Utilities Corporation (NCR00884)	Prefer appendices	
South Carolina Electric and Gas	Prefer appendices	
TO/TOP	Prefer appendices	
Tucson Electric Power Co.	Prefer appendices	
Western Area Power Administrtaion	Prefer appendices	

Organization	Yes or No	Question 9 Comment
Xcel Energy	Prefer appendices	
GCPD	Prefer appendices	Actually we prefer that they are separate from the standard entirely. See question 8.
Cleco	Prefer appendices	An appendix ensures the information is available and original at the time the document it supports was prepared.
ERCOT ISO	Prefer appendices	An Appendix would probably be easier to use, but either type of reference would suffice. Regardless of which is used, it should include a footnote that the information is “For Information Purposes Only” and are not a part of the Standard’s Requirements. If the information causes confusion, then it should be eliminated completely. Also, what types of materials are contemplated to be “reference materials”?
Oncor Electric Delivery	Prefer appendices	Appendices would memorialize documents vs URL links to reference materials that may change over time. This Standard was crafted from “todays” point of view and background information. Reference material might change and the URL would point to material not validating the current form, logic, and background of the Standard.
Entergy Services	Prefer appendices	Appendices, or reference to a single site for all referenced material, would be the most helpful from the standpoint of keeping the information together and more readily available.
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG, CNE & CENG)	Prefer appendices	BGE prefers that such materials be included in the appendices.
NERC Staff (12 staff members)	Prefer appendices	It is not clear what part of the standard is being balloted and what part is not. In addition, it is not clear what process will be used to modify the guideline/technical basis section of the standard. This needs to be determined before this standard can be balloted.
FRCC Manager of Operations	Prefer appendices	Links can get broken - official records (ie. standards) need to stand alone.
City of Tallahassee (TAL)	Prefer appendices	The fewer places I have to navigate to the better I like it. I find too many “broken” URLs. This will also make it easier when I download a “complete set” of standards from the NERC website.
Dominion	Prefer appendices	Unless a ‘failsafe’ process is developed to insure URL links are keep up-to-date, preference is to locate all referenced materials within the standard (same URL). However, there are a number of ways that

Organization	Yes or No	Question 9 Comment
		URL linkage could be done. One would be to locate all Guideline and Technical Basis documents on a webpage dedicated to such documents. This would allow URL linkage at a higher level than if there is URL linkage for each Guideline or Technical Basis document. This is probably the easiest to maintain. Another would be to link each Guideline or Technical Basis document referenced in a standard to the same URL as that standard. Maintaining URL linkage is probably medium. Yet another is to have the URL link to a webpage created specifically for that Guideline or Technical Basis document. This is likely to be the hardest (require most effort) to maintain.
CenterPoint Energy	Prefer appendices	URL links tend to change over time due to administrative requirements. Moving them to the appendix will avoid revisions to the Standard. See also answer to Q3 regarding the Guideline and Technical Basis Section.
Florida Municipal Power Agency (FMPA) and Some Members	Prefer appendices	URLs can break
Nebraska Public Power District	Prefer appendices	URLs change periodically.
North Carolina EMC	Prefer appendices	Will need to put something in place to make sure that the links get properly updated if they change.
Ameren	Prefer the inclusion of URL links	
Arizona Public Service Company	Prefer the inclusion of URL links	
Bonneville Power Administration	Prefer the inclusion of URL links	
Consolidated Edison Company of New York, Inc.	Prefer the inclusion of URL links	
Duke Energy	Prefer the inclusion of URL links	
Ga Transmission Corp	Prefer the inclusion	

Organization	Yes or No	Question 9 Comment
	of URL links	
IRC Standards Review Committee	Prefer the inclusion of URL links	
Manitoba Hydro	Prefer the inclusion of URL links	
Omaha Public Power District	Prefer the inclusion of URL links	
Pepco Holdings, Inc. - Affiliates	Prefer the inclusion of URL links	
Southern California Edison Company	Prefer the inclusion of URL links	
Utility Risk Management Corporation	Prefer the inclusion of URL links	
Progress Energy Carolinas	Prefer the inclusion of URL links	Additional reference documents provide additional information that may be needed to understand how to comply and the basis of requirements, but they should not be included as appendices. The use appendices could result in a SDT process/effort for minor revisions to the reference document.
American Transmission Company	Prefer the inclusion of URL links	Also see ATC's comment on "Guideline and Technical Basis Section" in Question #3 above.
Independent Electricity System Operator	Prefer the inclusion of URL links	In general the additional reference materials may make the document extremely voluminous so we prefer URL links.
Northeast Power Coordinating Council	Prefer the inclusion of URL links	Links are preferable to alleviate the concerns expressed in question 8 above, especially with respect to FERC approval.
JEA	Prefer the inclusion of URL links	No strong preference.

Organization	Yes or No	Question 9 Comment
Tampa Electric Company	Prefer the inclusion of URL links	None
Western Area Power Administration - Upper Great Plains Region	Prefer the inclusion of URL links	None
Orange and Rockland Utilities, Inc.	Prefer the inclusion of URL links	Prefer the inclusion of URL links
East Kentucky Power Cooperative, Inc.	Prefer the inclusion of URL links	Provides for clarity and readability.
Southen Company	Prefer the inclusion of URL links	See answer to number 8.
American Electric Power (AEP)	Prefer the inclusion of URL links	The use of URL links is probably most appropriate for an increasingly web-based reference repository.
SERC OC Standards Review Group	Prefer the inclusion of URL links	This format adds clarity and improves readability.
SERC Vegetation Management Sub-committee	Prefer the inclusion of URL links	This format adds clarity and improves readability.
ITC Holding	Prefer the inclusion of URL links	URL links provide immediate access, are less cumbersome, and usually provide additional research material when accessed.
FirstEnergy	Prefer the inclusion of URL links	We prefer URL links. Although, we are not clear what this question is asking regarding "additional technical/information materials". Is the team referring to "supplemental" reference documents such as the technical reference white paper that was recently posted for stakeholder review on March 24, 2010? If so, we agree that supplemental reference material be included through URL links, perhaps at the end of the "Guidelines and Technical Basis" section of the standard.
KCPL	Prefer appendices	Although a good idea generally, too many times URL links change name or something else that makes the imbedded link unusable or takes you to the wrong place. Having an appendix ensures the

Organization	Yes or No	Question 9 Comment
		information is available and original at the time the document it supports was prepared.

10. Do you agree with the addition of the Background Section to allow provision of background information, and to elaborate on the reliability-related drivers for the standard/change? Please explain.

Summary Consideration: Most of the comment forms (42 out of 54) indicate agreement with the addition of the Background Section.

Some commenters expressed similar concerns as those for Text Boxes and the Guideline and Technical Basis Section that the information should not be subject to FERC's review and approval, and that the Background may contain Requirement material that is enforceable. Other commenters suggested that this Section is not needed given the addition of the Guideline and Technical Basis Section.

The SCPS believes that the Background Section serves a different purpose than the Guideline and Technical Basis Section. The Background Section provides the background that led to the development of the standard, tying it to the reliability drivers and principles. In essence, the Background Section gives readers the reasons for and the events that led to the development of the standard. The Guideline and Technical Basis Section serves a very different purpose as it provides readers with the technical background, general guidelines, and general practices or technical merits that the responsible entities could take or consider to help them meet the reliability requirements. The Guideline and Technical Basis Section can also be used to provide some examples to illustrate the coverage or intent of the requirements.

On this basis, the SCPS believes it is in the interest of the majority of commenters to keep the Background Section. The SCPS will communicate to the standard drafting team that the Background Section must not contain requirement material, and should not include any technical information that should be provided in the Guideline and Technical Basis Section. The Background Section will remain at the front of the standard. As noted in response to other questions, a legal statement will be added to clarify which sections of the standard are mandatory and enforceable.

Organization	Yes or No	Question 10 Comment
ERCOT ISO	No	Again, it is preferable to include this type of information in an Appendix as long as it is made clear that this is additional information and is not a part of the Standard's Requirements. However, if there is a chance that the additional information included in the Appendix is going to cloud the Requirements spelled out in the Standard, then our preference is to eliminate the additional information completely.
SERC OC Standards Review Group	No	Inclusion of a background section in a document that will be approved wholly by FERC give undue credence and weight to statements which may be included that are not necessarily factual 100% of the time. For example, the first sentence of the last paragraph of the background section reads as follows: "Since vegetation growth is constant and always present, unmanaged vegetation poses an increased outage risk, especially when numerous transmission lines are operating at or near their Rating." Obviously, woody stems do not grow during the dormant season, yet the background asserts that it does. There are other areas in this sentence that are not completely factual and should not be in a reliability standard. We recommend that the text "grid reliability" be substituted for "Bulk Electric System" on page 6 of the draft.
Consumers Energy	No	Not necessary.

Organization	Yes or No	Question 10 Comment
Northeast Power Coordinating Council	No	NPCC participating members believe this is more informational and appropriate on the individual standard’s NERC Website “Under Development” page, in an announcement, cover letter, or to be distributed with the standard drafts.
Nebraska Public Power District	No	Same as item 7.
CenterPoint Energy	No	See answer to Q3.
Florida Municipal Power Agency (FMPA) and Some Members	No	The background belongs in the Guidelines and not as part of the standard.
FRCC Manager of Operations	No	The background section should be re-named "Technical Basis". Trim content and leave only the first and last paragraphs. In addition, all 5 paragraphs of the section as written should be moved to the front of the Guidelines and Technical Basis document as a "Background" section of that separate document. NERC should limit its use of "background" information within the reliability standard itself.
TO/TOP	No	The background section should be re-named "Technical Basis". Trim content and leave only the first and last paragraphs. In addition, all 5 paragraphs of the section as written should be moved to the front of the Guidelines and Technical Basis document as a "Background" section. NERC should limit its use of "background" information in reliability standards.
Cleco	No	The inclusion of the text implies additional requirements. Keep quidance to a separate paper.
Exelon	No	This information should be in appendices or reference documents available on the NERC standards site.
Ameren	Yes	
Arizona Public Service Company	Yes	
Bonneville Power Administration	Yes	
Central Maine Power, Iberdrola USA	Yes	
City of Tallahassee (TAL)	Yes	

Organization	Yes or No	Question 10 Comment
Duke Energy	Yes	
East Kentucky Power Cooperative, Inc.	Yes	
Ga Transmission Corp	Yes	
JEA	Yes	
Manitoba Hydro	Yes	
MRO's NERC Standards Review Subcommittee	Yes	
North Carolina EMC	Yes	
Omaha Public Power District	Yes	
Oncor Electric Delivery	Yes	
Pepco Holdings, Inc. - Affiliates	Yes	
PPL Electric Utilities Corporation (NCR00884)	Yes	
South Carolina Electric and Gas	Yes	
Southen Company	Yes	
Tennessee Valley Authority	Yes	
Tucson Electric Power Co.	Yes	
Utility Risk Management Corporation	Yes	

Organization	Yes or No	Question 10 Comment
Western Area Power Administrtaion	Yes	
SERC Vegetation Management Sub-committee	Yes	Allows for a more informed interpretation of the standard.
American Electric Power (AEP)	Yes	American Electric Power agrees with this change.
American Transmission Company	Yes	ATC agrees that the Background Section is helpful; however, NERC should define its purpose and goal. What is currently written is more than necessary to be included in this standard.
Dominion	Yes	Dominion agrees but suggests it be moved towards end (suggest between Administrative and Guideline/Technical basis sections).
Ad Hoc Group subteam formed to review draft standard	Yes	Great help in showing intent and reliability goal of the standard.
Southern California Edison Company	Yes	Including a background section should prove useful for future editions. However, at some point such information could be made accessible through URL links.
ITC Holding	Yes	ITC agrees with the addition of Background Section
GCPD	Yes	May help in iterpretations and in explaining to stakeholders in our organizations.
Tampa Electric Company	Yes	None
Western Area Power Administration - Upper Great Plains Region	Yes	None
Progress Energy Carolinas	Yes	Progress Energy agrees and believes that the background section will allow relevant background information that provided direction/guidance for the SDT to be readily available after the standard revision is adopted.
Entergy Services	Yes	The Background Section is helpful, but the last sentence states....."Thus, this Standard's emphasis is on vegetation grow-ins.". This statement seems to conflict with the outage Category 2 "Fall In" classification,

Organization	Yes or No	Question 10 Comment
		even though it is a fall in from within the ROW.
Xcel Energy	Yes	The Background section should be moved to the back, in front of the Guideline and Technical Basis.
IRC Standards Review Committee	Yes	This background is important for insertion at the beginning of a SAR. But for a standard-posting, it is suggested that this section is redundant and better inserted after the requirement and measures with the other Administrative materials.
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG, CNE & CENG)	Yes	This makes sense to BGE.
NERC Staff (12 staff members)	Yes	This provides a context for the requirements and is very beneficial in understanding the intent of the standard.
Independent Electricity System Operator	Yes	This section expands on the purpose statement and will promote a uniform understanding of the fundamental drivers for the standard and its requirements, as well as its philosophy and scope.
Consolidated Edison Company of New York, Inc.	Yes	We agree but believe the Background Section should be situated before the Applicability Section in the revised Standard and redundant verbiage should be removed.
Orange and Rockland Utilities, Inc.	Yes	We agree but believe the Background Section should be situated before the Applicability Section in the revised Standard and redundant verbiage should be removed.
FirstEnergy	Yes	We agree that a Background section is beneficial. However, we believe it may be more appropriate to move this information to the Guidelines section as a lead-in. Also, we suggest a rewording of the first sentence of the first paragraph on Pg. 2 which states: "Major outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations". We agree that vegetation can contribute to outages, but it cannot be the sole cause of major outages. Major outages can be prevented if other measures required by other NERC standards are implemented when vegetation causes a line or other equipment to malfunction. We suggest a rewording of this statement as follows: "Interference between vegetation and transmission lines located on many types of land have contributed to significant outages and operational challenges."
KCPL	No	I like information that helps to “guide” and “provide guidance”, however, we already having trouble with information from FAQ’s, White Papers, and other guiding documents creeping into the requirements by auditing teams. The inclusion of “guiding information” in the text of the Standard itself may promote adding to

Organization	Yes or No	Question 10 Comment
		requirements. Although helpful, I recommend removing this text from within the body of the Standard.

11. Do you agree with the addition of an Administrative Procedure Section to place administrative/procedural requirements that are contained in the existing standards but which do not meet the results-based or risk-based criteria? Please explain.

Summary Consideration: Most comment forms (36 out of 52) indicated agreement with this addition.

Some commenters questioned whether or not these Administrative Procedures are mandatory and if so, why they are not placed in the Requirements and Measures Section or at least renamed “Administrative Requirements”. They asked, if the administrative requirements are mandatory, are they subject to compliance audit and if so, would a monetary penalty be applied?

Some suggested that if the administrative procedures are not mandatory requirements, they should not be included in standards and proposed the alternative approach of collecting data/reports through the Rules or Procedure Section 1600.

The intent of creating the Administrative Procedure Section is to separate the procedural and administrative requirements from the results-based reliability requirements since not performing the former tasks does not adversely affect BES control or performance or expose the BES to reliability risks. The SCPS will provide further clarity to the intent of this Section, and consider the use of Rules of Procedure Section 1600 for data/report collection as an alternative.

Organization	Yes or No	Question 11 Comment
Consumers Energy	No	
Nebraska Public Power District	No	Administrative requirements should not be included in the Standard, they may be construed unintentionally as a requirement.
GCPD	No	Anything not directly associated with the compliance requirements or for help with interpretations should not be in the standard.
Northeast Power Coordinating Council	No	As stated earlier, NPCC participating members don’t understand if this section holds sanctionable requirements, and if so under what authority. Administrative items are best left to the ROP or Compliance documents. A results based standard’s primary focus should be on the requirements, and the goal or reliability objective. Taking administrative requirements out of the formal requirements section, adding them to another section, and still deeming them to be requirements is of no value to reducing the administrative burden on the industry. This makes the implementation of the standard more burdensome due to the fact that these additional “requirements” now reside in different places in the standard document. NPCC participating members suggest if these are truly valid requirements they need to be together with the other requirements. If they do not meet the results based criteria, and were included in this “Administrative Procedure” section strictly because of that, then they need to reside in another document. Their continued appearance in the document dilutes the integrity of the results based standard initiative.

Organization	Yes or No	Question 11 Comment
Exelon	No	Exelon is concerned this will raise questions concerning what criterion separates an administrative requirement from a results or risk based requirement. How are administrative requirements to be treated in the CMEP?
CenterPoint Energy	No	It is not clear if the Administrative Procedure is a mandatory activity. It would be helpful if the intent of this section was stated within the Standard.Also, this section in not parallel with the Rating and Rated Electrical Operating Conditions exception contained in R1 and R2. We recommend the following parallel wording for the first paragraph of this section:"The Transmission Owner will submit a quarterly report to its Regional Entity, or the Regional Entity's designee, identifying certain Sustained Outages of the categories defined below, while operating within the Rating and Rated Electrical Operating Conditions, determined by the Transmission Owner to have been caused by vegetation that includes, as a minimum, the following:"Also, the categories listed in this section do not have parallel language to M1 and M2. We recommend that this section should adopt the wording in M1 and M2 for the Sustained Outages to be reported. Currently, Category 2 and Category 4 do not distinguish between an IROL and Major WECC Transfer Path. This may become a tracking problem since they have different Violation Risk Factors. If this is not important, then Category 1A and 1B can be combined.
Consolidated Edison Company of New York, Inc.	No	It is somewhat confusing to have sanctionable requirements located in other sections of the Standard outside of 'Requirements and Measures.' The section title 'Administrative Procedure' is somewhat misleading; if it was renamed 'Administrative Requirements' we feel it would be clearer to the industry.
Orange and Rockland Utilities, Inc.	No	It is somewhat confusing to have sanctionable requirements located in other sections of the Standard outside of 'Requirements and Measures.' The section title 'Administrative Procedure' is somewhat misleading; if it was renamed 'Administrative Requirements' we feel it would be clearer to the industry.
SERC OC Standards Review Group	No	Reporting Outages is not a part of Vegetation Mgmt. Therefore, this reporting belongs in an Administrative Section or possibly via a NERC 1600 request. In no circumstance should it be a Requirement of the standard. In the last paragraph this section appears to place a requirement on a regional reliability entity: "The Regional Entity will report the outage information provided by Transmission Owners, as per the above, quarterly to NERC, as well as any actions taken by the Regional Entity as a result of any of the reported Sustained Outages." Was this really intended? What if the RE fails to make a report?
IRC Standards Review Committee	No	Some additional explanation is needed. If the requirement is to do inspections, and compliance is measured on that basis only then the Administrative Section is OK. If the entity is mandated to also meet the actions specified in the Administrative Section, then the change is not acceptable. This standard's example administrative section is introducing new requirements into the standard, and those requirements should be in the standard. In short, if there is a reliability requirement than that is what should be mandated.

Organization	Yes or No	Question 11 Comment
		The idea of mandating administrative items that are often designed to make auditing (not operations or planning) simpler should not be mandated.
FRCC Manager of Operations	No	The "Administrative" section needs to be streamlined - remove the first 2 paragraphs - quarterly reporting is no longer required and would be an administratively redundant process to the self-reporting of outages. Leave the outage categories to support consistent self-reports. Delete last paragraph - reporting by the Regional Entities to NERC is a delegated function that should be governed by the delegation agreements, rules of procedure or other internal ERO process, not within a reliability standard since REs and the EROs are not users, operators, etc of the BPS.
TO/TOP	No	The "Administrative" section needs to be streamlined - remove the first 2 paragraphs - quarterly reporting is no longer required and would be an administratively redundant process to the self-reporting of outages. Leave the outage categories to support consistent self-reports. Delete last paragraph - reporting by the Regional Entities to NERC is a delegated function that should be governed by the delgation agreements, rules of procedure or other internal ERO process, not a reliability standard.
Ad Hoc Group subteam formed to review draft standard	No	The administrative procedure section is appropriate under results-based requirements. However, we believe that reporting requirements established under other methods, such as the CMEP, may be confused by including it. It is unclear how non-conformance with administrative procedures would be handled. Perhaps administrative procedures would be better handled under ROP Section 1600 data requests or other Rules.
Cleco	No	The inclusion of the text implies additional requirements. Keep quidance to a separate paper.
Florida Municipal Power Agency (FMPA) and Some Members	No	The reporting requirements really boil down to a self-reporting or self-certification process since the only items to report would be violations to the standard. If such quarterly reporting is desired, it is really a self-certification process and should be governed by that process and not through a separate Administrative Procedure.FMPA recommends deleting the last paragraph - reporting by the Regional Entities to NERC is a delegated function that should be governed by the delegation agreements, rules of procedure or other internal ERO process, not within a reliability standard since REs and the EROs are not users, operators, etc of the BPS, and are not designated in the Applicability section.

Utility Risk Management Corporation	Yes	
Xcel Energy	Yes	Are we to understand that the requirements listed in the Administrative section are not sanctionable from a NERC compliance perspective?
American Transmission Company	Yes	ATC feels this adds good will on the part of the entity to submit necessary reports, however, ATC requests clarification whether this section is subject to NERC violations. (Currently not listed in Table 1 Time Horizons, VRFs and VSLs)
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG, CNE & CENG)	Yes	BGE agrees with addition of an Administrative Procedure section.
Duke Energy	Yes	During the WEBINAR, a question was raised regarding how failure to meet an Administrative/Procedural requirement would be addressed by the Regional Entity. Can the Standard Drafting Team prepare a response to the question?
JEA	Yes	However, it needs to be made clear whether this is subject to audit, and whether failure to meet the requirement is subject to the same or different enforcement procedures as the numbered requirements in the standard.
East Kentucky Power Cooperative, Inc.	Yes	I do not believe that reporting of outages is a part of development and implementation of a Vegetation Management Plan. I fail to see how it brings value to the standard.
ITC Holding	Yes	ITC agrees that the “administrative role” such as outage reporting; shouldn’t be a reliability requirement and are more appropriately defined as an administrative procedure. We would also like some clarification on whether this section of the standard is subject to NERC violations. Currently it’s not listed in Table 1 Time Horizons, VRFs and VSLs
Western Area Power Administration - Upper Great Plains Region	Yes	None

Organization	Yes or No	Question 11 Comment
Tampa Electric Company	Yes	Not sure why separating 1.A & 1.B is preferred over 1,2,3,4?
Progress Energy Carolinas	Yes	Progress Energy agrees that “Administrative” functions such as outage reporting should not be listed as a reliability requirement and are more appropriately defined as an administrative procedure. (Outage reporting is an administrative function that does not directly improve reliability which should be the focus of reliability standard requirements.)NERC has other formal information request procedures in place (such as a NERC 1600 request), if that becomes necessary to ensure outage reporting.
SERC Vegetation Management Sub-committee	Yes	Reporting Outages is not a part of Vegetation Mgmt. Therefore, this reporting belongs in an Administrative Section or possibly via a NERC 1600 request. In no circumstance should it be a Requirement of the standard.
Western Area Power Administrtaion	Yes	The Administrative Procedure section could be moved forward following the Background section to better introduce the general administrative overview for what would then become the following Requirements, Measures, etc. These general administrative and procedural requirements are more easily overlooked when they included at the back of the Standard.
American Electric Power (AEP)	Yes	This addition is acceptable
Independent Electricity System Operator	Yes	This section imposes an additional reporting requirement but there is no associated VRF or VSL. Is this intentional? How will failure to report on time be treated? This is unclear as is the significance of any such Administrative “Requirements” within the standard, in general. Is the intention to establish separate procedures to govern the administrative and reporting obligations of registered entities under the Rules of Procedure?
FirstEnergy	Yes	We agree with the Administrative Procedure Section. Monetary fines should not be imposed for noncompliance with administrative requirements.
KCPL	No	It is too easy to unintentionally infer or introduce something that is not intended to be a requirement, but gets interpreted as a requirement in this section. Standards should be clear in what is a requirement and what is helpful information. If these are requirements, then propose them as requirements. If not, then remove to another guiding document.

12. Is there any other information that should be included in the standard document? If so, please explain why you feel that this information should be included.

Summary Consideration: None of the commenters offered any suggestions for including additional information that has not already been suggested in one or more of the comments provided in Questions 3 to 11.

Some commenters provided comments on the standard content itself.

Some commenters commented on the “Informal Comment” process. While this process may be useful in speeding up the process of developing standards, it introduces a potential for a given Team to ignore valuable comments (either because the issue is unknown to them, or because the proposal does not agree with the team’s ideas). They suggested that all comments (both formal and informal) be posted immediately for all to review. The SCPS agrees with the suggestion however the software currently used to collect stakeholder feedback doesn’t format the data collected in a manner that is easy to understand. NERC staff is exploring alternatives that would make it easier for stakeholders to view comments as they are submitted. The informal commenting process is meant to collect industry views in the same manner as the formal commenting process; it differs only in not requiring the SDTs to provide a response to each comment. Notwithstanding this provision, the SDT is still obligated to post all comments and provide summary responses to the comments.

SERC OC Standards Review	Yes	As suggested in comment six, an improvement would be also listing the applicable table rows with each requirement which consolidates all pertinent info with the requirement. Also, adding the penalty matrix would

Organization	Yes or No	Question 12 Comment
Group		facilitate discussions with property owners/agencies resisting maintenance activates. This standard indicates a lack of recognition that vegetation outages are not necessarily reliability events. In the quest for improved reliability, spending the money necessary to achieve perfect compliance with R2, as stated, either will increase customer rates unnecessarily or cause the misallocation of maintenance funding away from maintenance activities that have a substantially higher impact on reliability.
SERC Vegetation Management Sub-committee	Yes	As suggested in comment six, an improvement would be also listing the applicable table rows with each requirement which consolidates all pertinent info with the requirement. Also, adding the penalty matrix would facilitate discussions with property owners/agencies resisting maintenance activates.
Arizona Public Service Company	Yes	Clearance 1 needs to be put back into this requirement as written. This is a vegetation management standard and there needs to be clear direction on how the system is going to be maintain at the time of maintenance. This ensures a clear direction to the utility the system has to be maintained. ANSI A-300 part 1 and 7 needs to be a requirement within the standard. Following this consensus agreement within the Professional Utility Vegetation Management sector outlines a process for providing a reliable transmission system. At a minimum ANSI A-300 part 1 and 7 should be incorporated into the Guideline and Technical Basis Section as a resource for compliance with this standard. Prudence would dictate that it be adopted into this draft as the foundation of any transmission vegetation management program as it is the accepted standard for professionals who are responsible for managing vegetation for electric utilities.Personnel qualifications need to be included in the standard and should include minimum measures such that there is consistency across the industry. This ensures that personnel are qualified and will have ongoing training and education in utility vegetation management. For example: The person who manages the field operation should have at least 5 years experience in vegetation management be an International Society of Arboriculture Certified Arborist and a Utility Specialist.
Ameren	Yes	In 4.3.1, suggest that "ice" be included in circumstances beyond the reasonable control of a TO in addition to the other "acts of God".
Entergy Services	Yes	More clarifying language throughout the document would be helpful.
Progress Energy Carolinas	Yes	None, other than the comment about potential improvements in question #6.
IRC Standards Review Committee	Yes	Regarding the new format, the idea of using "Informal Comment Periods" may be useful in speeding up the process of developing standards, but it also introduces a potential for a given Team to ignore valuable comments (either because the issue is unknown to them, or because the issue does not agree with their ideas). How will the Standards Committee or others ensure the quality of the process does not suffer in this way? What type of review process is contemplated to detect such behavior? Having the Formal

Organization	Yes or No	Question 12 Comment
		comments at the end of the process may prevent subject matter experts (SME) from seeing the comments and perspectives of other SMEs. The SRC suggests that all comments (both formal and informal) be posted immediately for all to review.
Xcel Energy	Yes	See comments to #1, #7 and #13 of this form
FirstEnergy	Yes	See our other comments.
Central Maine Power, Iberdrola USA	Yes	Table 2 expand footnote - State that table 2 is intended as a buiding block to develop clearance at time of vegetation management work. See TVMP for clearances.
CenterPoint Energy	Yes	The detailed rationale for the required one year inspection cycle in R6 should be included in the Technical Reference. The explanation provided in the Rationale that it “seems to be reasonable” and in the Technical Reference that it is “reasonable based on upon average growth rates across North America and common utility practice” are unfounded and arbitrary without a specific reference to a North American study. The Technical Reference should contain an example diagram of “the portion of the ROW where the corridor edge zones are designated by regulatory bodies for vegetation to exist” taken from the examples in the Definition of Terms Used in Standard section. It is unclear how this example should be interpreted for compliance should a Sustained Outage occur from vegetation growing within this zone. It is common for regulatory bodies to push utilities to plant trees or maintain trees within transmission rights of way to “hide the lines”, and it is unclear if this example is attempting to encourage such practice by regulatory bodies at the sacrifice of reliability.In general, the Technical Reference should contain more specific examples of violations of the Requirements and highlight specific exceptions related to vegetation related outages.The background and basis for adding the term “Active Transmission Line Right-of-Way” should be added to the Technical Reference.The background and basis for 4.2.4 that excludes the Standard from applying to fenced substations should be added to the Technical Reference.Just as the force majeure statement (4.3.1) was moved to the Applicability section of the Standard, the exception for applicability beyond the Rating and Rated Electrical Operating Conditions should be included in the Applicability section as well. Currently, it is only included in R1 and R2. It should be made clear if the other Requirements and Measurements must consider conditions beyond the Rating and Rated Electrical Operating Condition.Within the Requirements and Measures section there should be subheadings for each type of Requirement, performance-based, risk based, and competency-based. This classification is only indicated in the Technical Reference.
MRO's NERC Standards Review Subcommittee	Yes	The NSRS believes a section for definitions and abbreviated terms such as, Active ROW, MVCD, and WECC is needed. Also, See comment above in Question 9 on URL links.
Southen Company	Yes	We feel a definition of Category 3 outages (non reportable outages) should be included under the

Organization	Yes or No	Question 12 Comment
		administrative procedures. Although these outages are not reportable, this would provide a mechanism for classifying these outages so the utility can maintain evidence of its investigation and the rationale for not reporting them.
KCPL	No	

13. Do you have any other comment regarding the draft FAC-003-2 Transmission Vegetation Management standard that have not been addressed above? If yes, please provide a reference to the section, requirement, or subrequirement that you believe should be changed, added or deleted and the rationale for your proposal.

Summary Consideration:

1. **Reasonable control** - Some commenters expressed that the phrase "reasonable control" is difficult to enforce, while others wanted it moved to another section of the standard.
   The term "reasonable control" is prevalent in many force majeure clauses. It intends to limit the extent of compliance responsibility to those conditions that are within the sphere of the TO's ability. The SDT have determined that eliminating the word "reasonable" would not detract from the original intent and have made the change to the standard.
   The SDT does not have a preference for the location of the force majeure language. This is within the scope of the Standards Committee Process subcommittee to address.

2. **Differentiate between "human error" versus "human activity" –** Some commenters requested further explanation of these terms.
   The SDT intended for the term "human activity" to be used in the Background section of the standard and have removed "human error". The SDT intends the phrase human activity to describe those human actions that are outside the control of the Transmission Owner such as logging, vehicle contact with tree, removal or digging of vegetation, horticultural or agricultural or arboricultural activity. The SDT proposes the following new Force Majeure text:

   "This Standard does not apply to any occurrence, non-occurrence, or other set of circumstances that are beyond the control of a Transmission Owner subject to this reliability standard, including acts of God, flood, drought, earthquake, major storms, fire, hurricane, tornado, landslides, ice storms, vehicle contact with tree, human activity involving, removal of vegetation, installation of vegetation or digging around vegetation, animals severing trees, lightning, epidemic, strike, war, riot, civil disturbance, sabotage, vandalism, terrorism, wind shear, or fresh gales (or higher) that restricts or prevents performance to comply with this reliability standard's requirements. Nothing in this section should be construed to limit the Transmission Owner's right to exercise its full legal rights on the Active Transmission Line ROW."

3. **Competency-based requirement R3**: Some commenters expressed that R3 is deficient in detail.

   The SDT determined that the following parameters demonstrate competency:

   - Understands the dynamics of conductor movement over its operating range and design conditions, understands the inter-relationship between growth rates and inspection frequency and choice growth control method. And successfully implements the understanding as evidenced by lack of vegetation related outages.
   - Conducts inspections on a frequency that accounts for vegetation growth rates and local conditions.
   - Considers scheduling and permit lead times.
   - Designs work plans that levelizes work load.
   - Utilizes best industry practices such as ANSI A300.
   - Develops vegetation maintenance plans that account for vegetation growth rates and local conditions.
   - Incorporates a feedback mechanism in the program.

- Balancing ROW management with cost and science.
- Establishes wire security zones.
- Documents non-compatible species.
- Exercises full legal rights on the Active Transmission Line ROW to avoid outages.
- Knows the condition of its ROW.
- Gives clear direction to field personnel so that they know what to do to maintain the clearances.
- Addresses an interim corrective action plan.

The SDT proposes the following modification to R3:

*"**R3.** Each TO shall document the procedures, processes, or specifications it uses to prevent the encroachment of vegetation into the MVCD. Such documentation will incorporate the dynamics of a transmission line conductor's movement throughout its Rating and Rated Electrical Operating Conditions and the inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency, for the Transmission Owner's applicable lines."*

4. **Flexible annual work plan** – Some commenter indicated that the word "flexible" in requirement R7 is difficult to enforce without more detail.

The SDT modified the requirement as follows:

*"**R7.** Each Transmission Owner shall complete an annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made provided they do not put the transmission system at risk."*

5. **The SDT revised Section 4.2.2 –** The SDT did not agree to the removal of the reference to FAC-014 and have re-inserted it.

*"**4.2.2.** Overhead transmission lines operated below 200kV having been identified as an element of an Interconnection Reliability Operating Limit (IROL) designated in compliance with NERC Standard FAC-014."*

6. **Reporting –** Some commenters recommend keeping the outage reporting language in the technical requirements section.

The Standards Committee Process Subcommittee is the appropriate body to address this issue.

7. **Gallet distances** – Some commenters asked how can reliability be equal or better when Gallet distances are less than IEEE distances.

At the Gallet distance, the probability of Flashover is zero. The current in-force version of the FERC Transmission Vegetation Management Program Standard (FAC-003-1) uses the minimum air insulation distance (MAID) without tools formula provided in IEEE Std. 516-2003 to compute the required minimum vegetation clearance distance between a transmission line conductor and vegetation. The equations and methods provided in IEEE 516 were developed by an IEEE Task Force in 1968 from test data provided by thirteen independent laboratories. The distances provided in IEEE 516 Tables 5 and 7 are based on the withstand voltage of a dry rod-rod air gap, or in other words, dry laboratory conditions. Consequently, the validity of using these distances in an outside environment application has been questioned.

The current in-force version of FAC-003-01 allowed the TO's to use either Table 5 or Table 7 to establish the absolute lowest value for these minimum clearance distances. Table 5 could be used if the TO knew the maximum transient over-voltage factor for its system. Otherwise, Table 7 would have to be used. Table 7 represented minimum air insulation distances under the worst possible case transient over-voltage factor. These worst case transient over-voltage factors were as follows: 3.5 for voltages up to 362 kV phase to phase; 3.0 for 500 - 550 kV phase to phase; and 2.5 for 765 to 800 kV phase to phase. These worst case over-voltage factors were also a cause for concern in this particular application of the distances.

The SDT sought out a different method of establishing these absolute minimum clearance distances that considers both the outside weather environment and also the realistic maximum transient over-voltages factors for in service transmission lines.

In general, the worst case transient over-voltages occur on a transmission line when the line is open on one end and is opened on the other and then inadvertently re-energized when trapped charge is present. The intent of FAC-003 is to keep a transmission line that is *in service* from becoming de-energized (i.e. tripped out) due to spark-over from the line conductor to nearby vegetation. Thus, the worst case scenarios mentioned above can be ignored.

For the purposes of FAC-003, the worst case transient over-voltage then becomes the maximum value that can occur with the line energized. Typical values of transient over-voltages of in-service lines, as such, are not readily available in the literature because they are negligible compared with the maximums. A conservative value for the maximum transient over-voltage that can occur anywhere along the length of an in-service AC line is approximately 2.0 per unit. This value is a conservative estimate of the transient over-voltage that is created at the point of application (e.g. a substation) by switching a capacitor bank without a pre-insertion device (e.g. closing resistors). At voltage levels where capacitor banks are not very common (e.g. 362 kV), the maximum transient over-voltage of an "in-service" ac line are created by fault initiation on adjacent ac lines and shunt reactor bank switching. These transient voltages are usually 1.5 per unit or less.

Even though these transient over-voltages will not be experienced at locations remote from the bus at which they are created, in order to be conservative, it is assumed that all nearby ac lines are subjected to this same level of over-voltage. Thus, a maximum transient over-voltage factor of 2.0 per unit for transmission lines operated at 242 kV and below is considered to be a realistic maximum in this application. Likewise, for ac transmission lines operated at 362 kV and above a transient over-voltage factor of 1.4 per unit is considered a realistic maximum.

The Gallet Equation is a proven method of computing the required strike distances for proper transmission line insulation coordination. These equations were developed for both wet and dry applications and can be used with any value of transient over-voltage factor.

When one compares the Minimum Air Insulation Distances using the IEEE 516-2003 Table 7 (table D.5 for English values) with the critical spark-over distances computed using the Gallet wet equations, for each of the nominal voltage classes using identical transient over-voltage factors it is clear that the Gallet equations yield a more conservative (larger) minimum distance value.

The following table is an example of this comparison:

Comparison of spark-over distances computed using Gallet wet equations

vs.

IEEE 516-2003 MAID distances using realistic transient over-voltage factors

(AC) Nom System Voltage (kV)	(AC) Max System Voltage (kV)	Transient Over-voltage Factor (T)	Clearance (ft.) Gallet (wet) @ Alt. 3000 feet	IEEE 516 MAID (ft) @ Alt. 3000 feet
765	800	1.4	8.89	8.65
500	550	1.4	5.65	4.92
345	362	1.4	3.52	3.13
230	242	2.0	3.35	2.8
115	121	2.0	1.6	1.4

8. **Definition of Active Transmission Line ROW –** Some commenters indicated that the Active Transmission Line ROW definition is unclear.

The SDT thoughtfully considered FERC staff's concern regarding the Active Transmission Line Right-of-Way. However, in light of the Commission direction in Order 693, in response to First Energy's concern about unnecessary expense of managing unused rights-of-way, to include such a provision, the SDT was left with only two practical choices, the current proposed definition or a fill-in-the-blank site-specific TO-designated approach. Acknowledging the desire to eliminate fill-in-the-blank requirements, the SDT opted for the proposed definition. Therefore, the SDT respectfully suggests that no workable change can be made to this definition and still implements Commission direction and thus has opted to retain the current draft language.

9. **R4: "Responsible control center" and "verified knowledge"** – Some commenters remarked that there is no "Local Control Center" entity in Functional Model and that could be an enforcement issue. Other commenters sought clarification for the phrase "verified knowledge".

The SDT clarified R4, M4 and Rationale text box:

*“**R4.** Each Transmission Owner shall notify the responsible control center without undue delay when qualified personnel confirm the existence of a vegetation imminent threat. A vegetation imminent threat condition is one which is likely to cause a Fault at any moment.”*

*“**M4.** Each Transmission Owner that has experienced a confirmed vegetation imminent threat will have evidence that it notified the responsible control center.”*

*“**Rationale***

To ensure rapid notification of the correct personnel when an occurrence of a critical situation is observed. Qualified personnel may include line workers and utility arborists. The responsible control center is selected to ensure that the flow of operational information, which includes broken cross-arms and tree issues, will continue to the Transmission Operator (or its delegate).”

10. **R6 and R7** – Several commenters noted that R6 and R7 were assigned High VRFs although they previously were Medium.

SDT changed R6 and R7 from High to Medium. The justification is provided by NERC VRF Worksheet Tool and review of NERC VRF Guideline. (See attached VRF_Tool_R6.pdf and VRF_Tool_R7.pdf documents for the VM SDT consensus response utilizing the VRF Tool.)

11. **Requirements R1 and R2** – some commenters stated:

i. The MVCD requirements R1 and R2 need more detail to be enforceable and auditable. They do not see how FAC-003-2 addresses sag and sway with the elimination of Clearance 1.

ii. Concern that the VRF for lines covered in R2 is a Medium.

Consideration:

i. The SDT understands the commenter’s concern. The SDT worked on addressing the concern by drafting alternate language to be responsive to issues of enforceability and auditability and offer the following as an alternative R1/R2 for industry comment:

*“**R1.** Each Transmission Owner shall manage the floor of its Active Transmission Line ROW in accordance to one of the following at all times:*

A) A fixed maximum vegetation height of 15 feet from the ground at the mid-half of the span and 20 feet in the outside quarters of the span, or,

B) A calculated maximum vegetation height that is the sum of the minimum conductor height at “max sag” plus MVCD plus cycle growth, or,

C) A calculated minimum vegetation to conductor clearance that is the sum of “max sag” in the span plus MVCD plus cycle growth, or, *D) A value determined by the Transmission Owner to provide a separation between the conductor and the vegetation that is comparable to options A, B, or C.*

E) Any alternative approach that ensures no encroachment occurs within MVCD, considering the sag and sway of the conductor throughout its operating range under rated conditions.

F) A value to provide a separation between the conductor and the vegetation that is the sum of MVCD, and a value that considers the sag and sway of the conductor throughout its operating range under rated conditions plus 10 feet."

NOTE: The SDT suggests similar language as found in the posted draft for measures M1/M2 may be appropriate with this alternate R1/R2.

ii. The SDT considered the comments that pertain to the assignment of a Medium VRF to R2 on the basis of IROL/Major WECC Transfer Path designation. The SDT determined that the assignment of Medium is justified because the loss of non-IROL or non-Major WECC Transfer Path lines pose a lower reliability risk than those lines that are elements of an IROL or Major WECC Transfer Path.

Organization	Yes or No	Question 13 Comment
American Electric Power (AEP)		American Electric Power suggests replacing the term "Minimum Vegetation Clearance Distance" with "Critical Vegetation Clearance Distance." The use of "minimum" suggests that the minimum is acceptable. However, in dealing with landowners or land managers, we may not be able to negotiate any more than the minimum. "Critical" would help convey the sense that the distance borders on dangerous unacceptability.

FRCC Manager of Operations	Yes	- Applicability Section 4.3 - use the term "Exemptions" instead of "Other" as it is more descriptive.- As noted earlier - Applicability Section 5 - use the term "Technical Basis" instead of "Background" and streamline by removing paragraphs 2, 3 and 4.- R
American Transmission Company	Yes	(a) R1 and R2 (pg.7) - What is meant by “to avoid a Sustained Outage”. Could be argued that a grow-in that does not cause a Sustained Outage is acceptable. (Could this be a FERC issue?)(b) R5 (pg.9) - ATC believes the term “temporarily” should be stricken from the requirement. This leaves too much to interpretation and does not add to the requirement(c) R6 (pg.9) - The descriptive timeframe “at least once per calendar year” is used. What does this mean? Every 365 days or a 12 month period within a calendar year? NERC needs to define this.(d) R4 (pg.15 in the Guideline and Technical Basis) - The term “verified knowledge” is used which does not seem consistent with the definition of “Verified Knowledge” in R4 Rationale on pg.8.(e) R4 (pg.16 in the Guideline and Technical Basis) - The term “responsible control center” is used and further defined. ATC believes this is the Transmission Operator. This should either be moved to the “Definitions of Terms” section or to R4 of the standard where the term is used.
Western Area Power Administrtaion	Yes	1) It is suggested that the word "located" in the third bullet in Measure 1 and Measure 2 be replaced with the word "originating". As worded, M1 or M2 could be interpreted to mean that vegetation originating outside of the right-of-way which blows or sways into contact with conductors “located inside the ... right-of-way” would be evidence of a violation of R1 or R2. Utilities generally are very limited in their ability to manage vegetative conditions outside of their right-of-

Organization	Yes or No	Question 13 Comment
		ways.2) Please reference the comments under Question 2 above regarding the incompleteness of requirements R3 and R7 in fully replacing the CCZ management concepts utilized in the Draft 1 version of the proposed FAC-003-2.3) The requirement R4 Guidelines and Technical Basis narrative is inconsistent with requirement R4. Specifically, in the Guidelines and Technical Basis section the second paragraph's introductory sentence identifies a requirement for an imminent threat procedure, and the second bullet in this paragraph identifies a need to identify vegetation related conditions that warrant a response. Neither of these items are a requirement of R4 as currently written. R4 only speaks to the notification of the responsible control center when it has verified knowledge of a vegetation imminent threat condition.4) The requirement R7 Guidelines and Technical Basis section is written with an inappropriate bias towards very extensive or time based vegetation maintenance programs. Comments received from previous draft standard reviews have revealed that there are many other effective program approaches being utilized by the industry. It is suggested that this section be revised to broaden its scope to incorporate these other program approaches.
Ga Transmission Corp	Yes	1) I would like further examples of inactive portions of corridors. For example would a ten foot buffer strip that is in addition to a normal width to stay off a property line but is included in an easement plat but not cleared be considered inactive corridor or not? 2) The MVCD definition may not be realistic in its wording. Many utility companies may not be able to maintain these clearances at "design of Transmission Facility". This needs further definition maybe "NESC moderate wind". Many utilities in coastal areas will design lines for high sustained winds due to hurricanes these clearances may not be possible to maintain under these conditions however the line may be designed to with stand these winds.
FirstEnergy	Yes	1. Requirements R1 and R2 - We do not agree with the "zero tolerance" for real-time observation of encroachments that do not cause an outage. When discovered, most Transmission Owners (TO) take immediate action to alleviate encroachments and it is not appropriate to be fined for taking immediate action when no outage has occurred. Therefore, a violation should only occur when the TO has not immediately alleviated the situation within 24 hours. We suggest the following change to the first bullet in Measures M1 and M2: "Real-time observation of encroachment into the MVCD that is not corrected within 24 hours."2. Measurement M1 and M2 - For additional clarity, we suggest adding the following wording from Guideline and Technical Basis into M1 and M2 - "Brief encroachment by falling vegetation are not considered a violation."3. Requirement R4 - Since the intent of this requirement is the immediate notification of an imminent threat, we suggest adding the word "immediately" between "shall" and "notify".4. Requirement R5 - We suggest removing the term "temporarily" in the requirement. Some constraints faced by Transmission Owners are permanent and appropriate alternate action is permanently implemented. 5. Requirement R7 - Although we agree that the TO should be allowed to adjust the plan, the use of the term "flexible" is subjective. Additionally, the phrase "to ensure no vegetation encroachments occur within the MVCD" is redundant with the other requirements of the standard. Therefore, we suggest revising the wording of Requirement R7 to the following: "Each Transmission Owner shall implement an annual vegetation work plan. Adjustments to the work plan to defer work beyond the calendar year are acceptable and shall be documented."6. Coordination between Project 2007-07 and 2010-07 - Since the TO-GO interface team has identified the need for Generator Owner (GO) applicability in the FAC-003 standard, we believe that these two drafting teams should coordinate the addition of the GO into this Version 2 of

Organization	Yes or No	Question 13 Comment
		FAC-003. It would not seem sensible to revise Version 1 of FAC-003 to include the GO while Version 2 is developed and approved without applicability to the GO.7. Compliance Section - Under "Additional Compliance Information", we suggest removing the parenthetical phrase "See Administrative Procedure" and replace with "None". Since the Administrative Procedure is not part of the requirements, it is not sanctionable and should not be included in the Compliance Section.
MRO's NERC Standards Review Subcommittee	Yes	1. Need definition for the phrase “Major WECC Transfer Paths”.2. In question 2 of the comment form, it refers to the “bulk power system.” This standard does not cover the bulk power system, it covers lines above 200kV and certain ones below 200kV.
BGE (on behalf of parent/affiliate companies: CEG, CPSG, CECG, CNE & CENG)	Yes	4.2.4 States that the Standard is not applicable to “...to Facilities .... located inside the fenced area of a switchyard, station or substation”. This implies that anything within the fenced area of a switchyard, substation or power plant does not fall within the jurisdiction of FAC-003-2. Some fenced in areas could be very large and susceptible to vegetation encroachments issues.4.3.1 Suggest including in the Force Majeure government a phrase referencing government interference, such as “Federal, State or other regulatory interference, including legal or other legislative actions, that prevents performance to comply with this reliability standard.”M1 & M2 bullet: “Real-time observation of encroachment into the MVCD” implies that real-time observation of vegetation encroachment ensures reliable operation the Bulk Electric System. The reliability standard objective states;”To improve the reliability of the electric Transmission system by preventing those vegetation related outages that could lead to Cascading.”However, real time observation of current operating conditions provides no assurance that vegetation will not lead to outages. BGE recommends removing the language. If an inspector finds vegetation encroaching into the MVCD during a visual inspection he / she should immediately initiate an Immediate Threat Notification. Therefore, this measure has no value.Disagree with R6. - Inspection Frequency. Very prescriptive. Please consider allowing TO’s to select an annual frequency that best fits their requirements, such as calendar year, every growing season, every non-growing season, etc. BGE currently defines their inspection frequency as annually during the non-growing season, October 1 to May 1. BGE believes inspecting during the dormant season is a best practice due to the ability of the inspector to identify vegetation defects, especially off the ROW, which could be hidden during the growing season due to foliage, canopy cover, etc. Also, if a utility elects to leverage an advance technology, such as LiDAR, it provides the most effective results when LiDAR is utilize during the growing season, therefore allowing the results of the advance technology to enhance the fall to spring inspection cycle. All of the above comments are submitted on behalf of: - Baltimore Gas & Electric Company - Constellation Energy Group, Inc. - Constellation Power Source Generation, Inc. - Constellation Energy Commodities Group, Inc. - Constellation New Energy, Inc. - Constellation Energy Nuclear Group, Inc.
Arizona Public Service Company	Yes	APS objects to number 3 Objectives statement. This is the only reliability standard that has at its Objective to prevent vegetation related outages that could lead to cascading. This is a reliability standard and its objective needs to be: “To improve the electric Transmission system by preventing vegetation related outages.” Requirement 6: To ensure reliability the TO’s are responsible for doing an annual inspection. You either do it or don’t and if you don’t finish it you should be held accountable. There shouldn’t be a lower VSL because you didn’t finish all of it. This is poor

Organization	Yes or No	Question 13 Comment
		planning on the utilities part.Requirement R7: When developing the annual work plan the Transmission Owner should allow time for procedural requirements to obtain permits to work on federal, state, provincial, public, tribal lands. In some cases the lead time for obtaining permits may necessitate preparing work plans more than a year prior to work start dates. Transmission Owners may also need to consider those special landowner requirements as documented in easement instruments. There needs to be parameters for the TO to show they allowed time for procedural requirements. An example, some land agencies will give you permission to perform work in as little time as two weeks and others can take two years. Even within the same land agency the timing of approvals is a moving target. APS recommends the TO must show documentation it submitted their Vegetation Management Plan to the land agency at least 120 days prior to the required start date. If the land agency doesn't respond within this time frame and the utility can not perform the work they shouldn't be held responsible.
JEA	Yes	Generally, I believe this document is a huge improvement. The requirements are much clearer and easier to implement than some versions from the past. I do not understand why R7 is still in this standard however. It appears to be a requirement whose purpose is only to dictate HOW an entity must document its implementation of its vegetation management program. Thus, I believe this requirement should be removed.
Consolidated Edison Company of New York, Inc.	Yes	In R5, the SDT should better define the phrase 'where a transmission line is put at potential risk due to the constraint.' This is rather vague and could lead to inconsistent practices between utilities. Con Edison defines all undesirable species on the full width of the ROW as 'potential risks to the transmission line' regardless of height or location at the time of vegetation management. Interim corrective action should only be required when the potential risk is approaching the imminent threat classification.
Orange and Rockland Utilities, Inc.	Yes	In R5, the SDT should better define the phrase 'where a transmission line is put at potential risk due to the constraint.' This is rather vague and could lead to inconsistent practices between utilities. ORU defines all undesirable species on the full width of the ROW as 'potential risks to the transmission line' regardless of height or location at the time of vegetation management. Interim corrective action should only be required when the potential risk is approaching the imminent threat classification.
Florida Municipal Power Agency (FMPA) and Some Members	Yes	In the Applicability section, the use of the term "Other" should be changed to another term, such as Force Majeure, since its purpose is not to include scope into the standard, but exclude scope from the standard.R4 uses the term "responsible control center", which seems inappropriate. Consider using the term "responsible operating entity". The M4 is simply a restatement of R4 without an example of types of evidence, e.g., such as voice recording, operator logs, etc.R5, consider using a different term than "constrained", which has other transmission related connotations. Possibly "limited" or "hindered".FMPA disagrees with a 3 year retention schedule for all of the Requirements and Measures. R4 and M4 would seem to be supported by operator logs, voice recordings and such and three year retention for such evidence is inconsistent with other standards.

Organization	Yes or No	Question 13 Comment
ITC Holding	Yes	In the previous draft the VRF's R6 and R7 were listed as Medium; and in the latest revision they are listed as High VRF's, what is the reason for this change or is this just a mistake?"Temporarily" should be removed from the requirement (R5 pg.9) this will be an interpretation issue and doesn't add to the requirement.
Northeast Power Coordinating Council	Yes	NPCC participating members recognize the hard work the drafting team has done and appreciate the efforts to address the issues presented. An issue seems to be a recurring theme with the advent of the MVCD. Some believe that the eventual adoption of this standard with MVCD will result in the reduction of current trimming cycles and clearance distances. Opinions have been expressed that this may result in increased vegetation contacts and trips. After reviewing some of the MVCD distances, for example 3.12 feet at sea level for 345kV, some expressed the opinion that this is much less than what typical trim practices are today, and may actually "lower" the bar for trimming practices, and effectively allow a TO to trim less and reduce the margin of clearance.Requirement R1 discusses encroachment. M1 bullet 1 states one way to violate encroachment would be:"Real-time observation of encroachment into the MVCD..."From a practical standpoint what is meant here? Who would determine this and how would it be done? The intent is certainly to avoid a sustained outage. However, if a TO was in the process of trimming after an active growing season, and noticed a slight encroachment while trimming, would it be considered a reportable violation? How would the RE measure compliance with avoiding something, with the absence of a sustained outage reported? A statement should be added to the "Definition of Terms Used in Standard" section to indicate how terms defined in the NERC Glossary and used in the standard are identified (for example capitalizing the first letters of the term or using italics or bold font). To avoid confusion when a term might be used at the beginning of a sentence, bolding or italicizing the term should be considered. The Guideline and Technical Basis section should be a separate document, and not part of the standard (mentioned previously in question 8). It should be included in the Technical Reference Document.Applicability 4.2.4--A fenced area of a switchyard, station or substation can have vegetation that could present a potential risk to facilities. What is the reason for this exclusion, and the exclusion in Applicability Section 5--Background paragraph 3 "...this Standard does not apply...to line sections inside an electric station boundary."Referring to our previous responses to questions 1 and 2 for Requirements R1, R2, and R3, what rating is used? It is possible to operate above a facility's normal rating for a prescribed time (for example a transmission line may be operated above its normal rating but below its LTE rating for up to 4 hours). Operating at emergency ratings should be considered. During emergencies transmission lines might be loaded to their emergency ratings, thus increasing the sag, thus increasing the likelihood of a vegetation caused trip if the required clearances don't take into account the increased loading. Especially in an emergency loading scenario, operating into an avoidable potential risk is very undesirable. Referring to FAC-003 - Table 2 - Minimum Vegetation Clearance Distances (MVCD), for 345kV (line to line), 3.12 foot (assuming to ground) clearance is required at sea level. IEEE Std 516-2003 IEEE Guide for Maintenance Methods on Energized Power Lines dated July 29, 2003, Table 5 (p. 20), lists the MAID (minimum air insulation distance) for 345kV phase to phase equipment at altitudes below 900 meters (2953 feet) to be 2.88 meters (9.45 feet) phase to ground. It is understood that MAID is "The shortest distance in air between an energized electrical apparatus and/or a line worker's body at different potential...", but the clearance differences at the various voltage levels seem very significant. If a figure is referenced in a requirement (R3), it would be preferable to have

Organization	Yes or No	Question 13 Comment
		that figure positioned within that requirement. If that is not possible, it should be explicitly stated where the figure can be found. Requirement R5--Legal actions and other events that prevent vegetation maintenance work be included in the Introduction Section 4.3.1. What does “interim corrective action” mean specifically? The requirement as written needs to be made clearer. Without the Rationale box it loses its meaning (refer to the question 3 response).Interim Corrective Actions are explained on page 28 of the separate Technical Reference Document, with examples such as modifying the inspection interval, or limiting the loading on the line (effectively changing its rating) to minimize sag. “Interim corrective action” should be defined and added to the Glossary.Are voltages referred to in the Standard (Applicability Section) line to line or line to ground for ac systems? (345kV line to line is 199kV line to ground, below the 200kV threshold in the standard). Are the voltages also applicable to DC equipment?
Xcel Energy	Yes	On page 6, in paragraph 5 ("Background"), we suggest enhancing the 3rd paragraph by inserting the words "Active Transmission Right-of-Way", as follows: "...addresses vegetation management in the Active Transmission Right-of-Way along applicable overhead lines..." This change emphasizes that this does not apply to areas outside of the Active Transmission Right-of-Way. Comments to Requirments and Measures Section (pages 7 -9)The term Minimum Vegetation Clearance Distance (MVCD) should be explicitly defined as a new "definition" rather than explained in a "rationale" box. Additionally, formalizing the definition would give weight to how "Table 2" is supposed to be used. As it is currently drafted, the requirements of the standard don't refer to Table 2 at all. (i.e., - our understanding is that the rationale boxes are for clarification and the requirements should be able to convey what is necessary on their own.)MVCD - while we understand this as an 'engineering term', the terminology is difficult to convey since land owners tend to question the need to do anything more than the "minimum". We recommend revising the term to "Critical Clearance Distance (CCD)". M1 & M2 should be revised to insert the concept of "verified knowledge" (that is used in R4). This is because M1 & M2 do not clarify whose real-time obseration it is referencing. As such, we recommend stating "Real time verified knowledge of encroachement into the MVCD..." instead of just the term "observation" to make it clear that a trained, knowledgeable individual is making this determination. Also, it may make sense to turn "verified knowledge" into a defined term since it will be used in M1, M2 and R4. If it is not made a defined term, then the meaning in M1 & M2 must be clarified in those sections (maybe a cross refefrence to as defined in R4 and on page 15 will work). However, we think it is best to make it a defined term.R5: Rationale box: consider enhancing the second sentence by adding the word "significant", to read "...avoid significant risk..."R5: Requirement & Measure: consider adding exception language when the constraint is known to be longer than "temporary". e.g. - stand offs can occur on right of ways that cross federal and tribal lands and the entity cannot force the federal government to do do something.R6: Xcel Energy still believes the requirement in R6 that mandates an annual inspection is too onerous and is at odds with the results-based approach of these revisions. Xcel Energy urges the retention of the provision in the existing standard that allows the Transmission Owner to set the frequency of inspection. In some areas of the country, annual inspections may not be adequate. Yet in other areas, a longer inspection frequency may be perfectly reasonable and practical. Our point is that inspection frequency should not be treated as if it were “one size fits all”. If treated this way, we feel this could pose a risk to reliability and is not likely to be cost-effective. The Transmission Owner should be allowed some flexibility. However, if the drafting team disagrees and determines that an annual inspection is to be mandated, Xcel Energy believes that an exception to the

Organization	Yes or No	Question 13 Comment
		annual inspection is appropriate when a non-subjective advanced technology such as LIDAR is utilized to achieve actual clearance distances. This places the Transmission Owner in a situation where it can rationally determine that the objectively measured distances result in a situation where an inspection need not be performed within the next year. It is suggested that R6 be revised to read as follows: Each Transmission Owner shall perform a Vegetation Inspection of all applicable transmission lines at least once per calendar year, unless the Transmission Owner, based on a non-subjective advanced technology, such as LIDAR, determines that a longer inspection period is appropriate.R7: Revise the requirement to eliminate the superfulous language at the end of the sentence that says "... to ensure no vegetation encoachments occur wihtin the MVCD", i.e., R7 would read as "Each Transmission Owner shall execute a flexible annual vegetation work plan."
Independent Electricity System Operator	Yes	Our comments to this point have focussed exclusively on the proof-of-concept for using the results-based criteria for developing a reliability standard. We have one comment on the specifics of Requirement R7 and its Measure M7. The rationale for M7 states that a flexible annual vegetation work plan allows for work to be deferred into the following calendar year provided it does not have the potential to become an imminent threat. This will evidently require some kind of assessment in each case. Will entities be expected to document those assessments as evidence in support of its view that the associated vegetation did not have the potential to become an imminent threat, or would it be sufficient to look at the outcomes of these decisions to defer items in the work plan - i.e. there were no imminent threats and sustained outages? Finally, we applaud the drafting team for its efforts in developing this draft. The industry has often commented about overly prescriptive requirements and I believe this draft has focused on the “what” of the requirements and left the “how” up to the appropriate entities. In our view this draft, with its succinctly stated requirements, represents an important first step in the right direction. Thank you.
Ameren	Yes	Page 9, M7 - what are the limits of flexibility in executing "a flexible annual vegetation work plan"?
Duke Energy	Yes	Please review the VRF Guideline because we believe that the VRF’s for R6 and R7 should possibly be changed to “Medium” instead of “High”. They were “Medium” in the last draft of FAC-003-2.
Westchester County Board of Legislators	Yes	Please see e-mail sent to sar@nerc.com. Thank you.
Progress Energy Carolinas	Yes	Progress Energy believes that the VRFs for R6 and R7 should be returned to “medium” since no singular “risk-based” requirement in a defense in depth strategy should be depended upon to eliminate/prevent risk to grid reliability. In a defense in depth strategy, no one specific “risk-based” or “competency” requirement should be “high” unless failure to complete that singular requirement will result in an immediate “high” risk to grid reliability (if that is the case, then the standard is not truly employing a defense in depth approach). Also, R6 and R7 (which have a zero tolerance) have no differentiation between grid impacting facilities (IROL) and facilities primary impacting local customer reliability (i.e., radial lines to load, etc).

