13	Consumers Energy Company	No	This really is another attempt at avoiding defining a minimum clearance specification and is not practical. As written, this would require each Transmission Owner to define and document the procedures, processes or specification by individual span for every line owned or operated by the Transmission Owner. Each span varies in length and profile and a single line may have several different conductor types with different load ratings. Line loadings will vary along the line based on substation taps, etc. The dynamics described in the language could only be done on an individual span basis to be reasonably accurate. This is not practical from a planning standpoint or from a standpoint of implementing clearing work in the field.
	Response: The SDT thanks you for your comment. The intent of R3 in this version of the Standard is to make sure that the Transmission Owner adequately documents and demonstrates that it understands the complex relationship of conductor movement under thermal and wind load and vegetation growing and moving in proximity to the line. It leaves the decision to the Transmission Owner how to satisfy this		

	Organization	Yes or No	Question 4 Comment
	"competency based" requirement. While a Transmission Owner could certainly take the approach that each individual span be addressed separately, it is also possible for a Transmission Owner to have a specific "vegetation maximum height" approach based on the minimum ground clearance specification of an entire line. Either extreme would satisfy this requirement. A Transmission Owner also could have an approach that contained a mixture of the two extremes.

39	Tri-State Generation & Transmission	Yes	
40	Western Area Power Administration	Yes	
41	Western Electricity Coordinating Council	Yes	
	Response:		
42	Dominion	Yes	Although we agree with the intent of the proposed language, we feel the requirement should be revised to read:Each Transmission Owner shall document the procedures, processes, or specifications it uses to prevent the encroachment of vegetation into the MVCD. Such procedures, processes, or specifications shall consider the dynamics of a transmission line conductor's movement throughout its Rating and Rated Electrical Operating Conditions and the inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency, for the Transmission Owner's applicable lines.
	Response: The SDT thanks you for your comment. The SDT agrees that the wording in R3 should be modified. R3 has been revised to remove the reference to "incorporate the dynamics" and has recrafted the requirement wording similar to your latter recommendation.		
43	BC Hydro	Yes	As a competency requirement, R3 seems to be missing any requirement for a utility to define who is qualified to develop these plans, which is a departure from FAC-003-1 R1.3. I think that the utility should in their standards define who is qualified to develop their transmission vegetation management program
	Response: The SDT thanks you for your comment. While the SDT agrees that personnel qualifications are important in any pursuit for perfection, the overall approach for this version of the Standard is a "results based' product. In light of that, the SDT does not feel that a "fill in the blank" requirement for personnel		

	Organization	Yes or No	Question 4 Comment
	qualifications is necessary.		
44	Tampa Electric Company	Yes	This better clarifies section R3
	Response:		
45	Southern Company Transmission	Yes	While voting yes we are concerned about the interpretation of the expanded verbiage, how much documentation will be enough.
	Response: The SDT thanks you for your comment. The Technical Reference Document attempts to provide further explanation, along with examples, of how to present this information. While these examples are not in the Standard itself, the supplemental information in the Technical Reference Document should help the Transmission Owner understand the SDT's intent for the requirement, and therefore the documentation required to demonstrate competency.		

5. In response to comments received that requirement R7 is unclear with respect to flexible work plans, the SDT modified the requirement. Do you agree? Please explain.

Summary Consideration:

Of 45 respondents, there are 2 abstentions, 34 are in agreement, and 9 are in disagreement.

The major comment issues raised by those in disagreement are:

1. **The Requirement is vague and needs more specificity and explanation.**
    - **Does not require development of the Annual Vegetation Work Plan**
    - **Language allowing modifications to the Work Plan should specifically require documentation of changes**
    - **M7 is measuring completion of Work Plan, not prevention of encroachments into the MVCD**
    - **The phrase "…provided they do not put the transmission system at risk of a vegetation encroachment" could be better written as "…they do not allow encroachment of vegetation into the MVCD"**
2. **Examples describing potential reasons for plan modification should be clarified or eliminated.**
    - **Decreases in funding not valid.**
    - **Encroachments due to Major Storms are exempted in Footnote 2. R7 allows modification to Plan due to major storms but does not allow encroachments associated with plan change.**
    - **Generally. the examples identified are broad in nature**

Some minor comment issues are:

1. **Eliminate requirement or use the first sentence only.**
2. **Some concern with lack of agreement of language with other parts of the Standard.**

The VM SDT appreciated both the major and minor comment issues identified but decided that the requirement and measures are appropriate and clear as currently written and did not modify any of the language. The SDT reviewed the Funding Adjustment example for R7 and feels this is a valid reason for modifying the Annual Plan keeping in mind that a modification must not place the transmission system at risk of vegetation encroachment into the MVCD. In addition, as expressed in the Rationale, R7 sets the expectation that the work identified in the

annual work plan will be completed as planned. Documentation of the work completed (and any necessary modifications) as written together with the lack of a violation to either Requirement 1 or Requirement 2 is the overall reliability goal. The metric for the work plan is the percentage of the plan completed. The lack of a violation of R1 or R2 is the outcome of the ideal work plan. It is the responsibility of the Transmission Owner to manage the quality of the work plan and its associated modifications to mitigate the risk of a violation of R1 or R2. With Version 2, an outage is now clearly a violation of R1 and R2 and should not be linked to a failure of the work plan. The measure for the work plan is the percentage of the completed work as planned and we do not need to be subjectively trying to evaluate the quality of the Transmission Owner's work plan with this measure.

	Organization	Yes or No	Question 5 Comment
1	GDS Associates		
2	MWDSC (METROPOLITAN WATER DISTRICT OF SOUTHERN CALIFORNIA)		
3	Western Area Power Administration	No	As the list of “examples of reasons for modification” is not all inclusive, it is unnecessary and could result in confusion regarding compliance when a scenario other than one listed requires a change. Further, documentation of changes to the annual plan adds unnecessary administrative burden which is inconsistent with a performance based standards approach.
	Response: Thank you for your response. The SDT feels the list of examples, while not all inclusive, is helpful to the TO in determining how and when to apply flexibility to its annual plan, when required. It is important the TO documents modefication to the plan to insure the work not completed during that period is carried over and completed within a reasonable time frame.		
4	Ameren	No	Funding Adjustments (increase or decrease) - need more description to imply only when planned vegetation work is “over and above”.

	Organization	Yes or No	Question 5 Comment
	Response: Thank you for your comment. The SDT reviewed the Funding Adjustment example for R7 and feels this is a valid reason for modefying the Annual Plan keeping in mind that a modefication must not place the transmission system at risk of vegetation encroachement into the MVCD.		
5	MidAmerican Energy	No	MidAmerican supports the additional detail. However R7 should end after the first sentence. All additional material should be moved to the rationale box.
	Response: Thank you for your comment. The position of the SDT is to have this langiage in the requirement such to allow for flexibility to the work plan. Keep in mind Rationale language is clarifying documentation and not enforcable. The SDT feels it is important that the TO have the flexibility to revise its Annual Plan which is subject to many issues that can influence the completion of work.		
6	The United Illuminating Company	No	R1 and R2 are requirements that no encroachment occurs. R7, as proposed, requires a VMP to be completed to ensure no encroachment occurs. The Supplemental Reference for R7 does not describe the requirement of the annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD. The Reference states the requirement is established to diminish the risk of encroachment; which is very different from ensuring no encroachment. In the Reference for R7 the word “ensure” is only used to describe that flexibility in the VMP is allowed to ensure the reliability of the Transmission System.M7 is measuring work plan completion not the prevention of encroachment. United Illuminating suggests that R7 be changed to: Each Transmission Owner shall complete the work in an annual vegetation work plan to manage the prevention of vegetation encroachments occur within the MVCD. In this way, a violation of R1/R2 does not necessarily mean R7 is violated. The entity does not avoid a penalty for an encroachment because a violation of R1/R2 occurs for actual encroachment. If an encroachment occurs the compliance enforcement authority can review the entities vegetation management plan to determine if it is compliance with R7/M7.
	Response: Thank you for your comments. As expressed in the Rationale, R7 sets the expectation that the work identified in the annual work plan will be completed as planned. Documentation of the work completed (and any necessary modifications) as written together with the lack of a violation to either Requirement 1 or Requirement 2 is the overall reliability goal. The metric for the work plan is the percentage of the plan completed. The lack of a violation of R1 or R2 is the outcome of the ideal work plan. It is the responsibility of		