Organization	Yes or No	Question 13 Comment
North Carolina EMC	Yes	R4: The requirement to notify the responsible control center of an imminent threat may potentially result in confusion at the control center if the transmission lines in question are not part of the control center's actively monitored grid. As an example, NCEMC has a few short radial 230kV lines that fall under the requirements of this standard, but these lines are not shown on the BA's control center system because they are downstream from a protective device located at a tap off networked transmission lines. A vegetation-related outage on these lines would not result in any of the transmission elements continuously monitored by the control center being outaged, and the operator receiving a call notifying the imminent threat may not have any familiarity with the line section being identified, since it is not on their system. If prompt action to respond to any imminent threat is the intended goal, why not consider making it a significant part of the mitigating factors of an actual outage.
City of Tallahassee (TAL)	Yes	Recommend deleting the “to avoid a Sustained Outage” in R1 and R2. Has a violation occurred if a momentary (successful reclose) outage occurs but the TO did not “observe(s) vegetation within the” MVCD? While it may not have to be reported on the quarterly report, Table 1 for the Lower VSL seems to suggest a violation of the MVCD has occurred, even if it was not “observed” as “required” in the Guideline and Technical Basis.In the Guideline and Technical Basis, the final paragraph for R1 and R2, line 3 contains an extra word “...encroachment is not be a violation...”In the Guideline and Technical Basis, the third paragraph for R6, line 2/3 contains an extra word “...230kV transmission at least once line during the calendar year.”
Cleco	Yes	Requirement 4:Recommend the SDT consider modifying to make it clear the requirement applies to threats within the right of way (ROW).Requirement 4.3.1:Recommend adding human activities to the list of causes. Logging activities are listed but other human activities such as private property owner tree care operations are not.
Exelon	Yes	See R6. Exelon prefers “annual” to “calendar” but notes the requirement runs counter to the results based approach and could be interpreted to be inconsistent with R7.The Rationale for R6 is ambiguous and without justification suggests shorter but not longer cycles are acceptable. If local factors can shorten a cycle, they could also increase it. The Rational is in conflict with the prescriptive nature of the requirement.
NERC Staff (12 staff members)	Yes	Standard Development TimelineThe Development Steps Completed section of the standard is incomplete. This section should include the dates of previous postings. Draft 1 of revised standard was posted for stakeholder comment from 10/27/08 - 11/25/08. Draft 2 of revised standard was posted for stakeholder comment from 09/10/09 - 10/24/09.Definitions of Terms Used in StandardThe definition of Active Transmission Right-of-Way is ambiguous and subject to interpretation. This definition need to be revised to add clarity. It is unclear what “active transmission facilities” are. In the gray box, the SDT should explain what “active portions of corridors” are, and how that is different than the “land that is occupied by active transmission facilities.” The terminology should be consistent. The example should state whether the width is the portion that has been cleared or should be cleared and if it was not maintained and should have been. The SDT should explain the reference to the National Electrical Safety Code in the gray box, and how it differs from the IEEE clearances. In addition, the team should explain why the Table 2 clearances set forth

Organization	Yes or No	Question 13 Comment
		in the standard itself are not referenced. The examples in the “inactive portion” suggest that there are active transmission facilities (see references to conductors and circuits). The SDT should provide the rationale for excluded them from vegetation management. While vegetation is permitted to exist at the corridor edge, the SDT should address why there is no obligation to maintain it. The revised definition of Vegetation Inspection does not seem necessary. It appears that the SDT is using the definition to set an expectation for enforcement by adding “which may be combined with a general line inspection.” If both vegetation and general line inspections are to occur concurrently, there should be minimum background requirements to perform such inspections. We recommend that the last portion of the draft definition be moved to the Application Guideline section so the definition of Vegetation Inspection should be “The systematic examination of vegetation conditions on an Active Transmission Line Right of Way.”The team should consider making Minimum Vegetation Clearance Distance a defined term.Effective DatesThe effective date for Ontario needs to be tied to the effective date in the U.S.With respect to the second exception, the team should provide the rationale behind the exception for the effective date for “existing transmission line operated at 200kV or higher that is newly acquired by an asset owner and was not previously subject to this standard”. All existing transmission lines operated at 200 kV or higher are currently subject to vegetation management. Please explain why a new owner would get an exception for this.Based on the wording in the Exceptions section, it appears that some lines in the US could be brought into this standard prior to regulatory approval. (i.e. Lines operated below 200kV, designated by the Planning Coordinator as an element of an IROL or as a Major WECC transfer path, become subject to this standard 12 months after the date the Planning Coordinator or WECC initially designates the lines as being subject to this standard. An existing transmission line operated at 200kV or higher that is newly acquired by an asset owner and was not previously subject to this standard, becomes subject to this standard 12 months after the acquisition date of the line(s))ObjectiveThe purpose of this standard should not be limited to outages that lead to Cascading, but prevention of all vegetation related outagesApplicabilityThis standard should apply to Generation Owners.The term Facilities is defined to exclude those in a fenced area of a switchyard, station or substation. The SDT should provide the basis for the exclusion.Footnote 1 needs to be clarified. It is too cursory.The “Other” section should not be included in this section. It is the expectation that the Compliance Enforcement Authority will not expect the Transmission Owner to prevent tree contacts that the TO could not prevent. This might be better suited in the Application Guideline section.In the “Other” section, the SDT should provide rationale for why the standard is not intended to address “human errors”.The SDT might consider rewording the “Other” section as:”This Standard shall not apply in circumstances where a requirement of this Standard was not complied with due to Acts of God, flood, drought, earthquake, major storms, fire, hurricane, tornado, landslides, logging activities, animals severing trees, lightning, epidemic, strike, war, riot, civil disturbance, sabotage, vandalism, terrorism, wind shear, or fresh gales that restricts or prevents performance to comply with this Reliability Standard's requirements, so long as the non-compliance was not caused by the fault or negligence of the Transmission Owner.”The team should provide justification for the applicability criteria they have selected; specifically why a 200 kV cutoff was chosen.The team should provide justification for eliminating fall-ins from outside the ROW.BackgroundAs a general comment, the background section seems repetitive.The fourth paragraph of the background section notes that this standard is not intended to prevent customer outages due to tree contact with lower voltage distribution systems. It is clear from the applicability section that this pertains to 200 kV and higher, although the standard contemplates that some lower voltage facilities could be subject to the standard. The SDT

Organization	Yes or No	Question 13 Comment
		should address whether this paragraph also address customer outages due to tree contacts with respect to 200 kV or higher facilities.Requirements R1 and R2:R1If an auditor were to assess compliance with R1, they would need to have the list of conductors that were associated with an IROL or a Transfer Path. This list should be identified in the list of evidence that must be retained.R1 & R2 In the Rationale box, the term “a proven transmission design method” is used. Please describe what this refers to, and whether these refer to the IEEE minimum clearances. The SDT should state what the method was and what changes, if any, were made to it.The SDT should address why the requirements only reference line conductors and not transmission facilities or transmission lines (the VSLs refer to transmission lines).The word “encroaching” should be replaced with another word/phrase that clearly defines the concept for compliance purposes. The word, “encroach” could be interpreted differently by different people (how close can vegetation grow before it enters the MVCD and is it a violation of R1/R2 - is it 2”, 2’, 10”, 10’?), whereas the word “enter” is explicit.Guidance is offered in the Guideline section of the standard that implies that all TOs should retain this evidence, yet the evidence is not identified anywhere in the Measures or evidence retention sections of the standard.We suggest adding the phrase, “of its” to clarify that the TO is only responsible for facilities it owns. “In addition, the Transmission Owner should maintain detailed records of the findings of its planned inspections. This documentation constitutes evidence that the Transmission Owner had no encroachments into the MVCD Table distances.”Immediately after the phrase MVCD, we suggest including the text “as specified in FAC-003-2 Transmission Vegetation Management Table 2 - Minimum Vegetation Clearance Distances (MVCD). Table 2 is not referenced in any of the requirements. If you require entities to use the MVCD as stated in Table 2, then this should be referenced in at least R1 and R2.M1 & M2Overall, it appears that these measures are asking for evidence of non-compliance. The initial item under M1 & M2 (shown below) should be rephrased with the addition of the words “verbal or written report of a,” otherwise the measure doesn’t seem as though it could be used objectively. In addition, the words Real-time should be removed, as they ad confusion to the issue.”Verbal or written report of a observation of encroachment into the MVCD, or”The phrase “Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period” should be changed to a footnote that reads “Consider Multiple Sustained Outages on an individual line, if caused by the same vegetation, as one outage regardless of the actual number of outages due to the same piece of vegetation”Momentary outages due to vegetation are also a violation of R1. Momentary outages from tree contacts may not result in a sustained outage but are evidence of a tree within the MVCD. The requirement should not be limited to only sustained outages. Consider this scenario: An entity self-reports a violation of the standard. Does that mean that if there is no actual "real-time observation" or a "Sustained Outage" there is no violation? Who must do the observing? Please explain.Requirement R3 Consider this scenario: A Sustained Outage occurs on a location that was not considered and therefore was not part of the TO’s TVMP. Would this result in a violation simply because the location was not considered when the entity developed a TVMP?Requirement R4 Each requirement should identify “who shall do what under what conditions, for what reliability outcome.” R4 has no identified reliability outcome. What is the reason for making a prompt notification? Is it to give the real-time system operator information on which to develop and implement an action plan if there is an outage on the line with the imminent threat? Then that should be stated in the requirement. R4 contains explanatory information. The sentence “A vegetation imminent threat condition is one which is likely to cause a Sustained Outage at any moment” should be moved to the blue box.Please explain what

Organization	Yes or No	Question 13 Comment
		“verified knowledge” means. The Rationale section does not really address this. While this is in the Guidelines and Technical Basis section, it defines it as “implies reliable confirmation.” This should be clarified and put in the measures section.”Imminent threat” should be defined so that it does not evolve into an enforcement issue.”Notify the responsible control center” should be clarified so that it does not evolve into an enforcement issue.Application Guideline for R4 should contain provisions in the imminent threat procedure for notification of the land owner.M4 should provide examples of acceptable evidence.Requirement R5 This requirement does not include a reliability outcome. The requirement should be rewritten to include a reliability outcome.Requirement R6 The Rationale for R6 is that one year “seems to be reasonable.” The SDT should address how this relates to the practice in place now, and whether it is consistent with current practice or is more or less than current practice. If inconsistent, the SDT should provide an explanation.The Rationale states the TOs should consider other factors that could warrant more frequent inspections. If so, the SDT should explain whether we are requiring them to do so if such factors exist.This requirement does not include a reliability outcome. The requirement should be rewritten to include a reliability outcome.Requirement R7 R7 is ambiguous; it is not clear how this could be enforced objectively. The rationale for the “flexible” plan indicates that the owner can delay work as long as it will not pose an “imminent threat.” The SDT should explain what the Compliance Enforcement Authority would look at to determine that the work that was delayed was not causing an “imminent threat.” The SDT should address whether it would ever be acceptable to delay work on a critical line (covered under R1).In Requirement R7, please explain what “execute a work plan” means. Did the SDT mean implement a work plan? As drafted, it could be read to just have one in place. The SDT should explain what “flexible” means. Does it mean there will never be a FAC-003 violation if you fail to implement the plan? The Rationale says the work can be deferred if it does not have the potential to become an imminent threat. Please explain. Corresponding clarification changes should be made to the VSLs for this requirement.Either M7 or the evidence retention for M7 needs to include the annual work plan. Without that the Compliance Enforcement Authority can’t determine if the plan was executed. The VSLs for R7 imply that the entire annual plan will be accomplished. . . not a “flexible” amount of the plan - the VSLs don’t line up with the use of the word “flexible.”According to the VSL Guidelines the VSLs should be stated in language that identifies the degree of noncompliance in language that identifies the amount that was noncompliant, rather than the amount that was compliant. VSLs for R6 and R7 are stated in terms of the % of the required performance that was compliant and should be rephrased. GuidelinesThe following guidance is offered in the Guideline section of the standard:Documentation or other evidence of the work performed typically consists of signed-off work orders, signed contracts, printouts from work management systems, spreadsheets of planned versus completed work, timesheets, work inspection reports, or paid invoices. Other evidence may include photographs, work inspection reports and walk-through reports.Documentation is required when the annual work plan is adjusted or not completely implemented as originally planned. The reasons for the deferrals or changes and the expected completion date of postponed work should be documented.This implies that all TOs should retain this evidence, yet the evidence is not identified in nearly this level of detain in the Measures section of the standard. In addition, no part of the requirement or measure is clear in indicating that documentation is required to support the need for a work plan adjustment. Evidence Retention The evidence retention periods specified don’t reflect the guidance in the SDT Guidelines. Should the evidence retention be the later of three years or three years from the last audit? The second paragraph should be stricken because it seems to contradict the first paragraph

Organization	Yes or No	Question 13 Comment
		retention period.VSLsThe SDT should verify that the VSLs for Requirement 3 are properly calibrated.Administrative ProcedureThe Administrative Procedure does not require prompt reporting of sustained outages; rather it requires only a quarterly report. This appears to be less stringent than the current requirements as employed today.The SDT should explain what “blowing together” means, and how this is different from a tree that grows into a line.FootnotesFootnote 1 should be deleted or modified. It is only relevant in explaining the proposed modifications to the standard. In footnote 4 the word, “substantially” adds ambiguity.Guideline and Technical BasisIn the Guidelines and Technical Basis section, it states “Requirements 1 and 2 state if the TO observes vegetation within the distances prescribed in FAC-003 - Table 2 it is in violation of this Standard.” This is actually in the Measures 1 and 2 and not the requirements.General commentsThere seems to be a lot of information not captured in the Requirements but rather are in various other sections. The SDT should clearly delineate whether these other sections are considered part of the Standard or just informational.With the next posting of the standard, the drafting team should include the following four points for stakeholder review:1. Justification for selection of the applicable lines. 2. Table listing each FERC directive and stakeholder issue (from the Issues Database) associated with the standard and identification of how the team addressed each of these3. Table listing each VRF and identification of how the proposed VRF meets both NERC criteria for setting VRFs and FERC’s five Guidelines for approving VRFs4. Document identifying how the proposed VSLs meet both NERC criteria for setting VSLs and FERC’s four Guidelines for approving VSLs.There is a significant concern with the use of the Gallet equations in this standard. This standard eliminates Clearances 1 and 2 from the previous version and replaces it with a single Minimum Vegetation Clearance Distance (MVCD) based on the Gallet equations. This approach reflects the most basic lowest common denominator and significantly lowers the bar versus the performance expected from the existing standard. Further, it would not appear that responsible entities would use the Gallet equations as the basis for the development of the vegetation management program. Additionally, whereas the multiple clearance zones provide an indicator of proactive vegetation management, the current proposal does not provide an equivalent demonstration of proactive performance. This approach appears inconsistent with Order 693 and the presentation of NERC standards to provide a defense in depth strategy, which is a fundamental outcome of the results-based standards process. Order 693 states in P24 that the “reliability mandate of Section 215 of the Federal Power Act....contemplates the prevention of incidents, acts, and events that would interfere with the reliable operation of the Bulk Power System.” The SDT should consider adding more clarification to the draft standard and white paper describing the building blocks for determining how much vegetation management (trimming) needs to be performed based upon growth rate of vegetation and the time between trimmings to reflect a proactive approach.The SDT should consider the impact of moving the reporting requirement in the existing standard to the compliance section of the new standard. The team should consider the reporting of this activity on an exception basis within a pre-defined timeframe following the event. This approach would provide more timely awareness to the Regional Entity and NERC of an event than the quarterly reporting expectation, and provide opportunities for identification and implementation of mitigating strategies in a more timely manner. While this approach removes an administrative type requirement from the standard that is believed to provide a deterrent to responsible entities, the increased timeliness of reporting in an exception basis would provide greater benefit to the effort to maintain reliability.Transmission Line is a defined term. The SDT should consider using this term in place of “transmission line.”The report identified in the administrative section of draft 3 of FAC-003 is really a “Periodic Data Submittal” used

Organization	Yes or No	Question 13 Comment
		to assess compliance and does not belong in an administrative section of the standard - it belongs in the compliance section of the standard. "Periodic Data Submittals" is one of eight different compliance monitoring and enforcement processes that may be used to monitor and assess compliance. The eight processes are identified in the Uniform Compliance Monitoring and Enforcement Program of the North American Electric Reliability Corporation and should not be mixed in with other processes or procedures. Each standard must list the appropriate processes in the compliance section of the standard so that there is a clear understanding of the purpose of the data submittal.As drafted, FAC-003-2 applies only to Transmission Owners. It also should apply to Generator Owners. The SDT should explain whether the issues brought forward in the GO/TO Report been considered and are addressed as part of this revision.Please update the mapping document so that it compares the last version of the approved standard to the latest proposed version of the standard so that it is easy to compare the proposed standard to the standard that is in force now.
Utility Risk Management Corporation	Yes	Suggested Improvements to M1. and M2.The purpose of Requirements R1 and R2 is to require the prevention of vegetation encroachments within the MVCD. As made clear in the background and remaining FAC 003-2 requirements, the overarching intent of FAC 003-2 is to prevent sustained outages caused by vegetation that could lead to cascading. However, both M1 and M2 include real-time observations of encroachment into the MVCD as an automatic violation of R1 or R2, respectively (even though the violations may not result in penalty or fine). This is inconsistent with the "defense in depth" goal sought by the committee, as a real time observation using new technologies may in fact demonstrate that the Transmission Owner is in fact aggressively managing vegetation to meet the MVDC requirements and is discovering new encroachments and remediating them quickly and effectively and thereby is not in violation of the standard.Similar to imminent threats, remediation procedures should be permitted for encroachments as well and serve to make clear the observation is not automatically a violation. Classifying a real-time observation of an encroachment automatically as a violation of R1 or R2 penalizes a Transmission Owner for identifying vegetation threats, which are less severe than imminent threats. Under Requirement R4, the transmission owner is permitted to take appropriate actions to alleviate an imminent threat through short term corrective actions upon observation of any vegetation that is near to or is encroaching into the MVCD. (See FAC-003-2 Guideline and Technical Basis, Requirement R4). Considering the allowance for remedial action under Requirement R4 when facing a condition that is "likely to cause a Sustained Outage at any moment," it seems excessive to qualify a real-time observation of an encroachment as a violation of R1 or R2. We suggest a better approach is to modify M1 and M2 to allow for remedial action. Or, in the alternative, the standard should clarify that observations of encroachments using software-enabled technology, such as LIDAR coupled with work order management systems, do not constitute a "real time observation of an encroachment." First, by modifying M1 and M2 to allow for remedial action as suggested below will deal with the concern we raise:M1. Evidence of violation of Requirement R1 is limited to: o Real-time observation of encroachment into the MVCD which is not mediated in accordance with R4. o ... M2. Evidence of violation of Requirement R1 is limited to: o Real-time observation of encroachment into the MVCD which is not mediated in accordance with R4. o ... In the Alternative, "Real-Time Observation" Should be Clarified. As noted above, a real-time observation of an encroachment is evidence of a violation of Requirements R1 and R2. Observations in real time mean "an actual field observation or measurement of the conductor-to-vegetation distance and not a calculated

Organization	Yes or No	Question 13 Comment
		determination of relevant positions." (See FAC-003-2 Guidelines and Technical Basis, Requirements R1 and R2) Given the current definition, it is not clear observations using software-enabled LiDAR would trigger violations and thereby would discourage the Standard's emphasis on preventing sustained outages or Cascading due to grow-ins. This may result in penalties for registered entities that are engaged in good faith activities to prevent sustained outages. The meaning of "real-time observation" should be clarified as to remove any adverse incentives for vegetation inspection and management. To implement this suggestion as an alternative to allowing remediation to prevent an observation from being an automatic violation, the definition could be reworded to state:"Real-time observation" means an actual field observation or measurement of the conductor-to-vegetation distance which is not performed under the regular Vegetation Inspection of Requirement R6 or annual vegetation work plans in accordance with Requirement R7. Such observations do not include calculated determinations of relative vegetation positions. Conclusion:Adopting one or both of these proposed changes would help R1 and R2 measures more fully meet the goal of preventing overgrown vegetation and systemic failures triggered by flash over, as stated in the background section on page 6 of FAC-003-2. The current M1 and M2 use of real-time observations conflicts with the expectation that utilities engage in "defense in depth" measures. As the guidelines conclude regarding Requirements R1 and R2, the Transmission Owner is expected to have a cohesive vegetation management program for managing vegetation in such a manner as to maintain separation between conductors and vegetation. This is to function in conjunction with the imminent threat procedure to facilitate interim corrective action. "However, brief encroachments by falling vegetation are not considered to be a violation." Making the changes suggested above - coupled with the existing requirement that the utility mitigate an observation in accordance with the utility TVMP through a response schedule - thereby advance the goals of the standard and take away an impediment to aggressive defense in depth.
SERC OC Standards Review Group	Yes	The requirements (R6 and R7) for inspections and the performance of work plans are part of a defense-in-depth approach and as such the TO is not depending on singular requirements to prevent sustained outages, therefore, the VRF for R6 and R7 should remain medium not high. We applaud the attempt to improve the readability and ultimate comprehension of reliability standards by changing to this new template. We have included some comments also made by the SERC Vegetation Management Subcommittee (VMS)."The comments expressed herein represent a consensus of the views of the above named members of the SERC OC Standards Review group only and should not be construed as the position of SERC Reliability Corporation, its board or its officers."
SERC Vegetation Management Sub-committee	Yes	The requirements (R6 and R7) for inspections and the performance of work plans are part of a defense-in-depth approach and as such the TO is not depending on singular requirements to prevent sustained outages, therefore, the VRF for R6 and R7 should remain medium not high.
GCPD	Yes	The standard should include only R1, R2 and the Clearance Table. Everything else should be in guidelines as to how you might comply with the standard. If R3 thru R7 remain in the standard then it is virtually the same as it exists today, just put in a different order.

Organization	Yes or No	Question 13 Comment
CenterPoint Energy	Yes	The term "Active Transmission Line Right-of-way" (ATLROW) is not defined in sufficient detail in the Definition of Terms Used in the Standard section to know how to apply it to the Requirements and Measures. The Technical Reference merely depicts the relative position of energized conductors, but it does not show a graphical determination of the limits of the ATLROW. The ATLROW is missing a definable and determinable width in its current definition within the Standard which makes it an arbitrary term and does not allow for a clear and measurable expected outcome of each requirement. In several sections, the Standard relies on the specific determination of the physical width of the ATLROW to determine applicability of the requirements. The Vegetation Inspection definition refers to “on” an ATLROW. The Background section refers to “outside” the ATLROW. Table 1 refers to “within” and “on” the ATLROW. M1 and M2 refer to “inside” the ATLROW. R3 and M3 refer to “on” the ATLROW. The Administrative Procedure refers to “inside and/or outside” and “within” the ATLROW. The Guideline and Technical Basis section refers to “on or near” the ATLROW and the “limited” ATLROW “width”. It also says that, “The Transmission Owner should, therefore, endeavor to maintain its ATLROW to the full extent of its legal rights at all times in all cases.” Since the Standard does not currently define how a Transmission Owner is to determine the specific boundaries of the ATLROW, it would appear that the Transmission Owner is to make that determination on a case by case basis at its discretion. Should that not be the intent, we recommend the definition for the ATLROW to be, “A strip or corridor of land or aerial space that is occupied by energized transmission conductors with its operational clearance limits defined by the Transmission Owner’s specific legal rights but in no case less confining than the MVCD applied to the movement of the conductors within their Rating and Rated Electrical Operating Conditions.” This definition contains sufficient detail to determine the physical limits of the ATLROW, and it allows for vegetation management to apply within the full extent of the legal rights of the Transmission Owner while requiring a minimum area for vegetation management in undefined ROW’s to ensure Sustained Outages are minimized.M1 contains a reference to “real-time observation of encroachment into the MVCD” but does not explain who is to make the observation and where it is to be documented. If this is to be done by the Transmission Owner, then perhaps it should be a Measurement under R6 and recorded under M6.The language in R6 refers to inspecting “transmission lines” and Table 1 for R6 refers to inspecting “ROW”. Both areas should use consistent terminology.M1 and M2 have the potential for double jeopardy when a Sustained Outage occurs because the Violation Severity Level has an entry for an MVCD encroachment (which causes the outage) and another sister entry for the type of Sustained Outage. Some additional clarity in the application of M1 and M2 is necessary.R5 should include the exception stated in the Rationale text box to add clarity to the Requirement. R5 should read, “Each Transmission Owner shall take interim corrective action when it is temporarily constrained from performing planned vegetation work, where a transmission line is put at potential risk due to a constraint, except where the risk is avoided by implementing an alternate work methodology.” In the Guideline and Technical Basis section for R1 and R2 (page 15), there is a reference to records of “planned inspections” and “evidence” for no encroachment into the MVCD. This reference should be moved to R6 where the inspections are required. If R6 is intended to provide evidence for M1, then that should be stated in R6.In the Guideline and Technical Basis section for R6, the reference to the VSL calculation units and the example units should be consistent-the example should use “line miles”, not just “miles”.Table 2 contains several “*” in the voltage column that are not defined.In the Technical Reference on page 21, the following sentence should be deleted, “If constraints cannot be

Organization	Yes or No	Question 13 Comment
		overcome and if design clearances are sufficient, an exception to the Transmission Owner's 10-foot guideline might be made." The Technical Reference should not provide examples of granting exceptions as they may be misinterpreted as an endorsement by NERC to increase the planting of trees near and under transmission lines without taking into account several other factors such as ROW access, changing design conditions, future line additions and rebuilds. The inclusion of modifications to the wire zone on page 24 regarding the wire-border zone model should be re-examined to be sure they are specific to an environmental conservancy requirement while allowing for construction and inspection access as needed.In the Technical Reference on page 22 under Planning and Implementation, delete the sentence, "While designed primarily with transmission systems in mind, t is also applicable to distribution projects." The Standard should not imply its applicability to distribution systems since it is intended only as a transmission standard.In the Technical Reference, the last sentence on page 26 starting with "Appropriate actions..." should be moved to R5 where it applies. In general, the proposed FAC-003-2 has gone FAR beyond what was contemplated by the Commission in FERC Order 693 and equates to a total re-writing of the Standard for no apparent reason. The Commission's determination dealt with the following areas: (1) applicability; (2) inspection cycles; and (3) minimum clearances on National Forest Service lands. For instance in Paragraph 729, the Commission states, "As proposed in the NOPR, the Commission approves Reliability Standard FAC-003-1 with no proposed modification on the issue of clearances. The Commission reaffirms its interpretation that FAC-003-1 requires sufficient clearances to prevent outages due to vegetation management practices under all applicable conditions...." Rewriting the minimum clearances introduced a new set of confusing definitions, and further burdens the Transmission Owners with new documentation requirements with little if any benefit when compared to the Clearance 2 concept in the existing Standard.A preferred approach would have been to incorporate the following few items into the existing Standard: (1) the RC versus the RRO; (2) the designation of a specific inspection frequency; (3) the Gallet equation; and (4) the applicability to National Forest Service lands.
Ad Hoc Group subteam formed to review draft standard	Yes	The wording in R7 is troublesome. We believe that the process for developing the annual work plan is imbedded in R3. As discussed in question 2, demonstrating capability to actually perform those actions necessary to ensure no vegetation encroachments occur within the MVCD is the primary concern. Deferring such work into the next calendar year appears contrary to this concern and neutralizes the defense-in-depth concept by diminishing the imminent threat requirement of R4 to a primary means of defense. While we don't want to incent vague annual work-plans, we also don't want to remove the imperative that the work must be done.
Nebraska Public Power District	Yes	Under section 4.3.1 add in ice storms as one of the force majeure events. This type of event may impact many TOs and should be included.
Oncor Electric Delivery	Yes	Use of the Gallet equation to determine the minimum gap between vegetation and conductor to prevent sparkover seems to be appropriate. No utility should be managing to this distance but developing a distance beyond this would be arbitrary. This is a reliability standard not a worker safety or vegetation management practices standard. As Federal agencies and other entities are interpreting the Standard to limit normal vegetation management efforts, the FERC should develop and adopt an overarching memo allowing utilities to maintain vegetation under any agency

Organization	Yes or No	Question 13 Comment
		jurisdiction as a utility manages vegetation along the entire right-of-way corridor.
Western Area Power Administration - Upper Great Plains Region	Yes	WAPA - UGPR would like to see "ice storms" specifically mentioned in Section 4.3.1. Having additional clarification as to what is considered a "major storm" would also be helpful.
Bonneville Power Administration	Yes	We believe the minimum vegetation distances are very granular and nearly un-measurable in real life. When a person considers the table to be a list of minimums it seems that the regulated entities, or land owners would want the distances to be as close to the wire as possible. We would not want a non-technical manager to believe that any small distance outside of the noted distances is ok.
Omaha Public Power District	Yes	We have concern over establishing proof an outage is exempt due to fresh gale. A fresh gale, or even a localized thunderstorm, can easily produce wind gusts that exceed the lines rated capacity for blow out. If an outage occurs under these conditions, the standard provides an exemption under Section 4.3.1, but there is often no way to empirically prove conditions exceeded the lines normal operating conditions. How should a utility handle these situations?
Southen Company	Yes	We have concern over establishing proof an outage is exempt due to fresh gale. A fresh gale, or even a localized thunderstorm, can easily produce wind gusts that exceed the lines rated capacity for blow out. If an outage occurs under these conditions, the standard provides an exemption under Section 4.3.1, but there is often no way to empirically prove conditions exceeded the lines normal operating conditions. How should a utility handle these situations? Please note there is a typographical error in the third paragraph on page 15, "...encroachment violation is not be a violation..."We would like to thank the Standard Drafting Team for their hard work. The time and effort they have put into developing this standard is obvious.
Dominion	Yes	While not related solely to this standard, we suggest that no future standard be effective until approval has been granted by the applicable regulatory authority. Having an effective date that differs from the mandatory date is causing confusion/chaos on the part of the applicable registered entity(ies). With the current process, it is possible to have a standard that is mandatory conflict with a superseding newer version (or a new standard that contains requirements meant to supersede those in the mandatory standard). Applicable entity(ies) may not be able to comply with both when this is true, and may not be able to take steps necessary to transition from mandatory requirement to superseding requirement without becoming non-compliant.
Westchester County Board of Legislators		1. Bulk Electricity System NOPR – FERC recently issued a notice of proposed rulemaking to revise the definition of "bulk electric system" (BES) to include all transmission facilities with a rating of 100 kV or above. 130 FERC ¶ 61,204 (Mar. 18, 2010). If approved, such revision might significantly increase the amount of transmission facilities subject to standard FAC-003. In areas with dense residential and commercial development, this revision will exacerbate

Organization	Yes or No	Question 13 Comment
		existing conflicts between homeowners, municipalities, affected transmission owners (TOs), and regulating agencies. As described in comments below, compliance with the existing or perceived requirements in FAC-003 has produced numerous conflict in areas of dense development and narrow rights-of-way between homeowners, TOs, and regulating agencies because of economic, environmental, and aesthetic impacts. If FERC adopts the proposed BES definition, then the FAC-003 standard (current 001 and draft 002) should be extensively reviewed by the drafting team to evaluate the amount of affected facilities and the need for standard revision to avoid as far as possible further conflicts. 2. “Background” Section 5 – The draft adds a new section titled “Background” (Section 5). The existing standard FAC-003-1 does not include a similar section. This narrative section appears to provide interpretation on the rationale for a vegetation management reliability standard and to clarify the standard applicability. This discussion may be more appropriate in the accompanying technical reference, which describes and clarifies standard FAC-003. While identifying overgrown vegetation as cause of major outages and operational problems, this section fails to state that many other causes can lead to Cascading events. Indeed, of the many NERC reliability standards, only one, FAC-003, concerns vegetation management. While the August 2003 blackout was initiated by a tree contact, there were numerous other factors that caused this power outage to spread to over a dozen states. Section 5 should therefore be revised to clarify that FAC-003 is only one of many factors that can lead to a large-scale grid failure. 3. Standard Applicability Across Land Uses – Standard FAC-003-1 and the proposed draft do not vary in applicability, even though the types of land uses within and adjacent to transmission facilities vary widely. Among certain land uses, such as dense residential development, this can lead to substantial conflict between the TO and adjacent landowners, especially concerning environmental, aesthetic, and economic impacts. The Westchester County Board of Legislators identified such problems in its recent resolution, available at http://meetings.westchesterlegislators.com/Citizens/FileOpen.aspx?Type=4&ID=2828&AgencyName=WestchesterCounty . Notwithstanding the reliability imperative expressed by Congress in enacting Section 1211 of the 2005 Energy Policy Act, the implementation of reliability standard FAC-003 has produced significant challenges for all parties in suburban areas. In particular, surburban area homeowners, often on small parcels, that abut or are near to transmission rights-of-way have experienced dramatic impacts upon their properties and property values when TOs exercise their “full extent of legal rights at all times and in all cases”, as stated on page 18 of the draft. Therefore, the development of standard FAC-003 must consider this backdrop and select requirements and accompanying text that provide some balancing of electric reliabilty with environmental and economic impacts. As presently written, the draft does not acknowledge such balance. 4. Varying Conditions – Requirement R1.2.1 of Standard FAC-003-1 identifies numerous local conditions that should be considered in determining appropriate clearance distances. This balanced evaluation of factors should be retained in FAC-003-2. 5. Full Legal Rights – The draft encourages TOs to exercise full legal rights at all times and in all cases. This language

Organization	Yes or No	Question 13 Comment
		is not included in present standard FAC-003-1. As noted above, electric reliabilty and TO compliance with FAC-003 must not preclude other important societal factors. The language encouraging full exercise of legal rights should be removed from the draft.
KCPL	Yes	**<u>Requirement 4:</u>** Recommend the SDT consider modifying R4 to make it clear the requirement applies to that which is within the Right Of Way (ROW) for the transmission facility. Obviously, the Transmission Owner has no authority or control beyond the ROW. This is also an audit concern regarding “triggering” this requirement on a subjective evaluation of “imminent threat”. How does a Registered Entity, Regional Entity or Auditor determine what constitutes an “imminent threat”? This will be a matter of opinion and makes this a difficult requirement regarding compliance when a difference of opinion arises. In addition, as proposed, this requirement does not address the need to take immediate corrective actions to mitigate an imminent threat. The previous FAC-003 Standard included taking action to remove the “imminent threat” which is not included in this proposed version 2. What was the intention of the SDT in this regard? Recommend the SDT consider language to include taking action to remove the imminent threat. **<u>In the “Guideline and Technical Basis” section:</u>** 1. Under R6: believe the word “per” is missing in the first sentence of the third paragraph between “once (per) line”. 2. Under R7: concerned regarding the use of words such as “never”, “at all times”, and “in all cases” in the bulleted items with paragraph 6 in this section as a guiding document. This is the kind of material that is creeping into compliance audits and recommend softening this language. **<u>Violation Severity Levels</u>** 1. Do not agree with the zero tolerance for encroachments that do not result in a service interruption for R1 and R2. 2. Not notifying the Control Center should be a HIGH and not removing the imminent threat should be a SEVERE.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed

1. SC approved SAR for initial posting (January 11, 2007).
2. SAR posted for comment (January 15–February 14, 2007).
3. SAR posted for comment (April 10–May 9, 2007).
4. SC authorized moving the SAR forward to standard development (June 27, 2007).

Proposed Action Plan and Description of Current Draft

This is the second posting of the proposed revisions to the standard in accordance with Results-Based Criteria.

Future Development Plan

Anticipated Actions	Anticipated Date
Drafting team considers comments, makes conforming changes, and requests SC approval to proceed to formal comment and ballot.	June –July 2010
Recirculation ballot of standards.	July-August 2010
Receive BOT approval	August 2010

Effective Dates

1. First calendar day of the first calendar quarter one year after applicable regulatory authority approval for all requirements
2. First calendar day of the first calendar quarter one year following Board of Trustees adoption unless governmental authority withholds approval
3. First calendar day of the first calendar quarter that is at least one year following Board of Trustees adoption

Exceptions:

A line operated below 200kV, designated by the Planning Coordinator as an element of an IROL or as a Major WECC transfer path, becomes subject to this standard 12 months after the date the Planning Coordinator or WECC initially designates the lines as being subject to this standard.

An existing transmission line operated at 200kV or higher that is newly acquired by an asset owner and was not previously subject to this standard, becomes subject to this standard 12 months after the acquisition date of the line.

Version History

Version	Date	Action	Change Tracking
1	TBA	1. Added "Standard Development Roadmap." 2. Changed "60" to "Sixty" in section A, 5.2. 3. Added "Proposed Effective Date: April 7, 2006" to footer. 4. Added "Draft 3: November 17, 2005" to footer.	01/20/06
1	April 4, 2007	Regulatory Approval — Effective Date	New
2			

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary. When this standard has received ballot approval, the text boxes will be moved to the Guideline and Technical Basis Section.

Vegetation Inspection
The systematic examination of vegetation conditions on a maintained transmission line Right-of-Way which may be combined with a general line inspection.

The current glossary definition of this NERC term is modified to allow both maintenance inspections and vegetation inspections to be performed concurrently.

Current definition of Vegetation Inspection: The systematic examination of a transmission corridor to document vegetation conditions.

Introduction

1. **Title:** Transmission Vegetation Management

2. **Number:** FAC-003-2

3. **Objectives:** To improve the reliability of the electric Transmission system by preventing those vegetation related outages that could lead to Cascading.

4. **Applicability**

   4.1. Functional Entities:

   Transmission Owners

   4.2. Facilities: Defined below, including but not limited to those that cross lands owned by federal[1], state, provincial, public, private, or tribal entities:

   4.2.1. Overhead transmission lines operated at 200kV or higher.

   4.2.2. Overhead transmission lines operated below 200kV having been identified as included in the definition of an Interconnection Reliability Operating Limit (IROL) under NERC Standard FAC 014 by the Planning Coordinator.

   4.2.3. Overhead transmission lines operated below 200 kV having been identified as included in the definition of one of the *Major WECC Transfer Paths in the Bulk Electric System*.

   4.2.4. This Standard does not apply to Facilities identified above (4.2.1 through 4.2.3) located in the fenced area of a switchyard, station or substation.

   4.3. Enforcement: *The reliability obligations of the applicable entities and facilities are contained within the technical requirements of this standard. [Straw proposal]*

   4.4. Other:

   This Standard does not apply to any occurrence, non-occurrence, or other set of circumstances that are beyond the control of a Transmission Owner subject to this reliability standard, including acts of God, flood, drought, earthquake, major storms, fire, hurricane, tornado, landslides, ice storms, vehicle contact with tree, human activity involving: removal of, installation of, or digging around vegetation, animals severing trees, lightning, epidemic, strike, war, riot, civil disturbance, sabotage, vandalism, terrorism, wind shear, or fresh gale (or higher wind speed) that restricts or prevents performance to comply with this reliability standard's requirements. Nothing in this

[1] EPAct 2005 section 1211c: *"Access approvals by Federal agencies"*.

section should be construed to limit the Transmission Owner's right to exercise its full legal rights on the active transmission line ROW[2].

5. Background:

This NERC Vegetation Management Standard ("Standard") uses a defense-in-depth approach to improve the reliability of the electric Transmission System by preventing those vegetation related outages that could lead to Cascading. This Standard is not intended to address non-preventable outages such as those due to vegetation fall-ins or blow-ins from outside the Active Transmission Line Right-of-Way, vandalism, human activities and acts of nature. Operating experience indicates that trees that have grown out of specification have contributed to Cascading, especially under heavy electrical loading conditions.

With a defense-in-depth strategy, this Standard utilizes three types of requirements to provide layers of protection to prevent vegetation related outages that could lead to Cascading:

a) Performance-based — defines a particular reliability objective or outcome to be achieved.

b) Risk-based — preventive requirements to reduce the risks of failure to acceptable tolerance levels.

c) Competency-based — defines a minimum capability an entity needs to have to demonstrate it is able to perform its designated reliability functions.

The defense-in-depth strategy for reliability standards development recognizes that each requirement in a NERC reliability standard has a role in preventing system failures, and that these roles are complementary and reinforcing. Reliability standards should not be viewed as a body of unrelated requirements, but rather should be viewed as part of a portfolio of requirements designed to achieve an overall defense-in-depth strategy and comport with the quality objectives of a reliability standard. For this Standard, the requirements have been developed as follows:

- Performance-based: Requirements 1 and 2
- Competency-based: Requirement 3
- Risk-based: Requirements 4, 5, 6 and 7

Thus the various requirements associated with a successful vegetation program could be viewed as using R1, R2 and R3 as first levels of defense; while R4 could be a subsequent or final level of defense. R6 depending on the particular vegetation approach may be either an initial defense barrier or a final defense barrier.

[2] A strip or corridor of land that is occupied by active transmission facilities. This corridor does not include the parts of the Right-of-Way that are unused or intended for other facilities. However, it is not to be less than the width of the easement itself unless the easement exceeds distances as shown in Table 3 for various voltage classes.

Major outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations. Adherence to the Standard requirements for applicable lines on any kind of land or easement, whether they are Federal Lands, state or provincial lands, public or private lands, franchises, easements or lands owned in fee, will reduce and manage this risk. For the purpose of the Standard the term "public lands" includes municipal lands, village lands, city lands, and a host of other governmental entities.

This Standard addresses vegetation management along applicable overhead lines and does not apply to underground lines, submarine lines or to line sections inside an electric station boundary.

This Standard focuses on transmission lines to prevent those vegetation related outages that could lead to Cascading. It is not intended to prevent customer outages due to tree contact with lower voltage distribution system lines. For example, localized customer service might be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. However, this Standard is not written to address such isolated situations which have little impact on the overall electric transmission system.

Since vegetation growth is constant and always present, unmanaged vegetation poses an increased outage risk, especially when numerous transmission lines are operating at or near their Rating. This can present a significant risk of multiple line failures and Cascading. Conversely, most other outage causes (such as trees falling into lines, lightning, animals, motor vehicles, etc.) are statistically intermittent. These events are not any more likely to occur during heavy system loads than any other time. There is no cause-effect relationship which creates the probability of simultaneous occurrence of other such events. Therefore these types of events are highly unlikely to cause large-scale grid failures. Thus, this Standard's emphasis is on vegetation grow-ins.

Requirements and Measures

Rationale
The MVCD is a calculated minimum distance stated in feet (meters) to prevent spark-over between conductors and vegetation, for various altitudes and operating voltages. The distances in Table 2 were derived using a proven transmission design method.

R1. Each Transmission Owner shall manage vegetation to prevent encroachment that could result in a Sustained Outage of any line identified as an element of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions). Types of encroachment include:

1. An encroachment into the Minimum Vegetation Clearance Distance (MVCD) as shown in Table 2, observed in real time, absent a Sustained Outage,
2. An encroachment due to a fall-in from inside the active transmission line ROW that caused a vegetation-related Sustained Outage,
3. An encroachment due to blowing together of applicable lines and vegetation located inside the active transmission line ROW that caused a vegetation-related Sustained Outage,
4. An encroachment due to a grow-in that caused a vegetation-related Sustained Outage.

[VRF – High] [Time Horizon – Real-time]

M1. Each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R1. Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-Time observations of any MVCD encroachments.

Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period. If an investigation of a Fault by a qualified person confirms that a vegetation encroachment within the MVCD occurred, then it shall be considered a Real-time observation.

R2. Each Transmission Owner shall manage vegetation to prevent encroachment that could result in a Sustained Outage of applicable lines that are not elements of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions). Types of encroachment include:

1. An encroachment into the Minimum Vegetation Clearance Distance (MVCD) as shown in Table 2, observed in real time, absent a Sustained Outage,
2. An encroachment due to a fall-in from inside the active transmission line ROW that caused a vegetation-related Sustained Outage,
3. An encroachment due to blowing together of applicable lines and vegetation located inside the active transmission line ROW that caused a vegetation-related Sustained Outage,
4. An encroachment due to a grow-in that caused a vegetation-related Sustained Outage.

[VRF – Medium] [Time Horizon – Real-time]

Rationale

The MVCD is a calculated minimum distance stated in feet (meters) to prevent spark-over between conductors and vegetation, for various altitudes and operating voltages. The distances in Table 2 were derived using a proven transmission design method.

M2. Each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R2. Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-Time observations of any MVCD encroachments.

Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period. If an investigation of a Fault by a qualified person confirms that a vegetation encroachment within the MVCD occurred, then it shall be considered a Real-time observation.

R3. Each Transmission Owner shall document the procedures, processes, or specifications it uses to prevent the encroachment of vegetation into the MVCD. Such documentation will incorporate the dynamics of a transmission line conductor’s movement throughout its Rating and Rated Electrical Operating Conditions and the inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency, for the Transmission Owner’s applicable lines.

> **Rationale**
> Provide a basis for evaluation on the intent and competency of the Transmission Owner in maintaining vegetation. There may be many acceptable approaches to maintain clearances. However, the Transmission Owner should be able to state what its approach is and how it conducts work to maintain clearances. See Figure 1 for an illustration of possible conductor locations.

[VRF – Lower] [Time Horizon – Long Term Planning]

M3. The procedures, processes, or specifications provided demonstrate that the Transmission Owner can prevent encroachment into the MVCD considering the factors identified in the requirement.

R4. Each Transmission Owner, without any intentional time delay, shall notify the control center holding switching authority for the associated transmission line when qualified personnel confirm the existence of a vegetation condition that is likely to cause a Fault at any moment.

> **Rationale**
> To ensure expeditious communication between qualified field personnel and proper operating personnel when a critical situation is confirmed. Qualified field personnel may include lineworkers and utility arborists.

[VRF – Medium] [Time Horizon – Real-time]

M4. Each Transmission Owner that has a vegetation condition likely to cause a Fault at any moment, as confirmed by qualified personnel, will have evidence that it notified the control center holding switching authority for the associated transmission line without any intentional time delay. Examples of evidence may include control center logs, voice recordings, switching orders, clearance orders and subsequent work orders.

R5. Each Transmission Owner shall take corrective action when it is constrained from performing planned vegetation work, where a transmission line is put at potential risk due to the constraint.

[VRF – Medium] [Time Horizon – Operations Planning]

M5. Each Transmission Owner has evidence of the corrective action taken for each constraint where a transmission line was put at potential risk. Examples of acceptable forms of evidence may include initially-planned work orders, documentation of constraints from landowners, court orders, inspection records of increased monitoring, documentation of the de-rating of lines, revised work orders, invoices, and evidence that a line was de-energized.

Rationale

Legal actions and other events may occur which result in constraints that prevent the Transmission Owner from performing planned vegetation maintenance work.

In cases where the transmission line is put at potential risk due to constraints, the intent is for the Transmission Owner to put interim measures in place, rather than do nothing.

For example, in the 2003 NE blackout a Transmission Owner was prevented by a court order from performing planned work. However, when the court order expired, the TO failed to take action to maintain the vegetation resulting in a sustained outage that contributed to the cascade.

The corrective action process is not intended to address situations where a planned work methodology cannot be performed but an alternate work methodology can be used.

R6. Each Transmission Owner shall perform a Vegetation Inspection of all applicable transmission lines at least once per calendar year.

[VRF – Medium] [Time Horizon – Operations Planning]

M6. Each Transmission Owner has evidence that it conducted Vegetation Inspections at least once per calendar year for all applicable transmission lines. Examples of acceptable forms of evidence may include completed and dated work orders, dated invoices, or dated inspection records.

Rationale

Inspections are used by Transmission Owners to assess the condition of the ROW. The information from the assessment can be used to determine risk, determine future work and evaluate recently-completed work. This requirement sets a minimum Vegetation Inspection frequency of once per calendar year. Based upon average growth rates across North America and on common utility practice, this minimum frequency is reasonable. Transmission Owners should consider local and environmental factors that could warrant more frequent inspections.

R7. Each Transmission Owner shall complete the work in an annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made and documented provided they do not put the transmission system at risk of a vegetation encroachment. Examples of reasons for modification to annual plan may include:

- Change in expected growth rate/ environmental factors
- Major storms
- Rescheduling work between growing seasons
- Crew or contractor availability/ Mutual assistance agreements
- Identified unanticipated high priority work
- Weather conditions/Accessibility
- Permitting delays
- Land ownership changes/Change in land use by the landowner
- Funding adjustments (increase or decrease)
- Emerging technologies

Rationale

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. An annual vegetation work plan allows for work to be modified for changing conditions, taking into consideration anticipated growth of vegetation and all other environmental factors, provided that the changes do not violate the encroachment within the MVCD.

[VRF – Medium] [Time Horizon – Operations Planning]

M7. Each Transmission Owner has evidence that it completed its annual vegetation work plan. Examples of acceptable forms of evidence may include a copy of the completed annual work plan (including modifications if any), dated work orders, dated invoices, or dated inspection records.

Compliance

Compliance Enforcement Authority

- Regional Entity

Compliance Monitoring and Enforcement Processes:

- Compliance Audits
- Self-Certifications
- Spot Checking
- Compliance Violation Investigations
- Self-Reporting
- Complaints

Evidence Retention

The Transmission Owner retains data or evidence of Requirements R1 through R7, Measures M1 through M7 for three calendar years to show compliance unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

If a Transmission Owner is found non-compliant, it shall keep information related to the non-compliance until found compliant, or for the duration specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

Additional Compliance Information

Periodic Data Submittal: The Transmission Owner will submit a quarterly report to its Regional Entity, or the Regional Entity's designee, identifying all Sustained Outages of transmission lines determined by the Transmission Owner to have been caused by vegetation that includes, as a minimum, the following:

- o The name of the circuit(s), the date, time and duration of the outage; the voltage of the circuit; a description of the cause of the outage; the category associated with the Sustained Outage; other pertinent comments; and any countermeasures taken by the Transmission Owner.

A Sustained Outage is to be categorized as one of the following:

- o Category 1A — Grow-ins: Sustained Outages caused by vegetation growing into applicable transmission lines, that are identified as an element of an IROL or Major WECC Transfer Path, by vegetation inside and/or outside of the active transmission line ROW;

- o Category 1B — Grow-ins: Sustained Outages caused by vegetation growing into applicable transmission lines, but are not identified as an element of an IROL or Major WECC Transfer Path, by vegetation inside and/or outside of the active transmission line ROW;

- Category 2 — Fall-ins: Sustained Outages caused by vegetation falling into applicable transmission lines from within the active transmission line ROW;
- Category[3] 4 — Blowing together: Sustained Outages caused by vegetation and applicable transmission lines blowing together from within the active transmission line ROW.

The Regional Entity will report the outage information provided by Transmission Owners, as per the above, quarterly to NERC, as well as any actions taken by the Regional Entity as a result of any of the reported Sustained Outages.

[3] Category 3 reporting is eliminated.

At the request of the Standards Committee, stakeholders are asked to review and comment on the proposed VSLs for R1 and R2. Following the comment period and nonbinding poll, only one set of VSLs will move forward for R1 and R2.

Time Horizons, Violation Risk Factors, and Violation Severity Levels

Guidelines and Technical Basis

Requirements R1 and R2:
R1 and R2 are performance-based requirements. The reliability objective or outcome to be achieved is the prevention of vegetation encroachments within a minimum distance of transmission lines. Content-wise, R1 and R2 are the same requirements; however, they apply to different Facilities. Both R1 and R2 require each Transmission Owner to prevent vegetation from encroaching within the Minimum Vegetation Clearance Distance of transmission lines. R1 is applicable to lines “identified as an element of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions) to avoid a Sustained Outage”. R2 applies to all other applicable lines that are not an element of an IROL or Major WECC Transfer Path.

The separation of applicability (between R1 and R2) recognizes that an encroachment into the MVCD of an IROL or Major WECC Transfer Path transmission line is a greater risk to the electric transmission system. Applicable lines that are not an element of an IROL or Major WECC Transfer Path are required to be clear of vegetation but these lines are comparatively less operationally significant. As a reflection of this difference in risk impact, the Violation Risk Factors (VRFs) are assigned as High for R1 and Medium for R2.

These requirements (R1 and R2) state that if vegetation encroaches within the distances prescribed in Table 2, it is in violation of the standard. Table 2 delineates the distances necessary to prevent spark-over based on the Gallet equations as described more fully in a supplemental *Transmission Vegetation Management Standard FAC-003-2 Technical Reference*.

These requirements assume that transmission lines and their conductors are operating within their Rating. If a line conductor is intentionally or inadvertently operated beyond its Rating (potentially in violation of other standards), the occurrence of a clearance encroachment may occur. For example, emergency actions taken by a Transmission Operator or Reliability Coordinator to protect an Interconnection may cause the transmission line to sag more and come closer to vegetation, potentially causing an outage. Such vegetation-related outages are not a violation of these requirements.

Evidence of violation of Requirement R1 and R2 include real-time observation of a vegetation encroachment into the MVCD (absent a Sustained Outage), or a vegetation-related encroachment resulting in a Sustained Outage due to a fall-in from inside the active transmission line ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to blowing together of applicable lines and vegetation located inside the active transmission line ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to a grow-in. If an investigation of a Fault by a qualified person confirms that a vegetation encroachment within the MVCD occurred, then it shall be considered a Real-time observation.

With this approach, the VSLs were defined such that they directly correlate to the severity of a failure to keep vegetation away from conductors and to the corresponding performance level of the Transmission Owner’s vegetation program’s ability to meet the goal of “preventing a Sustained Outage that could lead to Cascading.” Thus violation severity increases with a Transmission Owner’s inability to meet this goal and its potential of leading to a Cascading event. The additional benefits of such a combination are that it simplifies the standard and clearly defines performance for compliance. A performance-based requirement of this nature will promote high quality, cost effective vegetation management programs that will deliver the overall end result of improved reliability to the system.

Multiple Sustained Outages on an individual line can be caused by the same vegetation, for example a limb that only partially breaks and intermittently contacts a conductor. Such events are considered to be a single vegetation-related Sustained Outage under the Standard where the Sustained Outages occur within a 24 hour period.

The MVCD is a calculated minimum distance stated in feet (or meters) to prevent spark-over, for various altitudes and operating voltages that is used in the design of Transmission Facilities. Keeping vegetation from entering this space will help prevent transmission outages.

Requirement R3:

Requirement R3 is a competency based requirement concerned with the procedures, processes, or specifications, a Transmission Owner uses for vegetation management.

An adequate transmission vegetation management program formally establishes the approach the Transmission Owner uses to plan and perform vegetation work to prevent transmission Sustained Outages and minimize risk to the Transmission System. The approach provides the basis for evaluating the intent, allocation of appropriate resources and the competency of the Transmission Owner in managing vegetation. There are many acceptable approaches to manage vegetation and avoid Sustained Outages. However, the Transmission Owner must be able to state what its approach is and how it conducts work to maintain clearances.

An example of one approach commonly used by industry is ANSI Standard A300, part 7. However, regardless of the approach a utility uses to manage vegetation, any approach a Transmission Owner chooses to use will generally contain the following elements:

1. *the maintenance strategy used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that MVCD clearances are never violated.*
2. *the work methods that the Transmission Owner uses to control vegetation*
3. *a stated Vegetation Inspection frequency*
4. *an annual work plan*

The conductor's position in space at any point in time is continuously changing as a reaction to a number of different loading variables. Changes in vertical and horizontal conductor positioning are the result of thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation. Physical loading applied to the conductor affects sag and sway by combining physical factors such as ice and wind loading. The movement of the transmission line conductor and the MVCD is illustrated in Figure 1 below.

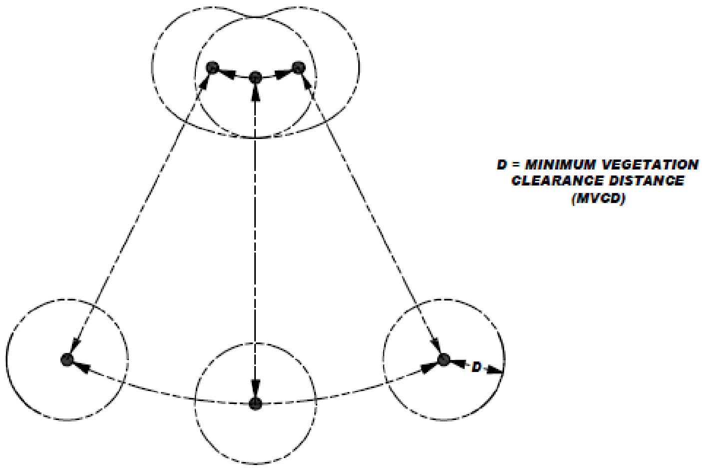

Figure 1

Cross-section view of a single conductor at a given point along the span showing six possible conductor positions due to movement resulting from thermal and mechanical loading.

Requirement R4:

R4 is a risk-based requirement. It focuses on preventative actions to be taken by the Transmission Owner for the mitigation of Fault risk when a vegetation threat is confirmed. R4 involves the notification of potentially threatening vegetation conditions, without any intentional delay, to the control center holding switching authority for that specific transmission line. Examples of acceptable unintentional delays may include communication system problems (for example, cellular service or two-way radio disabled), crews located in remote field locations with no communication access, delays due to severe weather, etc.

Confirmation is key that a threat actually exists due to vegetation. This confirmation could be in the form of a qualified employee who personally identifies such a threat in the field. Confirmation could also be made by sending out a qualified person to evaluate a situation reported by a landowner or an unqualified employee.

Vegetation-related conditions that warrant a response include vegetation that is near or encroaching into the MVCD (a grow-in issue) or vegetation that could fall into the transmission conductor (a fall-in issue). A knowledgeable verification of the risk would include an assessment of the possible sag or movement of the conductor while operating between no-load conditions and its rating.

The Transmission Owner has the responsibility to ensure the proper communication between field personnel and the control center to allow the control center to take the appropriate action until the vegetation threat is relieved. Appropriate actions may include a temporary reduction in the line loading, switching the line out of service, or positioning the system in recognition of the increasing risk of outage on that circuit. The notification of the threat should be communicated in terms of minutes or hours as opposed to a longer time frame for corrective action plans (see R5).

All potential grow-in or fall-in vegetation-related conditions will not necessarily cause a Fault at any moment. For example, some Transmission Owners may have a danger tree identification

program that identifies trees for removal with the potential to fall near the line. These trees would not require notification to the control center unless they pose an immediate fall-in threat.

Requirement R5:
R5 is a risk-based requirement. It focuses upon preventative actions to be taken by the Transmission Owner for the mitigation of Sustained Outage risk when temporarily constrained from performing vegetation maintenance. The intent of this requirement is to deal with situations that prevent the Transmission Owner from performing planned vegetation management work and, as a result, have the potential to put the transmission line at risk. Constraints to performing vegetation maintenance work as planned could result from legal injunctions filed by property owners, the discovery of easement stipulations which limit the Transmission Owner's rights, or other circumstances.

This requirement is not intended to address situations where the transmission line is not at potential risk and the work event can be rescheduled or re-planned using an alternate work methodology. For example, a land owner may prevent the planned use of chemicals on non-threatening, low growth vegetation but agree to the use of mechanical clearing. In this case the Transmission Owner is not under any immediate time constraint for achieving the management objective, can easily reschedule work using an alternate approach, and therefore does not need to take interim corrective action.

However, in situations where transmission line reliability is potentially at risk due to a constraint, the Transmission Owner is required to take corrective action to mitigate the potential risk to the transmission line. A wide range of actions can be taken to address various situations. General considerations include:

- Identifying locations where the Transmission Owner is constrained from performing planned vegetation maintenance work which potentially leaves the transmission line at risk.
- Developing the specific action to mitigate any potential risk associated with not performing the vegetation maintenance work as planned.
- Documenting and tracking the specific action taken for each location.
- In developing the specific action to mitigate the potential risk to the transmission line the Transmission Owner could consider location specific measures such as modifying the inspection and/or maintenance intervals. Where a legal constraint would not allow any vegetation work, the interim corrective action could include limiting the loading on the transmission line.
- The Transmission Owner should document and track the specific corrective action taken at each location. This location may be indicated as one span, one tree or a combination of spans on one property where the constraint is considered to be temporary.

Requirement R6:
R6 is a risk-based requirement. This requirement sets a minimum time period for completing Vegetation Inspections that fits general industry practice. In addition, the fact that Vegetation Inspections can be performed in conjunction with general line inspections further facilitates a

Transmission Owner's ability to meet this requirement. However, the Transmission Owner may determine that more frequent inspections are needed to maintain reliability levels, dependent upon such factors as anticipated growth rates of the local vegetation, length of the growing season for the geographical area, limited Active Transmission ROW width, and rainfall amounts. Therefore it is expected that some transmission lines may be designated with a higher frequency of inspections.

The VSL for Requirement R6 has VSL categories ranked by the percentage of the required ROW inspections completed. To calculate the percentage of inspection completion, the Transmission Owner may choose units such as: line miles or kilometers, circuit miles or kilometers, pole line miles, ROW miles, etc.

For example, when a Transmission Owner operates 2,000 miles of 230 kV transmission lines this Transmission Owner will be responsible for inspecting all 2,000 miles of 230 kV transmission lines at least once during the calendar year. If one of the included lines was 100 miles long, and if it was not inspected during the year, then the amount failed to inspect would be 100/2000 = 0.05 or 5%. The "Low VSL" for R6 would apply in this example.

Requirement R7:
R7 is a risk-based requirement. The Transmission Owner is required to implement an annual work plan for vegetation management to accomplish the purpose of this standard. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made and documented provided they do not put the transmission system at risk. The annual work plan requirement is not intended to necessarily require a "span-by-span", or even a "line-by-line" detailed description of all work to be performed. It is only intended to require that the Transmission Owner provide evidence of annual planning and execution of a vegetation management maintenance approach which successfully prevents encroachment of vegetation into the MVCD.

The ability to modify the work plan allows the Transmission Owner to change priorities or treatment methodologies during the year as conditions or situations dictate. For example recent line inspections may identify unanticipated high priority work, weather conditions (drought) could make herbicide application ineffective during the plan year, or a major storm could require redirecting local resources away from planned maintenance. This situation may also include complying with mutual assistance agreements by moving resources off the Transmission Owner's system to work on another system. Any of these examples could result in acceptable deferrals or additions to the annual work plan. Modifications to the annual work plan must always ensure the reliability of the electric Transmission system.

In general, the vegetation management maintenance approach should use the full extent of the Transmission Owner's easement, fee simple and other legal rights allowed. A comprehensive approach that exercises the full extent of legal rights on the active transmission line ROW is superior to incremental management in the long term because it reduces the overall potential for encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient.

When developing the annual work plan the Transmission Owner should allow time for procedural requirements to obtain permits to work on federal, state, provincial, public, tribal lands. In some cases the lead time for obtaining permits may necessitate preparing work plans more than a year prior to work start dates. Transmission Owners may also need to consider those special landowner requirements as documented in easement instruments.

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. Therefore, deferrals or relevant changes to the annual plan shall be documented. Depending on the planning and documentation format used by the Transmission Owner, evidence of successful annual work plan execution could consist of signed-off work orders, signed contracts, printouts from work management systems, spreadsheets of planned versus completed work, timesheets, work inspection reports, or paid invoices. Other evidence may include photographs, and walk-through reports.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed

1. SC approved SAR for initial posting (January 11, 2007).
2. SAR posted for comment (January 15–February 14, 2007).
3. SAR posted for comment (April 10–May 9, 2007).
4. SC authorized moving the SAR forward to standard development (June 27, 2007).

Proposed Action Plan and Description of Current Draft

This is the second~~first~~ posting of the proposed revisions to the standard in accordance with Results-Based Criteria. ~~The drafting team requests posting for a 30-day informal comment period.~~

Future Development Plan

Anticipated Actions	Anticipated Date
~~Drafting team considers comments, makes conforming changes, posts for 30-day informal comment period.~~	~~April 2010~~
Drafting team considers comments, makes conforming changes, and requests SC approval to proceed to formal comment and ballot.	June –July 2010
Recirculation ballot of standards.	July-August 2010
Receive BOT approval	August~~September~~ 2010

~~Definitions of Terms Used in Standard~~

~~This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.~~

~~Active Transmission Line Right-of-Way~~
~~A strip or corridor of land that is occupied by active transmission facilities. This corridor does not include the parts of the Right-of-Way that are unused or intended for other facilities.~~

~~Examples of active portions of corridors include:~~
~~The width of any Active Transmission Line Right-of-Way (ROW) is the portion of the ROW that has been cleared of vegetation to meet design clearance requirements such as National Electrical Safety Code or other design criteria, for the reliable operation of active facilities.~~

~~Examples of inactive portions of corridors include:~~

1) ~~The portions of the ROW acquired to accommodate future Facilities. Power plant exits are examples where large ROWs are obtained for maximum corridor utilization and may currently have fewer circuits constructed.~~
2) ~~The portion of the ROW where corridor edge zones are designated by regulatory bodies for vegetation to exist.~~
3) ~~The portions of the ROW where double-circuit structures are installed but only one circuit is currently strung with conductors.~~

~~Vegetation Inspection~~
~~The systematic examination of vegetation conditions on an Active Transmission Line Right-of-Way which may be combined with a general line inspection.~~

~~The current glossary definition of this NERC term is modified to allow both maintenance inspections and vegetation inspections to be performed concurrently.~~

~~Current definition of Vegetation Inspection: The systematic examination of a transmission corridor to document vegetation conditions.~~

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary. When this standard has received ballot approval, the text boxes will be moved to the Guideline and Technical Basis Section.

Vegetation Inspection
The systematic examination of vegetation conditions on a maintained transmission line Right-of-Way which may be combined with a general line inspection.

The current glossary definition of this NERC term is modified to allow both maintenance inspections and vegetation inspections to be performed concurrently.

Current definition of Vegetation Inspection: The systematic examination of a transmission corridor to document vegetation conditions.

Introduction

1. **Title:** Transmission Vegetation Management

2. **Number:** FAC-003-2

3. **Objectives:** To improve the reliability of the electric Transmission system by preventing those vegetation related outages that could lead to Cascading.

4. **Applicability**

4.1. Functional Entities:

~~**4.1.1**~~ Transmission Owners

4.2. Facilities: Defined below, including but not limited to those that cross lands owned by federal[1], state, provincial, public, private, or tribal entities:

~~**4.2.1.**~~ **4.2.1.** Overhead transmission lines operated at 200kV or higher.

~~**4.2.2.**~~ **4.2.2.** Overhead transmission lines operated below 200kV having been identified as included in the definition~~**elements**~~ of an Interconnection Reliability Operating Limit (IROL) under NERC Standard FAC 014 by the Planning Coordinator.~~).~~

~~**4.2.3.**~~ **4.2.3.** Overhead transmission lines operated below 200 kV having been identified as included in the definition of one of the *Major WECC Transfer Paths in the Bulk Electric System*.

~~**4.2.4.**~~ **4.2.4.** This Standard does not apply to Facilities identified above (4.2.1 through 4.2.3) located in the fenced area of a switchyard, station or substation.

4.3. Enforcement: *The reliability obligations of the applicable entities and facilities are contained within the technical requirements of this standard. [Straw proposal]*

~~**4.3.**~~4.4. **Other:**

~~**4.3.1.**~~ This Standard does not apply to any occurrence, non-occurrence, or other set of circumstances that are beyond the ~~reasonable~~ control of a Transmission Owner subject to this reliability standard~~Reliability Standard, and are not caused by the fault or negligence of the Transmission Owner~~, including acts of God, flood, drought, earthquake, major storms, fire, hurricane, tornado, landslides, ice storms, vehicle contact with tree, human activity involving: removal of, installation of, or digging around vegetation~~logging activities~~, animals severing trees, lightning, epidemic, strike, war, riot, civil disturbance, sabotage, vandalism, terrorism, wind shear, or fresh gale (or higher wind speed)~~gales~~ that restricts or prevents performance to comply with this reliability standard's requirements. Nothing in this section should be construed to limit

[1] EPAct 2005 section 1211c: *"Access approvals by Federal agencies"*.

the Transmission Owner's right to exercise its full legal rights on the active transmission line ROW[2].

5. Background:

This NERC Vegetation Management Standard ("Standard") uses a defense-in-depth approach to improve the reliability of the electric Transmission System by preventing those vegetation related outages that could lead to Cascading. This Standard is not intended to address non-preventable outages such as those due to vegetation fall-ins or blow-ins from outside the Active Transmission Line Right-of-Way, vandalism, human activities~~errors~~ and acts of nature. Operating experience indicates that trees that have grown out of specification have contributed to Cascading, especially under heavy electrical loading conditions.

With a defense-in-depth strategy, this Standard utilizes three types of requirements to provide layers of protection to prevent vegetation related outages that could lead to Cascading:

a) Performance-based — defines a particular reliability objective or outcome to be achieved.

b) Risk-based — preventive requirements to reduce the risks of failure to acceptable tolerance levels.

c) Competency-based — defines a minimum capability an entity needs to have to demonstrate it is able to perform its designated reliability functions.

The defense-in-depth strategy for reliability standards development recognizes that each requirement in a NERC reliability standard has a role in preventing system failures, and that these roles are complementary and reinforcing. Reliability standards should not be viewed as a body of unrelated requirements, but rather should be viewed as part of a portfolio of requirements designed to achieve an overall defense-in-depth strategy and comport with the quality objectives of a reliability standard. For this Standard, the requirements have been developed as follows:

- Performance-based: Requirements 1 and 2
- Competency-based: Requirement 3
- Risk-based: Requirements 4, 5, 6 and 7

Thus the various requirements associated with a successful vegetation program could be viewed as using R1, R2 and R3 as first levels of defense; while R4 could be a subsequent or final level of defense. R6 depending on the particular vegetation approach may be either an initial defense barrier or a final defense barrier.

[2] A strip or corridor of land that is occupied by active transmission facilities. This corridor does not include the parts of the Right-of-Way that are unused or intended for other facilities. However, it is not to be less than the width of the easement itself unless the easement exceeds distances as shown in Table 3 for various voltage classes.

Major outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations. Adherence to the Standard requirements for applicable lines on any kind of land or easement, whether they are Federal Lands, state or provincial lands, public or private lands, franchises, easements or lands owned in fee, will reduce and manage this risk. For the purpose of the Standard the term "public lands" includes municipal lands, village lands, city lands, and a host of other governmental entities.

This Standard addresses vegetation management along applicable overhead lines and~~that serve to connect one electric station to another. However, this Standard~~ does not apply to underground lines, submarine lines or to line sections inside an electric station boundary.

This Standard focuses on transmission lines to prevent those vegetation related outages that could lead to Cascading. It is not intended to prevent customer outages due to tree contact with lower voltage distribution system lines. For example, localized customer service might be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. However, this Standard is not written to address such isolated situations which have little impact on the overall electric transmission system~~Bulk Electric System~~.

Since vegetation growth is constant and always present, unmanaged vegetation poses an increased outage risk, especially when numerous transmission lines are operating at or near their Rating. This can present a significant risk of multiple line failures and Cascading. Conversely, most other outage causes (such as trees falling into lines, lightning, animals, motor vehicles, etc.) are statistically intermittent. These events are not any more likely to occur during heavy system loads than any other time. There is no cause-effect relationship which creates the probability of simultaneous occurrence of other such events. Therefore these types of events are highly unlikely to cause large-scale grid failures. Thus, this Standard's emphasis is on vegetation grow-ins.

Requirements and Measures

> **Rationale**
> The MVCD is a calculated minimum distance stated in feet (meters) to prevent spark-over between conductors and vegetation, for various altitudes and operating voltages. The distances in Table 2 were derived using a proven transmission design method.

R1. Each Transmission Owner shall manage ~~prevent~~ vegetation to prevent encroachment that could result in a Sustained Outage~~from encroaching within the Minimum Vegetation Clearance Distance (MVCD)~~ of any~~each~~ line ~~conductor that is~~ identified as an element of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions). Types of encroachment include:~~) to avoid a Sustained Outage.~~

An

~~**M1.** Evidence of violation of Requirement R1 is limited to:~~

1. ~~**Real-time observation of**~~ encroachment into the Minimum Vegetation Clearance Distance (MVCD) as shown in Table 2, observed in real time, absent a Sustained Outage,~~, **or**~~
    - **An encroachment**~~A vegetation-related Sustained Outage~~ due to a fall-in from inside the **active transmission line**~~Active Transmission Line~~ ROW **that caused a**~~, or~~
2. ~~**A**~~ vegetation-related Sustained Outage,
    - **An encroachment** due to blowing together of applicable lines and vegetation located inside the **active transmission line**~~Active Transmission Line~~ ROW **that caused a**~~, or~~
3. ~~**A**~~ vegetation-related Sustained Outage,
4. An encroachment due to a grow-in that caused a vegetation-related Sustained Outage.

[VRF – High] [Time Horizon – Real-time]

M1. Each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R1. Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-Time observations of any MVCD encroachments.

Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period. If an investigation of a Fault by a qualified person confirms that a vegetation encroachment within the MVCD occurred, then it shall be considered a Real-time observation.

R2. Each Transmission Owner shall manage vegetation to prevent encroachment that could result in a Sustained Outage of applicable lines that are not elements of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions). Types of encroachment include:

1. An encroachment into the Minimum Vegetation Clearance Distance (MVCD) as shown in Table 2, observed in real time, absent a Sustained Outage,
2. An encroachment due to a fall-in from inside the active transmission line ROW that caused a vegetation-related Sustained Outage,
3. An encroachment due to blowing together of applicable lines and vegetation located inside the active transmission line ROW that caused a vegetation-related Sustained Outage,
4. An encroachment due to a grow-in that caused a vegetation-related Sustained Outage.

Rationale

The MVCD is a calculated minimum distance stated in feet (meters) to prevent spark-over between conductors and vegetation, for various altitudes and operating voltages. The distances in Table 2 were derived using a proven transmission design method.

[VRF – Medium] [Time Horizon – Real-time]

- **M2.** Each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R2. Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-Time observations of any MVCD encroachments.

  Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period. If an investigation of a Fault by a qualified person confirms that a vegetation encroachment within the MVCD occurred, then it shall be considered a Real-time observation.

R3~~R2~~. Each Transmission Owner shall document the procedures, processes, or specifications it uses to prevent the encroachment of vegetation into~~from encroaching within~~ the MVCD. Such documentation will incorporate the dynamics of a transmission ~~of each applicable~~ line conductor's movement throughout its ~~conductor, which are not elements of an IROL and are not a Major WECC transfer path, (operating within~~ Rating and Rated Electrical Operating Conditions and the inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency, for the Transmission Owner's applicable lines) ~~to avoid a Sustained Outage~~.

~~**Rationale**~~

~~The MVCD is a calculated minimum distance stated in feet (meters) to prevent spark-over between conductors and vegetation, for various altitudes and operating voltages. The distances in Table 2 were derived using a proven~~

Rationale

Provide a basis for evaluation on the intent and competency of the Transmission Owner in maintaining vegetation. There may be many acceptable approaches to maintain clearances. However, the Transmission Owner should be able to state what its approach is and how it conducts work to maintain clearances. See Figure 1 for an illustration of possible conductor locations.

[VRF – Lower] [Time Horizon – Long Term Planning]

M3. The procedures, processes, or specifications provided demonstrate that the Transmission Owner can prevent

~~**M2.** Evidence of violation of Requirement R2 is limited to:~~

- ~~Real-time observation of~~ encroachment into the MVCD~~, or~~
- ~~A vegetation-related Sustained Outage due to a fall-in from inside the Active Transmission Line ROW, or~~
- ~~A vegetation-related Sustained Outage due to blowing together of applicable lines and vegetation located inside the Active Transmission Line ROW, or~~
- ~~A vegetation-related Sustained Outage due to a grow-in.~~

~~Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period.~~

~~**R3.** Each Transmission Owner shall have a documented transmission vegetation management program that describes how it conducts work on its Active Transmission Line ROWs to avoid Sustained Outages due to vegetation,~~ considering the factors identified in the requirement~~all possible locations the conductor may occupy assuming operation within Rating and Rated Electrical Operating Conditions~~.

Rationale

To ensure expeditious communication between qualified field personnel and proper operating personnel when a critical situation is confirmed. Qualified field personnel may include lineworkers and utility arborists.

~~Rationale~~

~~Provide a basis for evaluation on the intent and competency of the Transmission Owner in maintaining vegetation. There may be many acceptable approaches to maintain clearances. However, the Transmission Owner should be able to state what its approach is and how it conducts work to maintain clearances. See Figure 1 for an illustration of possible conductor locations.~~

~~**M3.** Each Transmission Owner has a documented transmission vegetation management program that describes how it conducts work on its Active Transmission Line ROW to avoid Sustained Outages due to vegetation, considering all possible locations the conductor may occupy assuming operation within Rating and Rated Electrical Operating Conditions.~~

R4. Each Transmission Owner, without any intentional time delay, shall notify the ~~responsible~~ control center holding switching authority for the associated transmission line when qualified personnel confirm the existence~~it has verified knowledge~~ of a vegetation ~~imminent threat~~ condition that ~~. A vegetation imminent threat condition is one which~~ is likely to cause a Fault~~Sustained Outage~~ at any moment.

[VRF – Medium] [Time Horizon – Real-time]

~~Rationale~~

~~To ensure rapid notification of the correct personnel when an occurrence of a critical situation is observed. Verified knowledge includes observations by journeyman lineman, utility arborist, or other qualified personnel, or a report verified by these personnel.~~

M4. Each Transmission Owner that has a vegetation condition likely to cause a Fault at any moment, as confirmed by qualified personnel,~~experienced a verified vegetation imminent threat~~ will have evidence that it notified the ~~responsible~~ control center holding switching authority for the associated transmission line without any intentional time delay. Examples of evidence may include control center logs, voice recordings, switching orders, clearance orders and subsequent work orders.

R5. Each Transmission Owner shall take ~~interim~~ corrective action when it is ~~temporarily~~ constrained from performing planned vegetation work, where a transmission line is put at potential risk due to the constraint.

[VRF – Medium] [Time Horizon – Operations Planning]

M5. Each Transmission Owner has evidence of the ~~interim~~ corrective action taken for each ~~temporary~~ constraint where a transmission line was put at potential risk. Examples of acceptable forms of evidence may include initially-planned work orders, documentation of constraints from landowners, court orders, inspection records of increased monitoring, documentation of the de-rating of lines, revised work orders, invoices, and evidence that a line was de-energized~~or inspection records~~.

Rationale

Legal actions and other events may occur which result in constraints that prevent the Transmission Owner from performing planned vegetation maintenance work.

In cases where the transmission line is put at potential risk due to constraints, the intent is for the Transmission Owner to put interim measures in place, rather than do nothing.

For example, in the 2003 NE blackout a Transmission Owner was prevented by a court order from performing planned work. However, when the court order expired, the TO failed to take action to maintain the vegetation resulting in a sustained outage that contributed to the cascade.

The corrective action process is not intended to address situations where a planned work methodology cannot be performed but an alternate work methodology can be used.

R6. Each Transmission Owner shall perform a Vegetation Inspection of all applicable transmission lines at least once per calendar year.

[VRF – Medium] [Time Horizon – Operations Planning]

M6. Each Transmission Owner has evidence that it conducted Vegetation Inspections at least once per calendar year for all applicable transmission lines. Examples of acceptable forms of evidence may include completed and dated work orders, dated invoices, or dated inspection records.

Rationale

Inspections are used by Transmission Owners to assess the condition of the ROW. The information from the assessment can be used to determine risk, determine future work and evaluate recently-completed work. This requirement sets a minimum Vegetation Inspection frequency of once per calendar

R7. Each Transmission Owner shall complete the work in an~~execute a flexible~~ annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made and documented provided they do not put the transmission system at risk of a vegetation encroachment. Examples of reasons for modification to annual plan may include:

Rationale

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. An annual vegetation work plan allows for work to be modified for changing conditions, taking into consideration anticipated growth of vegetation and all other environmental factors, provided that the changes do not violate the encroachment within the MVCD.

- Change in expected growth rate/ environmental factors
- Major storms
- Rescheduling work between growing seasons
- Crew or contractor availability/ Mutual assistance agreements
- Identified unanticipated high priority work
- Weather conditions/Accessibility
- Permitting delays
- Land ownership changes/Change in land use by the landowner
- Funding adjustments (increase or decrease)
- Emerging technologies

[VRF – Medium] [Time Horizon – Operations Planning]

M7. Each Transmission Owner has evidence that it completed its~~executed a flexible~~ annual vegetation work plan. Examples of acceptable forms of evidence may include a copy of the completed annual work plan (including modifications if any), dated work orders, dated invoices, or dated inspection records.

Compliance

Compliance Enforcement Authority

- Regional Entity

Compliance Monitoring and Enforcement Processes:

- Compliance Audits
- Self-Certifications
- Spot Checking
- Compliance Violation Investigations
- Self-Reporting
- Complaints

Evidence Retention

The Transmission Owner retains data or evidence of Requirements R1 through R7, Measures M1 through M7 for three calendar years to show compliance unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

If a Transmission Owner is found non-compliant, it shall keep information related to the non-compliance until found compliant, or for the duration specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

Additional Compliance Information

Periodic Data Submittal: ~~(See Administrative Procedure)~~

~~R1~~		~~Real-time~~	~~High~~	~~The Transmission Owner failed to prevent vegetation from encroaching within the MVCD of a transmission line as described in R1.~~	~~The Transmission Owner incurred a Sustained Outage due to vegetation falling into a transmission line as described in R1 from within the Active Transmission Line ROW.~~	~~The Transmission Owner incurred a Sustained Outage due to the blowing together of vegetation and a transmission line as described in R1 from within the Active Transmission Line ROW.~~	~~The Transmission Owner incurred a Sustained Outage due to vegetation growing into a transmission line as described in R1.~~
~~R2~~		~~Real-time~~	~~Medium~~	~~The Transmission Owner failed to prevent vegetation from encroaching within the MVCD of a transmission line as described in R2.~~	~~The Transmission Owner incurred a Sustained Outage due to vegetation falling into a transmission line as described in R2 from within the Active Transmission Line ROW.~~	~~The Transmission Owner incurred a Sustained Outage due to the blowing together of vegetation and a transmission line as described in R2 from within the Active Transmission Line ROW.~~	~~The Transmission Owner incurred a Sustained Outage due to vegetation growing into a transmission line as described in R2.~~
~~R3~~		~~Long-Term Planning~~	~~Lower~~		~~The Transmission Owner has a documented transmission vegetation management program, but the transmission vegetation management program does not describe how work is conducted on the Active Transmission Line ROWs to avoid Sustained Outages due to vegetation.~~	~~The Transmission Owner has a documented transmission vegetation management program, but the transmission vegetation management program does not consider all possible locations the conductor may occupy assuming operation within Rating and Rated Electrical Operating Conditions~~	~~The Transmission Owner does not have a documented transmission vegetation management program.~~

~~R4~~	~~Real-time~~	~~Medium~~				~~The Transmission Owner had verified knowledge of a vegetation imminent threat condition and did not notify the responsible control center.~~
~~R5~~	~~Operations Planning~~	~~Medium~~				~~The Transmission Owner did not take interim corrective action when it was temporarily constrained from performing planned vegetation work where an applicable transmission line was put at potential risk.~~
~~R6~~	~~Operations Planning~~	~~High~~	~~The Transmission Owner inspected greater than 95% but less than 100% of the ROW as measured by applicable line miles (kilometers) (based on units of choice: circuit, pole line, ROW, etc.).~~	~~The Transmission Owner inspected greater than 90% but less than or equal to 95% of the ROW as measured by applicable line miles (kilometers) (based on units of choice: circuit, pole line, ROW, etc.).~~	~~The Transmission Owner inspected greater than 85% but less than or equal to 90% of the ROW as measured by applicable line miles (kilometers) (based on units of choice: circuit, pole line, ROW, etc.).~~	~~The Transmission Owner inspected less than or equal to 85% of the ROW as measured by applicable line miles (kilometers) (based on units of choice: circuit, pole line, ROW, etc.).~~
~~R7~~	~~Operations Planning~~	~~High~~	~~The Transmission Owner executed greater than 95% but less than 100% of its annual work plan as adjusted.~~	~~The Transmission Owner executed greater than 90% but less than or equal to 95% of its annual work plan as adjusted.~~	~~The Transmission Owner executed greater than 85% but less than or equal to 90% of its annual work plan as adjusted.~~	~~The Transmission Owner executed less than or equal to 85% of its annual work plan as adjusted.~~

~~Administrative Procedure~~

The Transmission Owner will submit a quarterly report to its Regional Entity, or the Regional Entity's designee, identifying all Sustained Outages of transmission lines determined by the Transmission Owner to have been caused by vegetation that includes, as a minimum, the following:~~:.~~

- The name of the circuit(s), the date, time and duration of the outage; the voltage of the circuit; a description of the cause of the outage; the category associated with the Sustained Outage; other pertinent comments; and any countermeasures taken by the Transmission Owner.

A Sustained Outage is to be categorized as one of the following:

- Category 1A — Grow-ins: Sustained Outages caused by vegetation growing into applicable transmission lines, that are identified as an element of an IROL or Major WECC Transfer Path, by vegetation inside and/or outside of the active transmission line~~Active Transmission Line~~ ROW;
- Category 1B — Grow-ins: Sustained Outages caused by vegetation growing into applicable transmission lines, but are not identified as an element of an IROL or Major WECC Transfer Path, by vegetation inside and/or outside of the active transmission line~~Active Transmission Line~~ ROW;
- Category 2 — Fall-ins: Sustained Outages caused by vegetation falling into applicable transmission lines from within the active transmission line~~Active Transmission Line~~ ROW;
- Category[3] 4 — Blowing together: Sustained Outages caused by vegetation and applicable transmission lines blowing together from within the active transmission line~~Active Transmission Line~~ ROW.

The Regional Entity will report the outage information provided by Transmission Owners, as per the above, quarterly to NERC, as well as any actions taken by the Regional Entity as a result of any of the reported Sustained Outages.

[3] Category 3 reporting is eliminated.

At the request of the Standards Committee, stakeholders are asked to review and comment on the proposed VSLs for R1 and R2. Following the comment period and nonbinding poll, only one set of VSLs will move forward for R1 and R2.

Guidelines

~~Guideline~~ and Technical Basis

Requirements R1 and R2:

~~Requirements~~ R1 and R2 are performance-based requirements. The reliability objective or outcome to be achieved is the prevention of vegetation encroachments within a minimum distance of transmission lines. Content-wise, R1 and R2 are the same requirements; however, they apply to different Facilities. Both R1 and R2 require each ~~state that if a~~ Transmission Owner to prevent vegetation from encroaching within the Minimum Vegetation Clearance Distance of transmission lines. R1 is applicable to lines "identified as an element of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions) to avoid a Sustained Outage". R2 applies to all other applicable lines that are not an element of an IROL or Major WECC Transfer Path.

The separation of applicability (between R1 and R2) recognizes that an encroachment into the MVCD of an IROL or Major WECC Transfer Path transmission line is a greater risk to the electric transmission system. Applicable lines that are not an element of an IROL or Major WECC Transfer Path are required to be clear of vegetation but these lines are comparatively less operationally significant. As a reflection of this difference in risk impact, the Violation Risk Factors (VRFs) are assigned as High for R1 and Medium for R2.

These requirements (R1 and R2) state that if vegetation encroaches ~~observes vegetation~~ within the distances prescribed in ~~FAC-003 –~~ Table 2, it is in violation of the standard. Table 2 delineates~~this Standard. The MVCD table contains~~ the distances necessary to prevent ~~which are required to ensure that~~ spark-over ~~will not occur; the distances are~~ based on the Gallet equations as described more fully in a supplemental *Transmission Vegetation Management Standard FAC-003-2 Technical Reference*.

These requirements assume that transmission lines and their conductors are operating within their Rating. If a line conductor is intentionally or inadvertently operated beyond its Rating (potentially in violation of other standards), the occurrence of a clearance encroachment may occur. For example, emergency actions taken by a Transmission Operator or Reliability Coordinator to protect an Interconnection may cause the transmission line to sag more and come closer to vegetation, potentially causing an outage. Such vegetation-related outages are not a violation of these requirements.

Evidence of violation of Requirement~~. Requirements~~ R1 and R2 include real-time ~~refer to~~ observation of a vegetation encroachment into the MVCD (absent a Sustained Outage), or a vegetation-related encroachment resulting in a Sustained Outage due to a fall-in from inside the active transmission line ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to blowing together of applicable lines and vegetation located inside the active transmission line ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to a grow-in. If an investigation of a Fault by a qualified person confirms that a vegetation encroachment within the MVCD occurred, then it shall be considered a Real-time~~in "real time". This means an actual field~~ observation. ~~or measurement of the conductor-to-vegetation distance and not a calculated determination of relative positions.~~

With this approach, the VSLs were defined such that they directly correlate to the severity of a failure to keep vegetation away from conductors and to the corresponding performance level of the Transmission Owner's vegetation program's ability to meet the goal of "preventing a Sustained Outage that could lead to Cascading." Thus violation severity increases with a Transmission Owner's inability to meet this goal and its potential of leading to a Cascading event. The additional benefits of such a combination are that it simplifies the standard and clearly defines performance for compliance. A performance-based requirement of this nature will promote high quality, cost effective vegetation management programs that will deliver the overall end result of improved reliability to the system.

Multiple Sustained Outages on an individual line can be caused by the same vegetation, for example a limb that only partially breaks and intermittently contacts a conductor. Such events are considered to be a single vegetation-related Sustained Outage under the Standard where the Sustained Outages occur within a 24 hour period.

The MVCD is a calculated minimum distance stated in feet (or meters) to prevent spark-over, for various altitudes and operating voltages that is used in the design of Transmission Facilities. Keeping vegetation from entering this space will help prevent transmission outages. ~~The movement of the transmission line conductor and the MVCD is illustrated in Figure 1 below.~~

Requirement R3:

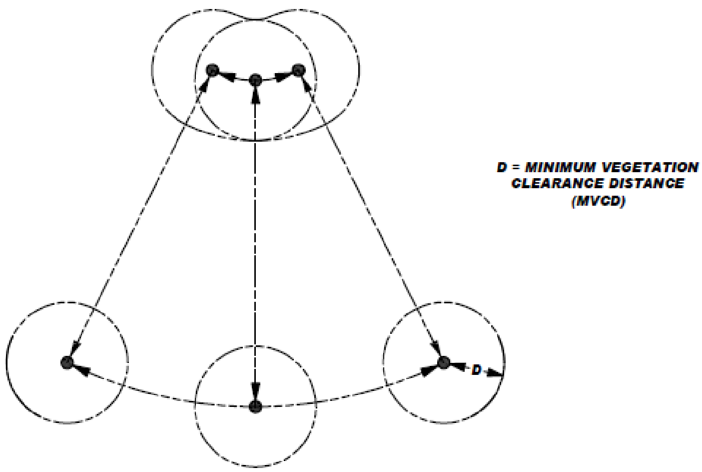
Requirement R3 is a competency based requirement concerned with the procedures, processes, or specifications, a Transmission Owner uses for vegetation management.

An adequate transmission vegetation management program formally establishes the approach the Transmission Owner uses to plan and perform vegetation work to prevent transmission Sustained Outages and minimize risk to the Transmission System. The approach provides the basis for evaluating the intent, allocation of appropriate resources and the competency of the Transmission Owner in managing vegetation. There are many acceptable approaches to manage vegetation and avoid Sustained Outages. However, the Transmission Owner must be able to state what its approach is and how it conducts work to maintain clearances.

An example of one approach commonly used by industry is ANSI Standard A300, part 7. However, regardless of the approach a utility uses to manage vegetation, any approach a Transmission Owner chooses to use will generally contain the following elements:

1. *the maintenance strategy used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that MVCD clearances are never violated.*
2. *the work methods that the Transmission Owner uses to control vegetation*
3. *a stated Vegetation Inspection frequency*
4. *an annual work plan*

The conductor's position in space at any point in time is continuously changing as a reaction to a number of different loading variables. Changes in vertical and horizontal conductor positioning are the result of thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation. Physical loading applied to the conductor affects sag and sway by combining physical factors such as ice and wind loading. The movement of the transmission line conductor and the MVCD is illustrated in Figure 1 below.



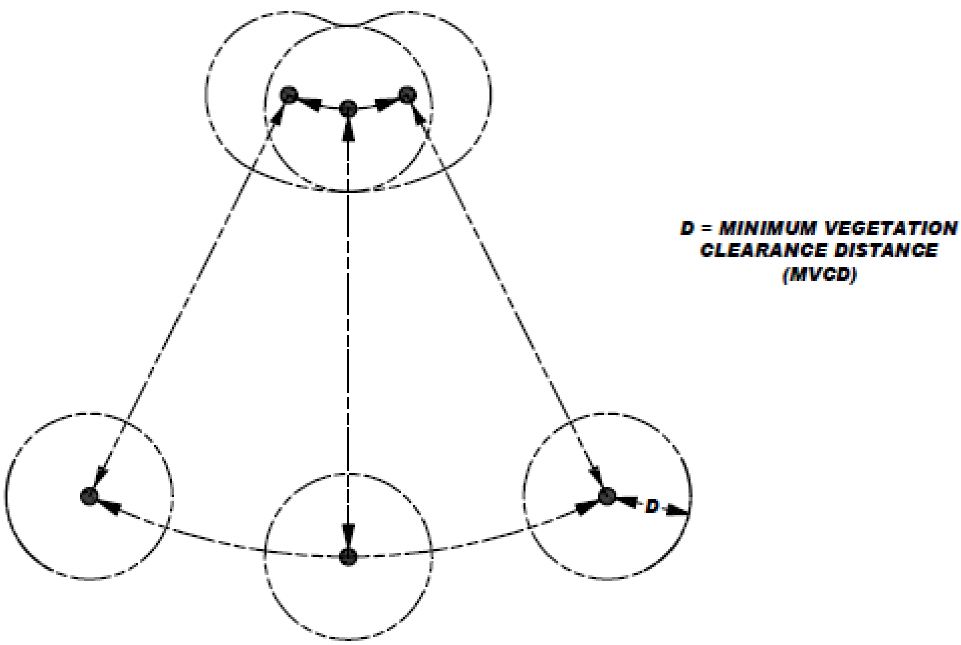


Figure 1

Cross-section view of a single conductor at a given point along the span showing six possible conductor positions due to movement resulting from thermal and mechanical loading.

Requirement R4:

R4 is a risk-based requirement. It focuses on preventative actions to be taken by the Transmission Owner for the mitigation of Fault risk when a vegetation threat is confirmed. R4 involves the notification of potentially threatening vegetation conditions, without any intentional delay, to the control center holding switching authority for that specific transmission line. Examples of acceptable unintentional delays may include communication system problems (for example, cellular service or two-way radio disabled), crews located in remote field locations with no communication access, delays due to severe weather, etc.

Confirmation is key that a~~By complying with encroachment-prevention Requirements R1 and R2, together with the competency-based Requirement R3 (for a documented transmission vegetation management program), the Transmission Owner will have a cohesive vegetation management program for managing vegetation in such a manner as to maintain separation between conductors and vegetation. Additionally, an effective imminent threat process and interim corrective action plan strategies should be executed to be successful in meeting these requirements. The Transmission Owner's maintenance approach should result in vegetation never approaching the distances listed in the MVCD Table. However, brief encroachments by falling vegetation are not considered to be a violation.~~

~~In addition, the Transmission Owner should maintain detailed records of the findings of its planned inspections. This documentation constitutes evidence that the Transmission Owner had no encroachments into the MVCD Table distances.~~

~~These requirements assume that transmission lines are operating within their Rating. If a line conductor is intentionally or inadvertently operated beyond its rating (potentially in violation of other standards), the occurrence of a clearance encroachment is not be a violation of this Standard. Conductor position, and the associated vegetation distance, that result from operation of a transmission line beyond its Rating (for example emergency actions taken by a TOP or RC to protect an Interconnection) is beyond the scope of this Standard.~~

~~**Requirement R3:**~~
~~An adequate transmission vegetation management program formally establishes the guidelines that are used by the Transmission Owner to plan and perform vegetation work that is necessary to prevent transmission outages and minimize risk to the Transmission System.~~

~~There may be many acceptable approaches to maintain clearances. However, the Transmission Owner should be able to state what its approach is and how it conducts work to maintain clearances. See Figure 1 for illustration of possible conductor locations.~~

~~**Requirement R4:**~~
~~The term "verified knowledge" implies reliable confirmation that an imminent~~ threat actually exists due to vegetation. This confirmation ~~Verification~~ could be in ~~that~~ the form of~~initial call-in came from~~ a qualified~~trained~~ employee who personally identifies~~able to identify~~ such a threat in the field. Confirmation ~~or it~~ could also be made~~verified~~ by sending out ~~such~~ a qualified~~trained~~ person to evaluate a situation reported by a landowner or an unqualified employee.~~confirm a call-in from a citizen.~~

Vegetation~~Two key elements of an acceptable imminent threat procedure are outlined below:~~
- ~~Specify the vegetation~~-related conditions that warrant a response ~~:~~

~~Examples of these vegetation-related conditions~~ include vegetation that is near or encroaching into the MVCD (a grow-in ~~growth~~ issue) or vegetation that could fall~~presents an imminent danger of falling~~ into the transmission conductor (a fall-in issue). A knowledgeable verification of the risk would include an assessment of the possible sag or movement of the conductor while operating between no-load conditions and its rating.~~)~~

- ~~Notify the appropriate operating authority:~~

The Transmission Owner has the responsibility to ensure the proper communication between field personnel and the control center~~operating authority~~ to allow the control center~~operating authority~~ to take the appropriate action until the vegetation threat is relieved.~~ ~~ Appropriate actions may include a temporary reduction in the line loading, ~~or~~ switching the line out of service, or positioning the system in recognition of the increasing risk of outage on that circuit. The notification of the threat should be communicated in terms of minutes or hours as opposed to a longer time frame for corrective action plans (see R5).~~.~~

> ~~The protocol for contacting the operating authority should be defined. Some Transmission Owners' processes may require a call directly to the operating authority, while other Transmission Owners may require a call to a supervisor or field forester who will in turn notify the proper operating authority.~~
>
> ~~The term "responsible control center" refers to personnel with direct responsibility for operating the transmission lines, such as the Transmission Owner's control center, an Independent System Operator, or other operating entity. In the case where the operating authority is not the Transmission Operator the communication between the Transmission Operator and the operating authority will occur by the normal policies that govern their relationship.~~

~~The imminent threat process should be implemented in terms of minutes or hours as opposed to a longer time frame for interim corrective action plans (see R5).~~

All potential grow-in~~serious growth~~ or fall-in vegetation-related conditions will ~~are~~ not necessarily cause a Fault at any moment.~~considered imminent threats under this Standard.~~ For example, some Transmission Owners may have a danger tree identification program that identifies trees for removal ~~trees~~ with the potential to fall near the line. These trees would~~are~~ not require notification to~~necessarily considered imminent threats under~~ the control center~~Standard~~ unless they pose an immediate fall-in threat.

Requirement R5:

R5 is a risk-based requirement. It focuses upon preventative actions to be taken by the Transmission Owner for the mitigation of Sustained Outage risk when temporarily constrained from performing vegetation maintenance.

~~There can be situations involving vegetation that are not considered vegetation-related imminent threats under this Standard. For example, a logging operation on or near the Active Transmission Line ROW can pose an immediate threat of a sustained outage and result in the initiation of an imminent threat process in the same manner as the presence of a nearby crane or the notification of a hot-spot on a conductor connector. Although the logging threat in this example tangentially involves vegetation, it is not considered a vegetation-related imminent threat under the Standard.~~

~~**Requirement R5:**~~

The intent of this requirement is to deal with situations that prevent the Transmission Owner from performing planned vegetation management work and, as a result, have the potential to put the transmission line at risk. Constraints to performing vegetation maintenance work as planned could result from legal injunctions filed by property owners, the discovery of easement stipulations which limit the Transmission Owner's rights, or other circumstances.

This requirement is not intended to address situations where the transmission line is not at potential~~immediate~~ risk and the work event can be rescheduled or re-planned using an alternate work methodology. For example, a land owner may prevent the planned use of chemicals on non-threatening, low growth vegetation but agree to the use of mechanical clearing. In this case the Transmission Owner is not under any immediate time constraint for achieving the management objective, can easily reschedule work using an alternate approach, and therefore does not need to take interim corrective action.

However, in situations where transmission line reliability is potentially at risk due to a constraint, the Transmission Owner is required to take ~~an interim~~ corrective action to mitigate the potential risk to the transmission line. A wide range of actions can be taken to address various situations. General considerations include:

- Identifying locations where the Transmission Owner is constrained from performing planned vegetation maintenance work which potentially leaves the transmission line at risk.
- Developing the specific action to ~~immediately~~ mitigate any potential risk associated with not performing the vegetation maintenance work as planned.
- Documenting and tracking the specific action taken for each location.

- In developing the specific action to mitigate the potential risk to the transmission line the Transmission Owner could consider location specific measures such as modifying the inspection and/or maintenance intervals. Where a legal constraint would not allow any vegetation work, the interim corrective action could include limiting the loading on the transmission line.
- The Transmission Owner should document and track the specific corrective action taken at each location. This location may be indicated as one span, one tree or a combination of spans on one property where the constraint is considered to be temporary.

Requirement R6:

R6 is a risk-based requirement. This requirement sets a minimum time period for completing ~~the~~ Vegetation Inspections that fits general industry practice. In addition, the fact that Vegetation Inspections can be performed in conjunction with general line inspections further facilitates a Transmission Owner's ability to meet this requirement. However, the Transmission Owner may determine that more~~. More~~ frequent inspections are~~may be~~ needed to maintain reliability levels, dependent~~depending~~ upon such factors as anticipated growth rates of the local vegetation, length of the growing season for the geographical area, limited Active Transmission ROW width, and rainfall amounts. Therefore it is expected that some transmission~~some~~ lines may be designated with a higher frequency of inspections.

The VSL for Requirement R6 has VSL categories ranked by the percentage of the required ROW inspections completed. To calculate the percentage of inspection completion, the Transmission Owner ~~lines~~ may choose units such as: line miles or kilometers, circuit miles or kilometers, pole line miles, ROW miles, etc.

For example, when~~If~~ a Transmission Owner operates 2,000 miles of 230 kV transmission lines this Transmission Owner will be responsible for inspecting all 2,000 miles of 230 kV transmission lines at least once ~~line~~ during the calendar year. If one of the included lines was 100 miles long, and if it was not inspected during the year, then the amount failed to inspect~~inspected~~ would be 100~~1900~~/2000 = 0.05~~95~~ or 5%.~~95%.~~ The "Low~~Lower~~ VSL" for R6 would apply in this example.

~~The standard allows Vegetation Inspections to be performed in conjunction with general line inspections as per the definition.~~

Requirement R7:

R7 is a risk-based requirement. The Transmission Owner is required to implement an annual work plan for vegetation management to accomplish the purpose of this standard. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made and documented provided they do not put the transmission system at risk. The annual work plan requirement is not intended to necessarily require a "span-by-span", or even a "line-by-line" detailed description of all work to be performed. It is only intended to require that the Transmission Owner provide evidence of annual planning and execution of a vegetation management maintenance approach which successfully prevents encroachment of vegetation into the MVCD.

The ability to modify the work plan allows ~~Documentation or other evidence of the work performed typically consists of signed-off work orders, signed contracts, printouts from work management systems, spreadsheets of planned versus completed work, timesheets, work inspection reports, or paid invoices. Other evidence may include photographs, work inspection reports and walk-through reports.~~

~~Documentation is required when the annual work plan is adjusted or not completely implemented as originally planned. The reasons for the deferrals or changes and the expected completion date of postponed work should be documented.~~

~~The flexibility to adjust the annual work plan must always ensure the reliability of the electric Transmission system. Flexibility is meant to address changing conditions of the vegetation on the Active Transmission Line ROW, emergencies, and other significant changing conditions.~~

~~This standard requires that the annual work plan be flexible to allow~~ the Transmission Owner to change priorities or treatment methodologies during the year as conditions or situations dictate. For example recent line inspections may identify unanticipated high priority work, weather conditions (drought) could make herbicide application ineffective during the plan year, or~~.~~ ~~Another situational variance could be~~ a major storm could require redirecting~~that redirects~~ local resources away from planned maintenance. This situation may also include complying with mutual assistance agreements by moving resources off the Transmission Owner's system to work on another system. Any~~Examples~~ of these examples could result in acceptable~~documented adjustments may include~~ deferrals or additions to the annual work plan. Modifications to the annual work plan must always ensure the reliability of the electric Transmission system.

In general, the
~~The work plan is not intended to be a "span-by-span" detailed description of all work to be performed. It is intended to require the Transmission Owner to annually plan and schedule vegetation work to prevent encroachment into the MVCD.~~

~~The Transmission Owner is required to implement the annual work plan for~~ vegetation management ~~to accomplish the purpose of this standard. This means that vegetation~~ maintenance approach should use~~ought to be performed to~~ the full extent of the Transmission Owner's easement, fee simple and other legal rights~~. It is intended to address the importance of maintaining all locations on the Active Transmission Line ROWs for reliability purposes in lieu of making special exceptions.~~

- ~~Property owners and other interested parties occasionally request special considerations to leave undesirable vegetation conditions. Such considerations must never be~~ allowed. ~~to impact reliability.~~
- ~~These undesirable vegetation conditions require more frequent work or inspections than other locations with similar vegetation threats and similar easement rights which are not subject to the special property owner requests.~~
- ~~The Transmission Owner's vegetation maintenance work necessary to implement the annual work plan is most effective when performed to the maximum extent allowed by any easement, fee simple and other legal rights.~~
- ~~The Transmission Owner should, therefore, endeavor to maintain its Active Transmission Line ROW to the full extent of its legal rights at all times and in all cases.~~

A comprehensive approach that exercises the full extent of legal rights on the active transmission line ROW is superior to incremental management in the long term because it reduces the overall potential for encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient. ~~at all locations on the Active Transmission Line ROW .~~

When developing the annual work plan the Transmission Owner should allow time for procedural requirements to obtain permits to work on federal, state, provincial, public, tribal lands. In some cases the lead time for obtaining permits may necessitate preparing work plans more than a year prior to work start dates. Transmission Owners may also need to consider those special landowner requirements as documented in easement instruments.

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. Therefore, deferrals or relevant changes to the annual plan shall be documented. Depending on the planning and documentation format used by the Transmission Owner, evidence of successful annual work plan execution could consist of signed-off work orders, signed contracts, printouts from work management systems, spreadsheets of planned

versus completed work, timesheets, work inspection reports, or paid invoices. Other evidence may include photographs, and walk-through reports.

~~The following conditions may result in adjustments to the annual work plan: abnormal weather such as drought, major storms, excessive rainfall, other environmental conditions such as infestation, disease, fire, etc. These conditions may be found as part of a special or scheduled Vegetation Inspection. Examples of annual work plan adjustments that are permitted may include revising the work plan priorities, rescheduling work to another time or selecting alternate vegetation control methods. Changes in land usage made by a property owner, such as timber clearing, may be another condition that warrants an adjustment.~~

346 - 500 kV	87.5 ft.
501 - 765 kV	100 ft.

Implementation Plan for FAC-003-2

Prerequisite Approvals
There are no other Reliability Standards or Standard Authorization Requests (SARs), in progress or approved, that must be implemented before this standard can be implemented.

FAC-003-2 – Vegetation Management

Revision to Sections of Approved Standards and Definitions
There are no proposed revisions to requirements in other already approved standards. There is a revised definition in the proposed standard. FAC-003-1 will be retired when FAC-003-2 becomes effective.

Compliance with Standard
The standard applies to Transmission Owners.

Effective Date
The effective date is the date entities are expected to meet the performance identified in this standard. The effective date allows entities time to make revisions to their existing transmission vegetation management programs to comply with the new requirements.

1. First calendar day of the first calendar quarter one year after applicable regulatory authority approval for all requirements
2. First calendar day of the first calendar quarter one year following Board of Trustees adoption unless governmental authority withholds approval
3. First calendar day of the first calendar quarter that is at least one year following Board of Trustees adoption

Exceptions:

A line operated below 200kV, designated by the Planning Coordinator as an element of an IROL or as a Major WECC transfer path, becomes subject to this standard 12 months after the date the Planning Coordinator or WECC initially designates the line as being subject to this standard.

An existing transmission line operated at 200kV or higher that is newly acquired by an asset owner and was not previously subject to this standard, becomes subject to this standard 12 months after the acquisition date of the line.

Unofficial Comment Form for 4th Draft of FAC-003-2 Transmission Vegetation Management —Project 2007-07 Vegetation Management

Please **DO NOT** use this form to submit comments. Please use the electronic form located at the site below to submit comments on the 4th Draft of FAC-003-2 Transmission Vegetation Management. Comments must be submitted by**, July 18, 2010**

http://www.nerc.com/filez/standards/Vegetation-Management_Project_2007-7.html

If you have questions please contact Harry Tom at Harry.Tom@nerc.net or by telephone at (860) 550-4157.

Background Information

The purpose of Project 2007-07 Vegetation Management is to:

- Assist in providing an adequate level of reliability for the North American electric Transmission System by verifying that the FAC-003-2 Transmission Vegetation Management standard is complete and that its requirements are set at an appropriate level to ensure reliability.
- Incorporate other general improvements described in the Standard Review Guidelines to bring FAC-003-2 Transmission Vegetation Management into conformance with the latest version of the Reliability Standards Development Procedure and the ERO Sanctions Guidelines.
- Consider comments received from ERO regulatory authorities and stakeholders on FAC-003-1 Transmission Vegetation Management as noted in the NERC Standards Issues Database.
- Satisfy the requirement for review of FAC-003-2 Transmission Vegetation Management within five-year review cycle.

In addition, on January 14, 2010, the NERC Standards Committee endorsed the use of Project 2007-07 Vegetation Management as the prototype for the proof-of-concept for using the results-based criteria for developing a reliability standard. The results-based initiative is intended to focus the collective effort of NERC and industry participants on improving the clarity and quality of NERC reliability standards by developing performance-based, risk-based and competency-based requirements that accomplish a reliability objective through a defense-in-depth strategy, while eliminating documentation-driven requirements that do not have an impact on bulk power system reliability.

The first draft of the revised standard was posted in a 'new' format from March 1-31, 2010 for an 'informal' comment period.

A summary of the SDT considerations for the responses to the March 1, 2010 submittal has been posted on the NERC website in lieu of a full Consideration of Comments Report.

Note-worthy modifications incorporated into this draft 4 of FAC-003-2 Transmission Vegetation Management include:

- Replaced the defined term "Active Transmission Line Right of Way" with footnote number 2 that provides a description of "active transmission line ROW" and added Table 3, "*Minimum Distance from the Centerline of the Circuit to the edge of the active transmission line ROW*" to support that description.

- Terminology changes in the "Force Majeure" statement related to the terms "reasonable" and "human activity"
- Terminology changes to Measures M1 and M2 related to observation in real time and the investigation of Faults.
- Changes to Requirement R3 to incorporate the various terms the industry uses for program documentation, and further changes to R3 that address the nature of the mutually dependent variables that can drive different approaches to vegetation maintenance.
- Clarifying verbiage in Requirement R4.
- Removal of the term "flexible" in R7
- Footnote changes for clarification to Table 2

The following questions will assist the SDT in finalizing the development of FAC-003-2 Transmission Vegetation Management. In addition, question #7, relative to Violation Severity Levels, has been included at the direction of the Standards Committee.

For questions where you agree with indicated statement, please state that you agree and if able, please provide supporting documentation. If you disagree with the statement, please explain why you disagree and provide a rationale to support your position. We would appreciate responses to as many of the following questions as possible.

1. The SDT replaced the defined term "Active Transmission Line Right of Way" with footnote number 2 that provides a description of "active transmission line ROW" and added Table 3, "*Minimum Distance from the Centerline of the Circuit to the edge of the active transmission line ROW*" to support that description. Do you agree? Please explain.

   ☐ Yes
   ☐ No
   Comments:

2. In response to comments received regarding the terms "reasonable" and "human errors/human activity", the SDT modified the Other Section and Background Section. Do you agree? Please explain.

   ☐ Yes
   ☐ No
   Comments:

3. In response to comments received regarding the language in M1 and M2, the SDT modified the first bulleted item and added a sentence to the end of the paragraph in M1 and M2. Do you agree? Please explain.

   ☐ Yes
   ☐ No
   Comments:

4. In response to comments received that requirement R3 is deficient in detail, the SDT modified the requirement. Do you agree? Please explain.

   ☐ Yes
   ☐ No

Comments:

5. In response to comments received that requirement R7 is unclear with respect to flexible work plans, the SDT modified the requirement. Do you agree? Please explain.

☐ Yes

☐ No

Comments:

6. In response to comments received that requirement R1/R2 may not adequately protect the transmission conductors under all conditions of sag and sway, the SDT drafted alternate language for the industry to provide feedback. The SDT did not opt to incorporate this language into "Draft 4" until further comment was solicited from industry. Which do you prefer? Please comment on your choice in the comment box below:

*"**Alternate R1/R2.** Each Transmission Owner shall manage the floor of its Active Transmission Line ROW in accordance to one of the following at all times:*

A) A fixed maximum vegetation height of 15 feet from the ground at the mid-half of the span and 20 feet in the outside quarters of the span, or,

B) A calculated maximum vegetation height that is the difference between the minimum conductor height at "max sag" minus MVCD minus cycle growth, or,

C) A calculated minimum vegetation to conductor clearance that is the sum of "max sag" in the span plus MVCD plus cycle growth, or,

D) A value determined by the Transmission Owner to provide a separation between the conductor and the vegetation that is comparable to options A, B, or C.

E) Any alternative approach that ensures no encroachment occurs within MVCD, considering the sag and sway of the conductor throughout its operating range under rated conditions.

F) A value to provide a separation between the conductor and the vegetation that is the sum of MVCD, and a value that considers the sag and sway of the conductor throughout its operating range under rated conditions plus 10 feet."

NOTE: The SDT suggests similar language as found in the posted draft for measures M1/M2 may be appropriate with this alternate R1/R2.

☐ Draft 4 version of R1/R2

☐ Alternate version of R1/R2

Comment:

7. The drafting team and NERC staff disagree on an appropriate set of VSLs for Requirements R1 and R2 and the Standards Committee has directed that both sets of VSLs be posted for stakeholder comments.

The drafting team has proposed the following VSLs for R1 and R2:

VSLs for R1 and R2 Proposed by the VM SDT				
R#	**Lower**	**Moderate**	**High**	**Severe**
R1 VM SDT	The Transmission Owner had an encroachment into the MVCD observed in real time, absent a Sustained Outage.	The Transmission Owner had an encroachment due to a fall-in from inside the active transmission line ROW that caused a vegetation-related Sustained Outage.	The Transmission Owner had an encroachment due to blowing together of applicable lines and vegetation located inside the active transmission line ROW that caused a vegetation-related Sustained Outage.	The Transmission Owner had an encroachment due to a grow-in that caused a vegetation-related Sustained Outage.
R2 VM SDT	The Transmission Owner had an encroachment into the MVCD observed in real time, absent a Sustained Outage.	The Transmission Owner had an encroachment due to a fall-in from inside the active transmission line ROW that caused a vegetation-related Sustained Outage.	The Transmission Owner had an encroachment due to blowing together of applicable lines and vegetation located inside the active transmission line ROW that caused a vegetation-related Sustained Outage.	The Transmission Owner had an encroachment due to a grow-in that caused a vegetation-related Sustained Outage.

VSLs for R1 and R2 Proposed by the VM SDT

The SDT assigned VSLs for R1 and R2 in accordance with its interpretation of the VSL Guidelines. To support that interpretation, the SDT cites page 3 of the VSL Guideline as justification. The VSL Guideline states that for – "Requirements with Parts that Contribute Unequally to the Requirement: If a requirement has several parts, and the parts contribute unequally to the reliability-related objective of the requirement, then noncompliance with each of the parts should be clearly associated with at least one of the VSLs."

The VSL Guidelines also goes on to say, "Requirements with Wide Range of Noncompliant Performance: If a requirement has a wide range of noncompliant performance that at least partially meets the intent of the requirement, then that requirement should have multiple VSLs. There are many different ways of developing VSLs to categorize different degrees of noncompliant performance. A set of VSLs developed should collectively address all of the elements in the requirement. Thus, if a requirement includes both specific actions and a timeframe for completion of those actions, then the VSLs should address noncompliance with both the completeness of the actions and the timeliness of those actions. Not all VSLs need to address both components of the requirement, but collectively the set of VSLs must address all aspects of the requirement." The SDT asserts that for Requirement R1 there is indeed a wide range of possible noncompliance for a failure to manage vegetation. Examples could include failure to manage vegetation along an entire line, failure to manage the floor of the right of way, failure to manage the edges of the right of way, or a failure to manage a single tree out of an otherwise-well-managed right of way.

The SDT points to the reliability objectives contained in requirements R1 and R2. The Transmission Owner is required to manage vegetation to prevent encroachments within the MVCD that could lead to Sustained Outages. These objectives address different degrees or types of vegetation encroachments and associated reliability results. For example, not all encroachments lead to Sustained Outages. Moreover, there is an operational differentiation between a fall-in, blow-together or grow-in event. A fall-in has never been known to cause a cascading outage. Therefore the team feels that a Lower VSL is appropriate. A blowing-together-caused fault is somewhat more egregious than a fall-in, as it has the potential for re-occurring and is therefore assigned a Higher VSL. A grow-in from vegetation on the active ROW that causes a sustained outage, on the other hand, has been the only known cause for the initiation of cascading outages to date in North America and this type of vegetation should be appropriately addressed by a Transmission Owner; thus the Severe VSL. For these reasons the SDT feels that the VSL assignments are appropriate.

VSLs for R1 and R2 Proposed by NERC Staff

The Standards Staff is concerned that the VSLs proposed by the VM SDT seem to be based on the likelihood that a violation of the requirement will result in a sustained outage – not in the degree to which the entity violated the requirement. As such, the VSLs developed by the VM SDT don't support NERC's VSL Guidelines. Both R1 and R2 require the responsible entity to ". . . manage vegetation to prevent encroachment that could result in a Sustained Outage . . ." Thus, any sustained outage associated with vegetation-related encroachment into the MVCD totally misses the intent of the requirement and meets the criteria for a Severe VSL. The drafting team's proposed VSL would assign some vegetation-related sustained outages of transmission lines as "moderate" or "high" VSLs.

NERC's VSL Criteria			
Lower	Moderate	High	Severe
Missing a minor element (or a small percentage) of the required performance The performance or product measured has significant value as it almost meets the full intent of the requirement.	Missing at least one significant element (or a moderate percentage) of the required performance. The performance or product measured still has significant value in meeting the intent of the requirement.	Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital component. The performance or product has limited value in meeting the intent of the requirement.	Missing most or all of the significant elements (or a significant percentage) of the required performance. The performance measured does not meet the intent of the requirement or the product delivered cannot be used in meeting the intent of the requirement.

The Standards Staff proposes the following VSLs:

VSLs for R1 and R2 Proposed by NERC Staff				
R#	Lower	Moderate	High	Severe
R1 NERC Staff	Not applicable.	Not applicable.	The Transmission Owner failed to manage vegetation to prevent encroachment into the MVCD of a line identified as an element of an IROL or Major WECC transfer path and encroachment into the MVCD as identified in FAC-003-Table 2 was observed in real time absent a Sustained Outage.	The Transmission Owner failed to manage vegetation to prevent encroachment into the MVCD of a line identified as an element of an IROL or Major WECC transfer path and a vegetation-related Sustained Outage was caused by one of the following: • A fall-in from inside the active transmission line ROW • Blowing together of applicable lines and vegetation located inside the active transmission line ROW • **A grow-in**

VSLs for R1 and R2 Proposed by NERC Staff				
R#	**Lower**	**Moderate**	**High**	**Severe**
R2 NERC Staff	Not applicable.	Not applicable.	The Transmission Owner failed to manage vegetation to prevent encroachment into the MVCD of a line not identified as an element of an IROL or Major WECC transfer path and encroachment into the MVCD as identified in FAC-003-Table 2 was observed in real time absent a Sustained Outage.	The Transmission Owner failed to manage vegetation to prevent encroachment into the MVCD of a line not identified as an element of an IROL or Major WECC transfer path and a vegetation-related Sustained Outage was caused by one of the following: • A fall-in from inside the active transmission line ROW • Blowing together of applicable lines and vegetation located inside the active transmission line ROW • **A grow-in**

Which set of proposed VSLs best supports NERC's VSL Criteria?

☐ VSLs proposed by the VM SDT

☐ VSLs proposed by NERC staff

Comments:

8. Is there anything that you have not addressed above regarding the draft FAC-003-2 Transmission Vegetation Management standard or the Technical Reference Document? If yes, please provide what you believe should be changed, added or deleted and the rationale for your proposal.

☐ Yes

☐ No

FAC-003-1 Mapping to Proposed NERC Reliability Standard FAC-003-2 RBS Draft 4

Standard FAC-003-1	Comment	Proposed Standard FAC-003-2 RBS Draft 4
Standard Development Roadmap	Modified per proposed SCPSC format for RBS	**Standard Development Timeline**
Definitions of Terms Used in Standard	During the first comment period, the SDT received several comments noting that many utilities typically combine the vegetation inspection with other maintenance inspections. Due to the comments, the SDT proposed a modified Vegetation Inspection definition to document the acceptability of this industry practice. As noted in the "Guidelines and Technical Basis" section, this broader definition facilitates a Transmission Owner's ability to meet the requirement and the added clarification aides compliance understanding to meet Requirement 6.	**Definitions of Terms Used in Standard** **Vegetation Inspection** The systematic examination of vegetation conditions on a maintained transmission line Right-of-Way which may be combined with a general line inspection. The current glossary definition of this NERC term is modified to allow both maintenance inspections and vegetation inspections to be performed concurrently. Current definition of Vegetation Inspection: The systematic examination of a transmission corridor to document vegetation conditions.
Effective Dates **5. Effective Dates:** **5.1.** One calendar year from the date of adoption by the NERC Board of Trustees for Requirements 1 and 2. **5.2.** Sixty calendar days from the date of adoption by the NERC Board of Trustees for Requirements 3 and 4.	In order to fully implement any new standard or requirement it is necessary to factor in a reasonable transitional period. As with the current version of FAC-003, the proposed version allows a reasonable time period before the standard is fully applicable. In addition to standardizing the implementation date to coincide with the beginning of a calendar month, the new version improves upon the current standard by recognizing that new lines may be added by the Planning Coordinator at any given time in the future. These new lines will necessarily require an extended effective date before the standard is applicable.	**Effective Dates** 1. First calendar day of the first calendar quarter one year after applicable regulatory authority approval for all requirements 2. First calendar day of the first calendar quarter one year following Board of Trustees adoption unless governmental authority withholds approval 3. First calendar day of the first calendar quarter that is at least one year following Board of Trustees adoption Exceptions: A line operated below 200kV, designated by the Planning Coordinator as an element of an IROL or as a Major WECC transfer path, becomes subject to this standard 12 months after the date the Planning Coordinator or WECC initially designates the lines as being subject to this standard. An existing transmission line operated at 200kV or higher that is newly acquired by an asset owner and was not previously subject to this standard, becomes subject to this standard 12

Standard FAC-003-1	Comment	Proposed Standard FAC-003-2 RBS Draft 4
		months after the acquisition date of the line.
1. Title: Transmission Vegetation Management Program		**1. Title:** Transmission Vegetation Management
2. Number: FAC-003-1		**2. Number:** FAC-003-2
3. Purpose: To improve the reliability of the electric transmission systems by preventing outages from vegetation located on transmission rights-of-way (ROW) and minimizing outages from vegetation located adjacent to ROW, maintaining clearances between transmission lines and vegetation on and along transmission ROW, and reporting vegetation related outages of the transmission systems to the respective Regional Reliability Organizations (RRO) and the North American Electric Reliability Council (NERC).	The SDT tightened up the Purpose statement to remove unnecessary wording and to remove redundant verbiage also contained in the Applicability section. The SDT also removed from the Purpose any mention of the reporting of vegetation-caused outages, in part because the Standard no longer requires reporting of outages due to vegetation falling from outside the right of way. The new, shorter Purpose statement is more goal-oriented as a Purpose statement should be, instead of containing rambling verbiage that re-states tasks and activities covered elsewhere in the Applicability or Requirements. The new Purpose statement is better because it provides clarity to industry stakeholders that only a narrow class of vegetation issues lead to large-scale blackouts. For instance, no cascading-style outage – anytime or anywhere – has ever been caused by a tree falling into a transmission line. This Purpose statement appropriately focuses the Standard's requirements on the areas of vegetation management that pose significant risk of cascading blackouts.	**3. Objective:** To improve the reliability of the electric Transmission system by preventing those vegetation related outages that could lead to Cascading.
4. Applicability: **4.1.** Transmission Owner **4.2.** Regional Reliability Organization **4.3.** This Standard shall apply to all transmission lines operated at 200 kV and above and to any lower voltage lines designated by the RRO as critical to the reliability of the electric system in the region.	The Drafting team divided the Applicability section into two parts (entity and facility) in order to provide structural clarity. This improvement in readability makes this structure better than that existing in Version 1. In the Functional Entity section, the team removed the RRO as directed by FERC since the RRO(s) have no Requirement compliance responsibilities. Additionally, the data reporting which was why the RRO had been included in this section, is no longer a Requirement.	**4. Applicability:** **4.1.** Functional Entities: **4.1.1** Transmission Owners **4.2.** Facilities: Defined below, including but not limited to those that cross lands owned by federal[1], state, provincial, public, private, or tribal entities: **4.2.1.** Transmission lines operated at 200kV

[1] EPAct 2005 section 1211c: *"Access approvals by Federal agencies"*

Standard FAC-003-1	Comment	Proposed Standard FAC-003-2 RBS Draft 4
	In the Facility section, the team added specific references to specific land types on which Transmission rights-of-way may exist. This change was made to make it clear where the Standard applies in response to industry comments indicating confusion with the existing Standard which did not specifically address the issue. This addition is an improvement from Version 1 since the issue will now be clearly addressed. Additionally, the team modified the entity to identify sub-200 kV lines which are covered by this standard. In keeping with the removal of the RRO from the Standards, the team received valuable input from industry and FERC staff. It became clear that for the time horizon needed for the activities associated with vegetation management, the Planning Coordinator had the appropriate wide-area view and time horizon. FERC staff expressed a strong preference for NERC standards to be consistent in the determination of sub-200 kV lines that are sufficiently important to be covered by this standard and others that have the 200 kV bright lines. Thus the team chose to use an existing identification process (found in Standard FAC-014). These changes make this version much better than Version 1 because a responsible entity has been identified and an already FERC-approved NERC Standard process replaces an undefined process in Version 1. The FERC Order also outlined that NERC should determine if the identification “net” caught all the sub-200 kV lines of importance. The Drafting team identified that WECC has developed a classification of lines that have importance to the Western Interconnection. Therefore, the Drafting team added those lines. This addition makes this version better than Version 1 by including important lines that might otherwise be potentially omitted. Finally, the Drafting team added the exclusions in 4.2.4 in response to significant industry comments for clarity in interpretation and implementation of the standard. The ambiguity of the existing Standard has led to confusion in industry and in compliance. This addition makes this version better than Version 1 because it clearly describes which facilities are applicable which will eliminate the confusion.	or higher. **4.2.2.** Overhead transmission lines operated below 200kV having been identified as included in the definition of an Interconnection Reliability Operating Limit (IROL) under NERC Standard FAC 014 by the Planning Coordinator. **4.2.3.** Overhead transmission lines operated below 200 kV having been identified as included in the definition of one of the *Major WECC Transfer Paths in the Bulk Electric System*. **4.2.4.** This Standard does not apply to Facilities identified above (4.2.1 through 4.2.3) located in the fenced area of a switchyard, station or substation.