	Organization	Yes or No	Question 5 Comment
	the Transmission Owner to manage the quality of the work plan and its associated modifications to mitigate the risk of a violation of R1 or R2. With Version 2, an outage is now clearly a violation of R1 and R2 and should not be linked to a failure of the work plan. The measure for the work plan is the percentage of the completed work as planned and we do not need to be subjectively trying to evaluate the quality of the Transmission Owner's work plan with this measure.		
7	CenterPoint Energy	No	See response to Q3 above.However, assuming R7 is not revised to exclude processes and procedures, the new wording is preferred since it is more specific. Additionally, a new ambiguous phrase is introduced, "provided they do not put the transmission system at risk of a vegetation encroachment", which we recommend to be changed to more specific wording, "provided they do not allow encroachment of vegetation into the MVCD".
	Response: Thank you for your comments. The SDT felt the language was appropriate.		
8	Southern Company Transmission	No	The first sentence of the Requirement 7 Rationale conflicts with the second sentence. The R7 Rationale should be reworded as follows:"This requirement sets the expectation that the work identified in the annual work plan should be completed as planned. However, an annual vegetation work plan must allow for work to be modified in response to changing conditions. These modifications must take into consideration the anticipated growth of vegetation and all other environmental factors, provided that the changes do not cause a vegetation encroachment within the MVCD."
	Response: Thank you for your comments. The SDT felt the language was appropriate.		
9	NERC Staff	No	This is the first instance in which an annual work plan is discussed. It would appear necessary to first develop an annual work plan component of the overall vegetation management program. There should also be some performance review or expectation that the annual plan as implemented achieved the intended program objectives, or that modifications would be necessary. Does R7 require both that a Transmission Owner has an annual vegetation

	Organization	Yes or No	Question 5 Comment
			work plan AND that it completes the work plan? Detail is required as to what is expected in the work plan, as there is currently no basis to judge whether the work plan is adequate or not adequate. And what does a modification entail? Does this mean reduction of performance, delay in performance, or complete postponement of performance? NERC staff is also concerned with the list of examples one might use to modify an annual plan. Several of these items should not pose any greater risk to vegetation contact and render the requirement virtually unenforceable. It provides a wide array of reasons to postpone vegetation management and may make it a very low priority for an entity: • “Rescheduling work between growing seasons”: This could be an honest change (if there are unexpected seasonal changes) or it could reflect bad initial planning. If there will be occasion for auditors and investigators to distinguish, there should be guidance on differentiating. • “Crew or contractor availability”: This could be an honest change (if there is an unexpected labor dispute or if crews are needed to help a neighboring utility during an unexpected emergency) or it could reflect bad initial planning. If there will be occasion for auditors and investigators to distinguish, there should be guidance on differentiating. Alternatively, it could be removed from the list as it is within the exclusive control of the Transmission Owner. • “Identified unanticipated high priority work”: This could be an honest change or it could reflect bad initial planning. If there will be occasion for auditors and investigators to distinguish, there should be guidance on differentiating. It is also vague and would necessitate a judgment call for enforcement. • “Permitting delays”: Annual plans should account for anticipated permitting schedules and maybe even add a factor for uncertainty. It is a planning issue for the entity and should not be an acceptable excuse for not conducting vegetation management. • “Land ownership changed”: If a landowner has the ability to affect the reliability of the bulk power system, the landowner should be subject to

	Organization	Yes or No	Question 5 Comment
			the reliability standards. A registered entity should be responsible for the land in its ROW, especially if it has turned control of the land, and the ability to affect reliability of the BPS, over to another entity or person for financial gain. • “Funding adjustments”: NERC staff is not convinced that this is a legitimate reason for adjusting an annual vegetation work plan. Economic considerations should not be a reason to delay or modify vegetation management. • “Emerging technologies”: It is unclear what this example is intended to accomplish. In general, these examples should be bounded in some way to ensure that a modification due to one of their occurrences does not impart a greater risk of vegetation contact.
	Response: Thank you for your comments. Per the SDT, developing the annual work plan is an understood requirement in order for the TO to complete the work plan. Thus, a requirement to develop the plan is not needed. R3 specifies the processes, procedures and/or specifications that are utilized by a TO to prevent an encroachment of the MVCD. This “Competency Based” requirement sets the core foundation that a TO will utilize to develop their annual work plan. **As expressed in the Rationale, R7 sets the expectation that the work identified in the annual work plan will be completed as planned. Documentation of the work completed (and any necessary modifications) as written together with the lack of a violation to either Requirement 1 or Requirement 2 is the overall reliability goal. The metric for the work plan is the percentage of the plan completed. The lack of a violation of R1 or R2 is the outcome of the ideal work plan. It is the responsibility of the Transmission Owner to manage the quality of the work plan and its associated modifications to mitigate the risk of a violation of R1 or R2. With Version 2, an outage is now clearly a violation of R1 and R2 and should not be linked to a failure of the work plan. The measure for the work plan is the percentage of the completed work as planned and we do not need to be subjectively trying to evaluate the quality of the Transmission Owner’s work plan with this measure.** **By bounding the flexibility as advocated, there are several variables involved such it makes it impractical to be able to address the many operational scenerios that a TO may experience. Thus, without being very prescriptive, the SDT feels that it is best to provide general guidance to what are valid modifications to the work plan.**		

	Organization	Yes or No	Question 5 Comment
10	Kansas City Power & Light	No	This requirement is in direct conflict with the “exclusions” as described in section 4.4. Section 4.4 makes it clear that effects of “major storms” on a vegetation programs efforts will be allowed as an exclusion toward compliance with these requirements, yet, R7 does not allow any encroachment due to modifications to a vegetation plans efforts due the “Major Storms” (second bullet) or “Weather conditions/Accessibility” (bullet 6). Please explain what is intended here that is different than what was intended in section 4.4.In addition, this presents some audit difficulties regarding the notion of detecting a “modified work plan”. Once a work plan is altered and new objectives are laid out, that becomes the plan and the plans that were replaced may be discarded since they would be of no value. Further, what difference does it make to track or monitor any changes to a work plan provided effective vegetation management is maintained? Recommend the SDT consider removing the language regarding “work plan flexibility” as this may suggest and impose an unnecessary compliance burden on Registered Entities and Auditors.
	Response: Thank you for your comments. The SDT views Major Storms in the list of examples differently than in Footnote 2. The example has more to do with schedules being revised as a result of a major storm while Footnote 2 refers to issues of sustained outages caused by circumstanses beyond the control of the Transmission Owner, and excepting resulting violations to the standard. **The SDT feels it is important to track and document changes in the work plan to insure rescheduled work is completed at some later date. Work plan flexibility through modification to the work plan is critical and must be recognized so that the Transmission Owner can propertly plan and revise work schedules when necessary.**		
11	Xcel Energy	No	What exactly does complete an annual work plan mean? It infers that an annual work plan must be developed/documented and executed. If this is the case, then clearly state as such.In general, R6 & R7 go against the grain of the results based standard concept. R1 already established that the Transmission Owner cannot have encroachment. R3 requires annual inspection (essentially establishing the plan). Why replicate in R6 & R7, it does not seem to serve any useful purpose.
	Response: Thank you for your comments. As stated in the Rationale, “This requirement sets the expectations that the work identified in the annual work plan will be completed as planned.” Because the		

	Organization	Yes or No	Question 5 Comment
	work plan is recurring in nature, a new work plan must be developed each year to state work planned for that period. This requirement directly supports Requirement 3 which calls for a documented vegetation management approach to prevent MVCD encroachments.

37	PPL Electric Utilities	Yes	
38	Progress Energy	Yes	
39	South Carolina and Gas	Yes	
40	Tri-State Generation & Transmission	Yes	
41	Western Electricity Coordinating Council	Yes	annual vegetation management plans must have some flexibility. If the TO has the authority to create the plan they should have the authority to modify the plan. The key point is that changes, particularly delays to planned work would have to be approved. Do not believe “decreases in funding” should be listed as a valid reason for modification of work plan related to a reliability standard.From an enforcement viewpoint, there is ambiguity or perceived ambiguity in “provided they do not put the transmission system at risk of a vegetation encroachment.” Provided the potential that there may never be a self-report addressing this violation.
	Response: Thank you for your comments. The SDT agrees the plan needs flexibility and the Transmission Owner has authority for plan oversite. No approval for changes is called for in the requirement, but documentation is required to note the change. **The SDT reviewed the Funding Adjustment example for R7 and feels this is a valid reason for modifying the Annual Plan keeping in mind that a modification must not place the transmission system at risk of vegetation encroachment into the MVCD.**		
42	Southern California Edison Company	Yes	SCE agrees with the revisions to R7, but notes the some minor edits to the text are still needed.
	Response: Thank you for your comments. The SDT felt the language was appropriate.		
43	MRO’s NERC Standards Review Subcommittee (nsrs)	Yes	The NSRS has issue with the word “may” (and its components along with the associated bulleted points) and recommends that it is removed and placed in the rational box.

	Organization	Yes or No	Question 5 Comment
	Response: Thank you for your comments. The SDT believes the requirement as written is needed to insure flexibility of work plan.		
44	BC Hydro	Yes	The requirement as currently worded, seems to assume but does not explicitly state that a utility must prepare and document an annual vegetation work plan and document in some manner any modifications to that work plan as they occur. The work plan change documentation should include any risks of work deferral and mitigation plans to address those risks if there are any.
	Response: Thank you for your comments. Per the SDT, developing the annual work plan is an understood requirement in order for the TO to complete the work plan. Thus, a requirement to develop the plan is not needed. R3 specifies the processes, procedures and/or specifications that are utilized by a TO to prevent an encroachment of the MVCD. This "Competency Based" requirement sets the core foundation that a TO will utilize to develop their annual work plan. **The lack of a violation of R1 or R2 is the outcome of the ideal work plan. It is the responsibility of the TO to manage the quality of the work plan and mitigate any risk to the system associated with modifications to the work plan.**		
45	Tampa Electric Company	Yes	These changes add greater clarity, as well as real world examples, to this standard.
	Response: Thank you for your comments.		