Standard FAC-003-1	Comment	Proposed Standard FAC-003-2 RBS Draft 4
		4.3. Enforcement: *The reliability obligations of the applicable entities and facilities are contained within the technical requirements of this standard. [Straw proposal]*
	Vegetation-related Sustained Outages that occur due to natural disasters are beyond the control of the Transmission Owner. These events are not classified as vegetation-related Sustained Outages and are therefore exempt from the Standard. Transmission lines are not designed to withstand the impacts of natural disasters such as flood, drought, earthquake, major storms, fire, hurricane, tornado, landslides, ice storms, etc. In the aftermath of catastrophic system damage from natural disasters the Transmission Owner's focus is on electric system restoration for public safety and critical support infrastructure. Sustained Outages due to human or animal activity are beyond the control of the Transmission Owner. These outages are not classified as vegetation-related Sustained Outages and are therefore exempt from the Standard. Examples of these events may include new plantings by outside parties of tall vegetation under the transmission line planted since the last Vegetation Inspection, tree contacts with line initiated by vehicles, logging activities, etc. This clarification of which outages are not applicable is an improvement to the language in requirement R3.2 in Version 1 and maintains the same level of reliability. The term "active transmission line ROW" as defined in footnote 2 is included to differentiate between Sustained Outages caused by vegetation growing either within or outside the ROW. This is in contrast to the version I definition of a simple ROW. This change is important because all Sustained Outages from vegetation growing on the ROW are violations of the Standard while all "off-ROW" Sustained Outages are not. The inclusion of the active transmission line ROW definition aids in compliance reporting and monitoring and helps Transmission Owner's implement their ROW management programs. This clarification places a	**4.4. Other:** This Standard does not apply to any occurrence, non-occurrence, or other set of circumstances that are beyond the control of a Transmission Owner subject to this reliability standard, including acts of God, flood, drought, earthquake, major storms, fire, hurricane, tornado, landslides, ice storms, vehicle contact with tree, human activity involving: removal of, installation of, or digging around vegetation, animals severing trees, lightning, epidemic, strike, war, riot, civil disturbance, sabotage, vandalism, terrorism, wind shear, or fresh gale (or higher wind speed) that restricts or prevents performance to comply with this reliability standard's requirements. Nothing in this section should be construed to limit the Transmission Owner's right to exercise its full legal rights on the active transmission line ROW[2] [2] A strip or corridor of land that is occupied by active transmission facilities. This corridor does not include the parts of the Right-of-Way that are unused or intended for other facilities. However, it is not to be less than the width of the easement itself unless the easement exceeds distances as shown in Table 3 for various voltage classes.

Standard FAC-003-1	Comment	Proposed Standard FAC-003-2 RBS Draft 4
	minimum limit on the distance between the circuit and the ROW edge for use on ROW's where a transmission Owner has excessive ROW width that is far wider then is typically managed for that voltage class.	
	Added new section titled, "Background" per SCPSC format.	**5. Background** This NERC Vegetation Management Standard ("Standard") uses a defense-in-depth approach to improve the reliability of the electric Transmission system by preventing those vegetation related outages that could lead to Cascading. This Standard is…
R1. The Transmission Owner shall prepare, and keep current, a formal transmission vegetation management program (TVMP). The TVMP shall include the Transmission Owner's objectives, practices, approved procedures, and work specifications**1**. **R1.1.** The TVMP shall define a schedule for and the type (aerial, ground) of ROW vegetation inspections. This schedule should be flexible enough to adjust for changing conditions. The inspection schedule shall be based on the anticipated growth of vegetation and any other environmental or operational factors that could impact the relationship of vegetation to the Transmission Owner's transmission lines. **R1.2.** The Transmission Owner, in the TVMP, shall identify and document clearances between vegetation and any overhead, ungrounded supply conductors, taking into consideration transmission line voltage, the effects of ambient temperature on conductor sag under maximum design loading, and the effects of wind velocities on conductor sway. Specifically, the Transmission Owner shall establish clearances to be achieved at the time of vegetation management work identified herein as Clearance 1, and shall also establish and	R1 and its five subparts outlining the TVMP have been replaced by R1, R2, R3, R4, R5 and R6. R1 in Version 1 is a documentation requirement defining what should be in a TVMP. The requirements in Version 2 were crafted to be "results based" that define the desired end result and not necessarily the route to get to the end result. The TVMP document in version 1 is replaced by the competency requirement R3 in version 2. The TO must demonstrate that it understands the complex relationship of conductor movement under thermal load and wind and a vegetation growing and moving in proximity to the line. In version 1 the TO can simply state that it mows or trims and what its Clearance 1 and 2 is. In version 2, the TO must define the concepts used by an inspector or a tree crew in making decisions about which tree needs maintenance and how much should be removed. The improvement is that the TO's documentation can be evaluated to specific construction and maintenance standards. R1.1 has been moved to R6. It requires that each line be inspected annually and clarifies, through the definition of a Vegetation Inspection, that these inspection may be part of a broader line inspection. This improvement takes out the ambiguity of the frequency of inspections. R1.2 in version 1 requires that the TO document Clearances 1 and 2. The results based requirements in R1 and R2 in version 2 require that the TO achieve conductor to vegetation separation by preventing encroachments into MVCD, a clearance defining "spark-	**R1.** Each Transmission Owner shall manage vegetation to prevent encroachment that could result in a Sustained Outage of any line identified as an element of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions). Types of encroachment include: 1. An encroachment into the Minimum Vegetation Clearance Distance (MVCD) as shown in Table 2, observed in real time, absent a Sustained Outage, 2. An encroachment due to a fall-in from inside the active transmission line ROW that caused a vegetation-related Sustained Outage, 3. An encroachment due to blowing together of applicable lines and vegetation located inside the active transmission line ROW that caused a vegetation-related Sustained Outage, 4. An encroachment due to a grow-in that caused a vegetation-related Sustained Outage. **R2**. Each Transmission Owner shall manage vegetation to prevent encroachment that could result in a Sustained Outage of applicable lines that are not elements of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions). Types of encroachment include:

Standard FAC-003-1	Comment	Proposed Standard FAC-003-2 RBS Draft 4
maintain a set of clearances identified herein as Clearance 2 to prevent flashover between vegetation and overhead ungrounded supply conductors. **R1.2.1.** Clearance 1 — The Transmission Owner shall determine and document appropriate clearance distances to be achieved at the time of transmission vegetation management work based upon local conditions and the expected time frame in which the Transmission Owner plans to return for future vegetation management work. Local conditions may include, but are not limited to: operating voltage, appropriate vegetation management techniques, fire risk, reasonably anticipated tree and conductor movement, species types and growth rates, species failure characteristics, local climate and rainfall patterns, line terrain and elevation, location of the vegetation within the span, and worker approach distance requirements. Clearance 1 distances shall be greater than those defined by Clearance 2 below. **R1.2.2.** Clearance 2 — The Transmission Owner shall determine and document specific radial clearances to be maintained between vegetation and conductors under all rated electrical operating conditions. These minimum clearance distances are necessary to prevent flashover between vegetation and conductors and will vary due to such factors as altitude and operating voltage. These Transmission Owner-specific minimum clearance distances shall be no less than those set forth in the Institute of Electrical and Electronics Engineers (IEEE) Standard 516-	over" distances derived scientifically from the Gallet equations. FERC, in order 693, along with several commenters questioned the use of the MAID tables in Version 1. Version 2 offers appropriate clearances that are based in science. In addition, there are separate requirements for lines that could be part of an IROL/WECC transfer path event and those that are not. This allows for different Violation Risk Factors. R1.3 of Version1 required that personnel in the TVMP be qualified. The requirement did not clearly specify what the qualification would be and left it up to the TO. This is considered a 'fill in the blank' requirement and was eliminated. R1.4 in version 1 required the TO to have a mitigation plan where clearances could not be attained. This is replaced in Version 2 by R5. The new wording resolves the confusion in using the term mitigation plan (an enforcement mitigation plan vs. a vegetation mitigation plan). It also allows for different VRF and VSL from the other components of version 1 R1. R1.5 the imminent threat process in version 1 is replaced by R4 in version 2. It is an improvement over version 1 in that reporting is directed to the switching authority which has direct ability to take action.	1. An encroachment into the Minimum Vegetation Clearance Distance (MVCD) as shown in Table 2, observed in real time, absent a Sustained Outage, 2. An encroachment due to a fall-in from inside the active transmission line ROW that caused a vegetation-related Sustained Outage, 3. An encroachment due to blowing together of applicable lines and vegetation located inside the active transmission line ROW that caused a vegetation-related Sustained Outage, 4. An encroachment due to a grow-in that caused a vegetation-related Sustained Outage. **Rationale (R1 and R2)** The MVCD is a calculated minimum distance stated in feet (meters) to prevent spark-over between conductors and vegetation, for various altitudes and operating voltages. The distances in Table 2 were derived using a proven transmission design method. **R3.** Each Transmission Owner shall document the procedures, processes, or specifications it uses to prevent the encroachment of vegetation into the MVCD. Such documentation will incorporate the dynamics of a transmission line conductor's movement throughout its Rating and Rated Electrical Operating Conditions and the inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency, for the Transmission Owner's applicable lines. **Rationale (R3)** Provide a basis for evaluation on the intent and competency of the Transmission Owner in maintaining vegetation. There may be many acceptable approaches to maintain clearances. However, the Transmission Owner should be able to state what its approach is and how it conducts work to maintain clearances. See Figure 1 for an illustration of possible conductor locations.

Standard FAC-003-1	Comment	Proposed Standard FAC-003-2 RBS Draft 4
2003 (*Guide for Maintenance Methods on Energized Power Lines*) and as specified in its Section 4.2.2.3, Minimum Air Insulation Distances without Tools in the Air Gap. **R1.2.2.1** Where transmission system transient overvoltage factors are not known, clearances shall be derived from Table 5, IEEE 516-2003, phase-to-ground distances, with appropriate altitude correction factors applied. **R1.2.2.2** Where transmission system transient overvoltage factors are known, clearances shall be derived from Table 7, IEEE 516-2003, phase-to-phase voltages, with appropriate altitude correction factors applied. **R1.3.** All personnel directly involved in the design and implementation of the TVMP shall hold appropriate qualifications and training, as defined by the Transmission Owner, to perform their duties. **R1.4.** Each Transmission Owner shall develop mitigation measures to achieve sufficient clearances for the protection of the transmission facilities when it identifies locations on the ROW where the Transmission Owner is restricted from attaining the clearances specified in Requirement 1.2.1. **R1.5.** Each Transmission Owner shall establish and document a process for the immediate communication of vegetation conditions that present an imminent threat of a transmission line outage. This is so that action (temporary reduction in line rating, switching line out of service, etc.) may be taken until the threat is relieved.		**R4.** Each Transmission Owner, without any intentional time delay, shall notify the control center holding switching authority for the associated transmission line when qualified personnel confirm the existence of a vegetation condition that is likely to cause a Fault at any moment. **Rationale (R4)** To ensure expeditious communication between qualified field personnel and proper operating personnel when a critical situation is confirmed. Qualified field personnel may include lineworkers and utility arborists. **R5.** Each Transmission Owner shall take corrective action when it is constrained from performing planned vegetation work, where a transmission line is put at potential risk due to the constraint. **Rationale (R5)** Legal actions and other events may occur which result in constraints that prevent the Transmission Owner from performing planned vegetation maintenance work. In cases where the transmission line is put at potential risk due to constraints, the intent is for the Transmission Owner to put interim measures in place, rather than do nothing. For example, in the 2003 NE blackout a Transmission Owner was prevented by a court order from performing planned work. However, when the court order expired, the TO failed to take action to maintain the vegetation resulting in a sustained outage that contributed to the cascade. The corrective action process is not intended to address situations where a planned work methodology cannot be performed but an alternate work methodology can be used.
R2. The Transmission Owner shall create and implement an annual plan for vegetation management work to ensure	The Standard Drafting Team revised the language in the existing standard which reads in part, "The Transmission Owner shall create and implement an annual plan..." to	**R7.** Each Transmission Owner shall complete the work in an annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD. Modifications to

Standard FAC-003-1	Comment	Proposed Standard FAC-003-2 RBS Draft 4
the reliability of the system. The plan shall describe the methods used, such as manual clearing, mechanical clearing, herbicide treatment, or other actions. The plan should be flexible enough to adjust to changing conditions, taking into consideration anticipated growth of vegetation and all other environmental factors that may have an impact on the reliability of the transmission systems. Adjustments to the plan shall be documented as they occur. The plan should take into consideration the time required to obtain permissions or permits from landowners or regulatory authorities. Each Transmission Owner shall have systems and procedures for documenting and tracking the planned vegetation management work and ensuring that the vegetation management work was completed according to work specifications.	"Each Transmission Owner shall complete the work in an annual vegetation work plan…" setting an expectation that the work identified will be completed, as noted in the Rationale. In addition, the Team eliminated prescriptive language in R2 of the existing standard. The revised requirement is an improvement upon the current standard in that it clearly establishes the true intent of this requirement, completing the work in the plan and ensuring no vegetation encroaches into the MVCD.	the work plan in response to changing conditions or to findings from vegetation inspections may be made and documented provided they do not put the transmission system at risk of a vegetation encroachment. Examples of reasons for modification to annual plan may include: • Change in expected growth rate/ environmental factors • Major storms • Rescheduling work between growing seasons • Crew or contractor availability/ Mutual assistance agreements • Identified unanticipated high priority work • Weather conditions/Accessibility • Permitting delays • Land ownership changes/Change in land use by the landowner • Funding adjustments (increase or decrease) • Emerging technologies **Rationale (R7)** This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. An annual vegetation work plan allows for work to be modified for changing conditions, taking into consideration anticipated growth of vegetation and all other environmental factors, provided that the changes do not violate the encroachment within the MVCD.
R3. The Transmission Owner shall report quarterly to its RRO, or the RRO's designee, sustained transmission line outages determined by the Transmission Owner to have been caused by vegetation. **R3.1.** Multiple sustained outages on an individual line, if caused by the same vegetation, shall be reported as one outage regardless of the actual number of outages within a 24-	R3 Moved: In general, reporting requirement elements are moved to the Additional Compliance Information section of the standard. Reporting elements are, in themselves, documentation rudiments and do not add or subtract from electric system reliability. Format changes R3.1 Moved: Explanatory text moved to M1 and M2 Informational in nature. Format change. R3.2 Moved: The exclusions for reporting an outage were	**Additional Compliance Information** ***Periodic Data Submittal:*** The Transmission Owner will submit a quarterly report to its Regional Entity, or the Regional Entity's designee, identifying all Sustained Outages of transmission lines determined by the Transmission Owner to have been caused by vegetation that includes, as a minimum, the following: o The name of the circuit(s), the date, time and duration of the outage; the voltage of the circuit; a

Standard FAC-003-1	Comment	Proposed Standard FAC-003-2 RBS Draft 4
hour period. **R3.2.** The Transmission Owner is not required to report to the RRO, or the RRO's designee, certain sustained transmission line outages caused by vegetation: (1) Vegetation related outages that result from vegetation falling into lines from outside the ROW that result from natural disasters shall not be considered reportable (examples of disasters that could create non-reportable outages include, but are not limited to, earthquakes, fires, tornados, hurricanes, landslides, wind shear, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods), and (2) Vegetation-related outages due to human or animal activity shall not be considered reportable (examples of human or animal activity that could cause a non-reportable outage include, but are not limited to, logging, animal severing tree, vehicle contact with tree, arboricultural activities or horticultural or agricultural activities, or removal or digging of vegetation). **R3.3.** The outage information provided by the Transmission Owner to the RRO, or the RRO's designee, shall include at a minimum: the name of the circuit(s) outaged, the date, time and duration of the outage; a description of the cause of the outage; other pertinent comments; and any countermeasures taken by the Transmission Owner. **R3.4.** An outage shall be categorized as one of the following: **R3.4.1.** Category 1 — Grow-ins: Outages caused by vegetation growing into lines from vegetation inside and/or outside of the ROW; **R3.4.2.** Category 2 — Fall-ins: Outages	placed in the Applicability Section – Other. The placement at the beginning of the Standard call attention to the overall impact to all requirements in the Standard R3.3 Moved: Outage information moved to Additional Compliance Information section. Informational in nature R3.4 Moved: Outage categories moved to Additional Compliance Information section. Informational in nature R3.4.1 Moved: Category 1 moved and expanded to differentiate between vegetation related sustained outages outside and within the ROW on IROL or Major WECC transfer path and non IROL lines or Major WECC transfer paths Category 1 outages were separated into 1A and 1B. R3.4.2 Moved: Category 2 reporting moved to Additional Compliance Information section. R3.4.3 Eliminated: Category 3 reporting for fall-in outside the right of way was eliminated. Vegetation fall-in's from outside the transmission right of way are not a standard violation and thus not a requirement. The reporting requirement is currently for informational purposes only. Added Category 4: Sustained outages from vegetation and conductors blowing together created a new Category 4 classification. Information located within the Additional Compliance Information section. No change in reliability.	description of the cause of the outage; the category associated with the Sustained Outage; other pertinent comments; and any countermeasures taken by the Transmission Owner. A Sustained Outage is to be categorized as one of the following: o Category 1A — Grow-ins: Sustained Outages caused by vegetation growing into applicable transmission lines, that are identified as an element of an IROL or Major WECC Transfer Path, by vegetation inside and/or outside of the active transmission line ROW; o Category 1B — Grow-ins: Sustained Outages caused by vegetation growing into applicable transmission lines, but are not identified as an element of an IROL or Major WECC Transfer Path, by vegetation inside and/or outside of the active transmission line ROW; o Category 2 — Fall-ins: Sustained Outages caused by vegetation falling into applicable transmission lines from within the active transmission line ROW; o Category[3]4 — Blowing together: Sustained Outages caused by vegetation and applicable transmission lines blowing together from within the active transmission line ROW. The Regional Entity will report the outage information provided by Transmission Owners, as per the above, quarterly to NERC, as well as any actions taken by the Regional Entity as a result of any of the reported Sustained Outages. 3 Category 3 reporting is eliminated.

Standard FAC-003-1	Comment	Proposed Standard FAC-003-2 RBS Draft 4
caused by vegetation falling into lines from inside the ROW; **R3.4.3.** Category 3 — Fall-ins: Outages caused by vegetation falling into lines from outside the ROW.		
R4. The RRO shall report the outage information provided to it by Transmission Owner's, as required by Requirement 3, quarterly to NERC, as well as any actions taken by the RRO as a result of any of the reported outages.	R4. Eliminated: RRO is now the Regional Entity. The Regional Entity is instructed per the periodic data submittal within the Additional Compliance Information section to report the outage information provided by Transmission Owners, as per the above, quarterly to NERC, as well as any actions taken by the Regional Entity as a result of any of the reported Sustained Outages. No change in reliability.

North American Electric Reliability Corporation

Vegetation Management Standard Drafting Team

June 28, 2010

Table of Contents

Introduction

This document is intended to provide supplemental information and guidance for complying with the requirements of Reliability Standard FAC-003-2.

The purpose of the Standard is to improve the reliability of the electric transmission system by preventing those vegetation related outages that could lead to Cascading.

Compliance with the Standard is mandatory and enforceable.

Special Note: The Application of Results-Based Approach to FAC-003-2

In its three-year assessment as the ERO, NERC acknowledged stakeholder comments and committed to:

i) addressing quality issues to ensure each reliability standard has a clear statement of purpose, and has outcome-focused requirements that are clear and measurable; and
ii) eliminating requirements that do not have an impact on bulk power system reliability.

In 2010, the Standards Committee approved a recommendation to use Project 2007-07 Vegetation Management as a first proof of concept for developing results-based standards.

The Standard Drafting Team (SDT) employed a defense-in-depth[1] strategy for FAC-003-2, where each requirement has a role in preventing those vegetation related outages that could lead to Cascading. This portfolio of requirements was designed to achieve an overall defense-in-depth strategy and to comply with the quality objectives identified in the *Acceptance Criteria of a Reliability Standard* document.

The SDT developed a portfolio of performance, risk, and competency-based mandatory reliability requirements to support an effective defense-in-depth strategy. Each Requirement was developed using one of the following requirement types:

a) Performance-based - defines a particular reliability objective or outcome to be achieved. In its simplest form, a results-based requirement has four components: who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome?
b) Risk-based - preventive requirements to reduce the risks of failure to acceptable tolerance levels. A risk-based reliability requirement should be framed as: who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome that reduces a stated risk to the reliability of the bulk power system?
c) Competency-based - defines a minimum set of capabilities an entity needs to have to demonstrate it is able to perform its designated reliability functions. A competency-based reliability requirement should be framed as: who, under what conditions (if any), shall have what capability, to achieve what particular result or outcome to perform an action to achieve a result or outcome or to reduce a risk to the reliability of the bulk power system?

The drafting team reviewed and edited version 1 of FAC-003-1 to remove prescriptive and administrative language in order to distill the technical requirements down to their

[1] A defense-in-depth strategy for reliability standards recognizes that each requirement in the NERC standards has a role in preventing system failures, and that these roles are complementary and reinforcing. These prevention measures should be arranged in a series of defensive layers or walls. No single defensive layer provides complete protection from failure by itself. But taken together, with well-designed layers including performance, risk, and competency-based requirements, a defense-in-depth approach can be very effective in preventing future large scale power system failures.

essential reliability content. Text that is explanatory in nature is placed in a special section of the standard entitled Guideline and Technical Basis to aid in the understanding of the requirements. Furthermore, Rationale text boxes are inserted alongside each requirement to communicate the foundation for the requirement.

Disclaimer

This supporting document is supplemental to the reliability standard FAC-003-2 — Transmission Vegetation Management and does not contain mandatory requirements subject to compliance review.

Preface

The NERC Vegetation Management Standard Drafting Team (VM SDT) acknowledges those across the industry who contributed to the development of this Standard and companion Technical Reference document. The Technical Reference document is intended to provide supplemental explanatory background and guidance related to requirements contained in the Standard but does not in itself contain requirements subject to compliance review.

The VM SDT believes that a well designed and executed Transmission Vegetation Management Program (TVMP) will have few problems meeting the requirements of this Standard. While the Standard requires a TVMP to contain certain elements, it allows the Transmission Owner flexibility in designing a TVMP to meet local needs provided it also meets the purpose of the Standard.

While there are many approaches to vegetation management, the VMSDT supports industry best practices contained in ANSI A300 (Part 7) – Integrated Vegetation Management (IVM) practices on Utility Rights-of-way, as well as the companion publication Best Management Practices – Integrated Vegetation Management, as an effective strategy to maintain compliance with this Standard. ANSI A300 (Part 7), approved by industry consensus in 2006, contains many elements needed for an effective TVMP as required by this Standard. One key element is the “wire zone – border zone” concept. Supported by over 50 years of continuous research, wire zone – border zone is a proven method to manage vegetation on transmission rights-of-ways and is an industry accepted best practice to help ensure electric system reliability.

The VM SDT believes that Transmission Owners who adopt and effectively implement IVM principles, particularly the “wire zone – border zone” concept, are far less likely to experience a vegetation caused outage than those who do not.

Definition of Terms

Vegetation Inspection** — The systematic examination of vegetation conditions on an Active Transmission Line Right-of-Way which may be combined with a general line inspection.

The inspection includes the identification of any vegetation that may pose a threat to reliability prior to the next planned inspection or maintenance work, considering the current location of the conductor and other possible locations of the conductor due to sag and sway for rated conditions.

This definition allows both maintenance inspections and vegetation inspections to be performed concurrently.

*To be added to the NERC glossary of terms with final approval of this standard revision
** This is a modification to a defined term in the NERC glossary.

Applicability of the Standard

4. Applicability

4.1. Functional Entities:
Transmission Owners

4.2. Facilities: *Defined below, including but not limited to those that cross lands owned by federal[1], state, provincial, public, private, or tribal entities:*

- ***4.2.1*** *Overhead transmission lines operated at 200kV or higher.*
- ***4.2.2*** *Overhead transmission lines operated below 200kV having been identified as included in the definition of an Interconnection Reliability Operating Limit (IROL) under NERC Standard FAC 014 by the Planning Coordinator.*
- ***4.2.3*** *Overhead transmission lines operated below 200 kV having been identified as included in the definition of one of the Major WECC Transfer Paths in the Bulk Electric System.*
- ***4.2.4*** *This Standard does not apply to Facilities identified above (4.2.1 through 4.2.3) located in the fenced area of a switchyard, station or substation.*

4.3. Enforcement: *The reliability obligations of the applicable entities and facilities are contained within the technical requirements of this standard.*

4.4. Other:
This Standard does not apply to any occurrence, non-occurrence, or other set of circumstances that are beyond the control of a Transmission Owner subject to this reliability standard, including acts of God, flood, drought, earthquake, major storms, fire, hurricane, tornado, landslides, ice storms, vehicle contact with tree, human activity involving: removal of, installation of, or digging around vegetation, animals severing trees, lightning, epidemic, strike, war, riot, civil disturbance, sabotage, vandalism, terrorism, wind shear, or fresh gale (or higher wind speed) that restricts or prevents performance to comply with this reliability standard's requirements. Nothing in this section should be construed to limit the Transmission Owner's right to exercise its full legal rights on the Active Transmission Line ROW.

In Order 693, FERC discussed the 200 kV bright-line test of applicability. While FERC did not change the 200 kV bright-line, the Commission remained concerned that there may be some transmission lines operating at lesser voltages that could have significant impact on the Bulk Electric System that should therefore be subject to this standard.

NERC Standard FAC-014 has the stated purpose, "*To ensure that System Operating Limits (SOLs) used in the reliable planning and operation of the Bulk Electric System (BES) are determined based on an established methodology or methodologies.*" FAC-014 requires Reliability Coordinators, Planning Coordinators, and Transmission Planners to have a methodology to identify all lines that might comprise an IROL. Thus, these entities would identify sub-200 kV lines that qualify as part of an IROL and should be subject to FAC-003-2.

[1] EPAct 2005 section 1211c: "*Access approvals by Federal agencies*".

Although all three entities may prepare the list of elements, FAC-003-2 presently does not specify that it is the list from the Planning Coordinator that should be used by Transmission Owners for FAC-003. However, the Time Horizon needed to plan vegetation management work does not lend itself to the operating horizon of a Reliability Coordinator. Additionally, the Planning Coordinator has a wider-area view than the Transmission Planner and could thus identify any elements of importance to a sub-set of its area that might be missed by a Transmission Planner.

Transmission Owners, who do not already get the list of circuits included in the definition of an IROL, can get them from the Planning Coordinator. Specifically R5 of FAC-014 specifies that "*The Reliability Coordinator, Planning Authority (Coordinator) and Transmission Planner shall each provide its SOLs and IROLs to those entities that have a reliability-related need for those limits and provide a written request that includes a schedule for delivery of those limits*"

Vegetation-related Sustained Outages that occur due to natural disasters are beyond the control of the Transmission Owner. These events are not classified as vegetation-related Sustained Outages and are therefore exempt from the Standard. Transmission lines are not designed to withstand the impacts of natural disasters such as flood, drought, earthquake, major storms, fire, hurricane, tornado, landslides, ice storms, etc. In the aftermath of catastrophic system damage from natural disasters the Transmission Owner's focus is on electric system restoration for public safety and critical support infrastructure.

Sustained Outages due to human or animal activity are beyond the control of the Transmission Owner. These outages are not classified as vegetation-related Sustained Outages and are therefore exempt from the Standard. Examples of these events may include new plantings by outside parties of tall vegetation under the transmission line planted since the last Vegetation Inspection, tree contacts with line initiated by vehicles, logging activities, etc.

The foregoing exemptions are addressed in a new subsection, 4.4 Other, of the Applicability section. Referred to collectively as force majeure events and activities, this section applies to all requirements in FAC-003-2.

The reliability objective of this NERC Vegetation Management Standard ("Standard") is to prevent vegetation-related outages which could lead to Cascading by effective vegetation maintenance while recognizing that certain outages such as those due to vandalism, human errors and acts of nature are not preventable. Operating experience clearly indicates that trees that have grown out of specification could contribute to a cascading grid failure, especially under heavy electrical loading conditions.

Serious outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations. To properly reduce and manage this risk, it is necessary to apply the Standard to applicable lines on any kind of land or easement, whether they are Federal Lands, state or provincial lands, public or private lands, franchises, easements or lands owned in fee. For the purposes of the Standard and this Technical Reference document, the term "public lands" includes municipal lands, village lands, city lands, and land owned by a host of other governmental entities.

The Standard addresses vegetation management along applicable overhead lines that serve to connect one electric station to another. However, it is not intended to be applied to lines sections inside the electric station fence or other boundary of an electric station, submarine or underground lines.

The Standard is intended to reduce the risk of Cascading involving vegetation. It is not intended to prevent customer outages from occurring due to tree contact with all transmission lines and voltages. For example, localized customer service might be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. However, this Standard is not written to address such isolated situations which have little impact on the overall Bulk Electric System.

Vegetation growth is constant and always present. Unmanaged vegetation poses an increased outage risk when numerous transmission lines are operating at or near their Rating. This poses a significant risk of multiple line failures and Cascading. On the other hand, most other outage causes (such as trees falling into lines, lightning, animals, motor vehicles, etc.) are statistically intermittent. The probability of occurrence of these events is not dependent on heavy loads. There is no cause-effect relationship which creates the probability of simultaneous occurrence of other such events. Therefore these types of events are highly unlikely to cause large-scale grid failures.

In preparing the original vegetation management standard in 2005, industry stakeholders set the threshold for applicability of the standard at 200kV. This was because an unexpected loss of lines operating at above 200kV has a higher probability of initiating a widespread blackout or cascading outages compared with lines operating at less than 200kV.

The original NERC Standard FAC-003-1 also allowed for application of the standard to “critical” circuits (critical from the perspective of initiating widespread blackouts or cascading outages) operating below 200kV. While the percentage of these circuits is relatively low, it remains a fact that there are sub-200kV circuits whose loss could contribute to a widespread outage. Given the very limited exposure and unlikelihood of a major event related to these lower-voltage lines, it would be an imprudent use of resources to apply the Standard to all sub-200kV lines. The drafting team, after evaluating several alternatives, selected the IROL and WECC Major Transfer Path criteria to determine applicable lines below 200 kV that are subject to this standard.

Active Transmission Line ROW

The term “Active Transmission Line Right of Way” is defined in the Standard in a footnote repeated for convenience below:

> *A strip or corridor of land that is occupied by active transmission facilities. This corridor does not include the parts of the Right-of-Way that are unused or intended for other facilities. However, it is not to be less than the width of the easement itself unless the easement exceeds distances as shown in Table 3 for various voltage classes.*

The term Right of Way (ROW) can be used in reference to many situations. This is partially because some lines are built on the land that is owned fee simple by the transmission owner, other lines are built across federal or provincial lands with only limited rights under a permit or agreement, and many other lines cross lands with only limited easement rights to construct, operate and maintain the line. Transmission line configurations on ROWs are present in many combinations of multiple circuits on various tower types. The number of circuits and configurations change along the length of the ROW due to circuits departing to other locations or terminating at nearby substations. Figures 1, 2 and 3 on the following pages depict several typical transmission line configurations on typical rights of way.

A Transmission Owner may plan for a nominal width along the entire length of a line during planning using its design specifications for a particular circuit configuration and voltage. The actual acquired ROW width at the time a circuit is constructed is however impacted in many cases, by other considerations. Those considerations include other future circuits that may be built adjacent to the subject line, or property parcels with unusual ‘extra” widths due to special property owner demands during initial acquisition, or other existing lines adjacent to the subject line (which may be retired or abandoned at a future date). Refer to Figures 1 and 3 for common examples of such situations.

This Standard requires the Transmission Owner to prevent sustained outages due to vegetation “growing into” or “blowing-together” with line conductors if that vegetation is under the line or growing beside the line (provided the Transmission Owner has the legal right to remove or trim the vegetation growing beside the line). Transmission Owners are also required to prevent sustained outages due to fall-ins from trees that, before falling, were standing inside the limits established in footnote 2 and associated “Table 3” (see below).

However it is recognized that any requirement in this standard to impose violations for sustained outages due to “fall-ins” must consider the impact of forcing the clearing of ROWs to the legal edge or to widths wider than they are typically managed. Therefore the standard drafting team inserted the subject footnote “active transmission line ROW” to provide a distance for a Transmission Owner to use if they do not already have a codified ROW width for a particular circuit or voltage”. This approach of defining “active” and “inactive” right of way is intended to clarify the confusion created by the current standard which simply states that a fall-in from within the ROW is a violation. This provides the Transmission Owner with a means to define a right of way width that is applicable to fall-ins, provided it is not less than those limits in “Table 3”.

69 - 138 kV	37.5 ft.
139 - 230 kV	50 ft.
231 - 345 kV	75 ft.
346 - 500 kV	87.5 ft.
501 - 765 kV	100 ft.

Requirements R1 and R2

> **Rationale**
> The MVCD is a calculated minimum distance stated in feet (meters) to prevent spark-over between conductors and vegetation, for various altitudes and operating voltages. The distances in Table 2 were derived using a proven transmission design method.

R1. *Each Transmission Owner shall manage vegetation to prevent encroachment that could result in a Sustained Outage of any line identified as an element of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions). Types of encroachment include:*

1. *An encroachment into the Minimum Vegetation Clearance Distance (MVCD) as shown in Table 2, observed in real time, absent a Sustained Outage,*
2. *An encroachment due to a fall-in from inside the Active Transmission Line ROW that caused a vegetation-related Sustained Outage,*
3. *An encroachment due to blowing together of applicable lines and vegetation located inside the Active Transmission Line ROW that caused a vegetation-related Sustained Outage,*
4. *An encroachment due to a grow-in that caused a vegetation-related Sustained Outage.*

R2. *Each Transmission Owner shall manage vegetation to prevent encroachment that could result in a Sustained Outage of applicable lines that are <u>not</u> elements of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions). Types of encroachment include:*

1. *An encroachment into the Minimum Vegetation Clearance Distance (MVCD) as shown in Table 2, observed in real time, absent a Sustained Outage,*
2. *An encroachment due to a fall-in from inside the Active Transmission Line ROW that caused a vegetation-related Sustained Outage,*
3. *An encroachment due to blowing together of applicable lines and vegetation located inside the Active Transmission Line ROW that caused a vegetation-related Sustained Outage,*
4. *An encroachment due to a grow-in that caused a vegetation-related Sustained Outage.*

M1. *Each Transmission Owner has evidence that it managed vegetation as described in R1. Examples of acceptable forms of evidence may include attestations, reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-Time observations of any MVCD encroachments.*

Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period. If an investigation of a Fault by a qualified person confirms that a vegetation encroachment within the MVCD occurred, then it shall be considered a Real-time observation.

M2. *Each Transmission Owner has evidence that it managed vegetation as described in R2. Examples of acceptable forms of evidence may include attestations, reports containing no*

Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-Time observations of any MVCD encroachments.

Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period. If an investigation of a Fault by a qualified person confirms that a vegetation encroachment within the MVCD occurred, then it shall be considered a Real-time observation.

R1 and R2 are performance-based requirements. The reliability objective or outcome to be achieved is the prevention of vegetation encroachments within a minimum distance of transmission lines. Content-wise, R1 and R2 are the same requirements; however, they apply to different Facilities. Both R1 and R2 require each Transmission Owner to prevent vegetation from encroaching within the Minimum Vegetation Clearance Distance of transmission lines. R1 is applicable to lines “identified as an element of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions) to avoid a Sustained Outage”. R2 applies to all other applicable lines that are not an element of an IROL or Major WECC Transfer Path.

The separation of applicability (between R1 and R2) recognizes that an encroachment into the MVCD of an IROL or Major WECC Transfer Path transmission line is a greater risk to the electric transmission system. Applicable lines that are not an element of an IROL or Major WECC Transfer Path are required to be clear of vegetation but these lines are comparatively less operationally significant. As a reflection of this difference in risk impact, the Violation Risk Factors (VRFs) are assigned as High for R1 and Medium for R2.

These requirements (R1 and R2) state that if vegetation encroaches within the distances in Table 1 in Appendix 1 of this supplemental Transmission Vegetation Management Standard FAC-003-2 Technical Reference document, it is in violation of the standard. Table 1 tabulates the distances necessary to prevent spark-over based on the Gallet equations as described more fully in Appendix 1 below.

These requirements assume that transmission lines and their conductors are operating within their Rating. If a line conductor is intentionally or inadvertently operated beyond its Rating (potentially in violation of other standards), the occurrence of a clearance encroachment may occur. For example, emergency actions taken by a Transmission Operator or Reliability Coordinator to protect an Interconnection may cause the transmission line to sag more and come closer to vegetation, potentially causing an outage. Such vegetation-related outages are not a violation of these requirements.

Evidence of violation of Requirement R1 and R2 include real-time observation of a vegetation encroachment into the MVCD (absent a Sustained Outage), or a vegetation-related encroachment resulting in a Sustained Outage due to a fall-in from inside the Active Transmission Line ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to blowing together of applicable lines and vegetation located inside the Active Transmission Line ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to a grow-in. If an investigation of a Fault by a qualified person confirms that a vegetation encroachment within the MVCD occurred, then it shall be considered a Real-time observation.

With this approach, the VSLs were defined such that they directly correlate to the severity of a failure to keep vegetation away from conductors and to the corresponding performance level of the Transmission Owner’s vegetation program’s ability to meet the goal of “preventing a Sustained Outage that could lead to Cascading.” Thus violation severity increases with a Transmission Owner’s inability to meet this goal and its potential of leading to a Cascading event. The additional benefits of such a combination are that it simplifies the standard and clearly defines performance for compliance. A performance-based requirement of this nature will promote high quality, cost effective vegetation management programs that will deliver the overall end result of improved reliability to the system.

Multiple Sustained Outages on an individual line can be caused by the same vegetation, for example a limb that only partially breaks and intermittently contacts a conductor. Such events are considered to be a single vegetation-related Sustained Outage under the Standard where the Sustained Outages occur within a 24 hour period.

The MVCD is a calculated minimum distance stated in feet (or meters) to prevent spark-over, for various altitudes and operating voltages that is used in the design of Transmission Facilities. Keeping vegetation from entering this space will help prevent transmission outages.

Requirement R3

Rationale
Provide a basis for evaluation on the intent and competency of the Transmission Owner in maintaining vegetation. There may be many acceptable approaches to maintain clearances. However, the Transmission Owner should be able to state what its approach is and how it conducts work to maintain clearances. See Figure 1 *[in Standard FAC-003-2]* for an illustration of possible conductor locations.

R3. *Each Transmission Owner shall document the procedures, processes, or specifications it uses to prevent the encroachment of vegetation into the MVCD. Such documentation will incorporate the dynamics of a transmission line conductor's movement throughout its Rating and Rated Electrical Operating Conditions and the inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency, for the Transmission Owner's applicable lines.*

M3. *The procedures, processes, or specifications provided demonstrate that the Transmission Owner can prevent encroachment into the MVCD considering the factors identified in the requirement.*

Requirement R3 is a competency based requirement concerned with the procedures, processes, or specifications, a Transmission Owner uses for vegetation management.

An adequate transmission vegetation management program formally establishes the approach the Transmission Owner uses to plan and perform vegetation work to prevent transmission Sustained Outages and minimize risk to the Transmission System. The approach provides the basis for evaluating the intent, allocation of appropriate resources and the competency of the Transmission Owner in managing vegetation. There are many acceptable approaches to manage vegetation and avoid Sustained Outages. However, the Transmission Owner must be able to state what its approach is and how it conducts work to maintain clearances.

An example of one approach commonly used by industry is ANSI Standard A300, part 7. However, regardless of the approach a utility uses to manage vegetation, any approach a Transmission Owner chooses to use will generally contain the following elements:

1. *the maintenance strategy used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that MVCD clearances are never violated.*
2. *the work methods that the Transmission Owner uses to control vegetation*
3. *a stated Vegetation Inspection frequency*
4. *an annual work plan*

The conductor's position in space at any point in time is continuously changing as a reaction to a number of different loading variables. Changes in vertical and horizontal conductor positioning are the result of thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation. Physical loading applied to the conductor affects sag and sway by combining physical factors such as ice and wind loading. The movement of the transmission line conductor and the MVCD is illustrated in Figure 5 below.

Conductor Dynamics

In order for a Transmission Owner to develop a specific maintenance approach, it is important to understand the dynamics of a line conductor's movement. This paper will first address the complexities inherent in observing and predicting conductor movement, particularly for field personnel. It will then present some examples of maintenance approaches which Transmission Owners may consider that take into account these complexities, while resulting in practical approaches for field personnel.

Additionally, it is important the Transmission Owner consider all conductor locations, the MVCD, and vegetation growth between maintenance activities when developing a maintenance approach.

Understanding Conductor Position and Movement

The conductor's position in space at any point in time is continuously changing as a reaction to a number of different loading variables. Changes in vertical and horizontal conductor positioning are the result of thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation. Physical loading applied to the conductor affects sag and sway by combining physical factors such as ice and wind loading.

As a consequence of these loading variables, the conductor's position in space is dynamic and moving. When calculating the range of conductor positions, the Transmission Owner should use the same design criteria and assumptions that the Transmission Owner uses when establishing Ratings and SOL, as described in other standards. Typically, the greatest conductor movement would be at mid-span. As the conductor moves through various positions, a spark-over zone surrounding the conductor moves with it. The radius of the spark-over zone may be found by referring to Table 1 ("Minimum Vegetation Clearance Distances") in the standard. For illustrations of this zone and conductor movements, Figures 4 through 6 below demonstrate these concepts. At the time of making a field observation, however, it is very difficult to precisely know where the conductor is in relation to its wide range of all possible positions. Therefore, Transmission Owners must adopt maintenance approaches that account for this dynamic situation.

For Consideration in Developing a Maintenance Approach

Figure 6

Selecting a Maintenance Approach

In order to maintain adequate separation between vegetation and transmission line conductors, the Transmission Owner must craft a maintenance strategy that keeps vegetation well away from the spark-over zone mentioned above. In fact, it is generally necessary to incorporate a variety of maintenance strategies. For example, one Transmission Owner may utilize a combination of routine cycles, traditional IVM techniques and long-term planning. Another Transmission Owner may place a higher reliance on frequent inspections and quick remediation as opposed to a cyclical approach. This variation of approaches is further warranted when factors, such as terrain, legal and other constraints, vegetation types, and climates, are considered in developing a Transmission Owner's specific approach to satisfying this requirement.

The following is a sample description of one combination of strategies which may be utilized by a Transmission Owner.
A Transmission Owner's basic maintenance approach could be to remove all incompatible vegetation from the right of way if it has the right to do so and has no constraints. In mountainous terrain, however, this strategy could change to one where the Transmission Owner manages vegetation based on vegetation-to-conductor clearances, since it might not be necessary to remove vegetation in a valley that is far below.

If faced with constraints and assuming a line design with sufficient ground clearance, the Transmission Owner 's approach could then be to allow vegetation such as fruit trees, but perhaps only up to a given height at maturity (perhaps 10 feet from the ground). If constraints cannot be overcome and if design clearances are sufficient, an exception to the Transmission Owner's 10-foot guideline might be made. Finally, if the Transmission Owner has chosen to utilize vegetation-to-conductor clearance distance methods, the Transmission Owner could have an inspection regimen in place to regularly ensure that any impending clearance problems are identified early for rectification.

ANSI A300 – Best Management Practices for Tree Care Operations

A description of ANSI A-300, part 7, is offered below to illustrate another maintenance approach that could be used in developing a comprehensive transmission vegetation management program.

Introduction

Integrated Vegetation Management (IVM) is a best management practice conveyed in the American National Standard for Tree Care Operations, Part 7 (ANSI 2006) and the International Society of Arboriculture *Best Management Practices: Integrated Vegetation Management* (Miller 2007). IVM is consistent with the requirements in FAC-003-02, and it provides practitioners with what industry experts consider to be appropriate techniques to apply to electric right-of-way projects in order to meet or exceed the Standard.

IVM is a system of managing plant communities whereby managers set objectives; identify compatible and incompatible vegetation; consider action thresholds; and evaluate, select and implement the most appropriate control method or methods to achieve set objectives. The choice of control method or methods should be based on the environmental impact and anticipated effectiveness; along with site characteristics, security, economics, current land use and other factors.

Planning and Implementation

Best management practices provide a systematic way of planning and implementing a vegetation management program. While designed primarily with transmission systems in mind, it is also applicable to distribution projects. As presented in ANSI A300 part 7 and the ISA best management practices, IVM consists of 6 elements:

1) Set Objectives
2) Evaluate the Site
3) Define Action Thresholds
4) Evaluate and Select Control Methods
5) Implement IVM
6) Monitor Treatment and Quality Assurance

The setting of objectives, defining action thresholds, and evaluating and selecting control methods all require decisions. The planning and implementation process is cyclical and continuous, because vegetation is dynamic and managers must have the flexibility to adjust their plans. Adjustments may be made at each stage as new information becomes available and circumstances evolve.

Set Objectives

Objectives should be clearly defined and documented. Examples of objectives can include promoting safety, preventing sustained outages caused by vegetation growing into electric facilities, maintaining regulatory compliance, protecting structures and security, restoring electric service during emergencies, maintaining access and clear lines of sight, protecting the environment, and facilitating cost effectiveness.

Objectives should be based on site factors, such as workload and vegetation type, in addition to human, equipment and financial resources. They will vary from utility to utility and project to project, depending on line voltage and criticality, as well as topographical, environmental, fiscal and political considerations. However, where it is appropriate, the overriding focus should be on environmentally-sound, cost effective control of species that potentially conflict with the electric facility, while promoting compatible, early successional, sustainable plant communities.

Work Load Evaluations

Work-load evaluations are inventories of vegetation that could have a bearing on management objectives. Work load assessments can capture a variety of vegetation characteristics, such as location, height, species, size and condition, hazard status, density and clearance from conductors. Assessments should be conducted considering voltage, conductor sag from ambient temperatures and loading, and the potential influence of wind on line sway.

Evaluate and Select Control Methods

Control methods are the process through which managers achieve objectives. The most suitable control method best achieves management objectives at a particular site. Many cases call for a combination of methods. Managers have a variety of controls from which to choose, including manual, mechanical, herbicide and tree growth regulators, biological, and cultural options.

Manual Control Methods

Manual methods employ workers with hand-carried tools, including chainsaws, handsaws, pruning shears and other devices to control incompatible vegetation. The advantage of manual techniques is that they are selective and can be used where others may not be. On the other hand, manual techniques can be inefficient and expensive compared to other methods.

Mechanical Control Methods
Mechanical controls are done with machines. They are efficient and cost effective, particularly for clearing dense vegetation during initial establishment, or reclaiming neglected or overgrown right of way. On the other hand, mechanical control methods can be non-selective and disturb sensitive sites.

Tree Growth Regulator and Herbicide Control Methods
Tree growth regulators and herbicides can be effective for vegetation management. Tree growth regulators (TGRs) are designed to reduce growth rates by interfering with natural plant processes. TGRs can be helpful where removals are prohibited or impractical by reducing the growth rates of some fast-growing species.

Herbicides control plants by interfering with specific botanical biochemical pathways. Herbicide use can control individual plants that are prone to re-sprout or sucker after removal. When trees that re-sprout or sucker are removed without herbicide treatment, dense thickets develop, impeding access, swelling workloads, increasing costs, blocking lines-of-site, and deteriorating wildlife habitat. Treating suckering plants allows early successional, compatible species to dominate the right-of-way and out-compete incompatible species, ultimately reducing work.

Cultural Control Methods
Cultural methods modify habitat to discourage incompatible vegetation and establish and manage desirable, early successional plant communities. Cultural methods take advantage of seed banks of native, compatible species lying dormant on site. In the long run, cultural control is the most desirable method where it is applicable.

A cultural control known as cover-type conversion provides a competitive advantage to short-growing, early successional plants, allowing them to thrive and eventually out-compete unwanted tree species for sunlight, essential elements and water. The early successional plant community is relatively stable, tree-resistant and reduces the amount of work, including herbicide application, with each successive treatment.

Wire-Border Zone
The wire-border zone technique is a management philosophy that can be applied through cultural control. W.C. Bramble and W.R. Byrnes developed it in the mid-1980s out of research begun in 1952 on a transmission right-of-way in the Pennsylvania State Game Lands 33 Research and Demonstration project (Yahner and Hutnik (2004).

The wire zone is the section of a utility transmission right-of-way directly under the wires and extending outward about 10 feet on each side. The wire zone is managed to promote a low-growing plant community dominated by grasses, herbs and small shrubs (under 3 feet in height at maturity). The border zone is the remainder of the right-of-way. It is managed to establish small trees and tall shrubs (under 25 feet in height at maturity). When properly managed, diverse, tree-resistant plant communities develop in wire and border zones. The communities not only protect the electric facility and reduce long-term maintenance, but also enhance wildlife habitat, forest ecology and aesthetic values.

Although the wire-border zone is a best practice in many instances, it is not necessarily universally suitable. For example, standard wire-border zone prescriptions may be unnecessary where lines are high off the ground, such as across low valleys or canyons, so the technique can be modified without sacrificing reliability.

One way to accommodate variances in topography is to establish different regions based on wire height. For example, over canyon bottoms or other areas where conductors are 100 feet or more above the ground, only a few trees are likely to be tall enough to conflict with the lines. In those cases, trees that potentially interfere with the transmission lines can be removed selectively on a case-by-case basis.

In areas where the wire is lower, perhaps between 50-100 feet from the ground, a border zone community can be developed throughout the right-of-way. Note that in many cases, conductor attachment points are more than 50 feet off the ground, so a border zone community can be cultivated near structures. Where the line is less than 50 feet off the ground, managers could apply a full wire-border zone prescription.

An environmental advantage of this type of modification is stream protection. Streams often course through the valleys and canyons where lines are likely to be elevated. Leaving timber or border zone communities in canyon bottoms helps shelter this valuable habitat, enabling managers to achieve environmentally sensitive objectives.

Implement IVM

All laws and regulations governing IVM practices and specifications written by qualified vegetation managers must be followed. Integrated vegetation management control methods should be implemented on regular work schedules, which are based on established objectives and completed assessments. Work should progress systematically, using control measures determined to be best for varying conditions at specific locations along a right-of-way. Some considerations used in developing schedules include the importance and type of line, vegetation clearances, work loads, growth rate of predominant vegetation, geography, accessibility, and in some cases, time lapsed since the last scheduled work.

Clearances Following Work

Clearances following work should be sufficient to meet management objectives, including preventing trees from entering the Minimum Vegetation Clearance Distance, electric safety risks, service-reliability threats and cost.

Monitor Treatment and Quality Assurance

An effective program includes documented processes to evaluate results. Evaluations can involve quality assurance while work is underway and after it is completed. Monitoring for quality assurance should begin early to correct any possible miscommunication or misunderstanding on the part of crewmembers. Early and consistent observation and evaluation also provides an opportunity to modify the plan, if need be, in time for a successful outcome.

Utility vegetation management programs should have systems and procedures in place for documenting and verifying that vegetation management work was completed to specifications. Post-control reviews can be comprehensive or based on a statistically representative sample. This final review points back to the first step and the planning process begins again.

Summary of A-300 example

Integrated Vegetation Management offers among others, a systematic way of planning and implementing a vegetation management program as presented in ANSI A300 Part 7. This methodology enables a program to comply with the NERC *Transmission Vegetation Management Program* standard (FAC-003-2). Managers should select control options to best promote management objectives.

Vegetation Inspections

As with the ANSI A-300 example, The Transmission Owner's transmission vegetation management program (TVMP) establishes the frequency of vegetation inspections based upon many factors. Such local and environmental factors may include anticipated growth rates of the local vegetation, length of the growing season for the geographical area, limited Active Transmission Rights of Way width, rainfall amounts, etc.

Annual Work Plan

Requirement R7 of the Standard addresses the execution of the annual work plan. A comprehensive approach that exercises the full extent of legal rights is superior to incremental management in the long term because it reduces overall encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient at all locations on the Active Transmission Line Right of Way. Removal is superior to pruning. Removal minimizes the possibility of conflicts between energized conductors and vegetation. Since this is not always possible, the Transmission Owner's approach should be to use its prescribed vegetation maintenance methods to work towards or achieve the maximum use of the Active Transmission Line Right of Way.

Requirement R4

R4. *Each Transmission Owner, without any intentional time delay, shall notify the control center holding switching authority for the associated transmission line when qualified personnel confirm the existence of a vegetation condition that is likely to cause a Fault at any moment.*

> **Rationale**
> To ensure expeditious communication between qualified field personnel and proper operating personnel when a critical situation is confirmed. Qualified field personnel may include lineworkers and utility arborists.

M4. *Each Transmission Owner that has a vegetation condition likely to cause a Fault at any moment, as confirmed by qualified personnel, will have evidence that it notified the control center holding switching authority for the associated transmission line without any intentional time delay. Examples of evidence may include control center logs, voice recordings, switching orders, clearance orders and subsequent work orders.*

R4 is a risk-based requirement. It focuses on preventative actions to be taken by the Transmission Owner for the mitigation of Fault risk when a vegetation threat is confirmed. R4 involves the notification of potentially threatening vegetation conditions, without any intentional delay, to the control center holding switching authority for that specific transmission line. Examples of acceptable unintentional delays may include communication system problems (for example, cellular service or two-way radio disabled), crews located in remote field locations with no communication access, delays due to severe weather, etc.

Confirmation is key that a threat actually exists due to vegetation. This confirmation could be in the form of a qualified employee who personally identifies such a threat in the field. Confirmation could also be made by sending out a qualified person to evaluate a situation reported by a landowner or an unqualified employee.

Vegetation-related conditions that warrant a response include vegetation that is near or encroaching into the MVCD (a grow-in issue) or vegetation that could fall into the transmission conductor (a fall-in issue). A knowledgeable verification of the risk would include an assessment of the possible sag or movement of the conductor while operating between no-load conditions and its rating.

The Transmission Owner has the responsibility to ensure the proper communication between field personnel and the control center to allow the control center to take the appropriate action until the vegetation threat is relieved. Appropriate actions may include a temporary reduction in the line loading, switching the line out of service, or positioning the system in recognition of the increasing risk of outage on that circuit. The notification of the threat should be communicated in terms of minutes or hours as opposed to a longer time frame for corrective action plans (see R5).

All potential grow-in or fall-in vegetation-related conditions will not necessarily cause a Fault at any moment. For example, some Transmission Owners may have a danger tree identification program that identifies trees for removal with the potential to fall near the line. These trees would not require notification to the control center unless they pose an immediate fall-in threat.

Requirement R5

R5. *Each Transmission Owner shall take corrective action when it is constrained from performing planned vegetation work, where a transmission line is put at potential risk due to the constraint.*

M5. *Each Transmission Owner has evidence of the corrective action taken for each constraint where a transmission line was put at potential risk. Examples of acceptable forms of evidence may include initially-planned work orders, documentation of constraints from landowners, court orders, inspection records of increased monitoring, documentation of the de-rating of lines, revised work orders, invoices, and evidence that a line was de-energized.*

Rationale

Legal actions and other events may occur which result in constraints that prevent the Transmission Owner from performing planned vegetation maintenance work.

In cases where the transmission line is put at potential risk due to constraints, the intent is for the Transmission Owner to put interim measures in place, rather than do nothing.

For example, in the 2003 NE blackout a Transmission Owner was prevented by a court order from performing planned work. However, when the court order expired, the TO failed to take action to maintain the vegetation resulting in a sustained outage that contributed to the cascade.

The corrective action process is not intended to address situations where a planned work methodology cannot be performed but an alternate work methodology can be used.

R5 is a risk-based requirement. It focuses upon preventative actions to be taken by the Transmission Owner for the mitigation of Sustained Outage risk when temporarily constrained from performing vegetation maintenance. The intent of this requirement is to deal with situations that prevent the Transmission Owner from performing planned vegetation management work and, as a result, have the potential to put the transmission line at risk. Constraints to performing vegetation maintenance work as planned could result from legal injunctions filed by property owners, the discovery of easement stipulations which limit the Transmission Owner’s rights, or other circumstances.

This requirement is not intended to address situations where the transmission line is not at potential risk and the work event can be rescheduled or re-planned using an alternate work methodology. For example, a land owner may prevent the planned use of chemicals on non-threatening, low growth vegetation but agree to the use of mechanical clearing. In this case the Transmission Owner is not under any immediate time constraint for achieving the management objective, can easily reschedule work using an alternate approach, and therefore does not need to take interim corrective action.

However, in situations where transmission line reliability is potentially at risk due to a constraint, the Transmission Owner is required to take an interim corrective action to mitigate the potential risk to the transmission line. A wide range of actions can be taken to address various situations. General considerations include:

- Identifying locations where the Transmission Owner is constrained from performing planned vegetation maintenance work which potentially leaves the transmission line at risk.
- Developing the specific action to mitigate any potential risk associated with not performing the vegetation maintenance work as planned.
- Documenting and tracking the specific action taken for each location.
- In developing the specific action to mitigate the potential risk to the transmission line the Transmission Owner could consider location specific measures such as modifying the inspection and/or maintenance intervals. Where a legal constraint would not allow any vegetation work, the interim corrective action could include limiting the loading on the transmission line.
- The Transmission Owner should document and track the specific corrective action taken at each location. This location may be indicated as one span, one tree or a combination of spans on one property where the constraint is considered to be temporary.

Requirement R6

R6. *Each Transmission Owner shall perform a Vegetation Inspection of all applicable transmission lines at least once per calendar year.*

M6. *Each Transmission Owner has evidence that it conducted Vegetation Inspections at least once per calendar year for applicable transmission lines. Examples of acceptable forms of evidence may include work orders, invoices, or inspection records.*

Rationale
Inspections are used by Transmission Owners to prevent the encroachment of vegetation into the MVCD and provide a basis for assessing risk. This requirement sets a minimum vegetation inspection frequency of once per calendar year. Based upon average growth rates across North America and on common utility practice, this minimum frequency is reasonable. Transmission Owners should consider local and environmental factors that could warrant more frequent inspections.

R6 is a risk-based requirement. This requirement sets a minimum time period for completing Vegetation Inspections that fits general industry practice. In addition, the fact that Vegetation Inspections can be performed in conjunction with general line inspections further facilitates a Transmission Owner's ability to meet this requirement. However, the Transmission Owner may determine that more frequent inspections are needed to maintain reliability levels, dependent upon such factors as anticipated growth rates of the local vegetation, length of the growing season for the geographical area, limited Active Transmission ROW width, and rainfall amounts. Therefore it is expected that some transmission lines may be designated with a higher frequency of inspections.

The VSL for Requirement R6 has VSL categories ranked by the percentage of the required ROW inspections completed. To calculate the percentage of inspection completion, the Transmission Owner may choose units such as: line miles or kilometers, circuit miles or kilometers, pole line miles, ROW miles, etc.

For example, when a Transmission Owner operates 2,000 miles of 230 kV transmission lines this Transmission Owner will be responsible for inspecting all 2,000 miles of 230 kV transmission lines at least once during the calendar year. If one of the included lines was 100 miles long, and if it was not inspected during the year, then the amount failed to inspect would be 100/2000 = 0.05 or 5%. The "Low VSL" for R6 would apply in this example.

Requirement R7

R7. *Each Transmission Owner shall complete the work in an annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made and documented provided they do not put the transmission system at risk of a vegetation encroachment. Examples of reasons for modification to annual plan may include:*

> **Rationale**
> This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. An annual vegetation work plan allows for work to be modified for changing conditions, taking into consideration anticipated growth of vegetation and all other environmental factors, provided that the changes do not violate the encroachment within the MVCD.

- *Change in expected growth rate/environmental factors*
- *Major storms*
- *Rescheduling work between growing seasons*
- *Crew or contractor availability/ Mutual assistance agreements*
- *Identified unanticipated high priority work*
- *Weather conditions/Accessibility*
- *Permitting delays*
- *Land ownership changes/Change in land use by the landowner*
- *Funding adjustments (increase or decrease)*
- *Emerging technologies*

M7. *Each Transmission Owner has evidence that it completed its annual vegetation work plan. Examples of acceptable forms of evidence may include a copy of the completed annual work plan (including modifications if any), dated work orders, dated invoices, or dated inspection records.*

R7 is a risk-based requirement. The Transmission Owner is required to implement an annual work plan for vegetation management to accomplish the purpose of this standard. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made and documented provided they do not put the transmission system at risk. The annual work plan requirement is not intended to necessarily require a “span-by-span”, or even a “line-by-line” detailed description of all work to be performed. It is only intended to require that the Transmission Owner provide evidence of annual planning and execution of a vegetation management maintenance approach which successfully prevents encroachment of vegetation into the MVCD.

The ability to modify the work plan allows the Transmission Owner to change priorities or treatment methodologies during the year as conditions or situations dictate. For example recent line inspections may identify unanticipated high priority work, weather conditions (drought) could make herbicide application ineffective during the plan year, or a major storm could require redirecting local resources away from planned maintenance. This situation may also include complying with mutual assistance agreements by moving resources off the Transmission Owner’s system to work on another system. Any of these examples could result in acceptable deferrals or additions to the annual work plan. Modifications to the annual work plan must always ensure the reliability of the electric Transmission system.

In general, the vegetation management maintenance approach should use the full extent of the Transmission Owner's easement, fee simple and other legal rights allowed. A comprehensive approach that exercises the full extent of legal rights on the Active Transmission Line ROW is superior to incremental management in the long term because it reduces the overall potential for encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient.

When developing the annual work plan the Transmission Owner should allow time for procedural requirements to obtain permits to work on federal, state, provincial, public, tribal lands. In some cases the lead time for obtaining permits may necessitate preparing work plans more than a year prior to work start dates. Transmission Owners may also need to consider those special landowner requirements as documented in easement instruments.

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. Therefore, deferrals or relevant changes to the annual plan shall be documented. Depending on the planning and documentation format used by the Transmission Owner, evidence of successful annual work plan execution could consist of signed-off work orders, signed contracts, printouts from work management systems, spreadsheets of planned versus completed work, timesheets, work inspection reports, or paid invoices. Other evidence may include photographs, and walk-through reports.

Appendix 1: Clearance Distance Derivation by the Gallet Equation

The Gallet Equation is a well-known method of computing the required strike distance for proper insulation coordination, and has the ability to take into account various air gap geometries, as well as non-standard atmospheric conditions. When the Gallet Equation and conservative probabilistic methods are combined, i.e. deterministic design, sparkover probabilities of 10^{-6} or less are achieved. This approach is well known for its conservatism and was used to design the first 500 kV and 765 kV lines in North America [1]. Thus, the deterministic design approach using the Gallet Equation is used for the standard to compute the minimum strike distance between transmission lines and the vegetation that may be present in or along the transmission corridor.

Method Explanation (Gallet Equation)

In 1975 G. Gallet published a benchmark paper that provided a method to compute the critical flashover voltage (CFO) of various air gap geometries [4]. The Gallet Equation uses various “gap factors” to take into account various air gap geometries. Various gap factor values are provided in [1]. If the vegetation in a transmission corridor, e.g. a tree, is assumed electrically to be a large structure then the CFO of such an air gap geometry can be computed for dry or wet conditions using a well established equation proposed by Gallet [1],[2],[4],

$$CFO_A = k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} \tag{1}$$

where,

k_w	is defined as the factor that takes into account wet or dry conditions (dry = 1.0 and wet = 0.96) and phase arrangement (multiply by 1.08 for outside phase), e.g. outside phase and wet conditions = (0.96)(1.08) = 1.037,
k_g	is defined as the gap factor (1.3 for conductor to large structure),
D	is the strike distance (m),
CFO_A	is the CFO for the relative air density (kV).
δ	is defined as the relative air density and is approximately equal to (2) where *A* is the altitude in km,

$$\delta = e^{-\frac{A}{8.6}} \tag{2}$$

$$m = 1.25G_0\left(G_0 - 0.2\right) \tag{3}$$

$$G_0 = \frac{CFO_s}{500 \cdot D} \tag{4}$$

$$CFO_s = k_w \cdot k_g \cdot \frac{3400}{1+\frac{8}{D}} \tag{5}$$

where CFO_S is the CFO for standard atmospheric conditions (kV). Using (1)-(5), the required CFO_A can be computed using an iterative process.

Once the CFO_A is known, deterministic methods can be used to determine the required clearance distance. If we let the maximum switching overvoltage be equal to the withstand voltage of the air gap (CFO_A - 3σ) then the CFO_A can be written as (6).

$$CFO_A = \frac{V_m}{1-3\left(\frac{\sigma}{CFO_A}\right)} \tag{6}$$

where

V_m is equal to the maximum switching overvoltage, i.e. the value that has a 0.135% chance of being exceeded,

σ is the standard deviation of the air gap insulation,

CFO_A is the critical flashover voltage of the air gap insulation under non-standard atmospheric conditions.

The ratio of σ to the CFO_A given in (6) can be assumed to be 0.05 (5%) [1]. Thus, (6) can be written as (7).

$$CFO_A = \frac{V_m}{0.85} \tag{7}$$

Substituting (7) into (1) we arrive at (8).

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} \tag{8}$$

Equation 8 relates the maximum transient overvoltage, V_m, to the air gap distance, D. Using (8) to compute the required clearance distance for the specified air gap geometry (conductor to large structure) results in a probability of flashover in the range of 10^{-6}.

Transient Overvoltage

In general, the worst case transient overvoltages occurring on a transmission line are caused by energizing or re-energizing the line with the latter being the extreme case if trapped charge is present. The intent of FAC-003 is to keep a transmission line that is *in service* from becoming de-energized (i.e. tripped out) due to sparkover from the line conductor to nearby vegetation. Thus, the worst case scenarios that are typically analyzed for insulation coordination purposes (e.g. line energization and re-energization) can be ignored. For the purposes of FAC-003-2, the worst case transient overvoltage then becomes the maximum value that can occur with the line energized. Determining a realistic value of transient overvoltage for this situation is difficult because the maximum transient overvoltage factors listed in the literature are based on a

switching operation of the line in question. In other words, these maximum overvoltage values (e.g. the values listed in [2], [3] and [5]) are based on the assumption that the subject line is being energized, re-energized or de-energized. These operations, by their very nature, will create the largest transient overvoltages. Typical values of transient overvoltages of in-service lines, as such, are not readily available in the literature because the resulting level of overvoltage is negligible compared with the maximum (e.g. re-energizing a transmission line with trapped charge). A conservative value for the maximum transient overvoltage that can occur anywhere along the length of an in-service ac line is approximately 2.0 p.u.[2]. This value is a conservative estimate of the transient overvoltage that is created at the point of application (e.g. a substation) by switching a capacitor bank without a pre-insertion device (e.g. closing resistors). At voltage levels where capacitor banks are not very common (e.g. 362 kV), the maximum transient overvoltage of an "in-service" ac line are created by fault initiation on adjacent ac lines and shunt reactor bank switching. These transient voltages are usually 1.5 p.u. or less [2]. It is well known that these theoretical transient overvoltages will not be experienced at locations remote from the bus at which they were created; however, in order to be conservative, it will be assumed that all nearby ac lines are subjected to this same level of overvoltage. Thus, a maximum transient overvoltage factor of 2.0 p.u. for 242 kV and below and 1.4 p.u. for ac transmission lines 362 kV and above is used to compute the required clearance distances for vegetation management purposes.

The overvoltage characteristics of dc transmission lines vary somewhat from their ac counterparts. The referenced empirically derived transient overvoltage factor used to calculate the minimum clearance distances from dc transmission lines to vegetation for the purpose of FAC-003-2 will be 1.8 p.u.[3].

Example Calculation

An example calculation is presented below using the proposed method of computing the vegetation clearance distances. It is assumed that the line in question has a maximum operating voltage of 550 kV_{rms} line-to-line. Using a per unit transient overvoltage factor of 1.4, the result is a peak transient voltage of 629 kV_{crest}. It is further assumed that the line in question operates at a maximum altitude of 7000 feet (2.134 km) above sea level.

The required withstand voltage of the air gap must be equal to or greater than 629 kV_{crest}. Since the altitude is above sea level, (1) - (5) have to be iterated on to achieve the desired result. Equation (9) can be used as an initial guess for the clearance distance.

$$D_i = \frac{8}{\frac{3400 \cdot k_w \cdot k_g}{\left(\frac{V_m}{0.85}\right)} - 1} \qquad (9)$$

For our case here, V_m is equal to 629 kV, k_w = 1.037 and k_g = 1.3. Thus,

$$D_i = \frac{8}{\frac{3400 \cdot k_w \cdot k_g}{\left(\frac{V_m}{0.85}\right)} - 1} = \frac{8}{\frac{3400 \cdot 1.037 \cdot 1.3}{\left(\frac{629}{0.85}\right)} - 1} = 1.535m \qquad (10)$$

Using (2)-(5) and (8) the withstand voltage of the air gap is next computed. This value will then be compared to the maximum transient overvoltage.

$$CFO_S = k_w \cdot k_g \cdot \frac{3400}{1+\frac{8}{D}} = 1.037 \cdot 1.3 \cdot \frac{3400}{1+\frac{8}{1.535}} = 737.7kV \tag{11}$$

$$\delta = e^{-\frac{A}{8.6}} = e^{-\frac{2.134}{8.6}} = 0.78 \tag{12}$$

$$G_O = \frac{CFO_S}{500 \cdot D} = \frac{737.7}{(500)\cdot(1.535)} = 0.961 \tag{13}$$

$$m = 1.25 \cdot G_O (G_O - 0.2) = 1.25 \cdot 0.961(0.961 - 0.2) = 0.915 \tag{14}$$

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} = (0.85)(1.037)(1.3)(0.78)^{0.915}\left(\frac{3400}{1+\frac{8}{1.535}}\right) = 499.8kV \tag{15}$$

The calculated V_m is less than 629 kV; thus, the clearance distance must be increased. A few iterations using (2)-(5) and (8) are required until the computed $V_m \geq 629$ kV. For this case it was found that D = 1.978 m (6.49 feet) yielded V_m = 629.3 kV. Using this clearance distance the following values were computed for the final iteration.

$$CFO_S = k_w \cdot k_g \cdot \frac{3400}{1+\frac{8}{D}} = 1.037 \cdot 1.3 \cdot \frac{3400}{1+\frac{8}{1.978}} = 908.5kV \tag{16}$$

$$\delta = e^{-\frac{A}{8.6}} = e^{-\frac{2.134}{8.6}} = 0.78 \tag{17}$$

$$G_O = \frac{CFO_S}{500 \cdot D} = \frac{908.5}{(500)\cdot(1.978)} = 0.919 \tag{18}$$

$$m = 1.25 \cdot G_O (G_O - 0.2) = 1.25 \cdot 0.919(0.919 - 0.2) = 0.825 \tag{19}$$

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} = (0.85)(1.037)(1.3)(0.78)^{0.825}\left(\frac{3400}{1+\frac{8}{1.978}}\right) = 629.3kV \tag{20}$$

Therefore, the minimum vegetation clearance distance for a maximum line to line ac operating voltage of 550 kV at 7000 feet above sea level is 1.978 m (6.49 feet). Table 1 provides calculated distances for various altitudes and maximum system operating ac voltages.

Standards Announcement

Initial Ballot Window Open
July 9–19, 2010

Now available at: https://standards.nerc.net/CurrentBallots.aspx

Project 2007-07: Transmission Vegetation Management

An initial ballot window for proposed standard FAC-003-2 — Transmission Vegetation Management is now open **until 8 p.m. Eastern on July 19, 2010**. An associated implementation plan has been posted with the revised standard.

Members of the ballot pool associated with this project will receive a separate e-mail with a link to the non-binding on the Violation Risk Factors (VRFs) and Violation Severity Levels (VSLs).

On March 18, 2010, FERC issued several orders and notices of proposed rulemakings pertaining to standards development activities and processes, suggesting a lack of progress in responding to directives from Order 693 as well in the timeliness of standards development in general. At the May 2010 NERC Board meeting, Gerry Cauley, NERC's President, also expressed these concerns, indicating that the resolution to these concerns is one of NERC's top priorities in the near term. As a result, the Standards Committee has authorized deviations from the normal standards development process for the Vegetation Management project, as well as other projects that have been through significant stakeholder review through the development process, to demonstrate that the NERC enterprise is responsive to FERC directives, and is making progress in developing new standards.

The Standards Committee approved the following deviations from the standards development process:

- The proposed changes to the standards will be posted for a shortened comment period;
- The ballot pool will be formed during the first few weeks of the comment period;
- The initial ballot will be conducted during the last 10 days of the comment period; and
- The drafting team may make modifications between the initial and recirculation ballots based on stakeholder comments to improve the overall quality of the standard.

Instructions

Members of the ballot pool associated with this project may log in and submit their votes from the following page: https://standards.nerc.net/CurrentBallots.aspx

Next Steps

Voting results will be posted and announced after the ballot window closes.

Project Background

The project is an update to FAC-003-1, which was approved in 2006. The items identified for revision include the incorporation of FERC Order 693 comments related to applicability, procedural repairs to conform to the current standards format and development procedure, technical updates and guidance to address stakeholder suggestions, and the elimination of "fill-in-the-blank" components.

Project page: http://www.nerc.com/filez/standards/Vegetation-Management_Project_2007-7.html

Special notes about this project:
The NERC Standards Committee endorsed the use of Project 2007-07: Vegetation Management as the prototype for the proof-of-concept for using the "results-based" criteria for developing a reliability standard. The overall approach includes considerably more emphasis on the "concepts and assumptions" underlying the development of requirements and goes beyond the steps most drafting teams use when developing a standard. Accordingly, the "look and feel" of the vegetation management standard is quite different than NERC's existing standards. However, at the core is a set of mandatory and enforceable requirements with useful guidance supporting these requirements, an approach NERC's legal counsel has reviewed and finds acceptable. More information about results-based standards can be found at:
http://www.nerc.com/filez/standards/Project2010-06_Results-based_Reliability_Standards.html

The Standards Committee approved the following deviations from the standards development process:

- The proposed changes to the standards will be posted for a shortened comment period;
- The ballot pool will be formed during the first few weeks of the comment period;
- The initial ballot will be conducted during the last 10 days of the comment period; and
- The drafting team may make modifications between the initial and recirculation ballots based on stakeholder comments to improve the overall quality of the standard.

Ballot Pool (through July 7, 2010)

Registered Ballot Body members may join the ballot pool **until 8 a.m. Eastern on July 7, 2010** to be eligible to vote in the upcoming ballot at the following page: https://standards.nerc.net/BallotPool.aspx. Members who join the ballot pool to vote on the standard will automatically be entered in a separate pool to participate in the non-binding poll of the associated violation risk factors (VRFs) and violation severity levels (VSLs). (As a reminder, this new approach for VRFs and VSLs is one of the updates reflected in the recently FERC-approved Reliability Standards Development Procedure – Version 7.)

During the pre-ballot window, members of the ballot pool may communicate with one another by using their "ballot pool list server." (Once the balloting begins, ballot pool members are prohibited from using the ballot pool list servers.) The list server for this ballot pool is: bp-2007-07_FAC-003-2_in@nerc.com

Comment Period (through July 17, 2010)

Please use this electronic form to submit comments. If you experience any difficulties in using the electronic form, please contact Lauren Koller at 609-524-7047.

Standards Announcement
Initial Ballot Results

Now available at: https://standards.nerc.net/Ballots.aspx

Project 2007-07: Transmission Vegetation Management
The initial ballot for proposed standard FAC-003-2 — Transmission Vegetation Management ended on July 19, 2010.

Ballot Results
Voting statistics are listed below, and the Ballot Results Web page provides a link to the detailed results:

Quorum: 86.18 %
Approval: 65.93 %

Since at least one negative ballot included a comment, and the affirmative votes did not meet the threshold for approval, these results are not final. Another comment and ballot period will be conducted.

Violation Risk Factor (VRF) and Violation Severity Level (VSL) Non-binding Poll Results
Only 6% of the non-binding polls for VRFs and VSLs were returned, rendering the results inconclusive. By comparison, the Underfrequency Load Shedding, Protection System Maintenance and Testing, Backup Facilities, and Transmission Loading Relief standards all had greater than 80% of the non-binding polls for VRFs and VSLs returned with an opinion.

Next Steps
The drafting team must draft and post responses to comments received through the public comment period and the initial ballot. The response to comments and proposed revisions will be posted for a 30-day comment period, and a "successive ballot" will be conducted during the last ten days of that 30-day comment period. A non-binding poll of the proposed VRFs and VSLs will also be conducted during the last ten days of the 30-day comment period.

Project Background
The project is an update to FAC-003-1, which was approved in 2006. The items identified for revision include the incorporation of FERC Order 693 comments related to applicability, procedural repairs to conform to the current standards format and development procedure, technical updates and guidance to address stakeholder suggestions, and the elimination of "fill-in-the-blank" components.

More information is available on the project page: http://www.nerc.com/filez/standards/Vegetation-Management_Project_2007-7.html

The NERC Standards Committee endorsed the use of Project 2007-07: Vegetation Management as the prototype for the proof-of-concept for using the "results-based" criteria for developing a reliability standard. The overall approach includes considerably more emphasis on the "concepts and assumptions" underlying the development of requirements and goes beyond the steps most drafting teams use when developing a standard. Accordingly, the "look and feel" of the vegetation management standard is quite different than NERC's existing standards. However, at the core is a set of mandatory and enforceable requirements with useful guidance supporting these requirements, an approach NERC's legal counsel has reviewed and finds acceptable. More information about results-based standards can be found at: http://www.nerc.com/filez/standards/Project2010-06_Results-based_Reliability_Standards.html

Standards Development Process

The *Reliability Standards Development Procedure* contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

Ballot Criteria

Approval requires both a (1) quorum, which is established by at least 75% of the members of the ballot pool for submitting either an affirmative vote, a negative vote, or an abstention, and (2) A two-thirds majority of the weighted segment votes cast must be affirmative; the number of votes cast is the sum of affirmative and negative votes, excluding abstentions and nonresponses. If there are no negative votes with reasons from the first ballot, the results of the first ballot shall stand. If, however, one or more members submit negative votes with reasons, a second ballot shall be conducted.

David Burke
Orange and Rockland Utilities, Inc.
Yes
There should be a statement in Table 3 that is consistent with footnote number 2 stating that the minimum width of the Active Transmission Line ROW is either the full width of the easement or, if the easement is wider than the distances in Table 3, the minimum distances must not be less than the distances shown in the Table.
Yes
Yes
Yes
Yes
Draft 4 version of R1/R2
Orange and Rockland Utilities, Inc prefers the Draft 4 version. The wording in the VSLs should be modified for both Requirements to include the phrase 'manage vegetation.' The phrase 'manage vegetation' requires a utility to take specific action to prevent encroachments/outages.
VSLs proposed by the VM SDT
The wording in the VM STD VSLs should be modified to include whether or not the TO managed any vegetation on that particular line. A more severe VSL should be assigned to any encroachment or sustained outage that was caused as a result of a TO not performing any vegetation management activities on that line. For example, if vegetation management activities were completed on 80% or 90% of the line and additional work was in progress on the remainder of the line but an encroachement or sustained

outage occurred on the spans that were scheduled to be done as part of the annual plan, the TO should be held accountable for this but at a lower severity level.
Yes
In R5, the SDT should better define the phrase 'where a transmission line is put at potential risk due to the constraint.' This is rather vague and could lead to inconsistent practices between utilities. Orange and Rockland Utilities, Inc. defines all undesirable species on the full width of the ROW as 'potential risks to the transmission line' regardless of height or location at the time of vegetation management. Interim corrective action should only be required when the potential risk is approaching the imminent threat classification.
Group
Western Area Power Administration
Brandy A. Dunn
Yes
Suggest using a total right-of-way width in Table 3 rather than a distance measured from centerline.
Yes
Yes
However, the last sentence added to the measure is imprecise and introduces undesirable subjectivity and confusion to the process for determining a compliance violation.
Yes
No
As the list of â€œexamples of reasons for modificationâ€☐ is not all inclusive, it is unnecessary and could result in confusion regarding compliance when a scenario other than one listed requires a change. Further, documentation of changes to the annual plan adds unnecessary administrative burden which is inconsistent with a performance based standards approach.
Draft 4 version of R1/R2
The current language of Draft 4 is the most flexible and offers industry the best opportunity for executing a cost effective and efficient program.
VSLs proposed by the VM SDT
Unlike a â€œgrow-inâ€☐, a â€œfall-inâ€☐ or â€œblow-inâ€☐ has never caused or contributed to a cascading outage. Further, the â€œzero toleranceâ€☐ approach of this standard remains impractical and unreasonable. The gradated indicators of program performance associated with a â€œfall-inâ€☐, â€œblow-inâ€☐ and â€œgrow-inâ€☐ offer some measure of reasonableness to the requirement.

No
There should be a statement in Table 3 that is consistent with footnote number 2 stating that the minimum width of the Active Transmission Line ROW is either the full width of the easement or, if the easement is wider than the distances in Table 3, the minimum distances must not be less than the distances shown in the Table. The use of a minimum distance from the centerline of the circuit or structure is an incorrect measure to use for a set clearance distance of the active transmission right-of-way. The description does not take into account vertical versus horizontal

design configuration. Consideration should be given for the type of construction as different construction types (H-Frame, Lattice towers, Monopole delta or vertical construction) will require different widths of a cleared right-of-way to provide the necessary openings for these circuits. A minimum distance for 345-kV is now set at 150 feet based on the minimum distances from centerline. This may be correct for certain H-Frame and Lattice Tower configurations but it is excessive for monopole situations. A single pole configuration with vertically aligned conductors does not need this full 150 foot width. It is strongly recommended that a minimum distance from conductor be used in place of a set distance from centerline. As long as there is at least 30 - 40 feet of clearance in the right-of-way from the outermost conductors (adjusted to account for maximum sway at mid-span for longer spans), then this is the distance that should be used to develop the right-of-way widths. For example, a monopole structure with vertically aligned conductors would result in a cleared active right-of-way width of only 80 feet (40 feet from conductor to edge of cleared active right-of-way) using the minimum distances from the conductors. There is no need to extend this distance another 35 feet (on each side) in order to obtain the full 150 foot width. This requirement is excessive and must be adjusted to account for line construction variations. Instead of using the term "Centerline" as referenced on Table 3, the use of "outer phase" or "phase closest to tree line" would be more appropriate. There is published literature using the term â€œcleared widthâ€□ to indicate the distance from the outer phase to the tree line. This distance should be used in the Active ROW definition. The word easement is also used in the definition. Is there a reason the Active ROW only includes easements, not fee ownership, license or some other right to occupy and manage the ROW? Would Active ROW include â€œdanger tree rightsâ€□ on land? These questions need to be addressed in the standard (in text) and technical reference document (in graphics).
Yes
No
A clarification for M1 is needed regarding whether entities will have to attest to the fact that there has never been an encroachment in the MVCD.
Yes
Yes
Alternate version of R1/R2
Alternate Version E would allow a Transmission Owner to use an approach consistent with the current version of FAC-003 by defining a minimum clearance distance and a vegetation management clearance distance. This approach has met the objectives of FAC-003 since 2006. Use of version E would change the standard from a prescriptive approach to a Transmission Owner defined approach. In addition, Alternate Version E is preferred as it allows for variations based on differences in conductor heights, topography and other situations where a set height is not necessarily required in all instances and allows for the utility to determine the maximum heights of vegetation without performing detailed calculations of what the maximum heights must be along the various distances within each conductor span. If the utility is tasked with managing the vegetation to ensure no encroachments into the MVCD then it should be up to the individual utility how best to determine its management strategies that incorporate the determination of maximum vegetation heights in each section on its system.
VSLs proposed by the VM SDT
The wording in the VM STD VSLs should be modified to include whether or not the TO managed any vegetation on that particular line. A more severe VSL should be assigned to any encroachment or sustained outage that was

caused as a result of a TO not performing any vegetation management activities on that line. For example, if vegetation management activities were completed on 80% or 90% of the line and additional work was in progress on the remainder of the line, but an encroachment or sustained outage occurred on the spans that were scheduled to be done as part of the annual plan, the TO should be held accountable for this but at a lower severity level.
Yes
NPCC wants to thank the SDT for the effort that has gone into developing this proposed revision to FAC-003. Overall the new version is consistent with FERC Order 693 and will be a straightforward, workable, and auditable standard. One item requiring clarification and change is the Active ROW definition. The recent addition of a centerline distance to edge of Active ROW is not acceptable. In many areas design standards allow a smaller ROW width with no compromise to â€œcleared widthâ€□ or tree related reliability of the line. The SDT needs to address this issue. In R5, the phrase 'where a transmission line is put at potential risk due to the constraint' should be better defined. This is vague and could lead to inconsistent practices between utilities. All undesirable species on the full width of the ROW are defined as 'potential risks to the transmission line' regardless of height or location at the time of vegetation management. Interim corrective action should only be required when the potential risk is approaching the imminent threat classification.
Individual
Weston Davis
Central Maine Power Company, Iberdrola USA
No
Table 3 distances may not be appropriate, for example table 3 should reflect a clearance zone based on construction type, topography, species, or growth rates. Table 3 could give the impression that the listed distances are the maximum, therefore suggest table 3 be removed or revised. The Active Transmisson Line Right-of-Way defination uses the word easement, which most likely would include danger trees in situations where danger removals are included in the the easement language. This would expand the scope of FAC 003 2 beyond the cleared right-of-way width.
No comment suggested.
No
Recommend SDT create two measures one measure if a tree violated the MVCD and no outage occurred and second measure and severity level if an outage occurred
Yes
Yes
Alternate version of R1/R2
VSLs proposed by the VM SDT
Agrees with SDT that violation risk factors must be ranked in accordance with impact on the bulk delivery system.

Kasia Mihalchuk
Manitoba Hydro
Yes
Please add metric equivalents in the standard. While it makes some aspects easier around pointing to what we need to keep "clear" to meet

NERC rules - it does limit some of our flexibility to design lines and ROWs to your own standards. Also, the minimum only applies when you have easement larger than the minimums in table 3, and I would assume that does not relieve you of the responsibility to maintain ROWs appropriately if the design of your lines requires a wider ROW.
Yes
Yes
Yes
Yes
Draft 4 version of R1/R2
I would suggest adding verbage to the draft 4 version to explicitly include the sag and sway of the conductor to the concept of "operating within rating and electrical operating conditionâ€œ
VSLs proposed by the VM SDT
No
Individual
Jonathan Appelbaum
The United Illuminating Company
No
The definition has been altered. The last sentence "However, it is not to be less than the width of the easement itself unless the easement exceeds distances as shown in Table 3 for various voltage classes..." was added. The concept of the easement is confusing and not included in the Supplemental Reference. Table 3 of the standard is titled "Minimum Distance from the Centerline of the Circuit to the edge of the active transmission line ROW", no mention of easements. It is suggested that the definition state "strip or corridor of land that is occupied by active transmission facilities. This corridor does not include the parts of the Right-of-Way that are unused or intended for other facilities. At a minimum the width is to be the distances as shown in Table 3 for various voltage classes." The proper location for the definition is in the Glossary.
Yes
Yes
Yes
No
R1 and R2 are requirements that no encroachment occurs. R7, as proposed, requires a VMP to be completed to ensure no encroachment occurs. The Supplemental Reference for R7 does not describe the requirement of the annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD. The Reference states the requirement is established to diminish the risk of encroachment; which is very different from ensuring no encroachment. In the Reference for R7 the word â€œensureâ€☐ is only used to describe that flexibility in the VMP is allowed to ensure the reliability of the Transmission System. M7 is measuring work plan completion not the prevention of encroachment. United Illuminating suggests that R7 be changed to: Each Transmission Owner shall complete the work in an annual vegetation work plan to manage the prevention of vegetation encroachments occur within the

MVCD. In this way, a violation of R1/R2 does not necessarily mean R7 is violated. The entity does not avoid a penalty for an encroachment because a violation of R1/R2 occurs for actual encroachment. If an encroachment occurs the compliance enforcement authority can review the entities vegetation management plan to determine if it is compliance with R7/M7.
Draft 4 version of R1/R2
UI prefers the draft language because we believe the intent of R1/R2 is to capture the actual occurrence of a vegetation related interruption or encroachment of vegetaion into the MVCD based on actual conditions.
VSLs proposed by NERC staff
United Illuminating agrees with NERC Staff that the Requirement is to prevent encroachment of any kind. Differentiating between fall-in and grow-in is of no consequence to the intent of the requirement.
Yes
R4: In R4 the phrase: without any intentional time delay, is a concern. There is a time line between identification and reporting of an imminent hazard that represents the minimal time required to complete this Requirement. Any situation where the time between observation and reporting is greater than this minimal time line indicates a time delay occurred. It will be left to the compliance enforcement authority to determine if this delay was intentional or not. It is not proper for the test to be based on Intentional versus Non-Intentional. Using other synonyms such as reasonable, expeditious, prompt, immediate or without hesitation all introduce a qualitative not a quantitative attribute to the measurement. The Supplemental Reference for R4 indicates that the imminent threat requirement is measured in minutes or hours; again no guidance for enforcement. R4 would be improved with an explicit time requirement of 6 hours between observation and report. This is measurable and clear. R4 should be: Each Transmission Owner shall notify the control center holding switching authority for the associated transmission line no more than 6 hours of a qualified personnel confirm the existence of a vegetation condition that is likely to cause a Fault at any moment. Other commenterâ€™s will argue that 6 hours is arbitrary or unduly prescriptive. I believe it is in line with the Supplemental Reference and adds clarity to the enforcement process. M4 becomes Each Transmission Owner that has a vegetation condition likely to cause a Fault at any moment, as confirmed by qualified personnel, will have evidence that it notified the control center holding switching authority for the associated transmission line within 6 hours of observation. The Transmission Owner can use the inspection as evidence of the time of observation. Effective Dates: The effective dates in the implementation Plan is in a different form then UI was expecting. Effective Date 1 UI has no comment. Effective date number 2 implies that if the BOT approves the standard and FERC takes no action (neither approves, remands or withholds approval of the standard) then the standard will become effective in one year. This seems to create the possibility of an effective standard without enforceability. Effective Date number 3 implies that regardless of any action by FERC the standard will become effective at least one year following BOT approval. Again this creates an effective standard without enforceability. Also the use of â€œat least one yearâ€☐ does not add any clarity to when the Standard would be effective any way.

Idaho Power Company
No
The way I interpret this, the new definition of active transmission line right of way takes away our ability to clear potential fall ins if they are outside of the active transmission line ROW>
Yes

Yes
Yes
Yes
Alternate version of R1/R2
I think this gives us more flexibility to maintain our clearances.
VSLs proposed by NERC staff
Yes
I would like to see something more from NERC to clear the way for utilities to do vegetation management on federal lands that will allow timely vegetation management without delays from these federal entities.
Individual
Sam Stonerock
Southern California Edison Company
Yes
SCE appreciates the SDTâ€™s efforts to replace the defined term with a set of minimum distances. However, the proposed new Table 3 appears to assume a horizontal configuration of transmission lines. Thus, it would appear that those lines configured vertically (for example, two circuits on opposite sides of a tower), the â€œactive right of wayâ€☐ required would be at least twice as large as that for horizontal lines. SCE respectfully recommends a footnote be added to Table 3 that allows the TO to recalculate the active right of way for lines in a vertical configuration, based on a horizontal line configuration.
Yes
SCE generally agrees with the information contained in Part 5 â€“ Background. However, we question the value of placing a rationale within the body of the standard. SCE respectfully recommends that the revised â€œBackgroundâ€☐ information be added to the beginning of the â€œGuidelines and Technical Basis,â€☐ which also includes explanations for various standard segments.
Yes
SCE generally agrees with the revisions to M1 and M2, however we would suggest the last sentence of the second paragraphs in both M1 and M2 be modified to read: M1- Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period. If an investigation of a Fault, by a qualified person, confirms that a vegetation encroachment, as described in R1 items 2-4 (above), occurred within the MVCD occurred, then it shall be considered a Real-time observation. M2- Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period. If an investigation of a Fault, by a qualified person, confirms that a vegetation encroachment, as described in R2 items 2-4 (above), occurred within the MVCD occurred, then it shall be considered a Real-time observation.
No
SCE prefers the Draft 3 version of R3 which read: â€œEach Transmission Owner shall have a documented transmission vegetation management program that describes how it conducts work on its Active Transmission Line ROWs to avoid Sustained Outages due to vegetation, considering all possible locations the conductor may occupy assuming operation within Rating and Rated Electrical Operating Conditions.â€☐ However, if the SDT believes it is prudent to revise R3 in response to certain commenters, SCE would respectfully recommend R3 be revised to read: â€œEach

Transmission Owner shall document the procedures, processes, or specifications it uses to prevent the encroachment of vegetation into the MVCD. Such documentation will account for the movement of transmission line conductors under their Rating and Rated Electrical Operating Conditions; and the inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency, for the Transmission Ownerâ€™s applicable lines.â€□
Yes
SCE agrees with the revisions to R7, but notes the some minor edits to the text are still needed.
Alternate version of R1/R2
SCE prefers the operational flexibility provided by the alternate version of R1/R2. We also note that dating back to development of FAC-003-1 and related comment periods, Transmission Owners have repeatedly stated that a â€œone-size-fits-allâ€□ TVMP is not viable or reasonable.
VSLs proposed by the VM SDT
SCE agrees with the SDT's rationale and proposals for VSL Criteria.
Yes
SCE questions the need for including the â€œGuidelines and Technical Basisâ€□ section within the body of the standard and is also curious as to the criteria used in developing new Table 3. SCE finds this Draft (4) to be the best work product thus far, and commends the SDT for its efforts and continued dedication to crafting a best-in-class standard.

Progress Energy
No
In Applicability Section 4.4, â€œactive transmission line ROWâ€□ is not capitalized indicating it is not a defined term, but Footnote 2 is effectively a definition for active transmission line ROW. However, in the first paragraph of Section 5 Background, Active Transmission Line Right-of-Way is capitalized indicating itâ€™s a defined term. It would seem cleaner to make â€œActive Transmission Line Right of Wayâ€□ a formal NERC definition. Alternatively and at a minimum, Footnote 2 should be revised to say â€œAn active transmission line ROW is a strip or corridorâ€¦â€□ and also in Section 5 Background, â€œActive Transmission Line Right of Wayâ€□ should be changed to no longer be capitalized.
Yes
Yes
Yes
Yes
Yes
1) On p. 3 of the redline, the table of Effective Dates is struck out, but the key (listed as 1, 2, 3 below the table: â€œ1. First calendar dayâ€¦â€□) remains but now the numbers 1, 2, and 3 no longer refer to the table of Effective Dates as the table has been struck. 2) The first paragraph under â€œExceptionsâ€□ could be reworded to be clearer. As currently proposed, it states lines below 200kV become subject to the standard 12 months after the lines are designated as being subject to the standard, which is somewhat circular. We propose instead: â€œA line operated below 200kV becomes subject to this standard 12 months after the date

the Planning Coordinator or WECC initially designates the line as an element of an IROL or as a Major WECC transfer path.â€☐ 3) Applicability Section 4.2.4 says the standard does not apply to Facilities located in the fenced area of a switchyard. However, p. 8 in Section 5 Background says the standard does not apply to underground or submarine lines or line sections inside a station boundary. Two things should be addressed to make these consistent: â€œFacilitiesâ€☐ is a NERC-defined term that includes more than just lines, and includes lines, generators, compensators, transformers, etc. Also, is the â€œstation boundaryâ€☐ always defined by the fenced area? Any potential conflict due to this inconsistency should be resolved. 4) In the redline of Draft 4, in R5 and M5, the word â€œinterimâ€☐ is struck through. However, the Rationale box says â€œâ€¦.the intent is for the Transmission Owner to put interim measures in placeâ€¦â€☐ The use of â€œinterimâ€☐ should be consistent between R5, M5 and the Rationale box. 5) R6 requires the TO to perform Vegetation Inspections â€œat least once per calendar yearâ€☐. There could potentially be future interpretation requests that question whether â€œonce per calendar yearâ€☐ means performance sometime during each year (i.e. 2010, 2011, etc.), or whether no more than 365 calendar days can elapse between inspections. The first interpretation could allow up to almost 2 years to elapse between inspections even when doing it â€œonce per calendar yearâ€☐. This should be clarified.
Individual
John Bee
Exelon
No
The term â€œCenterline of the Circuitâ€☐ in Table 3 is not defined. Until it is defined, there is no way to know if the standard is technically reasonable or whether existing circuits would be in violation of the standard and unable to operate. In addition, it is unclear what types of construction and span lengths were used to develop the distances for active right-of-way widths in Table 3. Furthermore, it is not clear whether Table 3 contains requirements against which compliance will be measured or best practice guidelines. Footnote 2, in the background section, compounds this ambiguity. In short, the lack of a definition for â€œCenterlineâ€☐ combined with Footnote 2 and Table 3 make this draft unclear and unenforceable. Exelon does not necessarily have easement widths for all transmission lines that equal those defined in Table 3 of this draft; This may require the acquisition of additional easements, if even possible.

Hugh Conley
Alleghney Power
No

Allegheny Power strongly disagrees with the numbers or widths stated within Table 3. These numbers seem arbitrary and have no accompanying reasonable explanation as to their origin, basis, or other criteria noting the rationale for inclusion in this standard. This inclusion effectively prohibits a TO from establishing corridor widths less than the widths (which may be easily possible by utilizing various tower or structures heights or configurations) stated in Table 3 without placing the TO in extreme jeopardy of non-compliance issues from a falling off-corridor tree, during minor storm conditions as an example. Furthermore, this Table insinuates the TO has no ability to successfully manage vegetation WITH NO RESULTING OUTAGES or encroachments within the MVCD from off-corridor trees where corridors are less that the widths stated in Table 3. Allegheny Power suggests that the definition of the â€œActive Transmission line Right Of Wayâ€☐ be â€œthe transmission line ROW corridor that is actively maintained as part of the entity's vegetation management plan.".

This is very unclear, and creates much uncertainty as to how certain potential outage situations should be reported. Clarification language should be added within the Standard to help define and guide the TO's actions when an outage occurs from a location at a point that is less than the documented ROW boundaries (Easements) but greater than the ROW distances represented in Table 3. It is unclear which distance should guide our reporting actionsâ€¦â€¦..ROW Document Width, Table 3 ROW Widths, or the lesser of the twoâ€¦â€¦. See scenarios / examples below for consideration to aid with clarification points: Example 1: If our documented ROW width for a 500kV line is 100' from centerline (200' total ROW width) and we have a fall in from 90' from centerline, do we report this as a Category 2 Outage due to the fact that it fell from within our ROW limits, or is it non-reportable due to the fact that it is located at a greater distance than 87.5' from the centerline of the ROW as listed in Table 3 in the Standard? Example 2: How does maintenance and outage reporting correlate with the example defined as followsâ€¦â€¦.You have a 230 kV line situated on one side of a 150' wide ROW that was initially cleared to a width that would accommodate 2 separate parallel transmission lines and structures. The second set of lines/structures have not yet been constructed, and the current Transmission line is situated on one side of the 150' ROW, and is being maintained to the edge of the actual ROW on the side of the ROW that it was constructed on (maintained to a distance of 50' from centerline that puts it at the legal edge of the ROW), but it has been typically maintained to a distance of approximately 60' from centerline to the inside portion/other side of the ROW (the side of the ROW

that has never been cleared), but a tree falls into the line from approx 58' from centerline (2' within the 60' distance typically being maintained on that line)â€¦â€¦.would this be considered a Category 2 outage since it was approx 2' within the average width being maintained on that side of the ROW or would it not be reported due to the fact that it was located at a distance greater than 50' as indicated in Table 3??
Yes
Yes
We agree, IF the determination is made by a Qualified Person to have been caused by vegetation breaking the MVCD (if not breaking MVCD in real time when observed) based on close observation/inspection and hard evidence that a Flashover occurred, and that there is no evidence that the issues spotted on the tree were caused by environmental or biological symptoms or stressors of the tree in question. Hard evidence has to be present to classify the item as a vegetation outage if the tree is not within MVCD when the real time observation is madeâ€¦..an assumption cannot be made that vegetation was the cause of an outage if the tree is situated at a distance that is greater than MVCD when observed unless there is hard evidence supporting the flashover as determined by a qualified person.
Yes
Yes
Draft 4 version of R1/R2
Draft 4 is acceptable, but if alternate language is chosen, it should be similar to option E, keeping the determination simple and with as few variables for interpretation as necessary.
VSLs proposed by the VM SDT
This gives the option to activate and follow the Imminent Threat Process if a breach of the MVCD is located and reported for isolated events absent a sustained outage. It gives the TO the opportunity to mitigate the issue when it is identified and corected prior to experiencing an outage..
Yes
ITEMS of concern listed below: ITEM 1: Page 13 of the Standard Draft 4 under Add'l Compliance Information - Periodic Data Submittalâ€¦â€¦Clarify if Immediate Reporting is expected for outages in Outage Categories 1A, 1B, 2, or 4â€¦â€¦..or if Quarterly Reporting is all that is expected. It does not specifically say that IMMEDIATE Reporting is Required for any outage type. It is assumed that IMMEDIATE reporting is required for some outages, but is unclear. ITEM 2: Agree that text boxes being used for additional clarity is a benefit if used in a correct and clear manner, but it needs to be specifically stated in the document that the text boxes are to be used for reference only, we will not be required to specifically follow the language in the rationale, and that and each utility should specify their own exact process for addressing each Requirement. ITEM 3: Language should be added to the Guideline and Technical Basis Section to clarify or re-state that this section that this section is for assisting entities in understanding how to comply with the standard but does not contain mandatory actions/activities. ITEM 4: Please clarify defining factors that constitute "wind shear or fresh gale" as referenced in Section 4.4 Other. This is a very unclear interpretation and will most likely be interpreted differently by all involved if not specified.

We believe Active Transmission ROW should be a defined term, not buried in a â€œfootnoteâ€ of the â€œOtherâ€ section of a Standard. It still begs the question â€“ what is an â€œactive transmission facilityâ€? Regarding the substance, overall we believe that the Active Transmission ROW should not include the new reference to Table 3. This newly added sentence in footnote 2, referencing Table 3, is confusing to interpret. If retained, please rephrase to make it clearer that a Transmission Owner never has to increase the size of its easement/land right to satisfy this table. As drafted, our team had various interpretations and it is unclear whether the intent is that a Transmission Owner has to increase its easement or acquire land to meet this requirement, or conversely if the easement is well beyond the values in Table 3, the Transmission Owner has to maintain that the entire easement or only the values in Table 3. â€œActive Transmission Right of Wayâ€ is still used in the first paragraph of the Background section. In total, we suggest that the definition of Activate Transmission ROW return to the version used in the prior draft and be placed in the definition section.
No
Xcel Energy urges the retention of the word "reasonable" as a modifier to "control" in Introduction, Section 4.4. The concept that a Transmission Owner should exercise reasonable control is sensible, and is of some aid in countering claims that any incident could be prevented. For example, in Colorado, the transmission of electricity has been judicially found to be subject to the highest degree of care. Without the inclusion of the word "reasonable," Xcel Energy could possibly be faced with a claim that for the exceptions set forth in Introduction, Section 4.4, to apply, the circumstances would have to be "beyond the control (using the highest degree of care) of Xcel Energy." Retention of "reasonable" helps counter such claims. Since this section appears to lean toward legal language, the use of the term â€œreasonableâ€ is better suited for the goal of this section.
No comments/no position
No
R3 requires the Transmission Owner to have a documented process that shall contain certain items. Please bulletize these items for clarity. Additionally, the measure for this requirement indicates that the process document elements â€˜preventâ€™ encroachment. It is presumed that the elements identified in the requirement are what need to be addressed in order to minimize the likelihood of encroachment. Essentially, M3 should be reworded to state â€œThe procedures, processes, or specifications provided incorporate the elements identified in R3 (dynamics of a transmission line conductorâ€™sâ€¦)
No
What exactly does complete an annual work plan mean? It infers that an annual work plan must be developed/documented and executed. If this is the case, then clearly state as such. In general, R6 & R7 go against the grain of the results based standard concept. R1 already established that the Transmission Owner cannot have encroachment. R3 requires annual inspection (essentially establishing the plan). Why replicate in R6 & R7, it does not seem to serve any useful purpose.
Draft 4 version of R1/R2
Any of the alternate versions would amplify or create issues between land owners and Transmission Owners and are contrary to concepts of Integrated Vegetation Management, in particular, best management practices.
VSLs proposed by the VM SDT
Yes
R1 & R2 states that â€œtypes of encroachments include:â€ â€“ is the way this is worded intended to imply there can be other types of

encroachments that are not listed? If not, then rephrase the leading sentence to be definitive and indicate that the types are the only categories to be considered. We suggest that the wording from the prior draft, i.e., â€œ . . . limited toâ€□. MCVD should be a defined term in the glossary, not in a â€œRationaleâ€□ box. R1 â€œ1â€□ should Real-time be capitalized to reflect the glossary definition? The term is used as â€œreal timeâ€□, â€œReal timeâ€□ and â€œReal Timeâ€□ throughout the standard. This seems to be just a drafting issue, but the same term should be used consistently. Need to establish somewhere that the entity defines what constitutes a â€œqualifiedâ€□ person. Further, some portions of the standard use the term â€œqualified personâ€□ (e.g., see M1) and others reference â€œqualified field personnelâ€□ (e.g., see the Rational Box near M3). It seems that all references should be to â€œqualified field personnel.â€□ R1 & R2 are duplicative. It appears the only reason for the separation is so that different VRFs can be assigned. Why not just have 1 requirement and indicate that the VRF is High for one set of lines and Med for others? In general, the â€œRationaleâ€□ boxes force the requirement language into a difficult to read format. R5/M5 â€“ the measures identified do not constitute â€œcorrective actionsâ€□, they merely identify documentation that work was attempted. Corrective actions should be â€œactionsâ€□, such as establish an increased monitoring plan, re-rating of the line, removal from service, etc. R6 â€“ Xcel Energy still believes the requirement in R6 that mandates an annual inspection is too onerous and is at odds with the results-based approach of these revisions. Xcel Energy urges the retention of the provision in the existing standard that allows the Transmission Owner to set the frequency of inspection. In some areas of the country, annual inspections may not be adequate. Yet in other areas, a longer inspection frequency may be perfectly reasonable and practical. Our point is that inspection frequency should not be treated as if it were â€œone size fits allâ€□. If treated this way, we feel this could pose a risk to reliability and is not likely to be cost-effective. The Transmission Owner should be allowed some flexibility. However, if the drafting team disagrees and determines that an annual inspection is to be mandated, Xcel Energy believes that an exception to the annual inspection is appropriate when a non-subjective advanced technology such as LIDAR is utilized to achieve actual clearance distances. This places the Transmission Owner in a situation where it can rationally determine that the objectively measured distances result in a situation where an inspection need not be performed within the next year. It is suggested that R6 be revised to read as follows: Each Transmission Owner shall perform a Vegetation Inspection of all applicable transmission lines at least once per calendar year, unless the Transmission Owner, based on a non-subjective advanced technology, such as LIDAR, determines that a longer inspection period is appropriate. The Effective Dates section is confusing â€“ exactly when would this standard be in effect? It lists 3 approvalsâ€¦do all three have to be met or just one? The reference to Major WECC transfer paths in the requirements introduces a weak element. The WECC major path designation and elements that comprise those paths should be controlled through a robust process and easily available to WECC members. Currently, there are some concerns around that process in general. NERCâ€™s concerns regarding reporting vegetation related outages within 48 hours should be addressed or clarified in the Compliance section. (i.e., incorporate or indicate that this supersedes that recommendation). Ref: Public Notice - NERC Compliance Process #2008 â€“ 001

No
The footnote definition is ok but Table 3 is poorly developed. The voltage classes should be better segregated (e.g. nominal voltage 69kV, 138kV,

230kV, 287kV, 345kV, 500kV, 765kV) along with distances in feet and metres as Canadian utilities are metric. Also the table should include recommended right of way widths for single circuits. The assumption made in the footnote is that the legal easement is larger than in Table 3. However, as currently defined, some of the distances in Table 3 exceed statutory rights of way at our utility and exceed engineering standards as defined by the Canadian Standards Association â€“ Overhead Systems (CAN/CSA C22.3 No. 1-6). Also, clearances will very much depend on line design (e.g. structure architecture such as flat, Post T, H-frame, steel lattice, and other variables such as ruling span length, conductor type used, etc.) To some degree this will vary quite a bit between utilities. As such Table 3 as currently presented is not workable.
Yes
Yes but there should be more commentary around exceptions. You should get away from certain descriptive terms and be more empirical when you can to avoid ambiguity. For example â€œFresh Galeâ€☐ on the Beaufort Scale is not common as there are several variants to this scale and on some scales is defined as â€œGaleâ€☐. So do you mean winds of 39-46 mph (62-74 kmh) or greater wind speed? If so, why not state that?
No
Overall, the definition of these measures is improved over draft 3. However, the standard should better define who a â€œqualified personâ€☐ is and who has the authority to make attestations. R1 and R2 could be better defined relative to the standard definitions in section 4.2 as to what voltage levels in R2 are part of the standard and what is excluded. That is: R1 is any circuit that is an element of an IROL or WECC transfer path regardless of the transmission voltage. R2 is any circuit >200kV which is not an element of an IROL or WECC transfer path. Lower voltage circuits that do not fit the R1 definition are not part of this standard.
Yes
As a competency requirement, R3 seems to be missing any requirement for a utility to define who is qualified to develop these plans, which is a departure from FAC-003-1 R1.3. I think that the utility should in their standards define who is qualified to develop their transmission vegetation management program
Yes
The requirement as currently worded, seems to assume but does not explicitly state that a utility must prepare and document an annual vegetation work plan and document in some manner any modifications to that work plan as they occur. The work plan change documentation should include any risks of work deferral and mitigation plans to address those risks if there are any.
Draft 4 version of R1/R2
The alternatives above are too prescriptive. A utility should set a preferred maintenance distance (i.e. clearance 1 in FAC-003-1) as routine expectation and outline mitigation strategies as required in areas where clearance 1 distances cannot be met to ensure that MVCD distances are not encroached upon. Given the various line design standards, it is the utility that must define those clearances and margins of error based on engineering standards and the types of vegetation and growth rates present in their operating area.
VSLs proposed by the VM SDT
The NERC staff recommendation is too restrictive and does not seem realistic in an operational sense. We do not agree that the standard should apply to outages from vegetation falling into the conductor from within the active transmission right of way. This normally would not occur except during storm events that would be excluded from this standard. It is operationally difficult to know precisely where the edge of the right of way is in all situations and under all conditions. Further, in clearing some sections to this degree, the utility could end up destabilizing what is

currently a stable, windfirm edge and pose higher security risks to the transmission system from destabilizing the vegetation through excessive clearing. So this gets down to semantics of how a utility might define their active right of way corridor relative to the legal statutory right of way edge. The risk of fall into outages needs to be managed but as currently defined this is too absolute a requirement. Fall-into outage risks need to be mitigated but they have not been a key element of any cascading failure and are hard to prevent. Even if a right of way were cleared sufficiently wide to avoid a fall-into outage, there is always a risk of branches being blown into the conductors from sailing during higher winds (e.g. Douglas-fir branches have excellent airborne gliding abilities). The greatest risk is from grow-into outages or from conductors and vegetation being blown into one another within the active right of way. Therefore, we prefer the VSLs set by the VM standard development team.
Yes
R4 â€“ There will likely be issues of definition over what constitutes an â€œintentional delayâ€□ in notification. The time for reasonable reporting needs to be quantified. The standard references Tables 2 and 3 but there is no Table 1 in the document. This is confusing and should be renumbered. This is likely a carry over from an earlier draft where a Table 1 has been renamed or dropped. As noted earlier in Q1, table 3 is poorly developed and should be revisited. How does one objectively measure compliance to MVCD distances? Use of LiDAR technology, laser rangefinders, etc. should be used and evidence of potential violations should be empirical and not based solely on subjective observations, even if they are performed by â€œqualified personnelâ€□. The technical document should include a glossary of all the acronyms used throughout the document as it has some excessive jargon and does not always read smoothly, especially compared to FAC-003-1. The use of explanation boxes is helpful.

Bonneville Power Administration
Denise Koehn
Yes
This distance is reasonable in the table, but due to widely varying designs of structures it does not give a relationship of the outside wire to edge of ROW. It should be noted as outside wire, phase or conductor to edge of ROW. In addition, the effective date should allow transmission owners time to achieve this distance, perhaps one cycle.
Yes
Yes
Yes
Yes
Alternate version of R1/R2
VSLs proposed by the VM SDT
Yes
The basis of managing vegetation to MVCD in Table 2 (essentially withstand distances) will likely prove problematic. BPA believes NERC should develop an additional table that calls out minimum "buffers" based on attributes such as line voltage, line rating etc. This table should be a companion to Table 2. It is NERC's responsibility to regulate and we believe that they should do so. In this case, the loss of flexibility for the

owners is not necessarily a bad thing.
Group
Arizona Public Service Company
Jana Van Ness, Director Regulatory Compliance
No
These clearances could exceed the permitted ROWâ€™s on federal lands and the utility has no legal right to clear beyond those rights. In some cases the permitted ROW can exceed those distance and federal agencies could not allow you to clear beyond those clearances in this version.
Yes
No
Do not agree with real-time observation. Utility can use technology to determine all rated conditions if a tree related outage occurred.
No
Still lacks detailed information. SDT needs to specify the documentation it is left up to interpretation by the utility.
Yes
Neither version is acceptable ANSI-A300 part 7 should be included here. Having set distances will give federal agencies the ability to minimize a utilities TVMP.
VSLs proposed by NERC staff
Requires a higher degree of accountability as it should be.
Yes
Qualifications needs to be put back in the standard. There needs to be a clearance 1 requirement.
Group
Western Electricity Coordinating Council
Steve Rueckert
Yes
Yes
however the statement of acceptable forms of evidence implies that a dated attestation alone could provide evidence of compliance. An attestation alone would not represent sufficient evidence to support a conclusion of compliance with encroachment limits only of the absence of an outage.
Yes
Yes
annual vegetation management plans must have some flexibility. If the TO has the authority to create the plan they should have the authority to modify the plan. The key point is that changes, particularly delays to planned work would have to be approved. Do not believe â€œdecreases in fundingâ€☐ should be listed as a valid reason for modification of work plan related to a reliability standard. From an enforcement viewpoint, there is ambiguity or perceived ambiguity in â€œprovided they do not put the transmission system at risk of a vegetation encroachment.â€☐ Provided the potential that there may never be a self-report addressing this violation.
Draft 4 version of R1/R2
Draft 4 should be sufficient. If industry believes MVCD is not adequate then the tables for MVCD should be modified to account for sag and sway.

Suggest including in â€œ4.4. Otherâ€☐ a phrase referencing government interference, such as â€œFederal, State or other regulatory interference, including legal or other legislative actions, that prevents performance to comply with this reliability standard.â€☐
No
M1 & M2 bullet: â€œReal-time observation of any MVCD encroachments.â€☐ implies that real-time observation of vegetation encroachment ensures reliable operation the Bulk Electric System. The reliability standard objective states; â€œTo improve the reliability of the electric Transmission system by preventing those vegetation related outages that could lead to Cascading.â€☐ However, real time observation of current operating conditions provides no assurance that vegetation will not lead to outages. BGE recommends removing the language. If an inspector finds vegetation encroaching into the MVCD during a visual inspection he / she should immediately initiate an Immediate Threat Notification. Therefore, this measure has no value.
Yes
Yes
Alternate version of R1/R2
BGE believes R1/R2 should contain language that ensures that vegetation is manage taking into account sag and sway throughout the conductors operating range as the alternate language above outlines. The six options proposed allows the Transmission Owner the flexability needed to manage the active ROW a varity of ways and at the same time ensures the reliable operation the Bulk Electric System with respect to vegetation.
VSLs proposed by the VM SDT
Yes
4.2.4 States that the Standard is not applicable to â€œâ€¦to Facilities â€¦. located inside the fenced area of a switchyard, station or substationâ€☐. This implies that anything within the fenced area of a switchyard, substation or power plant does not fall within the jurisdiction of FAC-003-2. Some fenced in areas could be very large and susceptible to vegetation encroachments issues. Suggest reference to â€œinside the fenceâ€☐ be removed. Disagree with R6. â€“ Inspection Frequency. Very prescriptive. Please consider allowing TOâ€™s to select an annual frequency that best fits their requirements, such as calendar year, every growing season, every non-growing season, etc. BGE currently defines their inspection frequency as annually during the non-growing season, October 1 to May 1. BGE believes inspecting during the dormant season is a best practice due to the ability of the inspector to identify vegetation defects, especially off the ROW, which could be hidden during the growing season due to foliage, canopy cover, etc. Also, if a utility elects to leverage an advance technology, such as LiDAR, it provides the most effective results when LiDAR is utilize during the growing season, therefore allowing the results of the advance technology to enhance the fall to spring inspection cycle. Table 1 â€“ Time Horizons, Violation Risk Factors, and Violation Severity Levels The VSLâ€™s for R7 all include â€œthe Transmission Owner failed

to completeâ€¦..% of its annual work plan (including modifications if any)â€☐. This is not clear to BGE. R7. allows plans to be modified due to changing conditions, for example ROW maintenance could be deferred to the following year due to mutual assistance agreements if the deferment does not violate the encroachment within the MVCD. The VSL implies this is a violation since the â€œmodificationâ€☐ deferred a certain percentage of the planned worked to the following year, therefore 100% of the planned worked wasnâ€™t completed. If the modification was excluded, than 100% of the planned work would have been completed.

The use of a minimum distance from the centerline of the circuit or structure is an incorrect measure to use for a set clearance distance of the active transmission right-of-way. Consideration should be given for the type of construction as different construction types (H-Frame, Lattice towers, Monopole delta or vertical construction) will require different widths of a cleared right-of-way to provide the necessary openings for these circuits. A minimum distance for 345-kV is now set at 150 feet based on the minimum distances from centerline. This may be correct for certain H-Frame and Lattice Tower configurations but it is excessive for monopole situations. A single pole configuration with vertically aligned conductors does not need this full 150 foot width. It is strongly recommended that a minimum distance from conductor be used in place of a set distance from centerline. As long as there is at least 30 - 40 feet of clearance in the right-of-way from the outermost conductors (adjusted to account for maximum sway at mid-span for longer spans), then this is the distance that should be used to develop the right-of-way widths. For example, a monopole structure with vertically aligned conductors would result in a cleared active right-of-way width of only 80 feet (40 feet from conductor to edge of cleared active right-of-way) using the minimum distances from the conductors. There is no need to extend this distance another 35 feet (on each side) in order to obtain the full 150 foot width. This requirement is excessive and must be adjusted to account for line construction variations. Instead of using the term "Centerline" as referenced on Table 3, the use of "outer phase" or "phase closest to tree line" would be more appropriate.
Yes
Yes
Yes
Yes
Alternate version of R1/R2
Option E above is preferred as it allows for variations based on differences in conductor heights, topography and other situations where a set height is not necessarily required in all instances and allows for the utility to determine the maximum heights of vegetation without performing detailed calculations of what the maximum heights must be along the various distances within each conductor span. If the utility is tasked with managing the vegetation to ensure no encroachments into the MVCD then it should be up to the individual utility how best to determine its management strategies that incorporate the determination of maximum vegetation heights in each section on its system.

We have concern with the â€œMinimum Distancesâ€☐ as listed in Table 3. What analytical methodology, criteria and rationale was utilized to determine each recommended distance? In addition, we have concerns regarding the change to a pre-determined distance. This seems to be a major shift from the vegetation to conductor methodology employed previously and throughout this standard? NERC/FERC must recognize that while protecting and securing grid reliability, each utility must also balance the environmental, political, customer and economic issues and impacts which will occur with the implementation of the Table 3 clearances. We question whether this is the most responsible action to take given the current state of the economy as well as the environmental and political sensitivity impacts which will result. Tampa Electric questions whether Table 3 will improve System reliability. Since the inception of standard FAC-003-1 Tampa Electric has not had a Category 1 or Category 2 outage on our 230kV Transmission System. We donâ€™t believe that the changes proposed to table 3 will improve overall service reliability. It is Tampa Electricâ€™s opinion that each utility should define the width of its own Active Transmission line ROW. However, if such a table is to be utilized, Tampa Electric recommends the following changes or adjustments to Table 3. 1. Expand the table to account for the various types of Transmission construction; i.e. vertical versus horizontal conductor configurations. 2. Use a distance from the outermost conductor, not the centerline. This will account for construction type and better achieve a consistent clearance from conductors. 3. We recommend reducing the distances in Table 3 by 12.5 feet for each voltage category. 4. Specify whether the voltage is based upon the design or operating voltage. 5. Reformat the voltage ranges to 100kV - 200kV, 200kV â€“ 300kV, 300kV â€“ 400kV, etc. as an example; this would create a more appropriate range of voltages and clearance distances. The reformatted voltage ranges eliminate confusion. For example, under the current proposal it is unclear in which category a nominal 230kV line should be since sometimes such a line can operate at up to 232kV during low-load conditions.
Yes
These changes add improved clarity and defintion to this section.
Yes
These changes allow for qualified review of field findings.
Yes
This better clarifies section R3
Yes
These changes add greater clarity, as well as real world examples, to this standard.
Draft 4 version of R1/R2
Quite frankly, the alternatives listed above, or for that matter any other vegetation managment options, should be establised by the utility. The goals in R1 & R2 are very clear. The alternatives listed above will create a double or triple standard of vegetation clearance for each different type of Transmission construction.
VSLs proposed by the VM SDT
Tampa Electric agrees with the SDT statement â€¦ â€œFor example, not all encroachments lead to Sustained Outages.â€☐ As such, we agree, a lower level of VSL is appropriate. Tampa Electric also agrees with this statement â€œ Moreover, there is an operational differentiation between a fall-in, blow-together or grow-in event. â€œ Recommend the team

examine the analytical rational for the following statements so as to better explain and clarify this issue to NERC. â€œA fall-in has never been known to cause a cascading outage. Therefore the team feels that a Lower VSL is appropriate. A blowing-together-caused fault is somewhat more egregious than a fall-in, as it has the potential for re-occurring and is therefore assigned a Higher VSL.â€☐

Silvia Parada Mitchell
No
Although there is support for making Active Transmission Line Right of Way a clearly defined term, and the foundation for compliance with FAC-003-2, the distances in the table are arbitrary and are not supported by any scientific or engineering analysis. It is possible that such a table could be interpreted to define the minimum width of future lines. Different construction configurations require different ROW widths.
Yes
No
The measure is adding to the requirement. The measure should define how a requirement is met and not interpret or add to the requirement, otherwise this will add to confusion, instead of clarity, which should be the goal of any revised reliability Standard. Also, the measure implies that a fault investigation must be done. As written, momentary outages are included, and a fault investigation should not be required for momentary outage. It also places the same weight of violation on a momentary outage as it does a Sustained outage, which appears on its face not to appropriate nor necessary to meet the goal of FAC-003-2. In addition, an outage investigation is not a finite process that produces identical homogenous results every time. Of particular concern is the possibility that should a Transmission Owner have one or more momentary outages and not find the cause, then later have another outage (Sustained or Momentary), such a finding appears to lead to a multiple violation. This is inconsistent with focusing requirements on reliability risks to the bulk electric system.
Yes
Yes
Draft 4 version of R1/R2
The alternative is a fill in the blanks requirement.
VSLs proposed by NERC staff
Again the drafting team is trying to control the terms of a requirement by using the compliance elements. FPL agrees there is a direct link between vegetation growing in to conductors from below has a direct correlation to cascading events and fall-in and blow-in outages are no more incidental than a cross arm failure to a cascading event. These components should be handled in the requirements and not in the compliance element.
Yes
R5 as written is vague. It leads to confusion in interpretation. FPL recommends the following wording. R5. The Transmission Owner shall certify each corridor or line section that it meets the standards it set forth under R3 until the next planned management cycle when it is completed. If a location in known to not meet the criteria defined under R3, a mitigation plan must be in place to prevent a violation of R1 or R2. R1 and R2 are too inclusive. They equate vegetation growing in to conductors from below the same as vegetation falling or blowing into the conductors

from within the Active ROW. There is no evidence that a cascading event has ever been caused by the latter two events. This standard should concentrate on vegetation growing from below the conductor. Suggested wording of R1 and R2 is as follows. R1. Each Transmission Owner shall manage vegetation to prevent encroachment into the Minimum Vegetation Clearance Distance (MVCD) as shown in Table 2 from within the active ROW on of any line identified as an element of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions). Encroachments are determined by: 1. An encroachment, observed in real time, 4. An encroachment due to a grow-in from below the conductor in the active ROW that caused a Fault. R1. Each Transmission Owner shall manage vegetation to prevent encroachment into the Minimum Vegetation Clearance Distance (MVCD) as shown in Table 2 from within the active ROW on of any line that is not an element of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions). Encroachments are determined by: 1. An encroachment, observed in real time, 4. An encroachment due to a grow-in from below the conductor in the active ROW that caused a Fault.

Depending on the intent this may create a problem. We are concerned the addition of Table 3 could be interpreted to mean something completely different than what we believe to be its intention. Please consider alternate wording to Footnote 2: A strip or corridor of land that is occupied by active transmission facilities. This corridor does not include the parts of the Right-of-Way that are unused or intended for other facilities. However, the active transmission line ROW cleared width it is not to be less than the width of the easement itself unless the easement exceeds distances as shown in Table 3 for various voltage classes. If the SDT determines keeping Table 3 is the appropriate course of action, we recommend clarifying its intent better; either in a footnote or in the title. Adding a footnote stating the Table is not applicable if the distance from the center line of the conductor to the right-of-way edge is less than the appropriate distance indicated in the table. Another option might be to add a statement to the title such as, â€œIf the distance from the centerline of the circuit to the edge of the easement is less than the values in Table 3, that distance is considered active ROWâ€☐.
Yes
Yes

Yes
While voting yes we are concerned about the interpretation of the expanded verbiage, how much documentation will be enough.
No
The first sentence of the Requirement 7 Rationale conflicts with the second sentence. The R7 Rationale should be reworded as follows: "This requirement sets the expectation that the work identified in the annual work plan should be completed as planned. However, an annual vegetation work plan must allow for work to be modified in response to changing conditions. These modifications must take into consideration the anticipated growth of vegetation and all other environmental factors, provided that the changes do not cause a vegetation encroachment within the MVCD."
Draft 4 version of R1/R2
We feel the alternative language is too confusing. Does a utility choose one option from the list and expect it to cover all situations, or can the utility pick one option from the list and apply that option to one span, and then another option for the next span. The proposed alternate verbiage makes no distinction as to when options can or cannot be utilized. The language in Draft 4 seems to cover the various scenarios a utility will face in its vegetation management program while giving the utility the flexibility necessary to address these situations in an appropriate manner.
VSLs proposed by the VM SDT
We support the SDT version of the VSLs. The version proposed by staff does not recognize the objective of FAC-003-2 which clearly states, â€œTo improve the reliability of the electric Transmission system by preventing those outages that could lead to Cascading.â€☐ If a fall-in occurs in an afternoon thunder storm and investigation reveals the tree was on the right-of-way by one or two feet, staffs VSLs would treat this outage with the same severity as an outage where a fully loaded line in a heat wave sagged into unmaintained brush growing directly beneath the conductor. The first case would rarely, if ever, lead to cascading. The second case could easily lead to cascading. Staffâ€™s VSLs seem to indicate a desire to â€œgold plateâ€™ the system to insure 100% reliability, which will never be achieved absent of unlimited resources and with total disregard to cost.
Yes
The NERC Glossary of Terms provides a definition for Flashover. The Rationale boxes for R1 and R2 use the term â€œspark-overâ€☐. This is inconsistent with other references in the Standard. Note that the term Flashover is used in footnote No.4. Please resolve the inconsistency between these terms. We are concerned FAC-003-2 is being developed under a zero tolerance philosophy, while other NERC standards do not adopt a zero tolerance philosophy. Industry performance under FAC-003-1 indicates the standard is working and that industry is responding to ensure reliability of the electric Transmission system. We would like to thank the SDT for the work they have put into developing the proposed draft.