6. In response to comments received that requirement R1/R2 may not adequately protect the transmission conductors under all conditions of sag and sway, the SDT drafted alternate language for the industry to provide feedback. The SDT did not opt to incorporate this language into "Draft 4" until further comment was solicited from industry. Which do you prefer? Please comment on your choice in the comment box below:

*"**Alternate R1/R2.** Each Transmission Owner shall manage the floor of its Active Transmission Line ROW in accordance to one of the following at all times:*

A) A fixed maximum vegetation height of 15 feet from the ground at the mid-half of the span and 20 feet in the outside quarters of the span, or,

B) A calculated maximum vegetation height that is the difference between the minimum conductor height at "max sag" minus MVCD minus cycle growth, or,

C) A calculated minimum vegetation to conductor clearance that is the sum of "max sag" in the span plus MVCD plus cycle growth, or,

D) A value determined by the Transmission Owner to provide a separation between the conductor and the vegetation that is comparable to options A, B, or C.

E) Any alternative approach that ensures no encroachment occurs within MVCD, considering the sag and sway of the conductor throughout its operating range under rated conditions.

F) A value to provide a separation between the conductor and the vegetation that is the sum of MVCD, and a value that considers the sag and sway of the conductor throughout its operating range under rated conditions plus 10 feet."

NOTE: The SDT suggests similar language as found in the posted draft for measures M1/M2 may be appropriate with this Alternate R1/R2.

Summary Consideration:

Of 45 respondents, there are 4 abstentions (expressed no preference for Draft or Alternate), 16 (two of which appear to be from the same company) are in agreement (that Alternate Language is preferred), and 25 are in disagreement (that Alternate is preferable, liking Draft language better).

The major comment issue raised is:

1. The only real issue raised in the comments by the 41 respondents that had a preference was that of the style of Requirement language appropriate for an RBS standard. Both groups agreed that either the Draft or Alternate language addressed the root requirement(s). In fact, respondents in both groups indicated that Option E

of the Alternate language was in essence the Draft language. (And of those in Alternate group that discussed the 6 options, E was the clear favorite, receiving five (5) mentions with A and C only receiving one (1).)

However, those that preferred the Alternate language cited that written in the form proposed by the Alternate language, the Requirements R1/R2 would provide much more flexibility and two respondents even cited that the Alternate allowed Transmission Owners to specify their own clearances.

For those voting for the Draft language (the majority), the most common reason cited was Draft language was less prescriptive. The second most common reason cited was that the Alternate Language would be confusing. And a couple commenters in this group opined that the Alternate language appeared to be “fill-in-the-blanks” language.

The VM SDT consideration for the major comment issue is:

1. **Based on the “vote” the team will retain the Draft language. Also, Option E was cited most often by the Alternate group as the most desirable of the options and is in fact essentially the Draft language. The SDT was additionally swayed by the comments about confusion and fill-in-the-blanks as two overriding premises behind the standards should be clarity and acceptance by FERC.**

A minor comment issue is:

1. **Commenters offered several minor wording changes to the Draft language.**

The VM SDT consideration for the minor comment issue is:

1. **The team has incorporated some of these minor wording changes and rejected others when the change was found to introduce other problems.**

	may simplify the application by Transmission Owners but is concerned that a majority of commenters find the alternate language confusing and potentially to be fill-in-the-blanks. Therefore, the team has decided to retain the language in the current Draft.		
10	PPL Electric Utilities	Alternate version of R1/R2	Alternate C provides assurances that growth rates, maintenance cycle, and max-sag are taken into consideration.
	Response: The SDT thanks you for your comments. The SDT recognizes that the alternate language offers many choices which may simplify the application by Transmission Owners but is concerned that a majority of commenters find the alternate language confusing and potentially to be fill-in-the-blanks. Therefore, the team has decided to retain the language in the current Draft because the SDT believes it already addresses the provisions you state, i.e. growth rates, maintenance cycle, etc.		
11	Hydro One	Alternate version of R1/R2	Alternate Version E would allow a Transmission Owner to use an approach consistent with the current version of FAC-003 by defining a minimum clearance distance and a vegetation management clearance distance. This approach has met the objectives of FAC-003 since 2006. Use of version E would change the standard from a prescriptive approach to a Transmission Owner defined approach. In addition, Alternate Version E is preferred as it allows for variations based on differences in conductor heights, topography and other situations where a set height is not necessarily required in all instances and allows for the utility to determine the maximum heights of vegetation without performing detailed calculations of what the maximum heights must be along the various distances within each conductor span. If the utility is tasked with managing the vegetation to ensure no encroachments into the MVCD then it should be up to the individual utility how best to determine its management strategies that incorporate the determination of maximum vegetation heights in each section on its system.
	Response: The SDT thanks you for your comments. 	Response: The SDT thanks you for your comments. The SDT recognizes that the alternate language offers many choices which may simplify the application by Transmission Owners but is concerned that a majority of commenters find the alternate language confusing and potentially to be fill-in-the-blanks. Therefore, the team has decided to retain the language in the current Draft.		
13	Idaho Power	Alternate version of R1/R2	Alternative R1/R2 allows the utility to maintain adequate clearances with their preferred approach.
	Response: The SDT thanks you for your comments. The SDT recognizes that the alternate language offers many choices which may simplify the application by Transmission Owners but is concerned that a majority of commenters find the alternate language confusing and potentially to be fill-in-the-blanks. Therefore, the team has decided to retain the language in the current Draft.		
14	FirstEnergy	Alternate version of R1/R2	Although we agree with the alternate version of R1/R2, we have the following comments:1. We assume that R1 and R2 will be written similar to the current proposal with regard to IROL (High VRF) and non-IROL (Medium VRF) transmission lines, respectively. This should be clear after changes have been made to the standard before the final ballot.2. Although the SDT states that it "suggests similar language as found in the posted draft for measures M1/M2 may be appropriate with this alternate R1/R2", we are not clear how these measures will be written and would like to see a draft of the measures so we can review and

	Organization	Yes or No	Question 6 Comment
			comment.3. The alternate requirements appear to be "planning" in nature instead of "real-time"; we assume the intention of the SDT was the latter. Therefore the requirements should be revised with language that is "real-time" in nature.
	Response: The SDT thanks you for your comments. The SDT recognizes that the alternate language offers many choices which may simplify the application by Transmission Owners but is concerned that a majority of commenters find the alternate language confusing and potentially to be fill-in-the-blanks. Therefore, the team has decided to retain the language in the current Draft.		
15	BGE Forestry Management	Alternate version of R1/R2	BGE believes R1/R2 should contain language that ensures that vegetation is manage taking into account sag and sway throughout the conductors operating range as the alternate language above outlines. The six options proposed allows the Transmission Owner the flexability needed to manage the active ROW a varity of ways and at the same time ensures the reliable operation the Bulk Electric System with respect to vegetation.
	Response: The SDT thanks you for your comments. The SDT recognizes that the alternate language offers many choices which may simplify the application by Transmission Owners but is concerned that a majority of commenters find the alternate language confusing and potentially to be fill-in-the-blanks. Therefore, the team has decided to retain the language in the current Draft because the SDT believes it already addresses the provisions you state, i.e. sag and sway.		
16	Idaho Power Company	Alternate version of R1/R2	I think this gives us more flexibility to maintain our clearances.
	Response: The SDT thanks you for your comments. The SDT recognizes that the alternate language offers many choices which may simplify the application by Transmission Owners but is concerned that a majority of commenters find the alternate language confusing and potentially to be fill-in-the-blanks. Therefore, the team has decided to retain the language in the current Draft.		
17	Northeast Utilities	Alternate version of R1/R2	Option E above is preferred as it allows for variations based on differences in conductor heights, topography and other situations where a set height is not necessarily required in all instances and allows for the utility to determine the maximum heights of vegetation without