Yes
However, due to different design attributes of transmission lines, it may be better to change the distance in Table 3 from a centerline distance to a â€œMinimum Full Active Transmission Line ROW Width Distanceâ€☐.
Yes
No
The last sentence of this modification could be misinterpreted by a compliance representative to imply that all Faults must be investigated to eliminate or confirm vegetation as the cause of the fault. There are several

sources (e.g. lightning, wind-blown debris) of Faults and several appropriate operational responses, some of which may not include field investigations, depending on the circumstances surrounding each Fault. Thus, the current wording is gray and should be modified to aid industryâ€™s understanding and thus to ensure compliance. The interpretation we suggest may not be obvious, but our experience with previous interpretations of certain facets of FAC-003-01 would indicate the need to better define the expectation. A potential modification to the last sentence of M1/M2 could be: If a later confirmation of a Fault by a qualified person shows that a vegetation encroachment within the MVCD has occurred, this shall be considered the equivalent of a Real-time observation.

Draft 4 version of R1/R2
ATC feels that Draft 4 Version of R1/R2 is the preferred version. The Alternate version is too prescriptive and has little flexability.
VSLs proposed by the VM SDT
ATC believes the VSLs proposed by the VM SDT best supports the NERCâ€™s VSL Criteria. The NERC Staff VSLs do not allow for Lower or Moderate VSLs which recognizes significant value as nearly meeting the intent of the requirement. Furthermore, it does not allow for encroachment where absent a sustained outage. Every encroachment in real time would not go directly to a â€œHighâ€☐ VSL where performance has limited value.
Yes
1.) Rationale boxes associated with R1, R2 and R3 within the standard include reference Tables and Figures in the â€œGuidelines and Technical Basisâ€☐ without specifying where they are located. ATC recommends inserting this information as applicable. 2.) ATC raises a previous draft concern on including Rationale Boxes plus Guidelines and Technical Basis as part of the NERC Reliability Standard. ATC recommends that the SDT either remove these sections or make them separate from the formal standard to eliminate any risk that these may be construed as requirements. An alternative method is to very clearly identify which parts

of the standard are subject to compliance and considered mandatory and which are not considered requirements and are only for guidance in meeting the requirements. 3.) ATC believes the Measurements are well written and provide guidance on acceptable compliance evidence related to the requirement. 4.) Measurement M2 related to R2 states that outages related to encroachments have records confirming no Real-Time observations of any MVCD encroachments. ATC feels this would be hard to prove as a negative. It could require one to show every single patrol or inspection has documentation stating no real time encroachments were observed. 5.) Editorial Comment on Draft SDT VSLs for R2: To clarify the statements made for the Moderate, High and Severe VSLs. please add the verbiage, â€œinto the MVCDâ€☐ after â€œThe TO had an encroachmentâ€¦â€¦.â€☐

A DC table for Table 3 similar to the MVCD table should be added. There should be a statement in Table 3 that is consistent with footnote number 2 stating that the minimum width of the Active Transmission Line ROW is either the full width of the easement or, if the easement is wider than the distances in Table 3, the minimum distances must not be less than the distances shown in the Table. The use of a minimum distance from the centerline of the circuit or structure is an incorrect measure to use for a set clearance distance of the active transmission right-of-way. The description does not take into account vertical versus horizontal design configuration. Consideration should be given for the type of construction as different construction types (H-Frame, Lat-tice towers, Monopole delta or vertical construction) will require different widths of a cleared right-of-way to provide the necessary openings for these circuits. A minimum distance for 345-kV is now set at 150 feet based on the minimum distances from centerline. This may be correct for certain H-Frame and Lattice Tower configurations but it is excessive for monopole situations. A single pole configuration with vertically aligned conductors does not need this full 150 foot width. It is strongly recommended that a minimum distance from conductor be used in place of a set distance from centerline. As long as there is at least 30 - 40 feet of clearance in the right-of-way from the outermost conductors (adjusted to account for maximum sway at mid-span for longer spans), then this is the distance that should be used to develop the right-of-way widths. For example, a monopole structure with vertically aligned conductors would result in a cleared active right-of-way width of only 80 feet (40 feet from conductor to edge of cleared active right-of-way) using the minimum distances from the conductors. There is no need to extend this distance another 35 feet (on each side) in order to obtain the full 150 foot width. This requirement is excessive and must be adjusted to account for line construction variations. Instead of using the term "Centerline" as referenced on Table 3, the use of "outer phase" or "phase closest to tree line" would be more appropriate. There is published literature using the term â€œcleared widthâ€☐ to indicate the distance from the outer phase to the tree line. This distance should be used in the Active ROW definition. The word easement is also used in the definition. Is there a reason the Active ROW only includes easements, not fee ownership, license or some other right to occupy and manage the ROW? Would Active ROW include â€œdanger tree rightsâ€☐ on land? These questions need to be addressed in the standard (in text) and technical reference document (in graphics).
Yes
No
A clarification for M1 is needed regarding whether entities will have to attest to the fact that there has never been an encroachment in the MVCD.

Yes
Yes
Alternate version of R1/R2
Alternate Version E would allow a Transmission Owner to use an approach consistent with the current version of FAC-003 by defining a minimum clearance distance and a vegetation management clearance distance. This approach has met the objectives of FAC-003 since 2006. Use of version E would change the standard from a prescriptive approach to a Transmission Owner defined approach. In addition, Alternate Version E is preferred as it allows for variations based on differences in conductor heights, topography and other situations where a set height is not necessarily required in all instances and allows for the utility to determine the maximum heights of vegetation without performing detailed calculations of what the maximum heights must be along the various distances within each conductor span. If the utility is tasked with managing the vegetation to ensure no encroachments into the MVCD then it should be up to the individual utility how best to determine its management strategies that incorporate the determination of maximum vegetation heights in each section on its system.
VSLs proposed by the VM SDT
The wording in the VM STD VSLs should be modified to include whether or not the TO managed any vegetation on that particular line. A more severe VSL should be assigned to any encroachment or sustained outage that was caused as a result of a TO not performing any vegetation management activities on that line. For example, if vegetation management activities were completed on 80% or 90% of the line and additional work was in progress on the remainder of the line, but an encroachment or sustained outage occurred on the spans that were scheduled to be done as part of the annual plan, the TO should be held accountable for this but at a lower severity level.
Yes
Hydro One wants to thank the SDT for the effort that has gone into developing this proposed revision to FAC-003. Overall the new version is consistent with FERC Order 693 and will be a straightforward, workable, and auditable standard. One item requiring clarification and change is the Active ROW definition. The recent addition of a centerline distance to edge of Active ROW is not acceptable. In many areas design standards allow a smaller ROW width with no compromise to â€œcleared widthâ€☐ or tree related reliability of the line. The SDT needs to address this issue. In R5, the phrase 'where a transmission line is put at potential risk due to the constraint' should be better defined. This is vague and could lead to inconsistent practices between utilities. All undesirable species on the full width of the ROW are defined as 'potential risks to the transmission line' regardless of height or location at the time of vegetation management. Interim corrective action should only be required when the potential risk is approaching the imminent threat classification.

MROâ€™s NERC Standards Review Subcommittee (nsrs)
Joseph DePoorter
Yes
The NSRS agrees in whole to the question but has the SDT taken into consideration the difference in ROW may be different in Urban and Rural settings?
Yes
The NSRS believes that the new definition provides greater clarity with respect what does not constitute a compliance violation versus the previous version.
Yes
No
The NSRS does not believe that the new specificity that has been added to R3 will improve the reliability of the BES. It is our opinion that the requirement would have been clearer if it had ended after the first

sentence. The additional language after the first sentence does not improve clarity. The whole (as written) requirement may be interpreted as a requirement for â€œeach spanâ€ of Transmission line that the Requirement will be applied to. In measures for other requirements the SDT has done a very good job of stating and clarifying (in their opinion) what acceptable forms of evidence are. M3 would benefit from this type of clarification.
Yes
The NSRS has issue with the word â€œmayâ€ (and its components along with the associated bulleted points) and recommends that it is removed and placed in the rational box.
Draft 4 version of R1/R2
It is the NSRSâ€™s opinion that that the requirement as currently written in version 4 is consistent with the intent of a standard; i.e. stating what is required as opposed to stating how to achieve what is required.
VSLs proposed by the VM SDT
Yes
1.) The NSRS notices that a previous draft concern on including Rationale Boxes plus Guidelines and Technical Basis as part of the NERC Reliability Standard. The NSRS recommends that the SDT either remove these sections or make them separate from the formal standard to eliminate any risk that these may be construed as requirements. An alternative method is to very clearly identify which parts of the standard are subject to compliance and considered mandatory and which are not considered requirements and are only for guidance in meeting the requirements. Such as; State within in the text that this information â€œIs not subject to enforcementâ€. 2.) The NSRS believes the Measurements are well written and provide guidance on acceptable compliance evidence related to the requirement. 3.) Measurement M2 related to R2 states that outages related to encroachments have records confirming no Real-Time observations of any MVCD encroachments. The NSRS feels this would be hard to prove as a negative. It could require one to show every single patrol or inspection has documentation stating no real time encroachments were observed. 4.) Editorial Comment on Draft SDT VSLs for R2: To clarify the statements made for the Moderate, High and Severe VSLs. please add the verbiage, â€œinto the MVCDâ€ after â€œThe TO had an encroachmentâ€¦â€¦.â€

Yes
No
- Need to specify who qualifies as â€œqualified personnelâ€ to observe the vegetation condition.
No
- We suggest to eliminate / change the word â€œdynamicsâ€ because can create confusion with regards to the extent of documentation that has to be prepared. - Requirement should clearly state the criteria as in the maximum design (rating) or maximum operating conditions
Alternate version of R1/R2
- E) seem more appropriate. The alternate R1/R2 standard requirements

shall reduce the number of possibilities and simplify the criteria towards the design / operating conditions and additional standards ought to be considered in concert with current standard.
Criteria will be probably best represented by a mix of the two VSLs as follows: - Keep the Lower and Moderate VSLs from SDT with both absent Sustained Outage. Add the fall-in as specific encroachment to the Lower VSL and grow-in as specific encroachment to the Moderate VSL - Keep the High / Severe VSLs from NERC
Yes
- Effective Dates. Clarify effective dates in paragraphs 2 and 3. This should only be applicable to Canada as Standard are not mandatory and enforceable in the US unless further approved by FERC. - Exceptions. Regional Differences must be approved just like NERC Standards, further explanation is required of these exceptions to garner a better understanding of the intent - Background. The paragraph exemplifying as a localized customer service may get disrupted if vegetation will make contact with a 69kV line is not appropriate for the standard while it is given that this applies to the BES 200kV and above. - Requirement R2. The paragraph â€œ[â€¦] Sustained Outage of applicable lines that are not elements [â€¦]â€☐ should state the voltage threshold of 200kV and above - Requirement R4. Who qualifies as â€œqualified personnelâ€☐ to observe the vegetation condition? Need clarification. - Requirement R5. Rationale. Corrective action guidance should be provided within the Requirement. Set the examples for the Guidelines section. - Guidelines and Technical Basis. oRequirement R1 and R2. The example meant to prove the point of â€œline conductor intentionally or inadvertently operated beyond its ratingâ€☐ is contradicting the guideline. The emergency actions should not violate any standards and should not cause an outage. If such thing happens, the vegetation related outages should be in violation of the requirements. oRequirement R3. How is every possible combination of wind speed, loading and conductor properties going to be addressed? Should a national standard be referenced as a minimum requirement? More guidance should be provided. oRequirement R5. Wouldn't a violation have occurred with the encroachment of the vegetation per R2? The potential to put the transmission system at risk is not well defined and could be interpreted as encroachment into the area defined by the appropriate table(s). Need clarification. oRequirement R7. Regarding the statement â€œIt is only intended to require that the Transmission Owner provide evidence of annual planning and execution of a vegetation management maintenance approach which successfully prevents encroachment of vegetation into the MVCDâ€☐ if no identifier is utilized how will compliance be gauged? By encroachment? By outage? Need clarification. oRequirement R7. Regarding the evidence of annual work plan execution, when would the change in plan need to be documented? Has this moved away from requiring the documentation of plan change at the time of occurrence? Need clarification.

Consumers Energy Company
No
Table 3 does not adequately address ROW width requirements based on the type of construction used for structures, especially for the two lower voltage classes, 69-138kV and 139-230 kV. Lines constructed on H-Frame structures have a much wider footprint across the ROW than do single pole construction and most steel tower construction types. The minimum ROW width listed in Table 3 for a 138 kV line constructed on a wooden H-Frame may put the outside conductor within MVCD under windy conditions due to wind displacement of conductors and trees. Consumers Energy recommends that Table 3 be modified to describe the minimum distance in the table is the vertical plane of the outside conductor to the edge of the active transmission ROW and therefore independent of the width of the structure construction type.
Yes
No
None of the three examples of acceptable forms of evidence provided in the revision prove that a Transmission Owner actively managed vegetation to prevent encroachment into the MVCD. The Measure should require proof of active ROW clearing activity per the transmission vegetation management plan, such as invoicing or crew field reports or vegetation inspection data from the annual vegetation inspection.
No
This really is another attempt at avoiding defining a minimum clearance specification and is not practical. As written, this would require each Transmission Owner to define and document the procedures, processes or specification by individual span for every line owned or operated by the Transmission Owner. Each span varies in length and profile and a single line may have several different conductor types with different load ratings. Line loadings will vary along the line based on substation taps, etc. The dynamics described in the language could only be done on an individual span basis to be reasonably accurate. This is not practical from a planning standpoint or from a standpoint of implementing clearing work in the field.

CenterPoint Energy
No
There is no rationale provided for the â€œminimum distancesâ€☐ stated in Table 3, and they far exceed the ROW widths that CenterPoint Energy owns (typical total 100â€™ ROW width for 2-ckt 345kV line) for its current 345kV system, and as such, are open for misapplication and misinterpretation as an intended minimum standard for making a fall-in determination for R1 and R2 outside the legal limits of the utility. Table 3 should be deleted. If kept, there should be sufficient rationale included within the Guidelines and Technical Basis to explain how it was derived and how it is to be used within the Standard. CenterPoint Energy agrees with the removal of â€œactive transmission line ROWâ€☐ as a defined term; however, the footnote should be deleted as well since it attempts to create a definition which is not accurate, necessary or useful. Throughout the Standard, the phrase â€œactive transmission line ROWâ€☐ should be replaced with â€œtransmission line ROWâ€☐ to eliminate the qualifying term â€œactiveâ€☐. In making a fall-in determination for R1 and R2, the limit should be â€œwithin the full extent of the Transmission Ownerâ€™s transmission ROW as defined by easement, fee simple, or other legal rightsâ€☐ as discussed in the Guidelines and Technical Basis regarding the vegetation management maintenance approach. This places the determination of the width of the ROW for determination of fall-in violations clearly on the Transmission Owner and the within the limits of its legal rights to control the vegetation that has fallen into the line under R1 and R2.
Yes
No preference.
No
CenterPoint Energy does not believe a performance based requirement should require evidence of processes and procedures to demonstrate compliance. However, if the majority of industry commenters agree with the SDTâ€™s approach, CenterPoint Energy has several concerns.

Assuming R1.1 and R2.1 regarding observations of encroachments are not deleted from the Standard, then only the first paragraph regarding forms of evidence is helpful and necessary. The second paragraph is not relevant or necessary. The special qualification of Sustained Outage should be contained in R1 and R2, not M1 and M2. Also, the reference to a â€œFaultâ€□ in M1 and M2 instead of a â€œSustained Outageâ€□ changes the scope of what is specified in R1 and R2 which is not reasonable. A â€œFaultâ€□ can be associated with a Momentary Outage or a Sustained Outage. The scope of R1 and R2 is specific to Sustained Outages.
No
See response to Q3 above. However, assuming R3 is not revised to exclude processes and procedures, we have no preference to the wording between the two drafts.
No
See response to Q3 above. However, assuming R7 is not revised to exclude processes and procedures, the new wording is preferred since it is more specific. Additionally, a new ambiguous phrase is introduced, â€œprovided they do not put the transmission system at risk of a vegetation encroachmentâ€□, which we recommend to be changed to more specific wording, â€œprovided they do not allow encroachment of vegetation into the MVCDâ€□.
Draft 4 version of R1/R2
CenterPoint Energy does not believe a performance based requirement should be this prescriptive. However, if the majority of industry commenters agree with the SDTâ€™s approach, CenterPoint Energy has several concerns. The terminology, â€œoperating within Rating and Rated Electrical Operating Conditionsâ€□ is sufficiently definitive. There is no need to be more prescriptive. Alternate R1/R2 (E) is already similar to the Draft 4 wording. Of the two alternative, we recommend keeping the Draft 4 wording as is; however, we recommend moving the applicability of transmission line ratings to the Applicability section of the Standard as â€œ4.5 Other: The Standard does not apply to any occurrence, non-occurrence, or other set of circumstances that are beyond the Rating and Rated Electrical Operating Conditions of the Facilities defined in 4.2.â€□ These conditions should be applicable to all elements and requirements of the Standard just as the force majeure statement does.
Neither. However, we recommend that High or Severe violations be based only on Sustained Outages experienced and the reliability importance of the transmission line. Any process or procedure based requirement, if kept within the Standard, should have a Lower or Moderate designation based on the utilities intent or capability to comply with the Requirement.
Yes
1. CenterPoint Energy believes the proposed FAC-003-2 is not a performance-based standard, despite being labeled as such, because it remains too focused on processes and procedures. CenterPoint Energy fails to see much difference in the approach from the current Standard. CenterPoint Energy believes a performance based requirement would provide performance criteria that an entity would be measured against. An example of a performance based requirement would be the following: R1. â€œEach Transmission Owner shall manage vegetation to prevent encroachment that results in no more than one (1) Sustained Outage per XXX circuit miles of applicable lines within any twelve (12) month period.â€□ M1. Each Transmission Owner has evidence that it had in no more than one (1) Sustained Outage per XXX circuit miles of applicable lines within any twelve (12) month period. Examples of acceptable forms of evidence may include dated reports of vegetation-related Sustained Outages or dated attestations as to no vegetation-related Sustained Outages have occurred. However, if the majority of industry commenters agree with the SDTâ€™s approach, CenterPoint Energy has the following additional concerns: 2. The phrases â€œactive transmission line ROWâ€□

and â€œActive Transmission Line ROWâ€☐ are no longer considered defined terms and should be deleted from the Standard along with footnote 2, the Compliance Section for Periodic Data Submittal as well as the Guidelines and Technical Basis. As found throughout the Standard, the phrase should be replaced with the common terms utilized in the Guidelines and Technical Basis section, â€œTransmission Ownerâ€™s transmission ROW as defined by easement, fee simple, or other legal rightsâ€☐. 3. In the Background section fall-ins are characterized as â€œstatistically intermittentâ€☐ and â€œthese types of events are highly unlikely to cause large-scale grid failuresâ€☐. We agree and therefore recommend that fall-ins be excluded from the Requirements R1, R2, and Periodic Data Submittal of outages. 4. R4 should be deleted. R4 is related to processes and procedures and should be combined into R3. The result of not following the notification process or procedure is that a Sustained Outage may occur that would be captured by M1 and M2. The process and procedure would be measured by M3. 5. R5 and M5 contain the ambiguous phrase, â€œwhere a transmission line is put at risk due to the constraintâ€☐. This phrase should be replaced with the more specific terminology in R1 and R2 as, â€œwhere a transmission line cannot perform within its Rating and Rated Electrical Operating Conditions due to the constraintâ€☐ or as in R3 as â€œwhere a transmission line will be subjected to an encroachment into the MVCD due to the constraintâ€☐. 6. For R6, the detailed rationale and studies used for the determination of the required one year inspection cycle should be included in the Guidelines and Technical Basis. The explanation provided in the Rationale that it is â€œbased upon average growth rates across North America and on common utility practiceâ€☐ are unfounded and arbitrary without a specific reference to a North American study. 7. R7 contains the ambiguous phrase, â€œprovided they do not put the transmission system at risk of a vegetation encroachmentâ€☐. This phrase should be replaced with the more specific terminology in the Rationale for R7 and Requirement R3 as â€œprovided they do not allow encroachment of vegetation into the MVCD.â€☐ 8. Just as the force majeure statement was moved to the Applicability section of the Standard, the exception for applicability beyond the Rating and Rated Electrical Operating Conditions should be included in the Applicability section as well. Currently, it is only included in R1, R2, and R3. It should be made clear that the other Requirements and Measurements ARE NOT applicable in situations beyond the Rating and Rated Electrical Operating Conditions. This is already discussed in the Guidelines and Technical Basis but not evident within the Standard. 9. The Periodic Data Submittal should be clarified to as to the specific conditions under which Sustained Outages are reported. The Applicability section includes the force majeure; however, other exclusions are not so evident. We recommend the wording be changed to include all applicable exclusions for added clarity. We recommend the following wording: â€œThe Transmission Owner will submit a quarterly report to its Regional Entity, or Regional Entityâ€™s designee, identifying the Sustained Outages caused by vegetation, as defined in the categories below, of transmission lines operating within Rating and Rated Operating Conditions as determined by the Transmission Owner, exclusive of the force majeure conditions in Section 4.4, that include, as a minimum, the following.â€☐ Also, the within the Categories listed, the phrases â€œactive transmission line ROWâ€☐ should be deleted and replaced with â€œTransmission Ownerâ€™s transmission ROW as defined by easement, fee simple, or other legal rightsâ€☐. This places the determination of the width of the ROW for determination of fall-in violations clearly on the Transmission Owner and the within the limits of its legal rights to control the vegetation that has fallen into the line under R1 and R2 causing the submittal of a reportable sustained outage. 10. The Guidelines and Technical Basis and the Technical Reference with the Gallet Equation should be combined into one document as a supplement to the Standard to avoid duplication in wording and misinterpretation of context. 11. We agree that the Rationale

test boxes should be deleted from the Standard and applicable explanatory text be included within the Guidelines and Technical Basis. 12. The Guidelines and Technical Basis should include the background and basis for 4.2.4 that excludes the Standard from applying to fenced substations. 13. The Guidelines and Technical Basis should contain more specific examples of violations of the Requirements and highlight specific exceptions related to vegetation related outages, especially fall-ins and force majeure exclusions. 14. The language in R6 refers to inspecting â€œtransmission linesâ€☐ and Table 1 for R6 refers to inspecting â€œROWâ€☐. Both areas should use consistent terminology. 15. In the Guidelines and Technical Basis section for R6, the reference to the VSL calculation units and the example units should be consistentâ€"the example should use â€œcircuit milesâ€☐, not just â€œmilesâ€☐. 16. In general, the proposed FAC-003-2 has gone FAR beyond what was contemplated by the Commission in FERC Order 693 and equates to a total re-writing of the Standard for no apparent reason. The Commission's determination dealt with the following areas: (1) applicability; (2) inspection cycles; and (3) minimum clearances on National Forest Service lands. For instance in Paragraph 729, the Commission states, â€œAs proposed in the NOPR, the Commission approves Reliability Standard FAC-003-1 with no proposed modification on the issue of clearances. The Commission reaffirms its interpretation that FAC-003-1 requires sufficient clearances to prevent outages due to vegetation management practices under all applicable conditionsâ€¦.â€☐ Rewriting the minimum clearances introduced a new set of confusing definitions, and further burdens the Transmission Owners with new documentation requirements with little if any benefit when compared to the Clearance 2 concept in the existing Standard. A preferred approach should be to incorporate the following few items into the existing Standard FAC-003-1: (1) the RC versus the RRO; (2) the designation of a specific inspection frequency; (3) the Gallet equation; and (4) the applicability to National Forest Service lands.

E Hahn
MWDSC
Yes
Requirement R4.uses the phrase "notify the control center holding switching authority for the associated transmission line" when a vegetation condition is confirmed which is likely to cause a Fault. Switching jurisdiction may be assigned to a manned substation located closer to a line rather than a remote 24/7 manned control center. However, the switching substation will notify its control center. The control center may need to notify and coordinate with its Balancing Authority or neighboring control centers. Suggest changing the phrase as follows: "notify the appropriate control center(s)for the associated transmission line"
Group
FirstEnergy
Sam Ciccone
No
We do not support replacement of the term Active Transmission Line Right of Way with Footnote #2. Since the term "active transmission line ROW" is used in the requirements, compliance section, and VSLs, and since the drafting team has a very definite view of what this term means, the term

should be a definition included in the NERC Glossary. Also, since ROW is defined in the NERC Glossary, it further supports the reasons this term should also be defined. Therefore, we suggest the team revert back to the Draft 3 proposed NERC Glossary term. Lastly, we do not support the addition of Table 3. We believe this adds unnecessary prescriptiveness to the requirements. It is also not clear if this Table was intended to be mandatory because the only reference in the table is in Footnote #2. If the SDT feels this table is a useful tool that should be included in the standard, then we suggest adding it to the Guidelines section as optional information. Also, reference to this Table 3 in the Active Transmission Line ROW definition should be removed.
Yes
While we agree with the changes proposed, we would recommend that the list contained in the "Other" section should be revised to include judicial actions such as injunctions. While this is not a natural occurring situation, it is certainly one that will prevent an entity from removing vegetation when needed or desired.
Yes
Although we agree with the language of M1 and M2 for the proposed R1 and R2 in the standard being balloted, we support the alternate versions of R1 and R2 (see comments in Question 6) and wish to see M1 and M2 developed for the alternate R1 and R2.
Yes
Yes
Alternate version of R1/R2
Although we agree with the alternate version of R1/R2, we have the following comments: 1. We assume that R1 and R2 will be written similar to the current proposal with regard to IROL (High VRF) and non-IROL (Medium VRF) transmission lines, respectively. This should be clear after changes have been made to the standard before the final ballot. 2. Although the SDT states that it "suggests similar language as found in the posted draft for measures M1/M2 may be appropriate with this alternate R1/R2", we are not clear how these measures will be written and would like to see a draft of the measures so we can review and comment. 3. The alternate requirements appear to be "planning" in nature instead of "real-time"; we assume the intention of the SDT was the latter. Therefore the requirements should be revised with language that is "real-time" in nature.
VSLs proposed by the VM SDT
FE supports the VSL proposed by the SDT. We believe these have been developed in accordance with the FERC approved VSL guidelines and represent the appropriate violation levels for situations of varying probabilities. History has proven the grow-ins are the biggest cause of vegetation contact issues, and fall-ins and blowing together vegetation are very hard to predict and control and should be at lower violation levels. Although we believe that an encroachment into the MVCD that causes no system disturbance should not be penalized if an entity takes immediate action to restore the minimum clearance, the assignment of a Lower VSL is appropriate. We believe that the NERC staff opinion that this situation warrants a High VSL does not demonstrate thorough rationalization because it fails to consider the consequences that would place a severe monetary penalty on an entity for a situation that did not cause a fault, outage, or cascade of the BES. Furthermore, it is clear from the bullet points under R1 and R2 of the proposed standard language that the SDT intended that an encroachment with a sustained outage is different than and encroachment without a sustained outage otherwise they would not have specified the bulleted situations in detail. Had the SDT intended for there to be only two violation severity levels they would have only specified two bullet items: an encroachment with a sustained outage and

an encroachment without a sustained outage. The requirements are the only tools the drafting team has to specify its intent in this area and the approach they used is reasonable to provide these levels of differentiation.
Yes
FE has the following additional comments: 1. In the SDT consideration of comments from Draft 3, it was indicated that "The subcommittee will ask that NERC's legal department write a statement for addition to each standard to clarify which parts/elements of the standard are mandatory and enforceable and which are provided only as information". We would appreciate this statement be placed into the standard before the final ballot so stakeholders have an opportunity to review and comment on the wording. 2. We cannot comment on the Technical Reference Document since the latest draft was not posted for review. Does NERC intend to post this at a later time? If so, we ask that NERC give the industry enough time to adequately review the document so that we can provide quality feedback. 3. In the Guidelines and Technical Basis Section, in the first paragraph of Requirement R5, second sentence, the word "temporarily" should be removed since it was removed from the requirement.

Kansas City Power & Light
Michael Gammon
No
This needs to be a defined term since the Standard uses that as a basis for use with Table 3. Using this term as a footnote does not allow the industry to weigh in on its definition. Footnotes should not be used as a means of definition or clarification. Footnotes are for references to other sources of statements or documents that support a particular thought.
No
The theme of the â€œOtherâ€☐ section are the conditions for excluding applicable transmission facilities under certain conditions. Recommend the Drafting Team consider renaming this section to â€œExclusionsâ€☐. In addition, the term, â€œActive Transmission Line Right-of-Wayâ€☐ is capitalized in the â€œBackgroundâ€☐ section. If it is determined this term should not be a definition, then this should be lower case.
No
In response to the informal comment period, the SDT is clear that it believes the use of encroachment as a basis for determining the effectiveness and compliance of a vegetation management program. The purpose of this Standard is to identify the criteria for effective monitoring of vegetation in transmission right-of-way and to take appropriate actions when that monitoring identifies the need to â€œclearâ€☐ vegetation to prevent potential transmission facility outages resulting from contact with vegetation. These proposed Measures as written do not give credit to the Transmission Owners for effectively monitoring their systems and taking appropriate actions in regard to vegetation clearing. Why does it make sense to punish and penalize a Transmission Owner for discovering an encroachment when they take the appropriate actions to remedy the condition before any facility outage occurs that results in compromising the reliability of the Bulk Electric System? These Measures and Standard should recognize the good practices of effective response to a vegetation condition and penalize ineffective response. Highly recommend the SDT consider including appropriate language to recognize effective remedial actions by Transmission Owners and by doing so, recognize effective efforts instead of punishing them. In addition, proving encroachments have not occurred will pose audit challenges in determining that encroachments have not occurred for the Auditors as well as Registered Entities. If no encroachments occur, then there is nothing to report or record. This is a weak platform to stand compliance on. Facility interruption events caused by vegetation contacts is definitively measurable and recordable. Recommend the SDT reconsider the concept

of compliance with FAC-003 on the basis of sustained outages.
No
It is unclear that this requirement may utilize the industry practice of â€œruling spanâ€☐ methods to determine the vegetation clearances for a transmission facility. â€œRuling spanâ€☐ methods are used to determine the construction design for transmission facilities and includes maintaining safe clearance distances. This requirement could be interpreted as being applied to every individual span to determine vegetation clearances for a transmission facility which would not be practical.
No
This requirement is in direct conflict with the â€œexclusionsâ€☐ as described in section 4.4. Section 4.4 makes it clear that effects of â€œmajor stormsâ€☐ on a vegetation programs efforts will be allowed as an exclusion toward compliance with these requirements, yet, R7 does not allow any encroachment due to modifications to a vegetation plans efforts due the â€œMajor Stormsâ€☐ (second bullet) or â€œWeather conditions/Accessibilityâ€☐ (bullet 6). Please explain what is intended here that is different than what was intended in section 4.4. In addition, this presents some audit difficulties regarding the notion of detecting a â€œmodified work planâ€☐. Once a work plan is altered and new objectives are laid out, that becomes the plan and the plans that were replaced may be discarded since they would be of no value. Further, what difference does it make to track or monitor any changes to a work plan provided effective vegetation management is maintained? Recommend the SDT consider removing the language regarding â€œwork plan flexibilityâ€☐ as this may suggest and impose an unnecessary compliance burden on Registered Entities and Auditors.
Alternate version of R1/R2
Prefer Alternative E from the list above. Please clarify the meaning of sway in Alternative E. Is that wind blowout?
VSLs proposed by the VM SDT
Although the Drafting Team is favored here, it makes little sense in the NERC Staff VSL to have an encroachment with no sustained outage as a HIGH VSL. No compromise of the real-time reliability of the bulk electric system occurred. How could that be a HIGH? If it is determined to use the VSLs proposed by NERC Staff, it is recommended to change the HIGH VSL to LOWER.
Yes
1. Part R4.3, â€œEnforcement, under Section 4, â€œApplicabilityâ€☐, is confusing as to why it is needed. What is the intended purpose of this part? It is clear that each Requirement, Measure, VRF and VSL when adopted by the NERC BOT and FERC become mandatory and enforceable on the declared effective date(s). There is no need for Part R4.3 to reinforce the compliance enforcement dictated by the established NERC Rules of Procedure. 2. Requirement R4: The requirement is clear to notify the appropriate control center regarding conditions that might cause a fault on a transmission facility. The requirement should be clear, this for the Transmission Owners applicable lines and recommend the SDT modify the language in R4 to that end. In addition, there is no action other than notification in regards to this operating condition. Highly recommend the SDT consider adding language to take â€œimmediate actionsâ€☐ to remedy the vegetation condition and remove the threat. 3. Requirements R5 & R7 are not clear in that they are for the Transmission Owners applicable lines. This has been a common theme throughout this Standard and by the omission of this language, it is not clear that the intended scope of the requirements do not go beyond the applicable lines.
Group
NERC Staff
Mallory Huggins

Yes
No
NERC staff does not support the language in the Other Section. Staff believes that the force majeure provision is unnecessary and calls into question whether NERC and the regions have enforcement discretion to take such things into account in applying other standards that do not include this type of provision.
No
With respect to both M1 and M2, NERC staff finds the â€œacceptable forms of evidenceâ€☐ incomplete. To assess compliance, the auditors would also need to see the processes and procedures identified under Requirement R3 and the annual work plan under Requirement R7 to see how the entity planned to prevent sustained outages and what the entity had done to implement that plan. Finally, what is the purpose of the following sentence?: â€œIf an investigation of a Fault by a qualified person confirms that a vegetation encroachment within the MVCD occurred, then it shall be considered a Real-time observation.â€☐ Recommend adding each report of a real-time observation of encroachment into the MVCD to the periodic data submittal.
No
The removal of programmatic details from R3 renders the auditing task much more difficult. How does one assess the quality of the program except through the results required in R1 and R2? Since maintaining specific cut-to clearances is not required, there is much greater subjectivity in application that greatly complicates the auditor job. If the team does not want to limit the available approaches, it could provide flexibility by offering an array of deterministic formulas or approaches for maintaining vegetation. This might include maintaining vegetation to remain within a certain height from the ground given maximum sag distances. Additionally, this requirement does not seem to require the entity to actually follow its policies and procedures (unlike, for instance, R7). What is a violation here? Not having the documented procedure(s) OR whether the documented procedure(s) actually demonstrate that the entity can prevent encroachment? NERC staff is also concerned with some of the language in M3. Consider the following modification: â€œThe Transmission Owner will have procedures, processes, or specifications as identified in Requirement R3, records showing work done to support its annual work plan identified in Requirement R7, and its quarterly vegetation reports, to demonstrate that it can prevent encroachment into the MVCD.â€☐ Finally, with respect to the Rationale associated with R3, how would NERC enforce poor intent or a poor indication of competency (especially if the entity was performing well)? Recommend: Provide a basis for evaluating whether the Transmission Ownerâ€™s procedures, processes, or specifications used to maintaining vegetation are achieving that goal. There may be many acceptable approaches to controlling vegetation so that it does not encroach into the MVCD. And one small copyedit: â€œinterrelationshipsâ€☐ should not have a hyphen.
No
This is the first instance in which an annual work plan is discussed. It would appear necessary to first develop an annual work plan component of the overall vegetation management program. There should also be some performance review or expectation that the annual plan as implemented achieved the intended program objectives, or that modifications would be necessary. Does R7 require both that a Transmission Owner has an annual vegetation work plan AND that it completes the work plan? Detail is required as to what is expected in the work plan, as there is currently no basis to judge whether the work plan is adequate or not adequate. And what does a modification entail? Does this mean reduction of performance, delay in performance, or complete postponement of performance? NERC staff is also concerned with the list of examples one might use to modify

an annual plan. Several of these items should not pose any greater risk to vegetation contact and render the requirement virtually unenforceable. It provides a wide array of reasons to postpone vegetation management and may make it a very low priority for an entity: -â€œRescheduling work between growing seasonsâ€☐: This could be an honest change (if there are unexpected seasonal changes) or it could reflect bad initial planning. If there will be occasion for auditors and investigators to distinguish, there should be guidance on differentiating. -â€œCrew or contractor availabilityâ€☐: This could be an honest change (if there is an unexpected labor dispute or if crews are needed to help a neighboring utility during an unexpected emergency) or it could reflect bad initial planning. If there will be occasion for auditors and investigators to distinguish, there should be guidance on differentiating. Alternatively, it could be removed from the list as it is within the exclusive control of the Transmission Owner. -â€œIdentified unanticipated high priority workâ€☐: This could be an honest change or it could reflect bad initial planning. If there will be occasion for auditors and investigators to distinguish, there should be guidance on differentiating. It is also vague and would necessitate a judgment call for enforcement. -â€œPermitting delaysâ€☐: Annual plans should account for anticipated permitting schedules and maybe even add a factor for uncertainty. It is a planning issue for the entity and should not be an acceptable excuse for not conducting vegetation management. -â€œLand ownership changedâ€☐: If a landowner has the ability to affect the reliability of the bulk power system, the landowner should be subject to the reliability standards. A registered entity should be responsible for the land in its ROW, especially if it has turned control of the land, and the ability to affect reliability of the BPS, over to another entity or person for financial gain. -â€œFunding adjustmentsâ€☐: NERC staff is not convinced that this is a legitimate reason for adjusting an annual vegetation work plan. Economic considerations should not be a reason to delay or modify vegetation management. -â€œEmerging technologiesâ€☐: It is unclear what this example is intended to accomplish. In general, these examples should be bounded in some way to ensure that a modification due to one of their occurrences does not impart a greater risk of vegetation contact.
Draft 4 version of R1/R2
NERC staff supports the Draft 4 version. The six options listed in the alternative version of R1/R2 do not seem manageable from a utility perspective. But while staff prefers the existing language, it continues to emphasize that fall-ins from outside the ROW can impact the line and need to be taken into consideration.
VSLs proposed by NERC staff
NERC staff supports the VSLs proposed by NERC staff. The SDTâ€™s VSLs are too low, and they do not seem to differentiate between various levels of compliance. Still, staff is concerned that the difference between an encroachment that leads to an outage and one that does not is based on nothing but luck.
Yes
EFFECTIVE DATES -The first item should be re-written to â€œFirst calendar day of the first calendar quarter one year after the date of the order approving the standard from applicable regulatory authorities where such explicit approval is required.â€☐ -The second item is not needed and should be removed. -The third item is okay but the phrase â€œwhere explicit regulatory approval is not requiredâ€☐ should be removed. EXCEPTIONS -Identifying a critical line and then waiting 12 months to perform vegetation management is counter to the risk avoidance strategy that the standard is attempting to accomplish. In effect, this standard permits an entity to identify a major WECC path or an IROL just prior to peak season and then not complete any vegetation management activities until just before the next season 12 months later. This is wholly inappropriate. -Using the phrase â€œan element of an IROLâ€☐ seems confusing because â€œElementâ€☐ is a term defined in the glossary.

Further, IROL is an identified limit, not a physical component. This should be reworded to say â€œa facility that is identified to be part of an interface or path impacting an IROL.â€☐ This is also seen in R1 and R2 and needs to be adjusted there as well. -For newly acquired assets, the 12 month window may be appropriate, but there needs to be a much nearer term inspection undertaken to identify â€œriskyâ€☐ vegetation. DEFINITION -The modified definition assumes the ROW is maintained, which may not be the case (for instance, if a newly acquired asset has not yet been acted upon). An entity could interpret the new definition to indicate that the new owner cannot be performing an initial vegetation inspection if the ROW has not yet been maintained. The phrase â€œmaintained transmission lineâ€☐ should be changed to â€œapplicable transmission line.â€☐ -The inclusion of the phrase â€œwhich may be combined with a general line inspectionâ€☐ is unnecessary and should be removed. In fact, the current definition does not restrict combining the inspection with other field visits, while in the proposed definition that vegetation inspection can only be combined with a general line inspection. OBJECTIVES (SECTION 3) -NERC staff is concerned that the purpose states â€œthat could lead to Cascading.â€☐ This qualifier limits the purpose of the standard, which should be to prevent vegetation-related outages. The more outages there are, the less the overall system reliability; it does not necessarily have to lead to Cascading to be significant and represent a reasonable risk to the BES. -The term â€œmaintainâ€☐ might be better than â€œimprove.â€☐ APPLICABILITY (SECTION 4) 4.1 Functional Entities -Noticeably absent from the standard is coverage for transmission facilities that connect generators to the interconnected bulk power system. As such, the team should add Generator Owners to the applicability and include such language that was proposed by the ad hoc team: transmission facilities that connect generators to the bulk power system that exceed two spans from the fence-line of the generating plant; coupled with the previous discussion, this provides complete coverage for all transmission facilities and switchyards and substations. This is what is needed to ensure no gaps in vegetation management coverage. 4.2 Facilities -The identification of critical facilities herein does not recognize the overarching criteria that are being developed in support of the PRC-023 order, and in some respects, in response to Order 693 directives to define the criteria for â€œcritical facilities.â€☐ The FAC-003-2 SDT should work in conjunction with the PRC-023 team, which is establishing a set of criteria for identifying critical facilities such that the outcome across all NERC standards is consistent. -â€œTransmission lineâ€☐ should be capitalized as a NERC-defined term. -4.2.4: This exclusion seems strange. It would appear that there are no expectations for vegetation management in switchyards, which is unacceptable. We should be able to develop language that requires that a Transmission Owner or Generator Owner maintain vegetation within fenced areas of the switchyard, station, or substation to the same clearances as one does for the ROWs, without necessarily obligating them to an annual cycle of inspection or management. REQUIREMENT R4 -â€œQualified personnel" should be defined. In the Rationale, some examples are listed, but who else counts as â€œqualified field personnelâ€☐? -â€œAt any momentâ€☐ is an unnecessary qualifier and should be removed (same for M4). -With respect to the phrase â€œintentional time delay,â€☐ intent is a tricky thing to prove. Most standards set clear timelines which kick in regardless of intent, because it diminishes reliability to base a standard on intent. The SDT should consider doing so here. REQUIREMENT R5 -NERC staff is confused by the overall purpose of this requirement. It appears to be a defense to a possible violation for failure to perform some planned vegetation work, but it flips it around and makes it a requirement. A better approach would be to just deal with this in addressing the mitigating/aggravating factors under a violation of R1 and R2. -The team should be more specific with respect to expectations for â€œcorrective action.â€☐ There needs to be an expectation that the corrective action needs to maintain an equivalent level of performance consistent with the intent of the vegetation management program. This could include, for example re-rating lines to reduce max sag until the condition is rectified, enhanced inspection cycles to monitor conditions, etc. It would be useful to define a metric for the success of corrective actions. -The team should be clearer on what constitutes a â€œconstraint.â€☐ Is it only legal constraints? One interpretation could be resource constraints, which would certainly not be appropriate in this context. The phrase â€œdue to constraintsâ€☐ is also used in the Rationale section. In this context, â€œconstraintâ€☐ appears to mean congestion on a transmission line. This seems very different from being â€œconstrained from performing planned vegetation work.â€☐ In fact, the existence of congestion on a line does not necessarily create risk. We would not want entities to make the economic determination that they will put off required vegetation work because it would cost too much in energy sales profits. REQUIREMENT R6 -It would appear necessary to require the use of the inspection information to guide or modify program development as is identified in the Rationale box accompanying the requirement. This is referred to in R7 but is not identified as an expectation from R6. -What are "all applicable transmission lines"? Are those lines covered by both R1 and R2? Clarify this. -â€œOnce per calendar year" requires more guidance. Would two inspections on 12/31/2010 and 1/1/2011 satisfy this requirement? Shouldn't there be a requirement to space these inspections out? Recommend: once per calendar year with no more than 15 months between inspections. -The last sentence of R6â€™s Rationale states that â€œTransmission Owners should consider local and environmental factors that could warrant more frequent inspection.â€☐ But the way the requirement is written, there is no basis for requiring anything more frequent than once per calendar year. If the intent is to have stricter timelines for different registered entities, then the standard would need to be revised. COMPLIANCE Additional Compliance Information/Categories of Sustained Outages -Category 3 (Fall-ins from outside the ROW) should be reinstated. Even if it is not required by the standards, Category 3 reporting should be kept. -There is currently a public bulletin to encourage Transmission Owners to report Category 1 and 2 outages within 48 hours. The SDT should consider adding this as a requirement and including it in the new standard as such. VSLs -The VSL for R3 should be shifted to an approach that simply counts the missing elements: lower = missing one element; moderate = missing two elements; high= missing three elements; severe = not having documents. -The VSL for R4 uses the phrase â€œvegetation threat,â€☐ which needs to either be conformed to the text of the drafting team or defined. This VSL also uses the phrase â€œintentional delayâ€☐ A truly intentional delay should be labeled as severe, not just high. (And as already stated, intent is a very tricky thing to prove.) -For the VSL for R5, there may be ways to differentiate violations based on whether the entity identified appropriate corrective actions (versus missing obvious alternatives), attempted corrective actions but failed, considered alternative corrective action, etc. -For the VSL for R6, the SDT should differentiate between the criticality of different lines. At the very least, a failure to inspect R1 lines should be a more severe violation than a failure to inspect R2 lines. -The VSL for R7 should perhaps be differentiated based on whether the incomplete work related to critical versus non-critical or less critical lines (i.e., R1 lines vs. R2 lines). GUIDELINES AND TECHNICAL BASIS R1/R2 -â€œIf an investigation of a fault by a qualified person confirms that a vegetation encroachment within the MVCD occurred, then it shall be considered a Real-time observationâ€☐: This is an important statement and should be included as part of the requirement itself. R3 -With respect to the phrase â€œan adequate transmission vegetation management program,â€☐ the standard talks about factors to consider, but the requirement does not include any provisions on which to base a determination of adequacy. NERC staff believes it should. -The guideline states, â€œThis approach provides the basis for evaluating the intent,

allocation of appropriate resources and the competency of the Transmission Owner in managing vegetation,â€☐ but nothing in the requirements actually provide explicitly for such evaluations. R4 -â€œCellular service or two-way radio disabledâ€☐ should not be considered an acceptable unintentional delay. This seems to be within the entityâ€™s control: there may be a difference between whether the cell service problems are due to network problems as opposed to the entity failing to charge the phone or pay the bill. -â€œRemote field locationsâ€☐ should not be considered an acceptable unintentional delay. This is not entirely beyond the registered entity's control. There may be a difference between a work site that is isolated from radio or cellular networks versus the fact that the employee simply left the radio in the truck. -â€œVegetation-related conditions that warrant a responseâ€☐ should be defined in the standard. -It is not clear to NERC staff that a lineman or an arborist is capable of completing â€œan assessment of the possible sag or movement of the conductorâ€☐ out in the field in real time. However, if this is the expectation, it should be written into the requirements. -The fourth paragraph states that the â€œTransmission Owner has the responsibility to ensure the proper communicationâ€¦â€☐ Earlier in this section, however, it says that the condition of the communication system is not considered to be intentional delay. This inconsistency needs to be addressed. This sentence should also include a requirement for correcting the vegetation encroachment. -The phrase â€œminutes or hoursâ€☐ is used in the final sentence of the fourth paragraph of this sentence. This detail should be written more clearly and written into the standards. Is 24 hours still hours? What about 48 hours? R6 -With respect to the following sentence, beginning with â€œTherefore it is expected,â€☐ NERC staff is concerned that nothing in the requirement actually makes this expectation enforceable. It would be best to require each TO that experiences a vegetation related sustained outage to investigate the outage and make revisions to its TVMP if the investigation shows that the growth rates of vegetation under the TOâ€™s control do not match those anticipated in the TVMP. R7 -The second paragraph states that â€œrecent line inspections may identify unanticipated high priority work.â€☐ But the fifth bullet in R7 does not indicate that the higher priority work was identified in a recent line inspection. R7 should be revised to make that caveat clear. -The second paragraph references â€œModifications to the annual work plan.â€☐ Presumably, these modifications would not excuse compliance with R1, R2, and R6. That should be made clearer in the requirements. TABLE 3 -None of the requirements actually reference this table. That should be modified.

Louis Slade
No
The distances proposed in Table 3 â€“ Minimum Distance from the Centerline of the Circuit to the edge of the active transmission line ROW may not be consistent with the centerline distances cleared and maintained by the TO. For example, a TO maintaining 75â€™ from centerline for a 500kV circuit would be required to clear and maintain an additional 12.5â€™ to meet the proposed standardâ€™s requirement. We suggest either allowing individual TOs to maintain active ROW widths consistent with their normal clearing/maintenance practices, going back to Draft 3â€™s definition of Active Transmission Line Right-of-Way, or changing the footnote in Draft 4 to read: A strip or corridor of land that is occupied by active transmission facilities. This corridor does not include the parts of the Right-of-Way that are unused or intended for other facilities. However, the portion of the ROW that has been cleared must at least meet design clearance requirements such as National Electric Safety Code or other design criteria, for the reliable operation of active facilities.
Yes

Yes
Yes
Although we agree with the intent of the proposed language, we feel the requirement should be revised to read: Each Transmission Owner shall document the procedures, processes, or specifications it uses to prevent the encroachment of vegetation into the MVCD. Such procedures, processes, or specifications shall consider the dynamics of a transmission line conductorâ€™s movement throughout its Rating and Rated Electrical Operating Conditions and the inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency, for the Transmission Ownerâ€™s applicable lines.
Yes
Draft 4 version of R1/R2
The alternate language proposed above suggests that methodologies typically incorporated into processes, procedures, or specifications (as required by R3) should also be included into performance-based requirements R1 and R2. The incorporation of this language into R1 and R2 would change these requirements from performance-based requirements to hybrid performance/competency-based requirements. The intent of R1 and R2 is to define a failure to prevent encroachment into the MVCD. Ensuring that a TOâ€™s processes, procedures, or specifications demonstrate adequate means of protecting conductors falls under R3, which incorporates transmission conductor and vegetation dynamics and interrelationships. Therefore, methodologies employed to manage the floor of active transmission ROW should be incorporated into the documentation required by R3 and proof that vegetation was managed in accordance with processes, procedures, or specifications to prevent encroachment into the MVCD will be demonstrated by compliance with R1 and R2.
VSLs proposed by NERC staff
As all parts of R1/R2 seem to contribute equally to the intent of the requirement â€“ shall manage vegetation to prevent encroachment that could result in a Sustained Outage - NERCâ€™s proposed VSLs best address noncompliance with the requirements.
Yes
In R4 and M4, the phrase "without any intentional time delay" has been added. We recommend removing this language from the requirement as it is not possible to measure intent.
Individual
George Czerniewski
Consolidated Edison Company of New York Inc
Yes
The same verbiage in footnote number 2 should appear below Table 3 to avoid any confusion.
Yes
Yes
Yes
Yes
Draft 4 version of R1/R2
Consolidated Edison Company of New York, Inc prefers the Draft 4 version. The wording in the VSLs should be modified for both Requirements to

include the phrase 'manage vegetation'. The phrase 'manage vegetation' requires a utility to take specific action to prevent encroachments/outages.
VSLs proposed by the VM SDT
The wording in the VM STD VSLs should be modified to include whether or not the TO managed any vegetation on that particular line. A more severe VSL should be assigned to any encroachment or sustained outage that was caused as a result of a TO not performing any vegetation management activities on that line. For example, if vegetation management activities were completed on 80% or 90% of the line and additional work was in progress on the remainder of the line but an encroachement or sustained outage occurred on the spans that were scheduled to be done as part of the annual plan, the TO should be held accountable for this but at a lower severity level.
Yes
In R5, the SDT should better define the phrase 'where a transmission line is put at potential risk due to the constraint.' This is rather vague and could lead to inconsistent practices between utilities. Con Edison defines all undesirable species on the full width of the ROW as 'potential risks to the transmission line' regardless of height or location at the time of vegetation management. Interim corrective action should only be required when the potential risk is approaching the imminent threat classification.

Consideration of Comments on Initial Ballot — Project 2007-07 Vegetation Management FAC-003-2
Date of Initial Ballot: 7/9/2010 - 7/19/2010

Summary Consideration: In general, there were no common themes and as such each comment was responded to individually.

If you feel that the drafting team overlooked your comments, please let us know immediately. Our goal is to give every comment serious consideration in this process. If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Gerry Adamski, at 609-452-8060 or at gerry.adamski@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

Voter	Entity	Segment	Vote	Comment
Kirit S. Shah	Ameren Services	1	Negative	(1) Need clarification on Footnote number 2 and Table 3 : Does this mean wider ROW easements will need to be acquired to be compliant or will this apply to ROW's for new circuits going forward? (2)R7 - Funding Adjustments (increase or decrease) - need more description to imply only when planned vegetation work is "over and above". (3) R5 - What constitutes a "potential risk"? Breaking the MVCD or getting close to it? (4) R7 - No work plan can ensure that NO vegetation encroachments will occur; can language be added similar to "to ensure that no vegetation encroachments 'from vegetation within the active right of way' occur within the MVCD"?
Response: **(1) No, the SDT has re-established the concept of an Active Transmission Line ROW by changing the definition of Right of Way with the same principles which was almost universally accepted by industry. After thorough analysis of potential modifications to Table 3 and other alternatives, the team found no specific, prescriptive, or formulaic language which can be applied across the US, Canada and Mexico, thus the team reverted to the Active Transmission Line ROW, removed Footnote 2 and Table 3.** **(2) The SDT limits the reasons for plan adjustment by whether the changes place the system at risk of a violation of the MVCD as defined in R1 and R2.** **(3) The SDT recognizes that defining any risk is subjective. Removing the term does not change the fact that each TO must determine the risk and respond accordingly.** **(4) The SDT has incorporated your suggestions.**				
Danny McDaniel	Cleco Power LLC	1	Negative	1. Encroachment into the MVCD should require the owner to take immediate corrective action to mitigate the threat. But such an encroachment should not be reportable as a violation. Owners may be hesitant to report if they known it is a violation. Recommend the SDT consider modifying the measures for R1 and R2 to be applicable only in the interruption of transmission facility or allow the reporting but don't make it a violation of compliance. R4 states "Each Transmission Owner, without any intentional time delay, shall notify the control center holding switching authority for the associated transmission line when qualified
Bryan Y Harper	Cleco Utility Group	3	Negative

<tr><td>Matthew D Cripps</td><td>Cleco Power LLC</td><td>6</td><td>Negative</td><td>personnel confirm the existence of a vegetation condition that is likely to cause a Fault at any moment" 2. In R4, the use of "intentional" is a vague term. As other standards prescribe, set a time at which the control center should be notified. R5 states: "Each Transmission Owner shall take corrective action when it is constrained from performing planned vegetation work, where a transmission line is put at potential risk due to the constraint." 3. In R5, the use of "potential risk" is a vague term. R5 should read as follows: Each Transmission Owner shall take corrective action when it is constrained from performing planned vegetation work. R7 states: "Each Transmission Owner shall complete the work in an annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD ...." 4. The first sentence should not include the phrase "to ensure no vegetation encroachments occur within the MVCD" since the requirement is to do the work in the work plan. The added phrase adds ambiguity, e.g., if there is an encroachment, is R7 violated since it does not meet the "ensure" phrase? Would this cause a double jeopardy situation with R1 and R2?</td></tr>
<tr><td colspan="5">Response:
1. The SDT discussed this issue at length. However, NERC and FERC interpret vegetation growing into MAID as too great a risk to allow. While MAID is replaced with the MVCD the risk is still there.
2. The SDT debated a set time limit. The team could not find a time that would fit all situations. Intentional would apply if a TO withheld notification after having confirmed that risk conditions exist.
3. The SDT removed the vague language.
4. There are opportunities for double jeopardy between R1/R2 and R7 without this language. The occurrence of double jeopardy has not been born out.</td></tr>
<tr><td>Saurabh Saksena</td><td>National Grid</td><td>1</td><td>Negative</td><td rowspan="2">1. The recent addition of a centerline distance to edge of Active ROW is not acceptable to National Grid. In many areas we use design standards that allow a much lesser ROW width with no compromise to “cleared width” or tree related reliability of the line. Instead of using the term “Centerline” as referenced on Table 3, the use of “outer phase” or “phase closest to tree line” would be more appropriate. 2. National Grid also has issues with the term "easements" in the definition and seek clarification on several questions - is there a reason the Active ROW only includes easements, not fee ownership, license or some other right to occupy and manage the ROW? Would Active ROW include “danger tree rights” on land?</td></tr>

Response: **Please refer to the SDT responses on the comment form.**				
Michael Gammon	Kansas City Power & Light Co.	1	Negative	Although the proposed FAC-003 standard has many improvements and advancements that are desirable over the existing FAC-003 standard, the handling and treatment of encroachments as proposed without consideration of recognizing an organizations efforts in responding to an encroachment situation makes this proposal less desirable and is a major concern regarding the risk that the associated penalties and assessments place on organizations.
Scott Heidtbrink	Kansas City Power & Light Co.	5	Negative	
Response: The SDT thanks you for your comments. Zero tolerance for vegetation caused outages is a stated goal of FERC and NERC as it relates to this standard. Quote from NERC: ***Vegetation Management*** *— While four transmission outages due to vegetation occurred in a single afternoon five years ago, preliminary data suggests that only six such outages occurred in the first six months of 2008 – none of which caused customers to lose power. Transmission line outages due to vegetation contact are still a cause for concern, however, and this remains a top priority for NERC. Through its standards and compliance enforcement, NERC now has a zero-tolerance policy in place, where the goal is to correct issues that may arise long before any customers are affected.* **This policy is part of FAC-003-1 and in concept did not change with the proposed version. The SDT recognizes this concern and has developed gradation taking into account line criticality in VRF's and type of outage not contained in the current version FAC-003-1. Finally, It is also important to note that each and every incident or potential violation is investigated and addressed based on the specific circumstances surrounding the particular event. These investigations should necessarily take into consideration and recognize the utility's individual efforts in responding to an encroachment situation.**				
Thomas R. Glock	Arizona Public Service Co.	3	Negative	APS supports retention of FAC-003-1 as currently effective, as it is working well for the industry. APS does not support a change to this standard for the following reasons: o The minimum clearances must be sufficient to avoid any sustained vegetation-related outages for all applicable conditions. ? . ? Clearance 1 should remain in the standard as it ensures clear direction to the utility on how the system is to be maintained, and provides assistance to the Transmission Owners in dealings with federal land agencies on vegetation management issues. Elimination of the discretion in clearance 1 will significantly degrade this support. ? ANSI-A300 should remain in the standard. Though simply a footnote in the currently effective version, ANSI-A300 should be a requirement in the standard. Relevant Registered Entities should be held to following ANSI A-300 standards and BMP's for best management practices. o APS does not agree with the removal of 'fill in the blank' components where the Transmission Owner determines the requirement with no limits or direction. Examples include and "personnel requirements" in version 1. The SDT removed this requirement from the current version. ? Personnel qualifications should be remain a requirement. The standard should recognize certification programs through the International Society of Arboriculture that certify a minimum level of competence to manage

Voter	Entity	Segment	Vote	Comment
				a vegetation management program which required ongoing training and education to keep up with the latest technologies on UVM. ? There are other standards that require qualifications and training. ? The revised standard dilutes accountability for maintaining the full width of utilities easement. The active ROW should be wide enough to prevent outages caused by grow-in and blow-in events. ? The changes to R1, allowing a real-time observations to evidence encroachments, does not take into account all rated conditions and the time the recording was made. Real-time observations will not account for changing conditions and increase in load. Available technologies, such as LIDAR, can simulate all-rated conditions, contour and tree height to remove these potential trees hazards before an outage occurs. ? The utilities should be required to inspect all the lines annually. ? The standard should include a footnote that provides that a utility will not be held accountable for not completing its annual work plan if federal or state agencies fail to approve annual work plans within 90 days of submittal, or that takes into account the time it takes the utility to get approval.

Response: Thank you for your comments.

- **The SDT is changing the Standard in response to the SAR. The success of the existing standard will be preserved and enhanced with this revision.**
- **If vegetation is maintained as required in this draft of the standard in requirements R1 and R2, then no vegetation-related sustained outages, caused by vegetation from within the ROW, within the control of the TO can occur.**
- **Clearance 1 was a fill-in the blank requirement and did not provide the TO any new easement rights, or land permit rights across any lands whether those land be privately owned or publicly owned; therefore Clearance 1 remains removed from this draft. Furthermore, the relevance of Clearance 1 depends on several other factors such as length of maintenance cycles, inspection frequency and growth rates. R3 is now used as a more comprehensive method to address these concerns in lieu of a Clearance 1 requirement.**
- **In order to meet the SAR FAC-003 is required. ANSI-A300 is not sufficient to meet the SAR requirements and contains many elements that do not need to be related to transmission system electrical reliability.**
- **The SDT suggests that the submittal of a NERC SAR on the PER standards be considered to address any proposed personnel qualifications, certifications or training issues.**
- **The SDT is following NERC guidelines as they understand them.**
- **The SDT has re-established the concept of an Active Transmission Line ROW by changing the definition of Right of Way with the same principles which was almost universally accepted by industry. Outages arising from vegetation from outside the ROW are not violations of the standard. The SDT had determined this to be the most appropriate assignment of an area of maintenance responsibility considering the numerous variations in easements and permit rights across North America.**
- **The Standard requires the maintenance to be performed such that loading to Rating and Rated Conditions, and the dynamics of sag and sway are taken into consideration. Additionally any real time observations of encroachments into the MVCD are to be reported as violations of the standard. The SDT does not see the need to be prescriptive as to the technology or tools the TO used to be compliant with the Standard, but is confident that if the vegetation in maintained such that no encroachments are ever observed, and no outages are ever occur, then the reliability purpose of the standard will be fully accomplished. Furthermore, the results from a LIDAR survey are temporal in nature.**

Voter	Entity	Segment	Vote	Comment
Any program relying on LIDAR would incur a substantial cost with a long term commitment that may not be justified for many Transmission Owners. • **FERC requested a defined period for inspection. The SDT agrees with you that annual inspection is required. Therefore the SDT has made annual inspections a Requirement of this Standard. As to all lines versus applicable lines, FERC has accepted the 200 kV bright line for this standard. They did order the SDT to ensure that no sub-200 kV lines that are important to the Bulk Electric System are missing from the Applicability of the standard. The SDT has incorporated a FERC accepted test (as found in the referenced Standard) to make sure no such important lines are missing.** • **The SDT agrees that erroneous obstacles to compliance with the standard should be addressed. However, they cannot be resolved in this forum, or through language inserted in this standard. This Standard places requirements on the Transmission Owners, not on landowners. There is no legal mechanism for this Standard to take rights from property owners and assign them to the Transmission Owner.**				
John J. Moraski	Baltimore Gas & Electric Company	1	Negative	BGE feels that the new standard does nothing to improve reliability over the existing standard. Furthermore, it could be argued that it potentially diminishes reliability, based on the new MVCD vs. Clearance 2 guidelines. It also includes requirements which could be perceived as being more confusing than the existing requirements in the current standard, e.g., the Active Right-of-Way, Calendar Year Inspections, etc. The new standard, If adopted, would almost certainly require a complete restructuring of all TVMPs and related compliance processes, with no commensurate value-added for individual utilities or the industry in general. In addition, it would do little to enhance the overall intent of the standard, which is to improve vegetation-related transmission reliability in North America.
Response: The SDT thanks you for your comments. The SDT believes the proposed version addresses concerns outlined in FERC Order 693 and improves reliability of the BES. The industry overwhelmingly agrees the MVCD based on the Gallet Equation is superior to that of the Clearance 2 fill-in the blank requirement in the current version and in fact can be a greater distance depending on the basis used for Clearance 2 determination. Based on your comment and others, the SDT has re-established the concept of an Active Transmission Line ROW by changing the definition of Right of Way with the same principles which were almost universally accepted by industry. After thorough analysis of potential modifications to Table 3 and other alternatives, the team found no specific, prescriptive, or formulaic language which can be applied across the US, Canada and Mexico, thus the team reverted to a ROW definition, removed Footnote 2 and Table 3. While it is true that any change to the standard may result in changes to current documentation of practices and procedures (such as the TVMP), the SDT believes changes will be minor and be an improvement.				