	Organization	Yes or No	Question 6 Comment
			performing detailed calculations of what the maximum heights must be along the various distances within each conductor span. If the utility is tasked with managing the vegetation to ensure no encroachments into the MVCD then it should be up to the individual utility how best to determine its management strategies that incorporate the determination of maximum vegetation heights in each section on its system.
	Response: The SDT thanks you for your comments. The SDT recognizes that the alternate language offers many choices which may simplify the application by Transmission Owners but is concerned that a majority of commenters find the alternate language confusing and potentially to be fill-in-the-blanks. Therefore, the team has decided to retain the language in the current Draft.		
18	Consumers Energy Company	Alternate version of R1/R2	Prefer Alternative A
	Response: The SDT thanks you for your comments. The SDT recognizes that the alternate language offers many choices which may simplify the application by Transmission Owners but is concerned that a majority of commenters find the alternate language confusing and potentially to be fill-in-the-blanks. Therefore, the team has decided to retain the language in the current Draft.		
19	Kansas City Power & Light	Alternate version of R1/R2	Prefer Alternative E from the list above. Please clarify the meaning of sway in Alternative E. Is that wind blowout?
	Response: The SDT thanks you for your comments. The SDT recognizes that the alternate language offers many choices which may simplify the application by Transmission Owners but is concerned that a majority of commenters find the alternate language confusing and potentially to be fill-in-the-blanks. Therefore, the team has decided to retain the language in the current Draft. Sway is synonymous with wind blowout in Alternative E. Please refer to the Technical Reference document for further clarification on this issue.		
20	Southern California Edison Company	Alternate version of R1/R2	SCE prefers the operational flexibility provided by the alternate version of R1/R2. We also note that dating back to development of FAC-003-1 and related comment periods, Transmission Owners have repeatedly stated that a “one-size-fits-all” TVMP is not viable or reasonable.
	Response: The SDT thanks you for your comments. The SDT recognizes that the alternate language offers many choices which may simplify the application by Transmission Owners but is concerned that a majority of		

	Organization	Yes or No	Question 6 Comment
	commenters find the alternate language confusing and potentially to be fill-in-the-blanks. Therefore, the team has decided to retain the language in the current Draft. The SDT completely agrees with your comment about the 'one-size-fits-all' issue. The SDT has struggled with the proper wording that would allow each Transmission Owner the flexibility necessary to minimize the risk of vegetation outages while adapting to their unique vegetation challenges in a cost-effective-to-consumers manner. The SDT would encourage you, in future comment periods, to offer specific wording that will address the deficiencies you identified and what persuaded you to choose the Alternate version of R1/R2 as the preferred version.		
21	Ameren	Draft 4 version of R1/R2	
22	Duke Energy	Draft 4 version of R1/R2	
23	Exelon	Draft 4 version of R1/R2	
24	Great River Energy	Draft 4 version of R1/R2	
25	ITC Transmission	Draft 4 version of R1/R2	
26	MidAmerican Energy	Draft 4 version of R1/R2	
27	Pepco Holdings, Inc - Affiliates	Draft 4 version of R1/R2	
28	Tri-State Generation & Transmission	Draft 4 version of R1/R2	
29	Xcel Energy	Draft 4 version of R1/R2	Any of the alternate versions would amplify or create issues between land owners and Transmission Owners and are contrary to concepts of Integrated Vegetation Management, in particular, best management practices.
	Response: The SDT thanks you for your comments. Based on the industry support for the Draft 4 language, the SDT		

	Organization	Yes or No	Question 6 Comment
	has opted to retain the language in the current draft, in part because of the confusion you cited.		
30	American Transmission Company	Draft 4 version of R1/R2	ATC feels that Draft 4 Version of R1/R2 is the preferred version. The Alternate version is too prescriptive and has little flexability.
	Response: The SDT thanks you for your comments. Based on the industry support for the Draft 4 language, the SDT has opted to retain the language in the current draft; in part because of the prescriptive nature of the Alternate versions that you mentioned as well as it being noted as confusing.		
31	CenterPoint Energy	Draft 4 version of R1/R2	CenterPoint Energy does not believe a performance based requirement should be this prescriptive. However, if the majority of industry commenters agree with the SDT's approach, CenterPoint Energy has several concerns. The terminology, "operating within Rating and Rated Electrical Operating Conditions" is sufficiently definitive. There is no need to be more prescriptive. Alternate R1/R2 (E) is already similar to the Draft 4 wording. Of the two alternative, we recommend keeping the Draft 4 wording as is; however, we recommend moving the applicability of transmission line ratings to the Applicability section of the Standard as "4.5 Other: The Standard does not apply to any occurrence, non-occurrence, or other set of circumstances that are beyond the Rating and Rated Electrical Operating Conditions of the Facilities defined in 4.2." These conditions should be applicable to all elements and requirements of the Standard just as the force majeure statement does.
	Response: The SDT thanks you for your comments. Based on the industry support for the Draft 4 language, the SDT has opted to retain the language in the current draft, in part because of the prescriptive nature you mentioned as well as it being noted as confusing. The SDT has considered your excellent suggestion about the Applicability Section. However, after extensive discussion, the SDT opted not to add the language in the Applicability Section as the NERC framework for Applicability Sections seems to guide against it.		
32	Consolidated Edison Company of New York Inc	Draft 4 version of R1/R2	Consolidated Edison Company of New York, Inc prefers the Draft 4 version. The wording in the VSLs should be modified for both Requirements to include the phrase 'manage vegetation'. The phrase 'manage vegetation' requires a utility to take specific action to prevent encroachments/outages.

	Organization	Yes or No	Question 6 Comment
	Response: The SDT thanks you for your comments. The SDT has considered your excellent suggestion about the VSLs and decided to change the Requirements in the manner you describe.		
33	Entergy Services	Draft 4 version of R1/R2	Draft 4 is acceptable, but if alternate language is chosen, it should be similar to option E, keeping the determination simple and with as few variables for interpretation as necessary.
	Response: The SDT thanks you for your comments. The SDT recognizes that the alternate language offers many choices which could have simplified the application by Transmission Owners but is concerned that a majority of commenters find the alternate language confusing and potentially to be fill-in-the-blanks. Therefore the team has decided to retain the language in the current draft.		
34	Western Electricity Coordinating Council	Draft 4 version of R1/R2	Draft 4 should be sufficient. If industry believes MVCD is not adequate then the tables for MVCD should be modified to account for sag and sway.
	Response: The SDT thanks you for your comments. The SDT recognizes that the alternate language offers many choices which could have simplified the application by Transmission Owners but is concerned that a majority of commenters find the Alternate language confusing and potentially to be fill-in-the-blanks. Therefore the team has decided to retain the language in the current draft. The SDT is convinced that the technically defensible MVCD is adequate but appreciates the helpful suggestion nonetheless.		
35	Manitoba Hydro	Draft 4 version of R1/R2	I would suggest adding verbage to the draft 4 version to explicitly include the sag and sway of the conductor to the concept of "operating within rating and electrical operating condition"
	Response: The SDT thanks you for your comments. Based on the support for the Draft 4 language, the SDT has opted to retain the language in the current draft, in part because of the prescriptive nature you mentioned as well as it being noted as confusing. The SDT has considered your thoughtful and helpful suggestion about the explicit language which could be added to the Requirement to make it stand-alone and not rely on the Technical Reference document. The SDT, however, decided not to add the suggested verbiage because the team felt that the Rationale Box addressed this issue and the Requirement, if modified, would become somewhat confusing.		
36	MRO's NERC Standards Review	Draft 4 version of R1/R2	It is the NSRS's opinion that that the requirement as currently written in version 4 is consistent with the intent of a standard; i.e. stating what is

	Organization	Yes or No	Question 6 Comment
	Subcommittee (nsrs)		required as opposed to stating how to achieve what is required.
	Response: The SDT thanks you for your comments. Based on the support for the Draft 4 language, the SDT has opted to retain the language in the current draft, in part because of the prescriptive nature of the alternate that you cited, as well as it being noted as confusing.		
37	NERC Staff	Draft 4 version of R1/R2	NERC staff supports the Draft 4 version. The six options listed in the alternative version of R1/R2 do not seem manageable from a utility perspective. But while staff prefers the existing language, it continues to emphasize that fall-ins from outside the ROW can impact the line and need to be taken into consideration.
	Response: The SDT thanks you for your comments. The SDT recognizes that the alternate language offered many choices which may simplify the application by Transmission Owners but is concerned that a majority of commenters, including you, find the alternate language confusing and some even cite that it may potentially be fill-in-the-blanks. Therefore, the team has decided to retain the language in the current draft. Although the SDT understands that fall ins from off-ROW trees can negatively impact the lines and a sound TVMP would include a program to address these potential issues, it is not appropriate that off-ROW trees be included in a NERC Standard. This is mainly because a utility does not have the rights to remove private trees and the process to acquire rights to remove these trees is quite arduous and costly.		
38	Orange and Rockland Utilities, Inc.	Draft 4 version of R1/R2	Orange and Rockland Utilities, Inc prefers the Draft 4 version. The wording in the VSLs should be modified for both Requirements to include the phrase 'manage vegetation.' The phrase 'manage vegetation' requires a utility to take specific action to prevent encroachments/outages.
	Response: The SDT thanks you for your comments. The SDT has considered your excellent suggestion about the VSLs and decided to change the Requirements in the manner you describe.		
39	Tampa Electric Company	Draft 4 version of R1/R2	Quite frankly, the alternatives listed above, or for that matter any other vegetation managment options, should be establised by the utility. The goals in R1 & R2 are very clear. The alternatives listed above will create a double or triple standard of vegetation clearance for each different type of Transmission construction.