Voter	Entity	Segment	Vote	Comment
Paul Rocha	CenterPoint Energy	1	Negative	CenterPoint Energy believes the proposed FAC-003-2 is not a performance-based standard, despite being labeled as such, because it remains too focused on processes and procedures. CenterPoint Energy fails to see much difference in the approach from the current Standard. CenterPoint Energy believes a performance based requirement would provide performance criteria that an entity would be measured against. An example of a performance based requirement would be the following: R1. “Each Transmission Owner shall manage vegetation to prevent encroachment that results in no more than one (1) Sustained Outage per XXX circuit miles of applicable lines within any twelve (12) month period.” M1. Each Transmission Owner has evidence that it had no more than one (1) Sustained Outage per XXX circuit miles of applicable lines within any twelve (12) month period. Examples of acceptable forms of evidence may include dated reports of vegetation-related Sustained Outages or dated attestations as to no vegetation-related Sustained Outages have occurred.
Response: The SDT thanks you for your comments. FAC-003-2 is a “results based standard” (RBS) with a stated objective to prevent outages that could lead to cascading. Any requirement that has an allowance for a certain number of outages does not meet that objective.				
Russell A Noble	Cowlitz County PUD	3	Negative	Cowlitz votes negative with reluctance over two items: 1. Requirement R4 has a qualitative nature in the statement “without intentional time delay” which will leave room for subjective judgment on the part of the auditor in determining intent or the state of mind of the Transmission Owner. Cowlitz understands the need to communicate to the control center a vegetation condition that may cause a Fault at any moment as soon as possible. In this light, it is not possible to set a quantitative time limit for this report to occur for all occasions. In one scenario, a very short time limit may be arguable due to the proximity of available radio/telephone communications. However, in another remote situation it may take up to several hours to access communication equipment after discovery. Compounding the problem is the need to document the time of day versus location progress of the vegetation inspector to establish a discovery time stamp; this is not covered in M4. Cowlitz suggests the following changes (see standards VAR-002-1, IRO-006-3, TOP-003-0, TOP-

Voter	Entity	Segment	Vote	Comment
Bob Essex	Cowlitz County PUD	5	Negative	007-0 for similar verbiage): R4. Each Transmission Owner shall notify the control center holding switching authority for the associated transmission line when qualified personnel confirm the existence of a vegetation condition that is likely to cause a Fault at any moment as soon as possible, but no longer than one hour with the following exception: In areas where communication with the control center is not possible within one hour due to lack of radio/telephone service, the Transmission Owner shall document these areas along with the reasonable time frame for reaching radio/telephone service. 2. Cowlitz agrees with United Illuminating in that R7, as proposed, requires a VMP to be completed to ensure no encroachment occurs. The Supplemental Reference for R7 does not describe the requirement of the annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD. The Reference states the requirement is established to diminish the risk of encroachment; very different from ensuring no encroachment. In the reference for R7 the word “ensure” is only used to describe that flexibility in the VMP is allowed to ensure the reliability of the Transmission System. M7 is measuring work plan completion not the prevention of encroachment. United Illuminating and Cowlitz suggest that R7 be changed to: Each Transmission Owner shall complete the work in an annual vegetation work plan to manage the prevention of vegetation encroachments occur within the MVCD. In this way, a violation of R1/R2 does not necessarily mean R7 is violated. The entity does not avoid a penalty for an encroachment because a violation of R1/R2 occurs for actual encroachment. If an encroachment occurs the compliance enforcement authority can review the entities vegetation management plan to determine if it is compliance with R7/M7.

Response: The SDT thanks you for your comments.

1. **The time required by the TO to report an issue is subject to many variables such as available communication for the area which could be a hike-in location with no radio or cell phone coverage. For this reason it is difficult to establish a time period which would fairly apply to all TO’s.**
2. **Please refer to the following responses to questions (which are responsive to your reference to your conncurrence with the United Illuminating):**

   Question 1: Comment 12

   Question 5: Comment 6

   Question 6: Comment 44

   Question 7: Comment 14

   Question 8: Comment 39

Voter	Entity	Segment	Vote	Comment
Jason L. Murray	Alberta Electric System Operator	2	Negative	Due to slow vegetation growth rates in many parts of Alberta, not all transmission right-of-ways require annual inspection as required in R6. TOs should be able to include planned inspection cycles in their Transmission Vegetation Management Plan.
Response: Thank you for your comment. For the sake of consistency for all applicable entities, the SDT believes that an annual inspection complements the required annual work plan. The standard allows for both maintenance inspections and vegetation inspections to be performed concurrently. Additionally, annual inspections are useful to not only track growth, but also other potential issues such as identifying danger trees, landslides, erosion, and tree damage caused by animals.				
Ralph Frederick Meyer	Empire District Electric Co.	1	Negative	EDE agrees with the concers raised by United Illuminating and therefore also provides the following comments related to R7 and R4 for FAC-003-2. R4: The use of intentional time delay is a qualitative attribute and not a quantitative measure. It will lead to endless arguments over intentional versus non-intentional. EDE agrees with UI's comment: "In R4 the phrase: without any intentional time delay, is a concern. There is a time line between identification and reporting of an imminent hazard that represents the minimal time required to complete this Requirement. Any situation where the time between observation and reporting is greater than this minimal time line indicates a time delay occurred. It will be left to the compliance enforcement authority to determine if this delay was intentional or not. It is not proper for the test to be based on Intentional versus Non-Intentional. Using other synonyms such as reasonable, expeditious, prompt, immediate or without hesitation all introduce a qualitative not a quantitative attribute to the measurement. The Supplemental Reference for R4 indicates that the imminent threat requirement is measured in minutes or hours; again no guidance for enforcement. R4 would be improved with an explicit time requirement of 6 hours between observation and report. This is measurable and clear. M4 becomes Each Transmission Owner that has a vegetation condition likely to cause a Fault at any moment, as confirmed by qualified personnel, will have evidence that it notified the control center holding switching authority for the associated transmission line within 6 hours of observation." R7: R7, as proposed, requires a VMP to be completed to ensure no encroachment occurs. The Supplemental Reference for R7 does not describe the requirement of the annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD. The Reference states the requirement is established to diminish the risk of encroachment; very different from ensuring no encroachment. In the reference for R7 the word “ensure” is only used to describe that flexibility in the VMP is allowed to ensure the reliability of the Transmission System. M7 is measuring work plan completion not the prevention of encroachment. EDE agrees with United Illuminating suggestion that R7 be changed to: Each Transmission Owner shall complete the work in an annual vegetation work plan to manage the prevention of vegetation encroachments occur within the MVCD. In this way, a violation of R1/R2 does not necessarily mean R7 is violated. The entity does not avoid a penalty for an encroachment because a violation of R1/R2 occurs for actual

Voter	Entity	Segment	Vote	Comment
				encroachment. If an encroachment occurs the compliance enforcement authority can review the entities vegetation management plan to determine if it is compliance with R7/M7. EDE also agrees with concerns raised by FMPA that Periodic data submittals as written are really periodic self-certifications and ought to be named such, or 100% compliance reduced to a more reasonable target
Response: Thank you for your comment. The SDT believes that it was not prudent to suggest a quantitative time element for notification in R4. The technical reference offers examples of acceptable unintentional delays for your review. Confirmation that a threat actually exists due to vegetation is key. **Based on comments, the language in R7 has been modified.**				
Robert Martinko	FirstEnergy Energy Delivery	1	Negative	FirstEnergy appreciates the hard work of the drafting team, but unfortunately we must cast a Negative vote for the standard as written. If the SDT agrees with our comments below and makes the suggested changes, we will consider supporting this standard in the recirculation ballot. In the latest Draft 4, the SDT added a Table 3 titled "Minimum Distance from the Centerline of the Circuit to the edge of the active transmission line ROW". We do not support the addition of Table 3 because we believe it adds unnecessary prescriptiveness to the requirements. It is also not clear if this Table was intended to be mandatory because the only reference in the table is in Footnote #2. Furthermore, the SDT did not offer any rationale for the minimum distances shown. If the SDT feels this table is a useful tool that should be included in the standard, then we suggest adding it to the Guidelines and Technical basis section as optional information with a discussion of the basis for the values chosen. The standard being balloted includes an R1 and R2 detailing requirements for managing vegetation. In addition, the SDT has asked for industry feedback on an alternate R1/R2 through the comment form which may lead to changes to the standard after this initial ballot. FirstEnergy supports the alternate R1/R2 but as we stated in the comment form, we still need to see the final verbiage of the alternate R1/R2 along with their associated measures M1 and M2 which have not yet been developed. Therefore, we cannot support the standard until the alternate R1, R2, M1 and M2 are developed.
Kevin Querry	FirstEnergy Solutions	3	Negative	
Douglas Hohlbaugh	Ohio Edison Company	4	Negative	
Kenneth Dresner	FirstEnergy Solutions	5	Negative	
Mark S Travaglianti	FirstEnergy Solutions	6	Negative	
Response: Thank you for your comment. In response to comments regarding the addition of the "Minimum Distance from the Centerline of the Circuit to the edge of the active transmission line ROW" Table 3, the SDT agrees to remove this table and use the new definition of Right of Way. Additionally, language in M1/M2 has been modified based on comments received.				

Voter	Entity	Segment	Vote	Comment
Frank Gaffney	Florida Municipal Power Agency	4	Negative	My biggest problem is with R1 and R2 "Each Transmission Owner shall manage vegetation to prevent encroachment that could result in a Sustained Outage of applicable lines .... Types of encroachment include: 1. An encroachment into the Minimum Vegetation Clearance Distance (MVCD) as shown in Table 2, observed in real time, absent a Sustained Outage, 2. An encroachment due to a fall-in from inside the active transmission line ROW that caused a vegetation-related Sustained Outage, 3. An encroachment due to blowing together of applicable lines and vegetation located inside the active transmission line ROW that caused a vegetation-related Sustained Outage, 4. An encroachment due to a grow-in that caused a vegetation-related Sustained Outage" One fundamental problem with all the standards is the demand for no faults, no errors, 100% compliance. Requirements 1 and 2 basically say that any vegetation related outage, except for blow ins from outside the ROW, is a violation. A few issues with this: How would we "prove" that an outage is vegetation related or not, and if vegetation related, where the vegetation came from? Would this be a "guilty until proven innocent" paradigm, e.g., if we don't know what the cause was, then we assume guilty, or an "innocent until proven guilty" paradigm, e.g., clear evidence is needed to prove guilt? Current compliance monitoring and enforcement methods are to assume guilt with the need for clear evidence of innocence until a hearing is requested, at which point the paradigm is reversed. If this is how we expect it to happen? I could see a large number of "Possible" and "Alleged" violations where the cause of the sustained outage or the source of the vegetation is unknown, and a large number of hearings, unless we begin with the paradigm with "innocent until proven guilty", which is not the approach monitoring and enforcement take currently. The requirement and the measures do not match. The requirement is to "manage". Sometimes a well managed environment can still fail. The measures are "failures". If the measures are failures and any failure is a violation, then, the requirement should be to "prevent" not to "manage". Staff's proposed VSLs highlight this inconsistency. The 100% compliance requirement, as opposed to a statistical measure such as 99.99% availability, and Measures that say that any Sustained Outage is a possible violation unless proven otherwise leads us to extreme methods of management, such as possibly having video cameras monitoring the ROW at all times. Is this what the Drafting Team intends? FMPA would suggest that if perfromance is the real purpose of these standards, then "manage" is the wrong requirement, and "prevent" is a more appropriate term. If prevention is the real requirement, then we need a paradigm of "innocent until proven guilty" and any unknown source of a sustatined outage is assumed not to be a vioaltion until proven guilty, and, 100% is not a reasonable target, 99.99% or similar umber over a number of years (e.g., so many years rolling average) is a more reasonable target. Do we require 100% compliance with vehicle brakes (ala Toyota Prius)? Or tire blowouts (ala Ford Explorer)? With associated fines? If we did, the auto manufacturers would probably not offer cars to the American market due to too much risk and liability. TQM (total

Voter	Entity	Segment	Vote	Comment
				qulaity management) processes, such as six sigma (i.e., 6 standard deviations) do not mandate 100% reliability becuase 100% reliability is too expensive. Rather, we need a conservative target where outliers beyond regional management controls do not result in huge fines and huge liability (especially in consideration with FERC's proposed Policy Statement on Sanctions) R4 "Each Transmission Owner, without any intentional time delay, shall notify the control center holding switching authority for the associated transmission line when qualified personnel confirm the existence of a vegetation condition that is likely to cause a Fault at any moment" How is R4 even measureble? How are we to measure how someone would determine "the existence of a vegetation condition that is likely to cause a Fault at any moment"? Having the requirement in the standard may have the unintended consequence of reverse psychology e,g., not notifying may not even open up the question of compliance with this requirement. However, if a sustained outage were to occur as a result violating R1 or R2, would this requirement necessitate launching an investigation of whether or not "qualified" personnel would have seen a problem. I see this requirement as fraught with difficulties. Would this requirement essentially require a procedure for "detecting" in R3 in addition to "preventing" If 100% compliance is the chosen method for R1 and R2, why is R4 (and R5 for that matter) even needed? Obviously, if there is an impending failure that would cause a vioaltion of R1 and R2, then there is obviously incentive to report it to the System Operator. R7 "Each Transmission Owner shall complete the work in an annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made and documented provided they do not put the transmission system at risk of a vegetation encroachment. Examples of reasons for modification to annual plan may include ...." The first sentence should not include the phrase "to ensure no vegetation encroachments occur" since the requirement is to do the work in the work plan. The added phrase sinply adds ambiguity, e.g., if there is an encroashment, is R7 violated since it does not meet hte "unsure" phrase in addition to R1 and R2? Periodic Data Submittals Due to R1 and R2, this is really a self-certification process because essentially only violations to R1 and R2 as curently drafted would be reported. So, this section should be deleted in favor of a CMEP process for periodic self-certifications on the standard.

Response: Thank you for your comments. Based on recommendations, the language in M1/M2 has been modified. Proof that an outage was vegetation related will be determined through the investigation of the outage. If clear evidence as determined by the Transmission Owner exists, the entity would then self-report. R4 exists to ensure that "expeditious communication between the Transmission Owner **and proper operating personnel when a critical situation is confirmed." This situation does not necessarily imply a violation of R1 and R2. The intent is to minimize the risk of an event that could cause a cascading event. Regarding the inclusion of the phrase "to ensure no vegetation encroachments occur" in R7, the intent of the SDT is to include language to indicate who should do what when, where, and why as part of the Results Based Standards format.**

Silvia P Mitchell	Florida Power & Light Co.	6	Negative	NextEra Energy, Inc believes that this standard is a step in the right direction; however, it is not ready for ballot. The posted version uses the Measures and Compliance sections to define and interpret Requirements. The Requirements should stand by themselves. This version of the standard lumps grow-in violations with fall-in and blow-in violations. Fall-in and grow-in violations have no correlation to the cascading events stated in the purpose. We believe it needs more work before ballot approval.
Response: The SDT thanks you for your comment. The SDT modified R1 and R2 to incorporate the severity into the requirement. This will allow for a graded VSL. The team also modified the measure so that it does not qualify the requirement. These changes should resolve your issues.				
Larry E Watt	Lakeland Electric	1	Negative	o The draft standard requires perfection, which is an unreasonable performance metric o The standard is prone to arguments of whether or not an outage was caused by vegetation encroachment in the current "guilty until proven innocent" paradigm we are currently in o Are the requirements measurable (e.g., R4 and R5)? o Goals of requirements should not be mixed with the requirement itself. Goals add ambiguity of what is being measured, the requirement (e.g., "complete the work plan" in R7) or the goal (e.g., "ensure no vegetation encroachment occurs"). o Periodic data submittals as written are really periodic self-certifications and ought to be named such, or 100% compliance reduced to a more reasonable target
Response: The SDT thanks you for your comments. The SDT recognizes that the Standard as written is zero tolerance and believes it is compelled to write it that way. FERC staff and NERC assert that a revised standard cannot result in less reliability than the one it replaces, and, their belief is the current Standard is zero tolerance. The SDT believes that R4 and R5 are measurable as described. The RBS process is essentially “Who should perform What actions under What conditions.” Thus the Goals are included. Finally, FERC would prefer to have early warnings that reliability is at risk, rather than wait for that indication when the next blackout occurs. Hopefully, periodic data offers that early warning detection.				
David H. Boguslawski	Northeast Utilities	1	Negative	Our main issue is with the change in the Active ROW definition. The recent addition of a centerline distance to edge of Active ROW is not acceptable as it does not take into consideration the construction of the line (e.g., mono-pole vs. H-frame). For mono-pole construction, the use of the Table 3 centerline distance could result in additional clearing of the forested edge on existing ROWs with no value added to system reliability. Instead of using the term "Centerline" as referenced on Table 3, the use of "outer phase" or "phase closest to tree line" would be more appropriate.
Response: The SDT thanks you for your response. Due to many commenters having issues with trying to define a “minimum” width, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.				
Mace Hunter	Lakeland Electric	3	Negative	Perfection is not a reasionable performance metric

Response: See responses to Earl Burnside, PPL Electric Utilities.				
John C. Collins	Platte River Power Authority	1	Negative	PRPA appreciates the SDT's reliability objective through a defense-in-depth strategy and the improvements made to the standard since its last posting. However, several issues will cause us to vote negative. Our first concern is that a violation caused by an encroachment into the Minimum Vegetation Clearance Distance as shown in Table 2, observed in real time, absent a Sustained Outage does not improve reliability of the BES. Instead we believe the clearances to be achieved in the current version of the standard under R1.2. are a better measurement of expectations because they establish a clearance to be achieved at the time of work. Our next concern is with the ambiguity of the wording "without any intentional time delay" in R4 of the proposed standard. For instance, would a call from the lineworkers to his/her supervisor prior to a call to the control center constitute an intentional delay or would that be part of the confirmation process? We also question what constitutes qualified personnel in R4. Does this imply that R1.3. in the current standard requiring appropriate qualifications and training is still applicable although not implicated stated and will those qualifications be audited as they are now? Our last concern is that landowners will intentionally constrain and delay work through court orders pointing to our Federal requirement to take corrective action. We know this isn't the intent of the requirement but have some concern that it might be misinterpreted by landowners as their defense to force us to investigate or perform alternate work methodology.
Terry L Baker	Platte River Power Authority	3	Negative	
Response: Thank you for your comments. While the SDT has struggled with the issue of encroachments into the MVCD being a violation, the fact that a TO would allow vegetation to approach, let alone encroach the MVCD indicates a serious flaw in the TO's vegetation management program and its application. The TO has every right and should under the proposed standard establish clearance distances at the time of work (Clearance 1 in FAC-003-1) to allow for growth. With regard to Clearance 1 of version 1 the SDT considered it a "fill in the blank" requirement. Thus, including it in version 2 was considered prescriptive and unnecessary. **The time required by the TO to report an issue is subject to many variables such as available communication for the area which could be a hike-in location with no radio or cell phone coverage. For this reason it is difficult to establish a time period which would fairly apply to all TO's. Thus, the SDT has taken the approach which does create some subjectivity. With regard to your question regarding a call from a line worker to a supervisor being viewed as intentional delay, we would need to know if this call is part of your process for reporting imminent threats. If your process has this**				

Voter	Entity	Segment	Vote	Comment
check point or the flexibility for the lone worker to call a supervisor, then the SDT would not view this as an intentional delay. **Qualified personnel is a function of many variables such as the size of the TO's system, type and density of vegetation, access and complexity of the vegetation management program. All these factors will drive the qualification requirements as defined by the TO for personnel developing and administering the program. For instance a TO with little vegetation on its ROW may require little in the way of knowledge and methodologies in meeting this standard while those TO's with extensive and significant vegetation must use varied methodologies to control vegetation on its ROW such as mechanical control, manual control, herbicides and so on. Thus, the standard leaves it to the TO to define what defines qualified personnel. Refer to the reference document for more guidance.** **As you point out, it is not the intent of this standard to cause the landowner to intentionally constrain and delay work. But, it is also not the intent of the standard to drive the land owner or land manager to any other behaviors. It is the TO's responsibility to manage relationships and develop methodologies within and to the full extent of the easement or permit language. Requirement R5 deals with this issue and additional clarification is given in the Rationale for this requirement.**				
David Schumann	Florida Municipal Power Agency	5	Negative	R1 & R2 My biggest problem is with R1 and R2 "Each Transmission Owner shall manage vegetation to prevent encroachment that could result in a Sustained Outage of applicable lines .... Types of encroachment include: 1. An encroachment into the Minimum Vegetation Clearance Distance (MVCD) as shown in Table 2, observed in real time, absent a Sustained Outage, 2. An encroachment due to a fall-in from inside the active transmission line ROW that caused a vegetation-related Sustained Outage, 3. An encroachment due to blowing together of applicable lines and vegetation located inside the active transmission line ROW that caused a vegetation-related Sustained Outage, 4. An encroachment due to a grow-in that caused a vegetation-related Sustained Outage" One fundamental problem with all the standards is the demand for no faults, no errors, 100% compliance. Requirements 1 and 2 basically say that any vegetation related outage, except for blow ins from outside the ROW, is a violation. A few issues with this: How would we "prove" that an outage is vegetation related or not, and if vegetation related, where the vegetation came from? Would this be a "guilty until proven innocent" paradigm, e.g., if we don't know what the cause was, then we assume guilty, or an "innocent until proven guilty" paradigm, e.g., clear evidence is needed to prove guilt? Current compliance monitoring and enforcement methods are to assume guilt with the need for clear evidence of innocence until a hearing is requested, at which point the paradigm is reversed. If this is how we expect it to happen? I could see a large number of "Possible" and "Alleged" violations where the cause of the sustained outage or the source of the vegetation is unknown, and a large number of hearings, unless we begin with the paradigm with "innocent until proven guilty", which is not the approach monitoring and enforcement take currently. The requirement and the measures do not match. The requirement is to "manage". Sometimes a well managed environment can still fail. The measures are "failures". If the measures are failures and any failure is a violation, then, the requirement should be to "prevent" not to "manage". Staff's proposed VSLs highlight this inconsistency. The 100% compliance requirement, as opposed to a statistical measure such

Voter	Entity	Segment	Vote	Comment
				as 99.99% availability, and Measures that say that any Sustained Outage is a possible violation unless proven otherwise leads us to extreme methods of management, such as possibly having video cameras monitoring the ROW at all times. Is this what the Drafting Team intends? FMPA would suggest that if perfromance is the real purpose of these standards, then "manage" is the wrong requirement, and "prevent" is a more appropriate term. If prevention is the real requirement, then we need a paradigm of "innocent until proven guilty" and any unknown source of a sustatined outage is assumed not to be a vioaltion until proven guilty, and, 100% is not a reasonable target, 99.99% or similar umber over a number of years (e.g., so many years rolling average) is a more reasonable target. Do we require 100% compliance with vehicle brakes (ala Toyota Prius)? Or tire blowouts (ala Ford Explorer)? With associated fines? If we did, the auto manufacturers would probably not offer cars to the American market due to too much risk and liability. TQM (total qulaity management) processes, such as six sigma (i.e., 6 standard deviations) do not mandate 100% reliability becuase 100% reliability is too expensive. Rather, we need a conservative target where outliers beyond regional management controls do not result in huge fines and huge liability (especially in consideration with FERC's proposed Policy Statement on Sanctions) R4 "Each Transmission Owner, without any intentional time delay, shall notify the control center holding switching authority for the associated transmission line when qualified personnel confirm the existence of a vegetation condition that is likely to cause a Fault at any moment" How is R4 even measureble? How are we to measure how someone would determine "the existence of a vegetation condition that is likely to cause a Fault at any moment"? Having the requirement in the standard may have the unintended consequence of reverse psychology e,g., not notifying may not even open up the question of compliance with this requirement. However, if a sustained outage were to occur as a result violating R1 or R2, would this requirement necessitate launching an investigation of whether or not "qualified" personnel would have seen a problem. I see this requirement as fraught with difficulties. Would this requirement essentially require a procedure for "detecting" in R3 in addition to "preventing" If 100% compliance is the chosen method for R1 and R2, why is R4 (and R5 for that matter) even needed? Obviously, if there is an impending failure that would cause a vioaltion of R1 and R2, then there is obviously incentive to report it to the System Operator. R7 "Each Transmission Owner shall complete the work in an annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made and documented provided they do not put the transmission system at risk of a vegetation encroachment. Examples of reasons for modification to annual plan may include ...." The first sentence should not include the phrase "to ensure no vegetation encroachments occur" since the requirement is to do the work in the work plan. The added phrase sinply adds ambiguity, e.g., if there is an

<table>

<tr><td colspan="5">Response: Thank you for your comments. Your concern with respect to the cause of an outage is well-taken. As you know, transmission systems are subject to many different influences which can cause a sustained outage. Among those causes is the encroachment of vegetation into the MVCD which could be due to improper maintenance of vegetation on one’s ROW. However, there are many other causes which can initiate a sustained outage. A TO usually investigate a sustained outage in the field to determine, if possible, the cause of the outage. Typically, a vegetation caused outage will leave some evidence of the flashover such as burn marks on the conductor together with burned portions of the vegetation. Indications may be found to explain the outage due to other causes but in some cases the cause cannot be determined and the line is successfully re-energized without ever knowing what caused the outage. It is incumbent upon the TO to self- report those outages obviously caused by vegetation but unexplained outages would not fall under this requirement or standard.

The SDT believes the language in the requirement matches the language in the measure such as in R1 “Each Transmission Owner shall manage vegetation to prevent encroachment…” and in M1 “Each Transmission Owner has evidence that it managed vegetation to prevent encroachment…”. Your suggestion of using statistical analysis may work well with large TO’s with many miles of transmission ROW to spread small numbers of outages over but would disadvantage the small TO with significantly fewer miles of line. Only one outage on its system could result in huge fines.

The SDT believes R4 is a valid “Risk Based Requirement” giving guidance to industry on what to do upon discovery of an encroachment into the MVCD in order to prevent a sustained outage. The key is for the TO to communicate with the appropriate switching authority and the measure is evidence of such communication when a potential vegetation imminent threat occurs. R7, as documented in the Rationale, “…sets the expectation that the work identified in the annual work plan will be completed as planned”. Documentation of the work completed (and any necessary modifications) as written together with the lack of of a violation to either Requirement 1 or Requirement 2 is the overall reliability goal. The metric for the work plan is the percentage of the plan complete. The lack of a violation of R1 or R2 is the outcome of the ideal work plan. It is the responsibility of the TO to manage the quality of the work plan and its associated modifications to mitigate the risk of a violation of R1 or R2. With Version 2, an outage is now clearly a violation of R1 and R2 and should not be linked to a failure of the work plan. The measure for the work plan is the percentage of the completed as planned and we do not need to be subjectively trying to evaluate the quality of the TOs plan with this measure. With regard to the “Periodic Reporting Data Submittal” section the SDT agrees with reporting outage to the Regional Entity on a quarterly basis. In addition regulatory authorities are looking for leading reliability indicators which will support quarterly reporting rather than an annual self-certification.</td></tr>
<tr><td>Kenneth Simmons</td><td>Gainesville Regional Utilities</td><td>3</td><td>Negative</td><td>R4 The use of intentional time delay is a qualitative attribute and not a quantitative measure. How does one judge intentional versus non-intentional on a qualitative basis; subjective at best leading to many arguments between auditor and auditee?</td></tr>
<tr><td colspan="5">Response: Thank you for your comment. We agree the time required by the TO to report an issue is subject to many variables such as available communication for the area which could be a hike-in location with no radio or cell phone coverage. For this reason it is difficult to establish a time period which would fairly apply to all TO’s. Thus, the SDT has taken the approach which does create some subjectivity. The key is for the TO to have an imminent threat process that includes the communication with the appropriate switching authority. Luther E. Fair	Gainesville Regional Utilities	1	Negative	R4: The use of intentional time delay is a qualitative attribute and not a quantitative measure. It will lead to endless arguments over intentional versus non-intentional. R4 should be: Each Transmission Owner shall notify the control center holding switching authority for the associated transmission line no more than 6 hours of a qualified personnel confirm the existence of a vegetation condition that is likely to cause a Fault at any moment. R7: R7, as proposed, requires a VMP to be completed to ensure no encroachment occurs. The Supplemental Reference for R7 does not describe the requirement of the annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD. The Reference states the requirement is established to diminish the risk of encroachment; very different from ensuring no encroachment. In the reference for R7 the word “ensure” is only used to describe that flexibility in the VMP is allowed to ensure the reliability of the Transmission System. The above comments are from United Illuminating and shared by myself. Earl

David A. Lapinski	Consumers Energy	3	Negative	Table 3 does not adequately address ROW width requirements based on the type of construction used for structures, especially for the two lower voltage classes, 69-138kV and

Voter	Entity	Segment	Vote	Comment
David Frank Ronk	Consumers Energy	4	Negative	139-230 kV. Lines constructed on H-Frame structures have a much wider footprint across the ROW than do single pole construction and most steel tower construction types. The minimum ROW width listed in Table 3 for a 138 kV line constructed on a wooden H-Frame may put the outside conductor within MVCD under windy conditions due to wind displacement of conductors and trees. Consumers Energy recommends that Table 3 be modified to describe the minimum distance in the table is the vertical plane of the outside conductor to the edge of the active transmission ROW and therefore independent of the width of the structure construction type. MI and M2 fail to provide examples of acceptable forms of evidence to prove that a Transmission Owner actively managed vegetation to prevent encroachment into the MVCD. The Measures should require proof of active ROW clearing activity in accordance with the transmission vegetation management plan, such as invoicing or crew field reports or vegetation inspection data from the annual vegetation inspection R3 avoids defining a minimum clearance specification and is not practical. As written, this would require each Transmission Owner to define and document the procedures, processes or specification by individual span for every line owned or operated by the Transmission Owner. Each span varies in length and profile and a single line may have several different conductor types with different load ratings. Line loadings will vary along the line based on substation taps, etc. The dynamics described in the language could only be done on an individual span basis to be reasonably accurate. This is not practical from a planning standpoint or from a standpoint of implementing clearing work in the field.
Response: The SDT thanks you for your comments. **1) Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.** **2) M1 and M2 do provide samples of acceptable forms of evidence. The examples you have provided in your comment would also be acceptable forms of evidence. The SDT recognizes that there are many acceptable forms of evidence and only included three specific examples in both Measures M1 and M2 utilizing the phrase 'may include' so that the list is not limited to the samples provided.** **R3 specifically states that the TO shall prevent encroachment into the MVCD which is a defined minimum clearance distance, contrary to your comment. To prevent a Sustained Outage, each TO must recognize that each transmission line is unique and establish a general plan that encompasses each scenario. In their procedures or processes or specifications, the TO shall establish a maintenance strategy that ensures vegetation will never violate the MVCD. This strategy should take into consideration the dynamics of vegetation growth and conductor movement as explained in the Guidelines and Technical Basis section of the Standard (Page 21). This strategy does not necessarily require a span by span analysis.**				
Bernard Pelletier	Hydro-Quebec TransEnergie	1	Negative	Table 3 is not acceptable for HQTE. In many places, our standard of design allow us a ROW width much narrower. We think that Table 3 should cover only the lines operated at 200 kV or higher. Finally, the Table 3 should not be a requirement of the FAC-003-2.
Response: Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.

<tr><td colspan="5">Response: The SDT thanks you for your comments.
1. The SDT recognizes that the Standard as written is zero tolerance and believes it is compelled to write it that way because FERC staff and NERC assert that a revised standard cannot result in less reliability than the one it replaces and their belief is the current Standard is zero tolerance.
2. As explained in M1 and M2, only real time observations confirmed by a qualified person would constitute an encroachment. There may be some difficulty proving whether or not an outage was caused by vegetation but, if an investigation at any time reveals definitive evidence of a vegetation contact as determined by the Transmission Owner, this would be the proof.
3. The SDT believes that R4 and R5 are measurable as described in the Draft but would gladly accept suggestions for revision in future postings. The RBS process essentially is “Who should do what, under what conditions, when, and why?” Thus the Goals are included. Finally, FERC staff has stated that they would prefer to have early warnings that reliability is at risk rather than wait for that indication when the next blackout occurs. Thus, periodic data offers that early warning detection.
Periodic data submittal is not only restricted to self-certifications so the SDT has chosen to keep the language the same as currently drafted.</td></tr>

Robert D Smith	Arizona Public Service Co.	1	Negative	The reasons for APS to vote NO. The standard drafting team went above and beyond and changed the whole standard and didn't address all of FERC's concerns. (0) The minimum clearances must be sufficient to avoid any sustained vegetation-related outages for all applicable conditions. (1) The team eliminated clearance 1 requirement which isn't addressed in this revision according to FERC's request. FERC wanted this requirement to be standardized. Elimination of clearance 1 doesn't give utilities leverage when dealing with federal land agencies. They are making decisions without any education or knowledge on UVM activities which affect transmission reliability. There needs to be a clearance 1 requirement in the standard. If utilities are required to follow this standard it gives them leverage with dealing with these federal land agencies. (2) They removed ANSI-A300 from the standard. It was a footnote but should be part of the standard. Utilities should be held to following ANSI A-300 standards and BMP's for best management practices. By following these standards there wouldn't be a need for the FAC-003 standard. (3) Removal of 'fill in the blank' components where the Transmission Owner determines the requirement with no limits or direction. Examples include and "personnel requirements" in version 1. The SDT removed this requirement from the current version. ? Personnel qualifications should be a requirement. There are certification programs through the International Society of Arboriculture that certify a minimum level of competence to manage a vegetation management program. This also requires ongoing training and education to keep up with the latest technologies on UVM. ? There are other standards that require qualifications and training.

Voter	Entity	Segment	Vote	Comment
				(4) Application of new NERC Drafting Team Guidelines (DTG) to the standard. Examples include the replacement of the current compliance section with Violation Risk Factors (VRFs) and Violation Severity Levels (VSLs) as referenced in the Sanction Guidelines. Additionally, documentation and implementation elements are separated into different requirements in the proposed standard as required by the DTG. (5) This requirement in regard to outages from within the ROW was diluted to remove accountability from maintaining the full width of utilities easement. An outage is an outage from a grow-in or from a blow in. If a utility has rights to maintain vegetation there shouldn't be any outages due to vegetation from blowing into the conductors. The active ROW should be wide enough to prevent these types of outages. o Address the applicability and appropriateness of IEEE 516 in determining clearance distances. ? No issues with the change to Gallet equation. ? The issue is each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R1. Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-Time observations of any MVCD encroachments. ? (6) A real-time observation doesn't take into account all rated conditions and the time the recording was made. Conditions change and if load is increased those previous observations could be potential outages. I would assume our Energy Control people would want to be confident there wouldn't be any tree-related issues if load had to be increased. ? There is technology available with LIDAR to simulate all-rated conditions, contour and tree height to remove these potential trees hazards before an outage occurs. o Address applicability of this standard to sub 200kV lines that could place the grid at an unacceptable risk of instability, separation, or cascading failures. ? (7)The utilities should be required to inspect all the lines annually. The change isn't what FERC requested. o Address applicability to federal lands. ?

Voter	Entity	Segment	Vote	Comment
				(8)There should be a footnote that if federal or state agencies fail to approve annual work plans within 90 days of submittal the utility will not be held accountable for not completing its annual work plan or taking into account the time it takes to get approval. We have land agencies that give us approvals within 2 weeks and others that have taken over a year. Utilities are at their mercy on the approval process. If there is turn-over in the land agency the approval process changes again and it is impossible to determine the anticipated timeline by state, tribal and federal agencies. ? The SDT didn't address the need for FERC oversight on federal lands as the example listed above. Agencies are not qualified to make decisions on utility vegetation management and can change utilities TVMP. (9)Finally the current version FAC-003-1 is performing and there is no need to make the change.

Response: Thank you for your comments.

(0)If vegetation is maintained as required in this draft of the standard in requirements R1 and R2, then no vegetation related sustained outages, caused by vegetation from within the ROW, within the control of the TO can occur.

(1) Clearance 1 was a fill-in the blank requirement and did not provide the TO any new easement rights, or land permit rights across any lands whether those land be privately owned or publicly owned; therefore Clearance 1 remains removed from this draft. Furthermore, the relevance of Clearance 1 depends on several other factors such as length of maintenance cycles, inspection frequency and growth rates. R3 is now used as a more comprehensive method to address these concerns in lieu of a Clearance 1 requirement.

(2) In order to meet the SAR FAC-003 is required. ANSI-A300 is not sufficient to meet the SAR requirements and contains many elements that do not need to be related to transmission system electrical reliability.

(3)The SDT suggests that the submittal of a NERC SAR on the PER standards be considered to address any proposed personnel qualifications, certifications or training issues.

(4) The SDT is following NERC guidelines as they understand them.

(5) The SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way; subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed. Outages arising from vegetation from outside the ROW are not violations of the standard. The SDT had determined this to be the most appropriate assignment of an area of maintenance responsibility considering the numerous variations in easements and permit rights across North America.

(6)The Standard requires the maintenance to be performed such that loading to Rating and Rated Conditions, and the dynamics of sag and sway are are taken into consideration, additionally any real time observations of encroachments into the MVCD are to be reported as violations of the standard. The SDT does not see the need to be prescriptive as to the technology or tools the TO used to be compliant with the Standard, but is confident that if the vegetation in maintained such that no encroachments are ever observed, and no outages are ever occur, then the reliability purpose of the standard will be fully accomplished. Furthermore, the results from a LIDAR survey are temporal in nature. Any program relying on LIDAR would incur a substantial cost with a long term commitment that may not be justified for many Transmission Owners.

(7) FERC requested a defined period for inspection. The SDT agrees with you that annual inspection is required. Therefore the SDT has made annual inspections a Requirement of this Standard. As to all lines versus applicable lines, FERC has accepted the 200 kV bright line for this standard. They did order the SDT to ensure that no sub-200 kV lines that are important to the Bulk Electric System are missing from the Applicability of the standard.

Voter	Entity	Segment	Vote	Comment
The SDT has incorporated a FERC accepted test (as found in the referenced Standard) to make sure no such important lines are missing. **(8)The SDT agrees that erroneous obstacles to compliance with the standard should be addressed. However, they cannot be resolved in this forum, or through language inserted in this standard. This Standard places requirements on the Transmission Owners, not on landowners. There is no legal mechanism for this Standard to take rights from property owners and assign them to the Transmission Owner.** **(9)The SDT is changing the Standard in responds to the SAR. The success of the existing standard will be preserved and enhanced with this revision.**				
Paul Shipps	Lakeland Electric	6	Negative	The standard is prone to arguments of whether or not an outage was caused by vegetation encroachment.
Response: Thank you for your comments. **The Compliance Section of the Standard provides the direction under which the Compliance Monitoring and Enforcement Processes and the TOs must report compliance to this standard. All possible violations need adequate investigation to determine if a vegetation related outage occurred. The SDT recognizes that such determination are often very challenging, however more prescriptive language on investigations has been seen as necessary by the SDT and would not contribute to increased reliability. NERC also requires the TOs to document all outages and their related causes in the TADS system.**				
Daniel Brotzman	Commonwealth Edison Co.	1	Negative	The term “Centerline of the Circuit” in Table 3 is not defined. Until it is defined, there is no way to know if the standard is technically reasonable or whether existing circuits would be in violation of the standard and unable to operate. In addition, it is unclear what types of construction and span lengths were used to develop the distances for active right-of-way widths in Table 3. Furthermore, it is not clear whether Table 3 contains requirements against which compliance will be measured or best practice guidelines. Footnote 2, in the background section, compounds this ambiguity. In short, the lack of a definition for “Centerline” combined with Footnote 2 and Table 3 make this draft unclear and unenforceable. Exelon does not necessarily have easement widths for all transmission lines that equal those defined in Table 3 of this draft; This may require the acquisition of additional easements, if even possible.
Response: Thank you for your comments. **In response to your comments and similar comments to yours, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.**				
Alan Gale	City of Tallahassee	5	Negative	There is still confusion in R7. If I do not complete the work plan, but do not have any encroachments, have I violated R7? As worded I would argue no. I do not believe the ambiguity can remain in the standard. If the goal is to complete the work plan (as modified) leave out the "to ensure no vegetation encroachments..." If the goal is to have no encroachments, do not rely on a work plan to exist. Make the standard "Each TO shall ensure no vegetation encroachments occur." I do agree with the performance based

Voter	Entity	Segment	Vote	Comment
				approach and format.
Response: Thank you for your comments. The SDT considered your response but feels that when one considers all the text in R7, M7, the Rationale and the related VSL, along with the text in the Guidelines and Technical Basis, it is sufficiently clear that this requirement is about the completion of the work plan.				
Roger C Zaklukiewicz		8	Negative	To maintain reliability, the minimum distance from a conductor to tall vegetation should be measured from the conductor nearest the edge of the cleared ROW to the edge of the ROW and not from the center line of the transmission structure. The type of transmission line configuration, horizontal or vertical - monopole versus H-Frame versus lattice-structure versus a V-Guided structure will influence how effective a transmission circuit's performance or reliability is when the measurement is made from the centerline of the transmission line. Table 3 should be modified to reflect this concern to ensure the reliability of the EPS.
Response: In response to your comments and similar comments to yours, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way; subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.				
Brian Evans-Mongeon	Utility Services, Inc.	8	Negative	Utility Services supports the NPCC position on the fixes to this standard proposal.
Response: Thank you for your comments. Please refer to our response to NPCC.				
John K Loftis	Dominion Virginia Power	1	Negative	We do not agree with replacing the term “Active Transmission Line Right of Way” with footnote 2. Our objection is around the distances proposed in Table 3. Minimum Distance from the Centerline of the Circuit to the edge of the active transmission line ROW may not be consistent with the centerline distances cleared and maintained by the TO. For example, a TO maintaining 75’ from centerline for a 500kV circuit would be required to clear and maintain an additional 12.5’ to meet the proposed standard’s requirement. We suggest either allowing individual TOs to maintain active ROW widths consistent with their normal clearing/maintenance practices, going back to Draft 3’s definition of Active Transmission Line Right-of-Way, or changing the footnote in Draft 4 to read: A strip or corridor of land
Michael F Gildea	Dominion Resources Services	3	Negative	
Mike Garton	Dominion Resources, Inc.	5	Negative	

Voter	Entity	Segment	Vote	Comment
Louis S Slade	Dominion Resources, Inc.	6	Negative	that is occupied by active transmission facilities. This corridor does not include the parts of the Right-of-Way that are unused or intended for other facilities. However, the portion of the ROW that has been cleared must at least meet design clearance requirements such as National Electric Safety Code or other design criteria, for the reliable operation of active facilities.
Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way; subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.				
Ronald L Donahey	Tampa Electric Co.	3	Negative	We have concern with the “Minimum Distances” as listed in Table 3. What analytical methodology, criteria and rationale was utilized to determine each recommended distance? In addition, we have concerns regarding the change to a pre-determined distance. This seems to be a major shift from the vegetation to conductor methodology employed previously and throughout this standard? NERC/FERC must recognize that while protecting and securing grid reliability, each utility must also balance the environmental, political, customer and economic issues and impacts which will occur with the implementation of the Table 3 clearances. We question whether this is the most responsible action to take given the current state of the economy as well as the environmental and political sensitivity impacts which will result. Tampa Electric questions whether Table 3 will improve System reliability. Since the inception of standard FAC-003-1 Tampa Electric has not had a Category 1 or Category 2 outage on our 230kV Transmission System. We don’t believe that the changes proposed to table 3 will improve overall service reliability. It is Tampa Electric’s opinion that each utility should define the width of its own Active Transmission line ROW. However, if such a table is to be utilized, Tampa Electric recommends the following changes or adjustments to Table 3. 1. Expand the table to account for the various types of Transmission construction; i.e. vertical versus horizontal conductor configurations. 2. Use a distance from the outermost conductor, not the centerline. This will account for construction type and better achieve a consistent clearance from conductors. 3. We recommend reducing the distances in Table 3 by 12.5 feet for each voltage category. 4. Specify whether the voltage is based upon the design or operating voltage. 5. Reformat the voltage ranges to 100kV - 200kV, 200kV - 300kV, 300kV - 400kV, etc. as an example; this would create a more appropriate range of voltages and clearance distances. The reformatted voltage ranges eliminate confusion. For example, under the current proposal it is unclear in which category a nominal 230kV line should be since sometimes such a line can operate at up to 232kV during low-load conditions.
Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.				

Voter	Entity	Segment	Vote	Comment
Joseph O'Brien	Northern Indiana Public Service Co.	6	Negative	While there are some enhancements to the organization and content of the standard such as the addition of the Guidelines and Technical Basis section, clarification of what constitutes evidence of compliance, and tailoring of VSL severity levels for the requirements based on the risk each poses to the likelihood of contributing to a cascade, too many elements present in FAC-003-1 and which are vital to preventing vegetation caused outages and maximizing system reliability, have been eliminated from FAC-003-2. Specifically, the elimination of concrete, declared and audited clearance standards between vegetation and conductors (the existing Clearance 1 and Clearance 2 (R1.2)) Requirements) in the revised standard is a major defect that will decrease system reliability. It has been indispensable for NIPSCO when communicating with stake holders (governments, interest groups, land owners, the public, etc.) to point to these clearance standards to give credibility and support to the kind of tree removal and trimming that is necessary to achieve the stated objective of zero preventable tree caused outages. Without these declared clearance standards in the NERC standard, utility vegetation managers will constantly be challenged by stake holders to show them that such work is required rather than an elective choice on the utility's part. One of the key lessons learned from the 2003 blackout and First Energy's overgrown ROW tree problem was that individual land owners, local governments, and interest groups will exert pressure on the utility to only do the minimum amount of vegetation management. Without external and enforceable Vegetation Clearance Standards and by returning to a pre-2003 regime where the extent of vegetation clearing is left to the individual discretion and pressures at each utility, there is no doubt that tree clearance conditions will deteriorate over time and put system reliability at greater risk of vegetation contact
Response: The SDT thanks you for your comments. At the request of FERC in Order 693, the SDT was asked to eliminate the fill-in-the-blank clearance requirements that are currently in FAC-003-1. A proven Engineering calculation was utilized to determine when a transmission line could spark over to vegetation without direct contact. Based on this calculation, each utility must determine what clearance levels need to be maintained as part of their TVMP. The current version does not preclude a utility from removing or pruning vegetation well beyond the MVCD, it just establishes a line in the sand that determines when a violation occurs. Individual TOs must establish a program that addresses the many variables that exist such as growth rates, vegetation management cycles, conductor sag and sway, etc. that could result in an encroachment of the MVCD which would be a direct violation of the standard. Establishing a specific clearance value to be attained during vegetation management activities is too prescriptive and is in direct conflict with the Results-Based Standard initiative that the SDT is currently implementing. Each TO must factor in delays and/or mitigation measures associated with stakeholder concerns but must clearly communicate the challenges with maintaining strict compliance with this zero-tolerance standard.

<tr><td>Greg Lange</td><td>Public Utility District No. 2 of Grant County</td><td>3</td><td>Negative</td><td>While this standard as written is a marked improvement to previous versions, to claim R1 and R2 as results based is simply not right. Had this standard revision not been advertised as the first RBS I probably would have voted yes. Results based by definition should be attained by something either happening or not and should be based on evidence that already exists. If you cause an outage and it is vegetation related then you violate. Why all the words around "managing vegetation encroachment" take care of that in the competency requirements.</td></tr>
<tr><td colspan="5">Response: The SDT thanks you for your comments. In a Results Based Standard, there are three different levels of defense to achieve the desired outcome (performance-based requirements, risk-based requirements and competency based requirements). R1 and R2 are considered Performance-Based requirements and are one component in the defense-in-depth strategy that is described in the Background Section of the current Draft. The MVCD is the minimum clearance distance before a spark-over occurs so R1 and R2 were designed to ensure that the TO manages vegetation appropriately before an outage occurs. If the TO was judged based on outages alone, the defense in depth strategy would fail and, thus, a less reliable standard would exist.</td></tr>
<tr><td>Gregory L Pieper</td><td>Xcel Energy, Inc.</td><td>1</td><td>Negative</td><td rowspan="4">Xcel Energy votes Negative for several reasons which are outlined in the comments submitted to NERC during the comment period that ran concurrently with this ballot. One of the primary objections is the requirement for an annual vegetation inspection. Xcel Energy urges the retention of the provision in the existing standard that allows the Transmission Owner to set the frequency of inspection.</td></tr>

Guy V. Zito	Northeast Power Coordinating Council, Inc.	10	Affirmative	Although NPCC and its members support the results based initiative and this proof of concept standard and format, there has been some concern with the proposed FAC-003-2. Some of NPCC's members that have active vegetation management programs have stated that in the application of Table 3 - specifically, the use of a "Minimum Distance from the Centerline of the Circuit". Mono-pole and frame construction have significantly different footprints which don't support a one size fits all approach. The use of Table 3 for 345kV, mono-pole construction could result in excessive clearing of additional forested edge on existing ROWs with little if any value added to system reliability and at great cost. There is an issue with use of the term "easements" in the definition and seek clarification on several questions-is there a reason the Active ROW only includes easements not fee ownership, license or some other right to occupy and manage the ROW? Would active ROW include "danger tree rights" on land? Not all entities that own transmission facilities and have vegetation management programs agree with these statements however there is cause enough for concern. In addition, this standard represents a "proof of concept for the "reliability based standards" initiative NERC is putting forward. NPCC RSC believe this initiative will result in better standards over time.
Response: The SDT thanks you for your affirmative vote and comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.				
Jason Shaver	American Transmission Company, LLC	1	Affirmative	ATC raises a concern on including Rationale Boxes plus Guidelines and Technical Basis as part of the NERC Reliability Standard. ATC recommends that the SDT either remove these sections or make them separate from the formal standard to eliminate any risk that these may be construed as requirements. An alternative method is to very clearly identify which parts of the standard are subject to compliance and considered mandatory and which are not considered requirements and are only for guidance in meeting the requirements.
Response: The SDT thanks you for your affirmative vote and comments. A "disclaimer" is addressed by the Standards Committee Process Subcommittee however its location remains under discussion.				
Horace Stephen Williamson	Southern Company Services, Inc.	1	Affirmative	Comments for this ballot are included in the Southern Company submitted comment form - Project 2007-07: Transmission Vegetation Management.
Richard J. Mandes	Alabama Power Company	3	Affirmative

Response: The SDT thanks you for your affirmative votes and comments. Please refer to the SDT responses in the Comment Report.				
Ajay Garg	Hydro One Networks, Inc.	1	Affirmative	Hydro One would like to submit the following comments for consideration of the SDT. 1. In the application of Table 3 - specifically, the use of a "Minimum Distance from the Centerline of the Circuit", Mono-pole and frame construction have significantly different footprints which don't support a one size fits all approach. The use of Table 3 for 345kV, mono-pole construction could result in excessive clearing of additional forested edge on existing ROWs with little if any value added to system reliability and at great cost. 2. The use of the term "easements" in the definition needs clarification. For example, is there a reason the Active ROW only includes easements and not ownership, license or some other right to occupy and manage the ROW? Would active ROW include "danger tree rights" on land?
Michael D. Penstone	Hydro One Networks, Inc.	3	Affirmative	
Response: The SDT thanks you for your affirmative vote and comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.				
Richard J. Padilla	Pacific Gas and Electric Company	5	Affirmative	In principle we agree but we have the following concerns: Removes reference to ANSI A300 as an effective management strategy to comply with the standard. We often point to ANSI A300 to support our position of "wire zone - border zone" vegetation management practices in public education and legal disputes. However, Eastern and Southern utilities, who dominate the VMSDT, feel that ANSI A300 places constraints on their desire to perform bare ground clearing, which A300 and PG&E does not endorse. Most Western utilities support retaining reference to A300. Minimum clearance distances have been reduced from the current IEEE 516 distances to the distances derived from the Gallet equation. Reduced clearance distances make it more difficult to justify some work with property owners. FERC and NERC have also stated they are opposed to reduced clearances. The VMSDT spent much time and effort to construct the standard in a manner where there is violation gradation within some requirements. NERC and FERC have indicated they disagree with the latitude to ignore the VSL's as proposed
Response: The SDT thanks you for your affirmative vote and comments. The proposed draft of FAC-003-2 continues to make reference to ANSI A300 as a best practice but short of endorsement into a requirement. This represents the best compromise that the team could achieve. **Use of the Gallet Equation, contrary to your comment, provides for greater distances than IEEE-516-2003 under the same conditions of elevation, voltage and transient overvoltage factor. Please refer to the Technical Reference Document (posted on NERC webpage) for more information.** **The SDT indeed has worked hard to achieve a technically valid set of VSLs for this standard and believe its perspective is correct.**				

Voter	Entity	Segment	Vote	Comment
Steven Grego	MEAG Power	3	Affirmative	MEAG is voting yes in support of the improvements and significant effort that went into modifying FAC-003-2 with the understanding that the vegetation management standard will continue to develop and evolve. Vegetation management's increased visibility and dramatically increased oversight is resulting in increasingly defined and demanding language contained in the standard's requirements. Some of the new requirements overreach but the intent is clear, create and manage a vegetation management program to prevent outages that potentially create a cascading outage threat. As the application of this new standard is reviewed over time, improved requirements and measures based on experience and results should be used to further improve the standard. Additional lines of lesser voltages will now be included under this standard. The tendency may be to include a line when in doubt even if there is a remote possibility that it can potentially cause a threat of a cascading outage. The same philosophy will occur with rights-of-way. The legal right-of-way will be cleared even if it was secured for a future line of greater voltage. We need to continue to review FAC-003-2 for future improvements to achieve reasonableness in protecting against cascading outages without heaping unnecessary costs on electric consumers.
Steven M. Jackson	Municipal Electric Authority of Georgia	3	Affirmative	
Response: The SDT thanks you for your affirmative vote and comments. The SDT agrees with your comments.				
Michael T. Quinn	Oncor Electric Delivery	1	Affirmative	Oncor believes that the proposed standard is a significant improvement over the current standard. We strongly support the suggested VSL's as proposed by the VMSDT. However, we also take the position that adoption of a virtual binary VSL to describe an encroachment without an outage, as a high VSL doesn't adequately address the different levels of encroachment and any potential impact that could lead to Cascading. Oncor is not aware of any vegetation fall-ins or blow-ins that have caused or have lead to Cascading.
Response: The SDT thanks you for your affirmative vote and comments. The SDT has worked hard to achieve a technically valid set of VSLs for this standard and believe its perspective is correct.				
Chifong L. Thomas	Pacific Gas and Electric Company	1	Affirmative	PG&E believes this version is an improvement over the last draft. However, PG&E is concerned with the removal of the reference to ANSI A300 as an effective management strategy to comply with the standard. ANSI A300 provides clarity on the "wire zone - border zone" vegetation management practices. PG&E is also concerned that the minimum clearance distances have been reduced from the current IEEE 516 distances to the distances derived from the Gallet equation. Reduced clearance distances make it more difficult to implement certain types of work needed to support reliability.
Response: The SDT thanks you for your affirmative vote and comments. The proposed draft of FAC-003-2 continues to make reference to ANSI A300 as a best practice but short of endorsement into a requirement. This represents the best compromise that the team could achieve.

Scott M. Helyer	Tenaska, Inc.	5	Affirmative	Please note that further changes may be needed to this standard to address issues related to generation interconnection facilities per other standards development efforts.
Response: The SDT thanks you for your affirmative vote and comments. The SDT is aware that a separate Project 2010-07 Transmission Requirements at the Generator Interface is underway to address the issue you raise.				
Brandy A Dunn	Western Area Power Administration	1	Affirmative	Please see comments provided on Official Comment Form
Response: The SDT thanks you for your affirmative vote and comments. Please refer to the responses in the Comment Report.				
Donald S. Watkins	Bonneville Power Administration	1	Affirmative	Regarding footnote number 2, and the description of an "Active Transmission Line Right of Way", BPA has the following comments: The distance is reasonable in the table, but due to widely varying designs of structures it does not give a relationship of the outside wire to edge of ROW. It should be noted as outside wire, phase or conductor to edge of ROW. In addition, the effective date should allow transmission owners time to achieve this distance, perhaps one cycle. Other Comments: The basis of managing vegetation to MVCD in Table 2 (essentially withstand distances) will likely prove problematic. BPA believes NERC should develop an additional table that calls out minimum "buffers" based on attributes such as line voltage, line rating etc. This table should be a companion to Table 2. It is NERC's responsibility to regulate and we believe that they should do so. In this case, the loss of flexibility for the owners is not necessarily a bad thing.
Rebecca Berdahl	Bonneville Power Administration	3	Affirmative	
Francis J. Halpin	Bonneville Power Administration	5	Affirmative	
Brenda S. Anderson	Bonneville Power Administration	6	Affirmative	
Response: The SDT thanks you for your affirmative votes and comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.				
Tim Kelley	Sacramento Municipal Utility District	1	Affirmative	SMUD appreciates the efforts of the Drafting Team. However, use of the phrase "intentional time delay" in R4 no clear definitive time frame for "intentional time delay" this leads to difficulty in its definition. SMUD respectively offers the recommendation for the DT to use a term along the lines of "expeditious."
James Leigh-Kendall	Sacramento Municipal Utility District	3	Affirmative	
Mike Ramirez	Sacramento Municipal Utility District	4	Affirmative	
Bethany Wright	Sacramento Municipal Utility District	5	Affirmative	
Response: The SDT thanks you for your affirmative votes and comments. The SDT struggled with the selection of language in R4 and considered your term among many others. The team ended up with the drafted version as the best compromise.				

Voter	Entity	Segment	Vote	Comment
Marjorie S. Parsons	Tennessee Valley Authority	6	Affirmative	Suggest a clarifying change to the language in footnote 2 and or Table 3 to address those lines that have ROW width variations from the prevailing width due to factors unrelated to the needs for vegetation maintenance for the subject line. Add the following sentence to footnote 2 "The widths and distances in Table 3 shall be that prevailing width of the ROW exclusive of any variations in the prevailing width due to factors unrelated to the needs for vegetation maintenance for the subject line." TVA asserts that the new language in R1, R2, M1, and M2 in concert with new language in R3 and M3 are fully adequate and superior to any of the proposed alternative A-F. TVA asserts that the VSLs as proposed by the SDT are appropriate since they reflect in various degrees the typical types of right of way maintenance failure. For example vegetation removal from under the conductors should be the highest priority work, followed by vegetation removal in the side-growth/blow-out areas, and lastly of all fall-in risks should be removed. TVA suggests that another sentence be added to the end of Section 4.4 Other, as follows: Nothing is this Standard is shall be used to require the Transmission Owner to acquire additional easement rights beyond those currently owned, or to perform any maintenance outside the limits of its legal rights.
Response: **The SDT thanks you for your affirmative vote and comments. Please see drafting team responses to your same comments in the Comment Report.**				
Paul B. Johnson	American Electric Power	1	Affirmative	The VSL chart states that it is a Lower Violation if the TO has an encroachment into the MVCD observed in real time, absent a sustained outage. While the Moderate and High categories specifically note that the reference is to inside the right-of-way, the Lower level does not. Should the Lower category read: " The Transmission Owner has an encroachment into the MVCD from inside the right-of-way in real time, absent a Sustained Outage"?
Edward P. Cox	AEP Marketing	6	Affirmative	
Response: **The SDT thanks you for your affirmative votes and comments. The suggested edit has been considered and the SDT determined that no change to the VSL would be made.**				
Robert Smith	Duke Energy	5	Affirmative	This Version 2 of FAC-003 takes a big step forward to clarify expectations and compliance with the standard. The results-based format is a big improvement.
Response: **The SDT thanks you for your affirmative vote and comment.**				

Voter	Entity	Segment	Vote	Comment
George T. Ballew	Tennessee Valley Authority	5	Affirmative	TVA suggests a clarifying change to the language in footnote 2 and or Table 3 to address those lines that have ROW width variations from the prevailing width due to factors unrelated to the needs for vegetation maintenance for the subject line. Add the following sentence to footnote 2 “The widths and distances in Table 3 shall be used as the prevailing width of the ROW regardless of any variations in width due to factors unrelated to the needs for vegetation maintenance for the subject line.” TVA asserts that the VSLs as proposed by the SDT are appropriate since they reflect in various degrees the typical types of right of way maintenance failure. For example vegetation removal from under the conductors should be the highest priority work, followed by vegetation removal in the side-growth/blow-out areas, and lastly of all fall-in risks should be removed. TVA suggests that another sentence be added to the end of Section 4.4 Other, as follows: Nothing in this Standard shall be used to require the Transmission Owner to acquire additional easement rights beyond those currently owned, or to perform any maintenance outside the limits of its legal rights.
Response: The SDT thanks you for your affirmative votes and comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed. **The SDT agrees with your comment on the VSLs, and the SDT points out that the following sentence at the end of Section 4.4 is comparable to your suggestion, “Nothing in this section should be construed to limit the Transmission Owner’s right to exercise its full legal rights on the ROW.”**				
Spencer Tacke	Modesto Irrigation District	4	Affirmative	We approve of the proposed revised standard as written. However, we have a concern about the Minimum Vegetation Clearance Distance (MVCD) of 2.97 feet shown in Table 2 for 230kV lines, as being too small. We will continue to maintain a much larger clearance than specified in Table 2, and in this case, no less than 10 feet of clearance for 230kV lines, taking into consideration the maximum sag designed for a given line. Thank you.
Response: The SDT thanks you for your affirmative vote and comments. The MVCD was set up to be a “minimum” distance to never violate. Certainly, each TO must maintain larger clearances in order to account for growth, movement of conductor and other factors that influence the distance between the conductor and vegetation. Use of the Gallet Equation provides for greater distances than IEEE-516-2003 under the same conditions of elevation, voltage and transient overvoltage factor. Please refer to the Technical Reference Document (posted on NERC webpage) for more information.				
James L. Jones	Southwest Transmission Cooperative, Inc.	1	Abstain	Entities have a problem with other Government Agencies in tha they are not real receptive for Vegetation Management. Burea of Land Management will usually take 2 years to get permission to trim vegetation in BLM ROW. State Land Department will usually not let you cut any cactuses in ROW on State land. ROW crossing on a Sovereign Indian Reservation is just as bad. If this is such a big issue for FERC/NERC, then they need to get other governmental agencies on board with them.

Voter	Entity	Segment	Vote	Comment
Response: **The SDT thanks you for your comments. Jurisdictional issues need to be addressed in other appropriate arenas. The Utility Arborist Association among other groups have sought to coordinate cooperation between agencies in the past.**				

NERC

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Consideration of Comments on 4th Draft of FAC-003-2 Transmission Vegetation Management —Project 2007-07 Vegetation Management

The Vegetation Management Standard Drafting Team thanks all commenters who submitted comments on the 4th draft of reliability standard FAC-003-2 — Transmission Vegetation Management. This standard and its associated implementation plan and technical reference paper were posted for a 30-day public comment period from June 17, 2010 through July 17, 2010. The stakeholders were asked to provide feedback on the standard through a special Electronic Comment Form. There were 45 sets of comments, including comments from more than 100 different people from over 50 companies representing 7 of the 10 Industry Segments as shown in the table on the following pages.

http://www.nerc.com/filez/standards/Vegetation-Management_Project_2007-7.html

The standard and its associated implementation plan and technical reference paper were balloted from July 9 – 19, 2010. The voting had a quorum of 86.18 percent and an affirmative vote of 65.93 percent. Because at least one negative ballot included a comment and the affirmative votes did not meet the two thirds threshold for approval, the results were not final.

On November 4, 2010, NERC staff provided a Quality Review of FAC-003-2 to the Standards Committee (SC). The SC met on November 11, 2010 to determine if the draft standard should proceed to posting. During the meeting, the SC requested the Vegetation Management Standard Development Team (VMSDT) to work with NERC staff in addressing the items identified in the Quality Review. The VMSDT conducted several conference calls and acted in good faith to produce Draft 5 of FAC-003-2. The VMSDT considered the feedback provided in the Quality Review by NERC staff and reached consensus in the following areas:

1. Elaborated upon the Purpose Statement to encompass more of the standard's content.
2. Added a Rationale text box to the section 4 - Applicability to explain the exclusion of substation facilities. Clarified 4.2.4 by adding specific boundary details.
3. Updated Requirement R1 and R2 to emphasize the "planning" time horizon as the applicable temporal context.
4. Elaborated upon the explanation in the Rationale text boxes for R1 and R2 to highlight the range of non-compliant performance.
5. Re-organized the content of Requirement R3 for improved readability.
6. Augmented Requirement R5 to include a "reliability objective".
7. Modified Requirement R6 and the associated VSLs for improved enforceability and for consistency in the units of measure between the Requirement and the associated VSLs.
8. Modified Requirement R7 and the associated VSLs for improved enforceability and for consistency in the units of measure between the Requirement and the associated VSLs.
9. Updated the Evidence Retention section in accordance with current guidelines.

Modifications incorporated into Draft 5 of FAC-003-2 in response to stakeholder comments include:

A. Removed reference to Active Transmission Line Right of Way (ROW).
B. Redefined the Glossary term for ROW to address Paragraph 734 of FERC Order 693 addressing the width of ROW to be maintained.
C. Redefined the Glossary term for Vegetation Inspection to include identifying hazards to the line inside the ROW.
D. Included the term referred to as "applicable lines" under Section 4.2 Facilities.

E. Removed Section4.4 and footnote 2 addressing "force majeure" and addressed the issue in new footnotes 2, 3 and 4.
F. In R1./R2 – M1/M2
    - Added reference "into the MVCD" (Minimum Vegetation Clearing Distance – MVCD) into the text.
    - Eliminated "types of encroachment" and added "The four types of failure to manage vegetation, in order of increasing severity."
    - In M1/M2, added a paragraph defining "later confirmation of a Fault by the TO as a real-time observation."
    - Added to the Rationale box types of failures to manage vegetation.
G. In R4, changed "qualified personnel" to TO.
H. In R5, added the term "is constrained from performing vegetation work" and referenced MVCD. Also removed reference to the 2003 northeast blackout from Rationale box
I. In R6, added the phrase " but no more than 18 months between inspections." Also added Footnote 3.
J. In R7, replaced major storms bullet with "circumstances that are beyond the control of a Transmission Owner." Also added Footnote 4 to this requirement.
K. In Additional Compliance Information
    - Category 2 was split into two parts recognizing Interconnection Reliability Operating Limits (IROL's) and Major Western Electric Coordinating Council (WECC) Transfer Paths.
    - Added Category 3 for Fall-ins from outside the ROW.
    - Category 4 was split into two parts recognizing IROL's and Major WECC Transfer Paths
L. Removed alternate versions of Violation Severity Levels (VSL's) for Requirements R1 and R2.
M. Deleted Table 3 from the Guidelines and Technical Basis section.

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herb Schrayshuen, at 609-452-8060 or at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

1. The SDT replaced the defined term "Active Transmission Line Right of Way" with footnote number 2 that provides a description of "active transmission line ROW" and added Table 3, "Minimum Distance from the Centerline of the Circuit to the edge of the active transmission line ROW" to support that description. Do you agree? Please explain.

Summary Consideration:

Of 45 respondents, there is 1 abstention, 19 are in agreement, and 25 are in disagreement.

The major comment issues raised are:

1. **The values used in Table 3 needs to be justified.**
2. **The definition of an active transmission line ROW ought to be a Glossary term.**
3. **The Table does not account for different structure designs and the term "centerline" is not applicable in all cases.**

The VM SDT considerations for the major comment issues are:

1. **The VM SDT added explanatory text in the Guideline and Technical Basis section.**
2. **Based on comments from 4th posting the SDT is revising the definition of ROW in the NERC Glossary.**
3. **Table 3 has been removed.**

Some minor comment issues are:

1. **Add distances for DC lines into Table 3.**
2. **The term and Table 3 needs further clarification.**

The VM SDT considerations for the minor comment issues are:

1. **Table 3 has been removed.**
2. **Table 3 has been removed.**

	Organization	Yes or No	Question 1 Comment
1	MWDSC (METROPOLITAN WATER DISTRICT OF SOUTHERN CALIFORNIA)		
2	Hydro One	No	A DC table for Table 3 similar to the MVCD table should be added.There should be a statement in Table 3 that is consistent with footnote number 2 stating that the minimum width of the Active Transmission Line ROW is either the full width of the easement or, if the easement is wider than the distances in Table 3, the minimum distances must not be less than the distances shown in the Table. The use of a minimum distance from the centerline of the circuit or structure is an incorrect measure to use for a set clearance distance of the active transmission right-of-way. The description does not take into account vertical versus horizontal design configuration. Consideration should be given for the type of construction as different construction types (H-Frame, Lat-tice towers, Monopole delta or vertical construction) will require different widths of a cleared right-of-way to provide the necessary openings for these circuits. A minimum distance for 345-kV is now set at 150 feet based on the minimum distances from centerline. This may be correct for certain H-Frame and Lattice Tower configurations but it is excessive for monopole situations. A single pole configuration with vertically aligned conductors does not need this full 150 foot width. It is strongly recommended that a minimum distance from conductor be used in place of a set distance from centerline. As long as there is at least 30 - 40 feet of clearance in the right-of-way from the outermost conductors (adjusted to account for maximum sway at mid-span for longer spans), then this is the distance that should be used to develop the right-of-way widths.For example, a monopole structure with vertically aligned conductors would result in a cleared active right-of-way width of only 80 feet (40 feet from conductor to edge of cleared active right-of-way) using the minimum distances from the conductors. There is no need to extend this distance another 35 feet (on each side) in order to obtain the full 150 foot width. This requirement is excessive and must be adjusted to account for line construction variations.

	Organization	Yes or No	Question 1 Comment
			Instead of using the term "Centerline" as referenced on Table 3, the use of "outer phase" or "phase closest to tree line" would be more appropriate. There is published literature using the term "cleared width" to indicate the distance from the outer phase to the tree line. This distance should be used in the Active ROW definition. The word easement is also used in the definition. Is there a reason the Active ROW only includes easements, not fee ownership, license or some other right to occupy and manage the ROW? Would Active ROW include "danger tree rights" on land? These questions need to be addressed in the standard (in text) and technical reference document (in graphics).
	Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
3	Allegheny Power	No	Allegheny Power strongly disagrees with the numbers or widths stated within Table 3. These numbers seem arbitrary and have no accompanying reasonable explanation as to their origin, basis, or other criteria noting the rationale for inclusion in this standard. This inclusion effectively prohibits a TO from establishing corridor widths less than the widths (which may be easily possible by utilizing various tower or structures heights or configurations) stated in Table 3 without placing the TO in extreme jeopardy of non-compliance issues from a falling off-corridor tree, during minor storm conditions as an example. Furthermore, this Table insinuates the TO has no ability to successfully manage vegetation WITH NO RESULTING OUTAGES or encroachments within the MVCD from off-corridor trees where corridors are less that the widths stated in Table 3.Allegheny Power suggests that the definition of the "Active Transmission line Right Of Way" be "the transmission line ROW corridor that is actively maintained as part of the entity's vegetation management plan.".
	Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
4	FPL Corporate Compliance	No	Although there is support for making Active Transmission Line Right of Way a clearly defined term, and the foundation for compliance with FAC-003-2, the distances in the table are arbitrary and are not supported by any scientific

	Organization	Yes or No	Question 1 Comment
			or engineering analysis. It is possible that such a table could be interpreted to define the minimum width of future lines. Different construction configurations require different ROW widths.
	Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
5	PPL Electric Utilities	No	Centerline (CL) distances shown in Table 3 are shown as Minimal distances from CL. If utility is not able to define its ultimate ROW, due to CL agreement or other circumstances, these minimal distances may not be applicable and as such could result in non-compliance as written.
	Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
6	Southern Company Transmission	No	Depending on the intent this may create a problem. We are concerned the addition of Table 3 could be interpreted to mean something completely different than what we believe to be its intention. Please consider alternate wording to Footnote 2: A strip or corridor of land that is occupied by active transmission facilities. This corridor does not include the parts of the Right-of-Way that are unused or intended for other facilities. However, the active transmission line ROW cleared width it is not to be less than the width of the easement itself unless the easement exceeds distances as shown in Table 3 for various voltage classes.If the SDT determines keeping Table 3 is the appropriate course of action, we recommend clarifying its intent better; either in a footnote or in the title. Adding a footnote stating the Table is not applicable if the distance from the center line of the conductor to the right-of-way edge is less than the appropriate distance indicated in the table.Another option might be to add a statement to the title such as, “If the distance from the centerline of the circuit to the edge of the easement is less than the values in Table 3, that distance is considered active ROW”.
	Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way.		

	Organization	Yes or No	Question 1 Comment
	Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
7	Ameren	No	Does this mean wider ROW easements will need to be acquired to be compliant or will this apply to ROW's for new circuits going forward?
	Response: Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
8	Progress Energy	No	In Applicability Section 4.4, "active transmission line ROW" is not capitalized indicating it is not a defined term, but Footnote 2 is effectively a definition for active transmission line ROW. However, in the first paragraph of Section 5 Background, Active Transmission Line Right-of-Way is capitalized indicating it's a defined term. It would seem cleaner to make "Active Transmission Line Right of Way" a formal NERC definition. Alternatively and at a minimum, Footnote 2 should be revised to say "An active transmission line ROW is a strip or corridor..." and also in Section 5 Background, "Active Transmission Line Right of Way" should be changed to no longer be capitalized.
	Response: Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
9	PNM	No	ROW easements vary according to land ownership therefore, potentially subjecting the utility to be liable for land outside of easement/ROW.
	Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
10	Central Maine Power Company, Iberdrola USA	No	Table 3 distances may not be appropriate, for example table 3 should reflect a clearance zone based on construction type, topography, species, or growth rates. Table 3 could give the impression that the listed distances are the maximum, therefore suggest table 3 be removed or revised.The Active Transmisson Line Right-of-Way defination uses the word easement, which most likely would include danger trees in situations where danger removals

	Organization	Yes or No	Question 1 Comment
			are included in the the easement language. This would expand the scope of FAC 003 2 beyond the cleared right-of-way width.
	Response: The SDT agrees that Table 3 does not reflect the structural differences which directly determines the right of way width. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
11	Consumers Energy Company	No	Table 3 does not adequately address ROW width requirements based on the type of construction used for structures, especially for the two lower voltage classes, 69-138kV and 139-230 kV. Lines constructed on H-Frame structures have a much wider footprint across the ROW than do single pole construction and most steel tower construction types. The minimum ROW width listed in Table 3 for a 138 kV line constructed on a wooden H-Frame may put the outside conductor within MVCD under windy conditions due to wind displacement of conductors and trees.Consumers Energy recommends that Table 3 be modified to describe the minimum distance in the table is the vertical plane of the outside conductor to the edge of the active transmission ROW and therefore independent of the width of the structure construction type.
	Response: The SDT agrees that Table 3 does not reflect the structural differences which directly determines the right of way width. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
12	The United Illuminating Company	No	The definition has been altered. The last sentence "However, it is not to be less than the width of the easement itself unless the easement exceeds distances as shown in Table 3 for various voltage classes..." was added. The concept of the easement is confusing and not included in the Supplemental Reference. Table 3 of the standard is titled "Minimum Distance from the Centerline of the Circuit to the edge of the active transmission line ROW", no mention of easements. It is suggested that the definition state "strip or corridor of land that is occupied by active transmission facilities. This corridor does not include the parts of the Right-of-Way that are unused or intended for other facilities. At a minimum the width is to be the distances as shown in Table 3 for various voltage classes."The

	Organization	Yes or No	Question 1 Comment
			proper location for the definition is in the Glossary.
	Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
13	Dominion	No	The distances proposed in Table 3 - Minimum Distance from the Centerline of the Circuit to the edge of the active transmission line ROW may not be consistent with the centerline distances cleared and maintained by the TO. For example, a TO maintaining 75' from centerline for a 500kV circuit would be required to clear and maintain an additional 12.5' to meet the proposed standard's requirement. We suggest either allowing individual TOs to maintain active ROW widths consistent with their normal clearing/maintenance practices, going back to Draft 3's definition of Active Transmission Line Right-of-Way, or changing the footnote in Draft 4 to read:A strip or corridor of land that is occupied by active transmission facilities. This corridor does not include the parts of the Right-of-Way that are unused or intended for other facilities. However, the portion of the ROW that has been cleared must at least meet design clearance requirements such as National Electric Safety Code or other design criteria, for the reliable operation of active facilities.
	Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
14	BC Hydro	No	The footnote definition is ok but Table 3 is poorly developed. The voltage classes should be better segregated (e.g. nominal voltage 69kV, 138kV, 230kV, 287kV, 345kV, 500kV, 765kV) along with distances in feet and metres as Canadian utilities are metric. Also the table should include recommended right of way widths for single circuits. The assumption made in the footnote is that the legal easement is larger than in Table 3. However, as currently defined, some of the distances in Table 3 exceed statutory rights of way at our utility and exceed engineering standards as defined by the Canadian Standards Association - Overhead Systems (CAN/CSA C22.3 No. 1-6). Also, clearances will very much depend on line design (e.g. structure architecture such as flat, Post T, H-frame, steel lattice, and other variables

	Organization	Yes or No	Question 1 Comment
			such as ruling span length, conductor type used, etc.) To some degree this will vary quite a bit between utilities. As such Table 3 as currently presented is not workable.
	Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
15	Exelon	No	The term "Centerline of the Circuit" in Table 3 is not defined. Until it is defined, there is no way to know if the standard is technically reasonable or whether existing circuits would be in violation of the standard and unable to operate. In addition, it is unclear what types of construction and span lengths were used to develop the distances for active right-of-way widths in Table 3. Furthermore, it is not clear whether Table 3 contains requirements against which compliance will be measured or best practice guidelines. Footnote 2, in the background section, compounds this ambiguity. In short, the lack of a definition for "Centerline" combined with Footnote 2 and Table 3 make this draft unclear and unenforceable. Exelon does not necessarily have easement widths for all transmission lines that equal those defined in Table 3 of this draft; This may require the acquisition of additional easements, if even possible.
	Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
16	Northeast Utilities	No	The use of a minimum distance from the centerline of the circuit or structure is an incorrect measure to use for a set clearance distance of the active transmission right-of-way. Consideration should be given for the type of construction as different construction types (H-Frame, Lattice towers, Monopole delta or vertical construction) will require different widths of a cleared right-of-way to provide the necessary openings for these circuits. A minimum distance for 345-kV is now set at 150 feet based on the minimum distances from centerline. This may be correct for certain H-Frame and Lattice Tower configurations but it is excessive for monopole situations. A single pole configuration with vertically aligned conductors does not need this full 150 foot width. It is strongly recommended that a minimum distance from

	Organization	Yes or No	Question 1 Comment
			conductor be used in place of a set distance from centerline. As long as there is at least 30 - 40 feet of clearance in the right-of-way from the outermost conductors (adjusted to account for maximum sway at mid-span for longer spans), then this is the distance that should be used to develop the right-of-way widths.For example, a monopole structure with vertically aligned conductors would result in a cleared active right-of-way width of only 80 feet (40 feet from conductor to edge of cleared active right-of-way) using the minimum distances from the conductors. There is no need to extend this distance another 35 feet (on each side) in order to obtain the full 150 foot width. This requirement is excessive and must be adjusted to account for line construction variations.Instead of using the term "Centerline" as referenced on Table 3, the use of "outer phase" or "phase closest to tree line" would be more appropriate.
	Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
17	Idaho Power Company	No	The way I interpret this, the new definition of active transmission line right of way takes away our ability to clear potential fall ins if they are outside of the active transmission line ROW>
	Response: The NERC Standard does limit or grant property rights. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
18	CenterPoint Energy	No	There is no rationale provided for the “minimum distances” stated in Table 3, and they far exceed the ROW widths that CenterPoint Energy owns (typical total 100’ ROW width for 2-ckt 345kV line) for its current 345kV system, and as such, are open for misapplication and misinterpretation as an intended minimum standard for making a fall-in determination for R1 and R2 outside the legal limits of the utility. Table 3 should be deleted. If kept, there should be sufficient rationale included within the Guidelines and Technical Basis to explain how it was derived and how it is to be used within the Standard. CenterPoint Energy agrees with the removal of “active transmission line ROW” as a defined term; however, the footnote should be deleted as well since it attempts to create a definition which is not accurate, necessary or

	Organization	Yes or No	Question 1 Comment
			useful. Throughout the Standard, the phrase "active transmission line ROW" should be replaced with "transmission line ROW" to eliminate the qualifying term "active". In making a fall-in determination for R1 and R2, the limit should be "within the full extent of the Transmission Owner's transmission ROW as defined by easement, fee simple, or other legal rights" as discussed in the Guidelines and Technical Basis regarding the vegetation management maintenance approach. This places the determination of the width of the ROW for determination of fall-in violations clearly on the Transmission Owner and the within the limits of its legal rights to control the vegetation that has fallen into the line under R1 and R2.
	Response: The SDT thanks you for your comments. The SDT disagrees with the point that the TO should be required to clear the entire extent of legal rights. FERC Order 693 agreed that expansion easements needed to be adressed. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
19	Northeast Power Coordinating Council	No	There should be a statement in Table 3 that is consistent with footnote number 2 stating that the minimum width of the Active Transmission Line ROW is either the full width of the easement or, if the easement is wider than the distances in Table 3, the minimum distances must not be less than the distances shown in the Table.The use of a minimum distance from the centerline of the circuit or structure is an incorrect measure to use for a set clearance distance of the active transmission right-of-way. The description does not take into account vertical versus horizontal design configuration. Consideration should be given for the type of construction as different construction types (H-Frame, Lattice towers, Monopole delta or vertical construction) will require different widths of a cleared right-of-way to provide the necessary openings for these circuits. A minimum distance for 345-kV is now set at 150 feet based on the minimum distances from centerline. This may be correct for certain H-Frame and Lattice Tower configurations but it is excessive for monopole situations. A single pole configuration with vertically aligned conductors does not need this full 150 foot width. It is strongly recommended that a minimum distance from conductor be used in place of a set distance from centerline. As long as there is at least 30 - 40 feet of clearance in the right-of-way from the outermost conductors (adjusted to account for maximum sway at mid-span for longer spans), then this is the

	Organization	Yes or No	Question 1 Comment
			distance that should be used to develop the right-of-way widths.For example, a monopole structure with vertically aligned conductors would result in a cleared active right-of-way width of only 80 feet (40 feet from conductor to edge of cleared active right-of-way) using the minimum distances from the conductors. There is no need to extend this distance another 35 feet (on each side) in order to obtain the full 150 foot width. This requirement is excessive and must be adjusted to account for line construction variations.Instead of using the term "Centerline" as referenced on Table 3, the use of "outer phase" or "phase closest to tree line" would be more appropriate. There is published literature using the term “cleared width” to indicate the distance from the outer phase to the tree line. This distance should be used in the Active ROW definition. The word easement is also used in the definition. Is there a reason the Active ROW only includes easements, not fee ownership, license or some other right to occupy and manage the ROW? Would Active ROW include “danger tree rights” on land? These questions need to be addressed in the standard (in text) and technical reference document (in graphics).
	Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
20	Arizona Public Service Company	No	These clearances could exceed the permitted ROW’s on federal lands and the utility has no legal right to clear beyond those rights. In some cases the permitted ROW can exceed those distance and federal agencies could not allow you to clear beyond those clearances in this version.
	Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
21	Entergy Services	No	This is very unclear, and creates much uncertainty as to how certain potential outage situations should be reported. Clarification language should be added within the Standard to help define and guide the TO's actions when an outage occurs from a location at a point that is less than the documented ROW boundaries (Easements) but greater than the ROW distances represented in Table 3. It is unclear which distance should guide our

	Organization	Yes or No	Question 1 Comment
			reporting actions........ROW Document Width, Table 3 ROW Widths, or the lesser of the two.......See scenarios / examples below for consideration to aid with clarification points:Example 1: If our documented ROW width for a 500kV line is 100' from centerline (200' total ROW width) and we have a fall in from 90' from centerline, do we report this as a Category 2 Outage due to the fact that it fell from within our ROW limits, or is it non-reportable due to the fact that it is located at a greater distance than 87.5' from the centerline of the ROW as listed in Table 3 in the Standard?Example 2: How does maintenance and outage reporting correlate with the example defined as follows.......You have a 230 kV line situated on one side of a 150' wide ROW that was initially cleared to a width that would accommodate 2 separate parallel transmission lines and structures. The second set of lines/structures have not yet been constructed, and the current Transmission line is situated on one side of the 150' ROW, and is being maintained to the edge of the actual ROW on the side of the ROW that it was constructed on (maintained to a distance of 50' from centerline that puts it at the legal edge of the ROW), but it has been typically maintained to a distance of approximately 60' from centerline to the inside portion/other side of the ROW (the side of the ROW that has never been cleared), but a tree falls into the line from approx 58' from centerline (2' within the 60' distance typically being maintained on that line).......would this be considered a Category 2 outage since it was approx 2' within the average width being maintained on that side of the ROW or would it not be reported due to the fact that it was located at a distance greater than 50' as indicated in Table 3??
	Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
22	Kansas City Power & Light	No	This needs to be a defined term since the Standard uses that as a basis for use with Table 3. Using this term as a footnote does not allow the industry to weigh in on its definition. Footnotes should not be used as a means of definition or clarification. Footnotes are for references to other sources of statements or documents that support a particular thought.
	Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way.		

	Organization	Yes or No	Question 1 Comment
	Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
23	Xcel Energy	No	We believe Active Transmission ROW should be a defined term, not buried in a “footnote” of the “Other” section of a Standard. It still begs the question - what is an “active transmission facility”? Regarding the substance, overall we believe that the Active Transmission ROW should not include the new reference to Table 3. This newly added sentence in footnote 2, referencing Table 3, is confusing to interpret. If retained, please rephrase to make it clearer that a Transmission Owner never has to increase the size of its easement/land right to satisfy this table. As drafted, our team had various interpretations and it is unclear whether the intent is that a Transmission Owner has to increase its easement or acquire land to meet this requirement, or conversely if the easement is well beyond the values in Table 3, the Transmission Owner has to maintain that the entire easement or only the values in Table 3.”Active Transmission Right of Way” is still used in the first paragraph of the Background section.In total, we suggest that the definition of Activate Transmission ROW return to the version used in the prior draft and be placed in the definition section.
	Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
24	ITC Transmission	No	We disagree with footnote comment as this adds confusion to the standard. Is a footnote considered part of the standard or not? The reference to table #3 is something new and has never been discussed or commented on prior to this revision and appears to be a bright line concept which we are in total disagree with.
	Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
25	FirstEnergy	No	We do not support replacement of the term Active Transmission Line Right of Way with Footnote #2. Since the term "active transmission line ROW" is used in the requirements, compliance section, and VSLs, and since the drafting team has a very definite view of what this term means, the term should be a

	Organization	Yes or No	Question 1 Comment
			definition included in the NERC Glossary. Also, since ROW is defined in the NERC Glossary, it further supports the reasons this term should also be defined. Therefore, we suggest the team revert back to the Draft 3 proposed NERC Glossary term.Lastly, we do not support the addition of Table 3. We believe this adds unnecessary prescriptiveness to the requirements. It is also not clear if this Table was intended to be mandatory because the only reference in the table is in Footnote #2. If the SDT feels this table is a useful tool that should be included in the standard, then we suggest adding it to the Guidelines section as optional information. Also, reference to this Table 3 in the Active Transmission Line ROW definition should be removed.
	Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
26	Tampa Electric Company	No	We have concern with the "Minimum Distances" as listed in Table 3. What analytical methodology, criteria and rationale was utilized to determine each recommended distance? In addition, we have concerns regarding the change to a pre-determined distance. This seems to be a major shift from the vegetation to conductor methodology employed previously and throughout this standard? NERC/FERC must recognize that while protecting and securing grid reliability, each utility must also balance the environmental, political, customer and economic issues and impacts which will occur with the implementation of the Table 3 clearances. We question whether this is the most responsible action to take given the current state of the economy as well as the environmental and political sensitivity impacts which will result. Tampa Electric questions whether Table 3 will improve System reliability. Since the inception of standard FAC-003-1 Tampa Electric has not had a Category 1 or Category 2 outage on our 230kV Transmission System. We don't believe that the changes proposed to table 3 will improve overall service reliability. It is Tampa Electric's opinion that each utility should define the width of its own Active Transmission line ROW. However, if such a table is to be utilized, Tampa Electric recommends the following changes or adjustments to Table 3.1. Expand the table to account for the various types of Transmission construction; i.e. vertical versus horizontal conductor configurations.2. Use a distance from the outermost conductor, not the centerline. This will account for construction type and better achieve a

	Organization	Yes or No	Question 1 Comment
			consistent clearance from conductors.3. We recommend reducing the distances in Table 3 by 12.5 feet for each voltage category. 4. Specify whether the voltage is based upon the design or operating voltage.5. Reformat the voltage ranges to 100kV - 200kV, 200kV - 300kV, 300kV - 400kV, etc. as an example; this would create a more appropriate range of voltages and clearance distances. The reformatted voltage ranges eliminate confusion. For example, under the current proposal it is unclear in which category a nominal 230kV line should be since sometimes such a line can operate at up to 232kV during low-load conditions.
	Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
27	American Transmission Company	Yes	
28	BGE Forestry Management	Yes	
29	Great River Energy	Yes	
30	MidAmerican Energy	Yes	
31	NERC Staff	Yes	
32	Pepco Holdings, Inc - Affiliates	Yes	
33	South Carolina and Gas	Yes	
34	Western Electricity Coordinating Council	Yes	

	Organization	Yes or No	Question 1 Comment
35	GDS Associates	Yes	- ROW abbreviation comes prior to the full term (marked footnote prior to the full term as stated in 5. Background). Please make correction accordingly.
	Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
36	Duke Energy	Yes	However, due to different design attributes of transmission lines, it may be better to change the distance in Table 3 from a centerline distance to a “Minimum Full Active Transmission Line ROW Width Distance”.
	Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
37	Idaho Power	Yes	I support the description for the active right of way. However, I believe there needs to be a provision that addresses identifying potential hazards outside the active right of ways that may pose a risk to the transmission lines.
	Response: The NERC Standard does limit or grant property rights. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
38	Manitoba Hydro	Yes	Please add metric equivalents in the standard.While it makes some aspects easier around pointing to what we need to keep "clear" to meet NERC rules - it does limit some of our flexibility to design lines and ROWs to your own standards. Also, the minimum only applies when you have easement larger than the minimums in table 3, and I would assume that does not relieve you of the responsibility to maintain ROWs appropriately if the design of your lines requires a wider ROW.
	Response: The NERC Standard does limit or grant property rights. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		

	Organization	Yes or No	Question 1 Comment
39	Southern California Edison Company	Yes	SCE appreciates the SDT's efforts to replace the defined term with a set of minimum distances. However, the proposed new Table 3 appears to assume a horizontal configuration of transmission lines. Thus, it would appear that those lines configured vertically (for example, two circuits on opposite sides of a tower), the "active right of way" required would be at least twice as large as that for horizontal lines. SCE respectfully recommends a footnote be added to Table 3 that allows the TO to recalculate the active right of way for lines in a vertical configuration, based on a horizontal line configuration.
	Response: The NERC Standard does limit or grant property rights. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
40	Western Area Power Administration	Yes	Suggest using a total right-of-way width in Table 3 rather than a distance measured from centerline.
	Response: The NERC Standard does limit or grant property rights. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
41	Tri-State Generation & Transmission	Yes	Table 3 should be referenced as a guideline only.
	Response: The NERC Standard does limit or grant property rights. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
42	MRO's NERC Standards Review Subcommittee (nsrs)	Yes	The NSRS agrees in whole to the question but has the SDT taken into consideration the difference in ROW may be different in Urban and Rural settings?
	Response: The NERC Standard does limit or grant property rights. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		

	Organization	Yes or No	Question 1 Comment
43	Consolidated Edison Company of New York Inc	Yes	The same verbiage in footnote number 2 should appear below Table 3 to avoid any confusion.
	Response: The NERC Standard does limit or grant property rights. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
44	Orange and Rockland Utilities, Inc.	Yes	There should be a statement in Table 3 that is consistent with footnote number 2 stating that the minimum width of the Active Transmission Line ROW is either the full width of the easement or, if the easement is wider than the distances in Table 3, the minimum distances must not be less than the distances shown in the Table.
	Response: The NERC Standard does limit or grant property rights. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		
45	Bonneville Power Administration	Yes	This distance is reasonable in the table, but due to widely varying designs of structures it does not give a relationship of the outside wire to edge of ROW. It should be noted as outside wire, phase or conductor to edge of ROW.In addition, the effective date should allow transmission owners time to achieve this distance, perhaps one cycle.
	Response: The NERC Standard does limit or grant property rights. Based on your comment and others, the SDT has revised the definition of Right of Way to embody the concept of an Active Transmission Right of Way. Subsequently the definition of Active Transmission Line Right of Way and Table 3 have been removed.		

2. In response to comments received regarding the terms "reasonable" and "human errors/human activity", the SDT modified the Other Section and Background Section. Do you agree? Please explain.

Summary Consideration:

Of 45 respondents, there are 3 abstentions, 38 are in agreement, and 4 are in disagreement.

The major comment issues raised are:

1. **Of the 4 in disagreement, only NERC believes "force majeure" statement is not necessary.**
2. **Three respondents believe the "force majeure" statement should be expanded to include Federal, State, Regulatory and legal interference.**

The VM SDT considerations for the major comment issues are:

1. **a) The SDT believes this language is appropriate for this standard due to the many factors related to vegetation that are truly outside the TO's control. Unlike the vast majority of other NERC standards, implementation of FAC-003 is not under the absolute control of the utilities. These influences range from landowner and agency obstacles to weather events, and as such the SDT believes the force majeure provisions should be applicable. The recognition of this provision is also supported by 90% of the industry. An attempt at similar language is contained in version 1 but it is ambiguous and lacks clarity. This language adds clarity and reduces the opportunity for mis-application. Further, TO's who elect to invoke "force majeure" must have supporting evidence of such action. The lack of a force majeure section means a Transmission Owner would have a violation of a Requirement, even if the penalty might have been mitigated by the circumstances.**

   b) However, the SDT moved the force majeure from applicability to a footnote (Footnote 2) based on comments concerning the structure of NERC standards. The footnotes are referenced in R1, R2, and R7. In R6, an exclusion clause was added in Footnote 3.

3. **The SDT recommends no expansion. The "force majeure" provision is intended to recognize circumstances that are completely outside the TO's control. Federal, State or regulatory interference is certainly a barrier but there are actions available to mitigate such interference. The TO should be aware of such interference and should take whatever corrective actions necessary, up to and including re-rating or de-energizing the line, to avoid a vegetation conflict.**

Some minor comment issues are:

1. **One respondent would like to specifically define wind speed.**
2. **Two respondents suggested moving the language elsewhere in the standard.**

The VM SDT considerations for the minor comment issues are:

1. **The SDT recommends no change. Wind speed is addressed by "fresh gale".**
2. **The SDT moved it to a footnote.**

	Organization	Yes or No	Question 2 Comment
1	MWDSC (METROPOLITAN WATER DISTRICT OF SOUTHERN CALIFORNIA)		
2	Western Electricity Coordinating Council		
3	Central Maine Power Company, Iberdrola USA		No comment suggested.
4	NERC Staff	No	NERC staff does not support the language in the Other Section. Staff believes that the force majeure provision is unnecessary and calls into question whether NERC and the regions have enforcement discretion to take such things into account in applying other standards that do not include this type of provision.
	Response: The SDT thanks you for your comments. The SDT believes this language is appropriate for this standard due to the many factors related to vegetation that are truly outside the TO's control. Unlike the vast majority of other NERC standards, implementation of FAC-003 is not under the absolute control of the		

	Organization	Yes or No	Question 2 Comment
	utilities. These influences range from landowner and agency obstacles to weather events, and as such the SDT believes the force majeure provisions should be applicable. The recognition of this provision is also supported by 90% of the industry. An attempt at similar language is contained in version 1 but it is ambiguous and lacks clarity. This language adds clarity and reduces the opportunity for mis-application. Further, TO's who elect to invoke "force majeure" must have supporting evidence of such action.		
5	BGE Forestry Management	No	Suggest including in "4.4. Other" a phrase referencing government interference, such as "Federal, State or other regulatory interference, including legal or other legislative actions, that prevents performance to comply with this reliability standard."
	Response: The SDT thanks you for your comments. The "force majeure" provision is intended to recognize circumstances that are completely outside the TO's control. Federal, State or regulatory interferrence is certainly a barrier but there are actions available to mitigate such interference. The TO should be aware of such interference and should take whatever corrective actions necessary, up to and including re-rating or de-energizing the line, to avoid a vegetation conflict.		
6	Kansas City Power & Light	No	The theme of the "Other" section are the conditions for excluding applicable transmission facilities under certain conditions. Recommend the Drafting Team consider renaming this section to "Exclusions". In addition, the term, "Active Transmission Line Right-of-Way" is capitalized in the "Background" section. If it is determined this term should not be a definition, then this should be lower case.
	Response: The SDT thanks you for your comments. The recommendation does not materially change the "force majeure" provision and the SDT does not recommend any change. The SDT did modify the ROW definition in response to industry concerns. Capitalization is now appropriate.		
7	Xcel Energy	No	Xcel Energy urges the retention of the word "reasonable" as a modifier to "control" in Introduction, Section 4.4. The concept that a Transmission Owner should exercise reasonable control is sensible, and is of some aid in countering claims that any incident could be prevented. For example, in Colorado, the transmission of electricity has been judicially found to be subject to the highest degree of care. Without the inclusion of the word "reasonable," Xcel Energy could possibly be faced with a claim that for the exceptions set forth in Introduction, Section 4.4, to apply, the circumstances would have to be "beyond the control (using the highest degree of care) of

	Organization	Yes or No	Question 2 Comment
			Xcel Energy." Retention of "reasonable" helps counter such claims. Since this section appears to lean toward legal language, the use of the term “reasonable” is better suited for the goal of this section.
	Response: The SDT thanks you for your comments. While we understand the concerns, the word reasonable is ambigous and open to intrepretation and therefore not an appropriate modifier to the language.		
8	Allegheny Power	Yes

35	The United Illuminating Company	Yes	
36	Tri-State Generation & Transmission	Yes	
37	Western Area Power Administration	Yes	
38	Great River Energy	Yes	GRE believes that the new definition provides greater clarity with respect what does not constitute a compliance violation versus the previous version.
	Response: The SDT thanks you for your comments and we are in agreement.		
39	CenterPoint Energy	Yes	No preference.
	Response:		
40	Southern California Edison Company	Yes	SCE generally agrees with the information contained in Part 5 - Background. However, we question the value of placing a rationale within the body of the standard. SCE respectfully recommends that the revised “Background” information be added to the beginning of the “Guidelines and Technical Basis,” which also includes explanations for various standard segments.
	Response: The SDT thanks you for your comments. It is not specific to “force majeure” and is best answered in general comments.		
41	MRO’s NERC Standards Review	Yes	The NSRS believes that the new definition provides greater clarity with respect what does not constitute a compliance violation versus the previous

	Organization	Yes or No	Question 2 Comment
	Subcommittee (nsrs)		version.
	Response: The SDT thanks you for your comments and we are in agreement.		
42	Tampa Electric Company	Yes	These changes add improved clarity and defintion to this section.
	Response: The SDT thanks you for your comments and we are in agreement.		
43	Idaho Power	Yes	This will allow the utilities to address conditions that are within their control.
	Response: The SDT thanks you for your comments and we are in agreement.		
44	FirstEnergy	Yes	While we agree with the changes proposed, we would recommend that the list contained in the "Other" section should be revised to include judicial actions such as injunctions. While this is not a natural occurring situation, it is certainly one that will prevent an entity from removing vegetation when needed or desired.
	Response: The SDT thanks you for your comments. The "force majeure" provision is intended to recognize circumstances that are completely outside the TO's control. Legal and judicial actions are certainly a barrier but there are other corrective actions available to mitigate such interference. The TO should be aware of such interference and should take whatever actions necessary, up to and including re-rating or de-energizing the line to avoid a vegetation conflict.		
45	BC Hydro	Yes	Yes but there should be more commentary around exceptions. You should get away from certain descriptive terms and be more empirical when you can to avoid ambiguity. For example "Fresh Gale" on the Beaufort Scale is not common as there are several variants to this scale and on some scales is defined as "Gale". So do you mean winds of 39-46 mph (62-74 kmh) or greater wind speed? If so, why not state that?
	Response: The SDT thanks you for your comments. The "force majeure" provision is not intended to address every possible exclusion but to be a general statement intended to recognize circumstances that are completely outside the TO's control.		

3. In response to comments received regarding the language in M1 and M2, the SDT modified the first bulleted item and added a sentence to the end of the paragraph in M1 and M2. Do you agree? Please explain.

Summary Consideration:

Of 45 respondents, there are 2 abstentions, 27 are in agreement, and 16 are in disagreement.

The major comment issues raised are:

1. **Definition of "qualified personnel".**
2. **Confusion around "real time observation of an encroachment into the MVCD" and documentation required to report a violation or attest that a violation did not occur. Also issues regarding an encroachment with no fault and/or momentary fault as being a violation.**

The VM SDT considerations for the major comment issues are:

1. **SDT changed the language to "confirmation by Transmission Owner".**
2. **Considered language proposed by Duke in comment 16 and adopted and modified by SDT.**

A minor comment issue is:

1. **The inclusion of examples in the requirement instead of the rationale box.**

The VM SDT consideration for the minor comment issue is:

1. **The SDT changed the language to "confirmation by Transmission Owner".**

	Organization	Yes or No	Question 3 Comment
1	MWDSC (METROPOLITAN		

	Organization	Yes or No	Question 3 Comment
	WATER DISTRICT OF SOUTHERN CALIFORNIA)		
2	Xcel Energy		No comments/no position
3	GDS Associates	No	- Need to specify who qualifies as "qualified personnel" to observe the vegetation condition.
	Response: Thank you for your comment. The SDT changed the wording to confirmation by the Transmission Owner.		
4	Hydro One	No	A clarification for M1 is needed regarding whether entities will have to attest to the fact that there has never been an encroachment in the MVCD.
	Response: Thank you for your comment. It is not the intent of this standard for entities to be required to prove a negative. The SDT believes the proposed language does not imply that an entity will be required to prove that an encroachment has not occurred.		
5	Northeast Power Coordinating Council	No	A clarification for M1 is needed regarding whether entities will have to attest to the fact that there has never been an encroachment in the MVCD.
	Response: Thank you for your comment. It is not the intent of this standard for entities to be required to prove a negative. The SDT believes the proposed language does not imply that an entity will be required to prove that an encroachment has not occurred.		
6	PPL Electric Utilities	No	As written M1 requires evaluation of condition by "qualified person" but no definition of qualified person given. Should be more direct and point to physical evidence of vegetation encroachment into MVCD, i.e. burned vegetation.
	Response: Thank you for your comment. The SDT changed the wording to confirmation by the Transmission Owner. It is not the intent of this standard for entities to be required to prove a negative. The SDT believes the proposed language does not imply that an entity will be required to prove that an encroachment has not occurred.		

	Organization	Yes or No	Question 3 Comment
7	CenterPoint Energy	No	CenterPoint Energy does not believe a performance based requirement should require evidence of processes and procedures to demonstrate compliance. However, if the majority of industry commenters agree with the SDT's approach, CenterPoint Energy has several concerns.Assuming R1.1 and R2.1 regarding observations of encroachments are not deleted from the Standard, then only the first paragraph regarding forms of evidence is helpful and necessary. The second paragraph is not relevant or necessary. The special qualification of Sustained Outage should be contained in R1 and R2, not M1 and M2. Also, the reference to a "Fault" in M1 and M2 instead of a "Sustained Outage" changes the scope of what is specified in R1 and R2 which is not reasonable. A "Fault" can be associated with a Momentary Outage or a Sustained Outage. The scope of R1 and R2 is specific to Sustained Outages.
	Response: Thank you for your comment. The SDT chose the word "fault" as it is a NERC defined term. A fault associated with vegetation indicates that encroachment into the MVCD occurred.		
8	Arizona Public Service Company	No	Do not agree with real-time observation. Utility can use technology to determine all rated conditions if a tree related outage occurred.
	Response: Thank you for your comment. The real-time observation reference applies to cases where vegetation encroaches into the MVCD but flash-over has not occurred. Enroachment into the MVCD where no fault occurs is the least severe violation of the requirement.		
9	MidAmerican Energy	No	Examples should be moved to the rationale boxes to avoid confusion on what is required and what is an example. All rationale boxes should have a disclaimer to the effect saying "For guidance only, not for enforcement".
	Response: Thank you for your response. Examples were included in the Requirement at the response of NERC staff to add clarity. By definition, verbiage within the rationale boxes are for guidance and are not enforcable.		
10	Kansas City Power & Light	No	In response to the informal comment period, the SDT is clear that it believes the use of encroachment as a basis for determining the effectiveness and compliance of a vegetation management program. The purpose of this Standard is to identify the criteria for effective monitoring of vegetation in

	Organization	Yes or No	Question 3 Comment
			transmission right-of-way and to take appropriate actions when that monitoring identifies the need to “clear” vegetation to prevent potential transmission facility outages resulting from contact with vegetation. These proposed Measures as written do not give credit to the Transmission Owners for effectively monitoring their systems and taking appropriate actions in regard to vegetation clearing. Why does it make sense to punish and penalize a Transmission Owner for discovering an encroachment when they take the appropriate actions to remedy the condition before any facility outage occurs that results in compromising the reliability of the Bulk Electric System? These Measures and Standard should recognize the good practices of effective response to a vegetation condition and penalize ineffective response. Highly recommend the SDT consider including appropriate language to recognize effective remedial actions by Transmission Owners and by doing so, recognize effective efforts instead of punishing them.In addition, proving encroachments have not occurred will pose audit challenges in determining that encroachments have not occurred for the Auditors as well as Registered Entities. If no encroachments occur, then there is nothing to report or record. This is a weak platform to stand compliance on. Facility interruption events caused by vegetation contacts is definitively measurable and recordable. Recommend the SDT reconsider the concept of compliance with FAC-003 on the basis of sustained outages.
	Response: Thank you for your comment. The real-time observation reference applies to cases where vegetation encroaches into the MVCD but flash-over has not occurred. Enroachment into the MVCD where no fault occurs is the least severe violation of the requirement. It is not the intent of this standard for entities to be required to prove a negative. The SDT believes the proposed language does not imply that an entity will be required to prove that an encroachment has not occurred.		
11	BGE Forestry Management	No	M1 & M2 bullet: “Real-time observation of any MVCD encroachments.” implies that real-time observation of vegetation encroachment ensures reliable operation the Bulk Electric System. The reliability standard objective states;”To improve the reliability of the electric Transmission system by preventing those vegetation related outages that could lead to Cascading.”However, real time observation of current operating conditions provides no assurance that vegetation will not lead to outages. BGE recommends removing the language. If an inspector finds vegetation encroaching into the MVCD during a visual inspection he / she should

	Organization	Yes or No	Question 3 Comment
			immediately initiate an Immediate Threat Notification. Therefore, this measure has no value.
	Response: Thank you for your comment. The real-time observation reference applies to cases where vegetation encroaches into the MVCD but flash-over has not occurred. Enroachment into the MVCD where no fault occurs is the least severe violation of the requirement.		
12	PNM	No	Needs a definition of Real Time Observations
	Response: Thank you for your comment. The SDT believes that “Real Time” observations (the actual time during which the observation occurs) is sufficiently clear.		
13	Consumers Energy Company	No	None of the three examples of acceptable forms of evidence provided in the revision prove that a Transmission Owner actively managed vegetation to prevent encroachment into the MVCD. The Measure should require proof of active ROW clearing activity per the transmission vegetation management plan, such as invoicing or crew field reports or vegetation inspection data from the annual vegetation inspection.
	Response: Thank you for your comment. The SDT would suggest you refer to R6 and R7, which addresses evidence of an annual vegetation inspection and work plan.		
14	BC Hydro	No	Overall, the definition of these measures is improved over draft 3. However, the standard should better define who a “qualified person” is and who has the authority to make attestations. R1 and R2 could be better defined relative to the standard definitions in section 4.2 as to what voltage levels in R2 are part of the standard and what is excluded. That is:R1 is any circuit that is an element of an IROL or WECC transfer path regardless of the transmission voltage.R2 is any circuit >200kV which is not an element of an IROL or WECC transfer path.Lower voltage circuits that do not fit the R1 definition are not part of this standard.
	Response: Thank you for your comment. The SDT changed the wording to confirmation by the Transmission Owner. R1 and R2 intentionally differentiate between the components of the transmission system that are part of the IROL or WECC Transfer Path and the BES. The SDT believes that violations in the IROL or WECC Transfer Paths pose a greater risk of cascading events, and therefore carry higher VSLs.		

	Organization	Yes or No	Question 3 Comment
15	Central Maine Power Company, Iberdrola USA	No	Recommend SDT create two measures one measure if a tree violated the MVCD and no outage occurred and second measure and severity level if an outage occurred
	Response: The SDT believes that enroachments into the MVCD where no fault occurs are a violation to the standard and should be included in R1 and R2.		
16	Duke Energy	No	The last sentence of this modification could be misinterpreted by a compliance representative to imply that all Faults must be investigated to eliminate or confirm vegetation as the cause of the fault. There are several sources (e.g. lightning, wind-blown debris) of Faults and several appropriate operational responses, some of which may not include field investigations, depending on the circumstances surrounding each Fault. Thus, the current wording is gray and should be modified to aid industry's understanding and thus to ensure compliance.The interpretation we suggest may not be obvious, but our experience with previous interpretations of certain facets of FAC-003-01 would indicate the need to better define the expectation.A potential modification to the last sentence of M1/M2 could be:If a later confirmation of a Fault by a qualified person shows that a vegetation encroachment within the MVCD has occurred, this shall be considered the equivalent of a Real-time observation.
	Response: Thank you for your comment. The SDT agrees with your recommendation and has adopted the proposed language. The SDT believes that faults that occur on applicable lines included in R1 and R2 should be investigated to determine if the cause was vegetation related. If an entity can determine to their satisfaction, through documentable means such as through technology or other sources, that the fault was caused by some other reason (i.e. lightning), it is the entity's decision whether or not to investigate further.		
17	FPL Corporate Compliance	No	The measure is adding to the requirement. The measure should define how a requirement is met and not interpret or add to the requirement, otherwise this will add to confusion, instead of clarity, which should be the goal of any revised reliability Standard.Also, the measure implies that a fault investigation must be done. As written, momentary outages are included, and a fault investigation should not be required for momentary outage.It also places the same weight of violation on a momentary outage as it does a Sustained outage, which appears on its face not to appropriate nor

	Organization	Yes or No	Question 3 Comment
			necessary to meet the goal of FAC-003-2. In addition, an outage investigation is not a finite process that produces identical homogenous results every time. Of particular concern is the possibility that should a Transmission Owner have one or more momentary outages and not find the cause, then later have another outage (Sustained or Momentary), such a finding appears to lead to a multiple violation. This is inconsistent with focusing requirements on reliability risks to the bulk electric system.
	Response: Thank you for your comment. A fault caused by the grow-in, fall-in, or blow-in of vegetation on the active right-of-way is a violation of the requirements regardless of whether the fault was momentary or sustained. Based on other comments, the SDT has modified the language in M1/M2.		
18	NERC Staff	No	With respect to both M1 and M2, NERC staff finds the “acceptable forms of evidence” incomplete. To assess compliance, the auditors would also need to see the processes and procedures identified under Requirement R3 and the annual work plan under Requirement R7 to see how the entity planned to prevent sustained outages and what the entity had done to implement that plan. Finally, what is the purpose of the following sentence?: “If an investigation of a Fault by a qualified person confirms that a vegetation encroachment within the MVCD occurred, then it shall be considered a Real-time observation.” Recommend adding each report of a real-time observation of encroachment into the MVCD to the periodic data submittal.
	Response: Thank you for your comment. The SDT believes that an attempt to list all “acceptable forms of evidence” would be difficult, as entities employ a myriad of documentation types. The SDT agrees that an auditor would need to see the processes and procedures indentified under R3 and R7 to perform an audit. An auditor with an understanding of vegetation management would be able to validate “acceptable forms of evidence” as part of compliance audit process. Real time observations of an encroachment into the MVCD is a violation of the standard and should be documented and self-reported. The RE’s currently require periodic reporting.		
19	Allegheny Power	Yes	
20	Ameren	Yes	
21	American	Yes

34	Progress Energy	Yes	
35	South Carolina and Gas	Yes	
36	Southern Company Transmission	Yes	
37	The United Illuminating Company	Yes	
38	Tri-State Generation & Transmission	Yes	
39	FirstEnergy	Yes	Although we agree with the language of M1 and M2 for the proposed R1 and R2 in the standard being balloted, we support the alternate versions of R1 and R2 (see comments in Question 6) and wish to see M1 and M2 developed for the alternate R1 and R2.
	Response: Thank you for your comment.		
40	Great River Energy	Yes	GRE agrees with the revisions made to this standard since the last posting and requests clarification on what constitutes a qualified person.
	Response: Thank you for your comment. The SDT changed the wording to confirmation by the Transmission Owner.		
41	Western Electricity Coordinating Council	Yes	however the statement of acceptable forms of evidence implies that a dated attestation alone could provide evidence of compliance. An attestation alone would not represent sufficient evidence to support a conclusion of compliance with encroachment limits only of the absence of an outage.
	Response: Thank you for your comment. Real time observations of an encroachment into the MVCD is a violation of the standard and should be documented and self-reported.		

	Organization	Yes or No	Question 3 Comment
42	Western Area Power Administration	Yes	However, the last sentence added to the measure is imprecise and introduces undesirable subjectivity and confusion to the process for determining a compliance violation.
	Response: Thank you for your comment. Based on the recommendation from several commentors, the last sentence in M1/M2 has been modified.		
43	Southern California Edison Company	Yes	SCE generally agrees with the revisions to M1 and M2, however we would suggest the last sentence of the second paragraphs in both M1 and M2 be modified to read: M1- Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period. If an investigation of a Fault, by a qualified person, confirms that a vegetation encroachment, as described in R1 items 2-4 (above), occurred within the MVCD occurred, then it shall be considered a Real-time observation.M2- Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period. If an investigation of a Fault, by a qualified person, confirms that a vegetation encroachment, as described in R2 items 2-4 (above), occurred within the MVCD occurred, then it shall be considered a Real-time observation.
	Response: Thank you for your comment. Based on the recommendation from several commentors, the last sentence in M1/M2 has been modified.		
44	Tampa Electric Company	Yes	These changes allow for qualified review of field findings.
	Response: Thank you for your comment.		
45	Entergy Services	Yes	We agree, IF the determination is made by a Qualified Person to have been caused by vegetation breaking the MVCD (if not breaking MVCD in real time when observed) based on close observation/inspection and hard evidence that a Flashover occurred, and that there is no evidence that the issues spotted on the tree were caused by environmental or biological symptoms or stressors of the tree in question. Hard evidence has to be present to classify

	Organization	Yes or No	Question 3 Comment
			the item as a vegetation outage if the tree is not within MVCD when the real time observation is made.....an assumption cannot be made that vegetation was the cause of an outage if the tree is situated at a distance that is greater than MVCD when observed unless there is hard evidence supporting the flashover as determined by a qualified person.
	Response: Thank you for your comment.		

4. In response to comments received that requirement R3 is deficient in detail, the SDT modified the requirement. Do you agree? Please explain.

Summary Consideration:

Of 45 respondents, there are 32 in agreement, 12 in disagreement and1 abstention.

The major comment issues raised are:

1. **The additional wording placed in the requirement after the first sentence adds confusion to the extent of documentation that will be required.**
2. **The use of the phrase "incorporate the dynamics" adds confusion to the requirement.**

The VM SDT considerations for the major comment issues are:

1. **The response pointed out that the reason that the additional wording was inserted was due to the numerous comments from the previous posting that the requirement needed more specificity.**
2. **The SDT agreed with some suggested wording to replace the phrase "incorporate the dynamics" and revised the requirement accordingly.**

Some minor comment issues are:

1. **One commenter questioned the use of the word "intent" in the rationale.**
2. **One commenter questioned the language of the measure.**
3. **One commenter was concerned that the removal of the programmatic details renders the requirement less auditable and questionably effective.**

The VM SDT considerations for the minor comment issues are:

1. **The wording in the rationale was changed to eliminate the word "intent".**
2. **In the response to the commenter questioning the language of the measure, the SDT explained that the focus of the measure is on the logic test of the Transmission Owner's vegetation maintenance program.**

3. In response to the commenter concerned about the programmatic details being removed, the SDT responded by explaining various ways that this requirement could be audited and further explained the main focus of the requirement.

	Organization	Yes or No	Question 4 Comment
1	MWDSC (METROPOLITAN WATER DISTRICT OF SOUTHERN CALIFORNIA)		
2	GDS Associates	No	- We suggest to eliminate / change the word “dynamics” because can create confusion with regards to the extent of documentation that has to be prepared.- Requirement should clearly state the criteria as in the maximum design (rating) or maximum operat
	Response: The SDT thanks you for your comment. The intent of the more detailed wording of R3 in this version of the Standard is to make sure that the Transmission Owner adequately documents and demonstrates that it understands the complex relationship of conductor movement under thermal and wind load and vegetation growing and moving in proximity to the line. In light of your comment, and similar comments from others, the SDT has revised the wording of R3. We feel that this change will alleviate any perceived confusion.		
3	PPL Electric Utilities	No	As written, R3 now requires documentation of conductor dynamics as related to ratings and rated operational conditions. Not clear how this information is to be presented and documented and how vegetation conditions that exist are to be documented to provide evidence that management processes and procedures are adequate to prevent encroachment into MCVD.
	Response: The SDT thanks you for your comment. The Technical Reference Document attempts to provide further explanation, along with examples, of how to present this information. While this information is not in the Standard itself, the supplemental information in the Technical Reference Document should help the Transmission Owner understand the SDT’s intent for the requirement. Also, The SDT has revised the wording in R3 and has removed the word “dynamics”.		

	Organization	Yes or No	Question 4 Comment
4	Great River Energy	No	GRE does not believe that the new specificity that has been added to R3 will improve the reliability of the BES. It is our opinion that the requirement would have been clearer if it had ended after the first sentence. The additional language after the first sentence does not improve clarity.In measures for other requirements the SDT has done a very good job of stating and clarifying (in their opinion) what acceptable forms of evidence are. M3 would benefit from this type of clarification.
	Response: The SDT thanks you for your comment. The previous version of the Standard was crafted very much as you suggest. Many commenters disagreed with this approach, which led to the SDT crafting this more verbose version.		
5	Kansas City Power & Light	No	It is unclear that this requirement may utilize the industry practice of “ruling span” methods to determine the vegetation clearances for a transmission facility. “Ruling span” methods are used to determine the construction design for transmission facilities and includes maintaining safe clearance distances. This requirement could be interpreted as being applied to every individual span to determine vegetation clearances for a transmission facility which would not be practical.
	Response: The SDT thanks you for your comment. The intent of R3 in this version of the Standard is to make sure that the Transmission Owner adequately documents and demonstrates that it understands the complex relationship of conductor movement under thermal and wind load and vegetation growing and moving in proximity to the line. It leaves the decision to the Transmission Owner how to satisfy this “competency based” requirement. While a Transmission Owner could certainly take the approach that each individual span be addressed separately, it is also possible for a Transmission Owner to have a specific “vegetation maximum height” approach, based on the minimum ground clearance specification of an entire line. Either approach would satisfy this requirement.		
6	MidAmerican Energy	No	MidAmerican supports the additional detail the R3 should end after the first sentence. The additional detail should be moved to the rationale box as additional guidance.
	Response: The SDT thanks you for your comment. If we understand your comment, the reason that R3 has greater detail was due to comments received after the last posting. The SDT felt compeled to add this additional information.		

	Organization	Yes or No	Question 4 Comment
7	Xcel Energy	No	R3 requires the Transmission Owner to have a documented process that shall contain certain items. Please bulletize these items for clarity.Additionally, the measure for this requirement indicates that the process document elements 'prevent' encroachment. It is presumed that the elements identified in the requirement are what need to be addressed in order to minimize the likelihood of encroachment. Essentially, M3 should be reworded to state "The procedures, processes, or specifications provided incorporate the elements identified in R3 (dynamics of a transmission line conductor's...)
	Response: : The SDT thanks you for your comment. The SDT feels that the requirement is adequate in a non-bullet form. R3 has been revised to clarify the intent of this "competency based" requirement. The measure for this requirement should be a "logic" test looking at the methodology that the Transmission Owner uses in order to determine what vegetation actions need to take place. The Technical Reference Document gives examples of several ways to satisfy this requirement. The SDT feels that the measure as stated is adequate.		
8	Southern California Edison Company	No	SCE prefers the Draft 3 version of R3 which read:"Each Transmission Owner shall have a documented transmission vegetation management program that describes how it conducts work on its Active Transmission Line ROWs to avoid Sustained Outages due to vegetation, considering all possible locations the conductor may occupy assuming operation within Rating and Rated Electrical Operating Conditions."However, if the SDT believes it is prudent to revise R3 in response to certain commenters, SCE would respectfully recommend R3 be revised to read:"Each Transmission Owner shall document the procedures, processes, or specifications it uses to prevent the encroachment of vegetation into the MVCD. Such documentation will account for the movement of transmission line conductors under their Rating and Rated Electrical Operating Conditions; and the inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency, for the Transmission Owner's applicable lines."
	Response: The SDT thanks you for your comment. The SDT agrees that the wording in R3 should be modified. R3 has been revised to remove the reference to "incorporate the dynamics" and has recrafted the requirement wording similar to your latter recommendation.		

	Organization	Yes or No	Question 4 Comment
9	CenterPoint Energy	No	See response to Q3 above. However, assuming R3 is not revised to exclude processes and procedures, we have no preference to the wording between the two drafts.
	Response: The SDT thanks you for your comment.		
10	Arizona Public Service Company	No	Still lacks detailed information. SDT needs to specify the documentation it is left up to interpretation by the utility.
	Response: The SDT thanks you for your comment. The SDT feels that the combination of the requirement wording and the examples and explanations in the Technical Reference Document are sufficient detail to portray the intent.		
11	MRO's NERC Standards Review Subcommittee (nsrs)	No	The NSRS does not believe that the new specificity that has been added to R3 will improve the reliability of the BES. It is our opinion that the requirement would have been clearer if it had ended after the first sentence. The additional language after the first sentence does not improve clarity. The whole (as written) requirement may be interpreted as a requirement for "each span" of Transmission line to which the Requirement will be applied. In measures for other requirements the SDT has done a very good job of stating and clarifying (in their opinion) what acceptable forms of evidence are. M3 would benefit from this type of clarification.
	Response: The SDT thanks you for your comment. The previous version of the Standard was crafted very much as you suggest. Many commenters disagreed with this approach, which led to the SDT to address this issue by adding the specificity. **R3 is a "competency based" requirement. The measure should be whether the methodology used by the TO to maintain vegetation passes the basic logic test. (eg: Our max growth rate is 3' per year. We have a minimum ground clearance spec for 230 kV of 24 feet at maximum sag. We maintain the lines every three years. During maintenance of 230 kV lines we remove all vegetation over 11.5 feet high) For a "results based" standard, the emphasis should be on the Tranmssion Owner demonstrating competency in its approach, however simple or complex that approach may be**		
12	NERC Staff	No	The removal of programmatic details from R3 renders the auditing task much more difficult. How does one assess the quality of the program except

	Organization	Yes or No	Question 4 Comment
			through the results required in R1 and R2? Since maintaining specific cut-to clearances is not required, there is much greater subjectivity in application that greatly complicates the auditor job. If the team does not want to limit the available approaches, it could provide flexibility by offering an array of deterministic formulas or approaches for maintaining vegetation. This might include maintaining vegetation to remain within a certain height from the ground given maximum sag distances. Additionally, this requirement does not seem to require the entity to actually follow its policies and procedures (unlike, for instance, R7). What is a violation here? Not having the documented procedure(s) OR whether the documented procedure(s) actually demonstrate that the entity can prevent encroachment? NERC staff is also concerned with some of the language in M3. Consider the following modification: “The Transmission Owner will have procedures, processes, or specifications as identified in Requirement R3, records showing work done to support its annual work plan identified in Requirement R7, and its quarterly vegetation reports, to demonstrate that it can prevent encroachment into the MVCD.” Finally, with respect to the Rationale associated with R3, how would NERC enforce poor intent or a poor indication of competency (especially if the entity was performing well)? Recommend: Provide a basis for evaluating whether the Transmission Owner’s procedures, processes, or specifications used to maintaining vegetation are achieving that goal. There may be many acceptable approaches to controlling vegetation so that it does not encroach into the MVCD. And one small copyedit: “interrelationships” should not have a hyphen.
	Response: The SDT thanks you for your comment.		

	Organization	Yes or No	Question 4 Comment
	Regarding the comments pertaining to the requirement wording: The intent of R3 in this version of the Standard is to make sure that the Transmission Owner adequately documents and demonstrates an understanding of the complex relationship of conductor movement under thermal and wind load and vegetation growing and moving in proximity to the line. The SDT points out that inclusion of a programatic list of activities by itself does nothing to to ensure reliability. R3 is a competency based requirement. The audit test is simply one of logic. Does the methodology the TO conveys in R3 logically ensure that no encroachments into the MVCD occur? The SDT feels that it is important for the Transmission Owner to have the flexiblity to choose how it satisfies this requirement and not to provide a limited menu of approaches that could be used. (eg: Our max growth rate is 3' per year. We have a minimum ground clearance spec for 230 kV of 24 feet at maximum sag. We maintain the lines every three years. During maintenance of 230 kV lines we remove all vegetation over 11.5 feet high) For a "results based" standard, the emphasis should be on the Tranmssion Owner demonstrating competency in its approach, however simple or complex that approach may be. The violation for this requirement would be either the TO failed to specify its approach or that the approach specified does not pass the logic test. Regarding the comments pertaining to the measures M3: The SDT feels that an auditor knowledgeable of utility vegetation management work would be capable to evaluate if a well documented approach is sufficient to ensure no vegetation encroachments into the MVCD. Regarding the comments pertaining to the Rationale: The drafting team agrees that "intent" is not measurable or enforceable and has removed it from the rationale. The evaluation and measurement of the competency is listed above.