	Organization	Yes or No	Question 6 Comment
	Response: The SDT thanks you for your comments. Based on the support for the Draft 4 language, the SDT has opted to retain the language in the current draft, in part because of the confusion you mentioned.		
40	Dominion	Draft 4 version of R1/R2	The alternate language proposed above suggests that methodologies typically incorporated into processes, procedures, or specifications (as required by R3) should also be included into performance-based requirements R1 and R2. The incorporation of this language into R1 and R2 would change these requirements from performance-based requirements to hybrid performance/competency-based requirements.The intent of R1 and R2 is to define a failure to prevent encroachment into the MVCD. Ensuring that a TO's processes, procedures, or specifications demonstrate adequate means of protecting conductors falls under R3, which incorporates transmission conductor and vegetation dynamics and interrelationships. Therefore, methodologies employed to manage the floor of active transmission ROW should be incorporated into the documentation required by R3 and proof that vegetation was managed in accordance with processes, procedures, or specifications to prevent encroachment into the MVCD will be demonstrated by compliance with R1 and R2.
	Response: The SDT thanks you for your comments. Based on the support for the Draft 4 language, the SDT has opted to retain the language in the current draft, in part because it was less prescriptive and more performance-based as you mentioned.		
41	FPL Corporate Compliance	Draft 4 version of R1/R2	The alternative is a fill in the blanks requirement.
	Response: The SDT thanks you for your comments. The SDT recognizes that the alternate language offers many choices which could have simplified the application by Transmission Owners but is concerned that a majority of commenters find the Alternate language confusing and, as you cite, potentially to be fill-in-the-blanks.		
42	BC Hydro	Draft 4 version of R1/R2	The alternatives above are too prescriptive. A utility should set a preferred maintenance distance (i.e. clearance 1 in FAC-003-1) as routine expectation and outline mitigation strategies as required in areas where clearance 1 distances cannot be met to ensure that MVCD distances are not encroached upon. Given the various line design

	Organization	Yes or No	Question 6 Comment
			standards, it is the utility that must define those clearances and margins of error based on engineering standards and the types of vegetation and growth rates present in their operating area.
	Response: The SDT thanks you for your comments. Based on the support for the Draft 4 language, the SDT has opted to retain the language in the current draft, in part because it was less prescriptive as you cited.		
43	Western Area Power Administration	Draft 4 version of R1/R2	The current language of Draft 4 is the most flexible and offers industry the best opportunity for executing a cost effective and efficient program.
	Response: The SDT thanks you for your comments. The SDT has struggled with wording to try to allow each Transmission Owner the flexibility necessary to minimize the risk of vegetation outages while adapting to their unique vegetation challenges in a cost-effective-to-consumers manner. Based on the support for the Draft 4 language, the SDT has opted to retain the language in the current draft, because the SDT believes it achieves the goal you cited.		
44	The United Illuminating Company	Draft 4 version of R1/R2	UI prefers the draft language because we believe the intent of R1/R2 is to capture the actual occurrence of a vegetation related interruption or encroachment of vegetaion into the MVCD based on actual conditions.
	Response: The SDT thanks you for your comments. Based on the support for the Draft 4 language, the SDT has opted to retain the language in the current draft. As you describe, this language captures the true intent of the Requirements in the least confusing and prescriptive manner, as confirmed by other comments received.		
45	Southern Company Transmission	Draft 4 version of R1/R2	We feel the alternative language is too confusing. Does a utility choose one option from the list and expect it to cover all situations, or can the utility pick one option from the list and apply that option to one span, and then another option for the next span. The proposed alternate verbiage makes no distinction as to when options can or cannot be utilized. The language in Draft 4 seems to cover the various scenarios a utility will face in its vegetation management program while giving the utility the flexibility necessary to address these situations in an appropriate manner.
	Response: The SDT thanks you for your comments. Based on the support for the Draft 4 language, the SDT has		

	Organization	Yes or No	Question 6 Comment
	opted to retain the language in the current draft, in part because of the confusion you cited.		

7. The drafting team and NERC staff disagree on an appropriate set of VSLs for Requirements R1 and R2 and the Standards Committee has directed that both sets of VSLs be posted for stakeholder comments. Which set of proposed VSLs best supports NERC's VSL Criteria?

Summary Consideration:

Of 45 respondents, 6 chose neither set of VSLs, 8 disagreed with the SDT, and 31 agreed with the SDT.

Among those who disagreed with the SDT the major comment issues raised are:

1. **VSLs are too low and they do not seem to differentiate between various levels of compliance. Commenter is concerned that the difference between an encroachment that leads to an outage and one that does not is based on nothing but luck.**
2. **The NERC staff set requires a higher degree of accountability.**

The VM SDT considerations for the major comment issues are:

1. **The VM SDT proposed a set of four VSLs to reflect the wide range of non-compliances to these requirements. The NERC staff on the other hand view the outcomes as narrow.**

   The comment that SDT VSLs are "too low" lacks context. The commenter does not offer a frame of reference in rendering its opinion of "too low".

   The comment about luck is without basis. The SDT asserts that vegetation related outages are directly related to the encroachment mechanism, i.e., how vegetation contacts conductors.

   The differing perspectives do not appear to be reconcilable. The VM SDT believes its VSL assignments follow the NERC VSL Guidelines and are technically valid.
2. **The VM SDT believes the VSLs are precisely set to reflect the degree of accountability that best matches the level of non-compliance. Grow-in's are classified in the highest level of violation severity precisely because it is indicative of the lowest quality of performance and therefore the entity must be held to the highest degree of accountability in that case.**

Some minor comment issues are:

1. **Criteria will be probably best represented by a mix of the two VSLs.**

2. Neither set is correct.

The VM SDT considerations for the minor comment issues are:

1. The VM SDT proposed a set of four VSLs to reflect the wide range of non-compliances to these requirements. The NERC staff on the other hand view the outcomes as very narrow. The differing perspectives do not appear to be reconcilable through a hybrid approach as you suggested.

2. The VM SDT believes its VSL assignments follow the NERC VSL Guidelines and are technically valid.

	Organization	Yes or No	Question 7 Comment
1	MWDSC (METROPOLITAN WATER DISTRICT OF SOUTHERN CALIFORNIA)		
2	Progress Energy		
3	Western Electricity Coordinating Council		
4	GDS Associates		Criteria will be probably best represented by a mix of the two VSLs as follows:- Keep the Lower and Moderate VSLs from SDT with both absent Sustained Outage. Add the fall-in as specific encroachment to the Lower VSL and grow-in as specific encroachment to the Moderate VSL- Keep the High / Severe VSLs from NERC
	Response: Thank you for your comment. The VM SDT proposed a set of four VSLs to reflect the wide range of non-compliances to these requirements. The NERC staff on the other hand view the outcomes as very narrow. The		

	Organization	Yes or No	Question 7 Comment
	differing perspectives do not appear to be reconcilable through a hybrid approach as you suggested.		
5	Pepco Holdings, Inc - Affiliates		Neither set is correct. The SDT proposed VSLs do not identify encroachment into the MVCD of a line not in an IROL or Major WECC transfer path, and the NERC Staff proposed VSLs do not do not identify encroachment into the MVCD of a line that is in an IROL or Major WECC transfer path
	Response: Thank you for your comment. Measures M1 & M2 along with The Rationale boxes for R1 & R2 can be used to understand what is meant by the MVCD. The Rational Box States: **"The MVCD is a calculated minimum distance stated in feet (meters) to prevent spark-over between conductors and vegetation, for various altitudes and operating voltages. The distances in Table 2 were derived using a proven transmission design method."**		
6	CenterPoint Energy		Neither. However, we recommend that High or Severe violations be based only on Sustained Outages experienced and the reliability importance of the transmission line. Any process or procedure based requirement, if kept within the Standard, should have a Lower or Moderate designation based on the utilities intent or capability to comply with the Requirement.
	Response: Thank you for your comment. The VM SDT proposed a set of four VSLs to reflect the wide range of non-compliances to these requirements. The NERC staff on the other hand view the outcomes as very narrow. The differing perspectives do not appear to be reconcilable. Your suggestion is appreciated, however the VM SDT believes its VSL assignments follow the NERC VSL Guidelines and are technically valid.		
7	Consumers Energy Company	VSLs proposed by NERC staff	
8	Idaho Power Company	VSLs proposed by NERC staff	
9	FPL Corporate Compliance	VSLs proposed by NERC staff	Again the drafting team is trying to control the terms of a requirement by using the compliance elements. FPL agrees there is a direct link between vegetation growing in to conductors from below has a direct correlation to cascading events and fall-in and blow-in outages are no

	Organization	Yes or No	Question 7 Comment
			more incidental than a cross arm failure to a cascading event. These components should be handled in the requirements and not in the compliance element.
	Response: Thank you for your comment. The VM SDT proposed a set of four VSLs to reflect the wide range of non-compliances to these requirements. The NERC staff on the other hand view the outcomes as very narrow. The differing perspectives do not appear to be reconcilable. The VM SDT believes its VSL assignments follow the NERC VSL Guidelines and are technically valid.		
10	Dominion	VSLs proposed by NERC staff	As all parts of R1/R2 seem to contribute equally to the intent of the requirement - shall manage vegetation to prevent encroachment that could result in a Sustained Outage - NERC's proposed VSLs best address noncompliance with the requirements.
	Response: Thank you for your comment. The VM SDT proposed a set of four VSLs to reflect the wide range of non-compliances to these requirements. The NERC staff on the other hand view the outcomes as very narrow. The differing perspectives do not appear to be reconcilable. The VM SDT believes its VSL assignments follow the NERC VSL Guidelines and are technically valid.		
11	NERC Staff	VSLs proposed by NERC staff	NERC staff supports the VSLs proposed by NERC staff. The SDT's VSLs are too low, and they do not seem to differentiate between various levels of compliance. Still, staff is concerned that the difference between an encroachment that leads to an outage and one that does not is based on nothing but luck.
	Response: Thank you for your comment. The VM SDT proposed a set of four VSLs to reflect the wide range of non-compliances to these requirements. The NERC staff on the other hand view the outcomes as very narrow. **The comment that SDT VSLs are "too low" lacks context. The commenter does not offer a frame of reference in rendering its opinion of "too low".** **The comment about luck is without basis. The MVCD distances are conservative and it is quite possible to be well within the MVCD and not have a flashover or an outage. This is based on physics, not "luck". Prudent inspection frequencies and a good imminent threat notification process are 2 things that could prevent encroachments from becoming an outage. Stating that it is only dependent on luck does not give proper credit to prudent operations.** **The SDT has revised R1 and R2 to clarify that the level of maintenance is the primary focus of this requirement that must be attained to be compliant. The VM SDT feels these changes will ensure congruence between the requirements**		

	Organization	Yes or No	Question 7 Comment
	and the VSL.		
12	Arizona Public Service Company	VSLs proposed by NERC staff	Requires a higher degree of accountability as it should be.
	Response: Thank you for your comment. The VM SDT proposed a set of four VSLs to reflect the wide range of non-compliances to these requirements. The VM SDT believes the VSLs are precisely set to reflect the degree of accountability that best matches the level of non-compliance. A grow-in is classified in the highest level of violation severity precisely because it is indicative of the lowest quality of performance. Therefore, the entity must be held to the highest degree of accountability for any maintenance failure that leads to a grow-in. The VM SDT believes its VSL assignments follow the NERC VSL Guidelines and are technically valid.		
13	Idaho Power	VSLs proposed by NERC staff	Seems like there should be a lesser severity level for violations for R3-R7.
	Response: Thank you for your comment. This question asks for feedback on the VSLs assigned to R1 and R2.		
14	The United Illuminating Company	VSLs proposed by NERC staff	United Illuminating agrees with NERC Staff that the Requirement is to prevent encroachment of any kind. Differentiating between fall-in and grow-in is of no consequence to the intent of the requirement.
	Response: Thank you for your comment. Please refer to the SDT response to NERC on this question.		
15	Allegheny Power	VSLs proposed by the VM SDT	
16	Ameren	VSLs proposed by the VM SDT	
17	BGE Forestry Management	VSLs proposed by the VM SDT	
18	Bonneville Power Administration	VSLs proposed by the VM SDT	
19	Duke Energy	VSLs proposed by the VM SDT	

	Organization	Yes or No	Question 7 Comment
20	Exelon	VSLs proposed by the VM SDT	
21	ITC Transmission	VSLs proposed by the VM SDT	
22	Manitoba Hydro	VSLs proposed by the VM SDT	
23	MidAmerican Energy	VSLs proposed by the VM SDT	
24	MRO's NERC Standards Review Subcommittee (nsrs)	VSLs proposed by the VM SDT	
25	Northeast Utilities	VSLs proposed by the VM SDT	
26	PPL Electric Utilities	VSLs proposed by the VM SDT	
27	South Carolina and Gas	VSLs proposed by the VM SDT	
28	Tri-State Generation & Transmission	VSLs proposed by the VM SDT	
29	Xcel Energy	VSLs proposed by the VM SDT	
30	Central Maine Power Company, Iberdrola USA	VSLs proposed by the VM SDT	Agrees with SDT that violation risk factors must be ranked in accordance with impact on the bulk delivery system.
	Response: Thank you for your comment.		

	Organization	Yes or No	Question 7 Comment
31	Kansas City Power & Light	VSLs proposed by the VM SDT	Although the Drafting Team is favored here, it makes little sense in the NERC Staff VSL to have an encroachment with no sustained outage as a HIGH VSL. No compromise of the real-time reliability of the bulk electric system occurred. How could that be a HIGH? If it is determined to use the VSLs proposed by NERC Staff, it is recommended to change the HIGH VSL to LOWER.
	Response: Thank you for your comment. The VM SDT believes its VSL assignments follow the NERC VSL Guidelines and are technically valid.		
32	American Transmission Company	VSLs proposed by the VM SDT	ATC believes the VSLs proposed by the VM SDT best supports the NERC's VSL Criteria. The NERC Staff VSLs do not allow for Lower or Moderate VSLs which recognizes significant value as nearly meeting the intent of the requirement. Furthermore, it does not allow for encroachment where absent a sustained outage. Every encroachment in real time would not go directly to a "High" VSL where performance has limited value.
	Response: Thank you for your comment. The VM SDT believes its VSL assignments follow the NERC VSL Guidelines and are technically valid.		
33	FirstEnergy	VSLs proposed by the VM SDT	FE supports the VSL proposed by the SDT. We believe these have been developed in accordance with the FERC approved VSL guidelines and represent the appropriate violation levels for situations of varying probabilities. History has proven the grow-ins are the biggest cause of vegetation contact issues, and fall-ins and blowing together vegetation are very hard to predict and control and should be at lower violation levels. Although we believe that an encroachment into the MVCD that causes no system disturbance should not be penalized if an entity takes immediate action to restore the minimum clearance, the assignment of a Lower VSL is appropriate. We believe that the NERC staff opinion that this situation warrants a High VSL does not demonstrate thorough rationalization because it fails to consider the consequences that would place a severe monetary penalty on an entity for a situation that did not cause a fault, outage, or cascade of the BES.Furthermore, it is clear

	Organization	Yes or No	Question 7 Comment
			from the bullet points under R1 and R2 of the proposed standard language that the SDT intended that an encroachment with a sustained outage is different than and encroachment without a sustained outage otherwise they would not have specified the bulleted situations in detail. Had the SDT intended for there to be only two violation severity levels they would have only specified two bullet items: an encroachment with a sustained outage and an encroachment without a sustained outage. The requirements are the only tools the drafting team has to specify its intent in this area and the approach they used is reasonable to provide these levels of differentiation.
	Response: Thank you for your comment. The VM SDT believes its VSL assignments follow the NERC VSL Guidelines and are technically valid.		
34	Great River Energy	VSLs proposed by the VM SDT	GRE prefers the Drafting Team's VSLs over the VSLs written by the NERC staff. The VSLs that were written by the SDT appear to be clearer and less subjective as opposed to the VSLs that were written by NERC staff. The VSLs written by the NERC staff came across as being less clear and more subjective.
	Response: Thank you for your comment. The VM SDT believes its VSL assignments follow the NERC VSL Guidelines and are technically valid.		
35	Southern California Edison Company	VSLs proposed by the VM SDT	SCE agrees with the SDT's rationale and proposals for VSL Criteria.
	Response: Thank you for your comment. The VM SDT believes its VSL assignments follow the NERC VSL Guidelines and are technically valid.		
36	Tampa Electric Company	VSLs proposed by the VM SDT	Tampa Electric agrees with the SDT statement ... "For example, not all encroachments lead to Sustained Outages." As such, we agree, a lower level of VSL is appropriate. Tampa Electric also agrees with this statement " Moreover, there is an operational differentiation between a fall-in, blow-together or grow-in event. "Recommend the

	Organization	Yes or No	Question 7 Comment
			team examine the analytical rational for the following statements so as to better explain and clarify this issue to NERC. "A fall-in has never been known to cause a cascading outage. Therefore the team feels that a Lower VSL is appropriate. A blowing-together-caused fault is somewhat more egregious than a fall-in, as it has the potential for re-occurring and is therefore assigned a Higher VSL."
	Response: Thank you for your comment. The VM SDT believes its VSL assignments follow the NERC VSL Guidelines and are technically valid.		
37	PNM	VSLs proposed by the VM SDT	The expectation is for perfection or zero encroachments at all times. It would be cost prohibitive to maintain the system under those rules. PNM recommends the VM SDT VSL's.
	Response: Thank you for your comment. The VM SDT believes its VSL assignments follow the NERC VSL Guidelines and are technically valid.		
38	BC Hydro	VSLs proposed by the VM SDT	The NERC staff recommendation is too restrictive and does not seem realistic in an operational sense. We do not agree that the standard should apply to outages from vegetation falling into the conductor from within the active transmission right of way. This normally would not occur except during storm events that would be excluded from this standard. It is operationally difficult to know precisely where the edge of the right of way is in all situations and under all conditions. Further, in clearing some sections to this degree, the utility could end up destabilizing what is currently a stable, windfirm edge and pose higher security risks to the transmission system from destabilizing the vegetation through excessive clearing. So this gets down to semantics of how a utility might define their active right of way corridor relative to the legal statutory right of way edge. The risk of fall into outages needs to be managed but as currently defined this is too absolute a requirement. Fall-into outage risks need to be mitigated but they have not been a key element of any cascading failure and are hard to prevent. Even if a right of way were cleared sufficiently wide to avoid a fall-into outage, there is always a risk of branches being blown into the conductors from sailing during higher winds (e.g. Douglas-fir branches have excellent airborne gliding

	Organization	Yes or No	Question 7 Comment
			abilities). The greatest risk is from grow-into outages or from conductors and vegetation being blown into one another within the active right of way. Therefore, we prefer the VSLs set by the VM standard development team.
	Response: Thank you for your comment. The VM SDT believes its VSL assignments follow the NERC VSL Guidelines and are technically valid.		
39	Consolidated Edison Company of New York Inc	VSLs proposed by the VM SDT	The wording in the VM STD VSLs should be modified to include whether or not the TO managed any vegetation on that particular line. A more severe VSL should be assigned to any encroachment or sustained outage that was caused as a result of a TO not performing any vegetation management activities on that line. For example, if vegetation management activities were completed on 80% or 90% of the line and additional work was in progress on the remainder of the line but an encroachement or sustained outage occurred on the spans that were scheduled to be done as part of the annual plan, the TO should be held accountable for this but at a lower severity level.
	Response: Thank you for your comment. The VM SDT believes its VSL assignments follow the NERC VSL Guidelines and are technically valid.		
40	Hydro One	VSLs proposed by the VM SDT	The wording in the VM STD VSLs should be modified to include whether or not the TO managed any vegetation on that particular line. A more severe VSL should be assigned to any encroachment or sustained outage that was caused as a result of a TO not performing any vegetation management activities on that line. For example, if vegetation management activities were completed on 80% or 90% of the line and additional work was in progress on the remainder of the line, but an encroachment or sustained outage occurred on the spans that were scheduled to be done as part of the annual plan, the TO should be held accountable for this but at a lower severity level.
	Response: Thank you for your comment. The VM SDT believes its VSL assignments follow the NERC VSL Guidelines and are technically valid.		

	Organization	Yes or No	Question 7 Comment
41	Northeast Power Coordinating Council	VSLs proposed by the VM SDT	The wording in the VM STD VSLs should be modified to include whether or not the TO managed any vegetation on that particular line. A more severe VSL should be assigned to any encroachment or sustained outage that was caused as a result of a TO not performing any vegetation management activities on that line. For example, if vegetation management activities were completed on 80% or 90% of the line and additional work was in progress on the remainder of the line, but an encroachment or sustained outage occurred on the spans that were scheduled to be done as part of the annual plan, the TO should be held accountable for this but at a lower severity level.
	Response: Thank you for your comment. The VM SDT believes its VSL assignments follow the NERC VSL Guidelines and are technically valid.		
42	Orange and Rockland Utilities, Inc.	VSLs proposed by the VM SDT	The wording in the VM STD VSLs should be modified to include whether or not the TO managed any vegetation on that particular line. A more severe VSL should be assigned to any encroachment or sustained outage that was caused as a result of a TO not performing any vegetation management activities on that line. For example, if vegetation management activities were completed on 80% or 90% of the line and additional work was in progress on the remainder of the line but an encroachement or sustained outage occurred on the spans that were scheduled to be done as part of the annual plan, the TO should be held accountable for this but at a lower severity level.
	Response: Thank you for your comment. The VM SDT believes its VSL assignments follow the NERC VSL Guidelines and are technically valid.		
43	Entergy Services	VSLs proposed by the VM SDT	This gives the option to activate and follow the Imminent Threat Process if a breach of the MVCD is located and reported for isolated events absent a sustained outage. It gives the TO the opportunity to mitigate the issue when it is identified and corrected prior to experiencing an outage..
	Response: Thank you for your comment. The VM SDT believes its VSL assignments follow the NERC VSL Guidelines and are technically valid.		

	Organization	Yes or No	Question 7 Comment
44	Western Area Power Administration	VSLs proposed by the VM SDT	Unlike a “grow-in”, a “fall-in” or “blow-in” has never caused or contributed to a cascading outage. Further, the “zero tolerance” approach of this standard remains impractical and unreasonable. The gradated indicators of program performance associated with a “fall-in”, “blow-in” and “grow-in” offer some measure of reasonableness to the requirement.
	Response: Thank you for your comment. The VM SDT believes its VSL assignments follow the NERC VSL Guidelines and are technically valid.		
45	Southern Company Transmission	VSLs proposed by the VM SDT	We support the SDT version of the VSLs. The version proposed by staff does not recognize the objective of FAC-003-2 which clearly states, “To improve the reliability of the electric Transmission system by preventing those outages that could lead to Cascading.” If a fall-in occurs in an afternoon thunder storm and investigation reveals the tree was on the right-of-way by one or two feet, staffs VSLs would treat this outage with the same severity as an outage where a fully loaded line in a heat wave sagged into unmaintained brush growing directly beneath the conductor. The first case would rarely, if ever, lead to cascading. The second case could easily lead to cascading. Staff’s VSLs seem to indicate a desire to “gold plate’ the system to insure 100% reliability, which will never be achieved absent of unlimited resources and with total disregard to cost.
	Response: Thank you for your comment. The VM SDT believes its VSL assignments follow the NERC VSL Guidelines and are technically valid.		

8. Is there anything that you have not addressed above regarding the draft FAC-003-2 Transmission Vegetation Management standard or the Technical Reference Document? If yes, please provide what you believe should be changed, added or deleted and the rationale for your proposal.

Summary Consideration:

Of the 45 respondents, 29 provided a comment. In general, there were no common themes and as such each comment was responded to individually. Of some note, two comments were especially lengthy and their well-considered responses are found below.

17	GDS Associates	Yes	- Effective Dates. Clarify effective dates in paragraphs 2 and 3. This should only be applicable to Canada as Standard are not mandatory and enforceable in the US unless further approved by FERC.- Exceptions. Regional Differences must be approved just li
	Response: The SDT thanks you for your response. NERC staff will review the effective date section and modify as necessary.		
18	Progress Energy	Yes	1) On p. 3 of the redline, the table of Effective Dates is struck out, but the key (listed as 1, 2, 3 below the table: “1. First calendar day...”) remains but now the numbers 1, 2, and 3 no longer refer to the table of Effective Dates as the table has been struck. 2) The first paragraph under “Exceptions” could be reworded to be clearer. As currently proposed, it states lines below 200kV become subject to the standard 12 months after the lines are designated as being subject to the standard, which is somewhat circular. We propose instead:”A line operated below 200kV becomes subject to this standard 12 months after the date the Planning Coordinator or WECC initially designates the line as an element of an IROL or as a Major WECC transfer path.”3)

	Organization	Yes or No	Question 8 Comment
			Applicability Section 4.2.4 says the standard does not apply to Facilities located in the fenced area of a switchyard. However, p. 8 in Section 5 Background says the standard does not apply to underground or submarine lines or line sections inside a station boundary. Two things should be addressed to make these consistent: "Facilities" is a NERC-defined term that includes more than just lines, and includes lines, generators, compensators, transformers, etc. Also, is the "station boundary" always defined by the fenced area? Any potential conflict due to this inconsistency should be resolved.4) In the redline of Draft 4, in R5 and M5, the word "interim" is struck through. However, the Rationale box says "....the intent is for the Transmission Owner to put interim measures in place..." The use of "interim" should be consistent between R5, M5 and the Rationale box.5) R6 requires the TO to perform Vegetation Inspections "at least once per calendar year". There could potentially be future interpretation requests that question whether "once per calendar year" means performance sometime during each year (i.e. 2010, 2011, etc.), or whether no more than 365 calendar days can elapse between inspections. The first interpretation could allow up to almost 2 years to elapse between inspections even when doing it "once per calendar year". This should be clarified.
	Response: The SDT thanks you for your response. NERC staff will review the effective date section and modify as necessary. Thank you for the wording, but overall industry consensus does not dictate a verbiage change. **Regarding station boundaries and underground lines, overall industry consensus is that line-based vegetation programs do not apply inside the station boundary. The SDT believes that "fence" is the best overall term for a station boundary.** **As to the use of "interim", the Rationale intends to provide clarifying text and there is no imperative that its language should be identical to the requirement verbiage. The SDT believes that the Rationale language properly conveys the intent.** **Regarding the inspection frequency, the SDT added an 18 month clause.**		
19	CenterPoint Energy	Yes	1. CenterPoint Energy believes the proposed FAC-003-2 is not a performance-based standard, despite being labeled as such, because it remains too focused on processes and procedures. CenterPoint Energy fails to see much difference in the approach from the current Standard.

	Organization	Yes or No	Question 8 Comment
			CenterPoint Energy believes a performance based requirement would provide performance criteria that an entity would be measured against. An example of a performance based requirement would be the following: R1. “Each Transmission Owner shall manage vegetation to prevent encroachment that results in no more than one (1) Sustained Outage per XXX circuit miles of applicable lines within any twelve (12) month period.” M1. Each Transmission Owner has evidence that it had in no more than one (1) Sustained Outage per XXX circuit miles of applicable lines within any twelve (12) month period. Examples of acceptable forms of evidence may include dated reports of vegetation-related Sustained Outages or dated attestations as to no vegetation-related Sustained Outages have occurred. However, if the majority of industry commenters agree with the SDT’s approach, CenterPoint Energy has the following additional concerns: 2. The phrases “active transmission line ROW” and “Active Transmission Line ROW” are no longer considered defined terms and should be deleted from the Standard along with footnote 2, the Compliance Section for Periodic Data Submittal as well as the Guidelines and Technical Basis. As found throughout the Standard, the phrase should be replaced with the common terms utilized in the Guidelines and Technical Basis section, “Transmission Owner’s transmission ROW as defined by easement, fee simple, or other legal rights”. 3. In the Background section fall-ins are characterized as “statistically intermittent” and “these types of events are highly unlikely to cause large-scale grid failures”. We agree and therefore recommend that fall-ins be excluded from the Requirements R1, R2, and Periodic Data Submittal of outages. 4. R4 should be deleted. R4 is related to processes and procedures and should be combined into R3. The result of not following the notification process or procedure is that a Sustained Outage may occur that would be

	Organization	Yes or No	Question 8 Comment
			captured by M1 and M2. The process and procedure would be measured by M3. 5. R5 and M5 contain the ambiguous phrase, "where a transmission line is put at risk due to the constraint". This phrase should be replaced with the more specific terminology in R1 and R2 as, "where a transmission line cannot perform within its Rating and Rated Electrical Operating Conditions due to the constraint" or as in R3 as "where a transmission line will be subjected to an encroachment into the MVCD due to the constraint". 6. For R6, the detailed rationale and studies used for the determination of the required one year inspection cycle should be included in the Guidelines and Technical Basis. The explanation provided in the Rationale that it is "based upon average growth rates across North America and on common utility practice" are unfounded and arbitrary without a specific reference to a North American study. 7. R7 contains the ambiguous phrase, "provided they do not put the transmission system at risk of a vegetation encroachment". This phrase should be replaced with the more specific terminology in the Rationale for R7 and Requirement R3 as "provided they do not allow encroachment of vegetation into the MVCD." 8. Just as the force majeure statement was moved to the Applicability section of the Standard, the exception for applicability beyond the Rating and Rated Electrical Operating Conditions should be included in the Applicability section as well. Currently, it is only included in R1, R2, and R3. It should be made clear that the other Requirements and Measurements ARE NOT applicable in situations beyond the Rating and Rated Electrical Operating Conditions. This is already discussed in the Guidelines and Technical Basis but not evident within the Standard. 9. The Periodic Data Submittal should be clarified to as to the specific conditions under which Sustained Outages are reported. The Applicability section includes the force majeure; however, other exclusions are not so evident. We recommend the wording be changed to include all applicable

	Organization	Yes or No	Question 8 Comment
			exclusions for added clarity. We recommend the following wording: "The Transmission Owner will submit a quarterly report to its Regional Entity, or Regional Entity's designee, identifying the Sustained Outages caused by vegetation, as defined in the categories below, of transmission lines operating within Rating and Rated Operating Conditions as determined by the Transmission Owner, exclusive of the force majeure conditions in Section 4.4, that include, as a minimum, the following." Also, the within the Categories listed, the phrases "active transmission line ROW" should be deleted and replaced with "Transmission Owner's transmission ROW as defined by easement, fee simple, or other legal rights". This places the determination of the width of the ROW for determination of fall-in violations clearly on the Transmission Owner and the within the limits of its legal rights to control the vegetation that has fallen into the line under R1 and R2 causing the submittal of a reportable sustained outage. 10. The Guidelines and Technical Basis and the Technical Reference with the Gallet Equation should be combined into one document as a supplement to the Standard to avoid duplication in wording and misinterpretation of context. 11. We agree that the Rationale test boxes should be deleted from the Standard and applicable explanatory text be included within the Guidelines and Technical Basis. 12. The Guidelines and Technical Basis should include the background and basis for 4.2.4 that excludes the Standard from applying to fenced substations. 13. The Guidelines and Technical Basis should contain more specific examples of violations of the Requirements and highlight specific exceptions related to vegetation related outages, especially fall-ins and force majeure exclusions. 14. The language in R6 refers to inspecting "transmission lines" and Table 1 for

	Organization	Yes or No	Question 8 Comment
			R6 refers to inspecting "ROW". Both areas should use consistent terminology. 15. In the Guidelines and Technical Basis section for R6, the reference to the VSL calculation units and the example units should be consistent-the example should use "circuit miles", not just "miles". 16. In general, the proposed FAC-003-2 has gone FAR beyond what was contemplated by the Commission in FERC Order 693 and equates to a total re-writing of the Standard for no apparent reason. The Commission's determination dealt with the following areas: (1) applicability; (2) inspection cycles; and (3) minimum clearances on National Forest Service lands. For instance in Paragraph 729, the Commission states, "As proposed in the NOPR, the Commission approves Reliability Standard FAC-003-1 with no proposed modification on the issue of clearances. The Commission reaffirms its interpretation that FAC-003-1 requires sufficient clearances to prevent outages due to vegetation management practices under all applicable conditions...." Rewriting the minimum clearances introduced a new set of confusing definitions, and further burdens the Transmission Owners with new documentation requirements with little if any benefit when compared to the Clearance 2 concept in the existing Standard. A preferred approach should be to incorporate the following few items into the existing Standard FAC-003-1: (1) the RC versus the RRO; (2) the designation of a specific inspection frequency; (3) the Gallet equation; and

	Organization	Yes or No	Question 8 Comment
			(4) the applicability to National Forest Service lands.
	Response: 1) The SDT thanks you for your responses. The standard is intended to be a Results-based standard and includes requirements that are risk-based, competency-based and performance-based. The SDT and NERC staff feels that it represents a significant departure from previous versions. The SDT has considered “per-mile”-based metrics, but believes that FERC will not approve such a metric due to statutory constraints and its stated criteria for approval of a standard. 2) Based on your comment and others, the SDT has revised the definition of ROW in the NERC Glossary and removed Table 3. 3) While the SDT agrees that fall-ins are statistically intermittent, the fall-ins from inside the ROW are under the control of the TO and represent an erosion of reliability. 4) The SDT agrees that there is some logic in your proposal, but the SDT feels that all TOs should have a procedure that results in a defense-in-depth strategy as is in the current draft. 5) R5 applies in the longer-term Operations Planning time horizon, whereas R1 and R2 apply in real time. On the other hand, R3 is a competency-type of requirement that applies in the Long-Term Planning Time Horizon. 6) The SDT posed the question of inspection frequency to the overall industry in an earlier posting and received general consensus that a one-year interval would be appropriate but did add an 18 month clause. 7) R7 addresses shorter-term risks, whereas the language in R3 is about the prevention of encroachments in the wider long-term horizon. 8) The SDT has considered your suggestion about the applicability section; however, after extensive consideration, the SDT opted not to add the language you suggested since the NERC framework for the Applicability section guides against it. 9) Thank you. The SDT agrees and hereby adds “. . . except as excluded in Footnote 2” before “that includes.” Regarding your suggestion on active TLROW, the SDT changed the definition of ROW in the NERC Glossary. 10) The issue of combining these documents will be addressed by NERC as the results-based standard-		

	Organization	Yes or No	Question 8 Comment
	making procedural document is finalized. **11) The final resolution of this issue will be addressed by NERC as the results-based standard-making procedural document is finalized.** **12) The SDT believes that industry generally supports the exclusion of substations from applicability of the standard, and does not believe that every clause or portion of the Standard needs an explanation in the *Guidelines and Technical Basis*.** **13) The team does not feel that extensive examples, especially of violations, have a place in the Standard.** **14) You have pointed out a conflict in nomenclature between two portions of the standard. The team will resolve the conflict.** **15) As mentioned in both M6 and the VSL table for R6, the TO may choose its unit of measure.** **16) The SDT considered the SAR and FERC Order 693 directives together with the imperative that reliability not suffer with the revised standard, and feels that it has improved the Standard accordingly.**		
20	Kansas City Power & Light	Yes	1. Part R4.3, “Enforcement, under Section 4, “Applicability”, is confusing as to why it is needed. What is the intended purpose of this part? It is clear that each Requirement, Measure, VRF and VSL when adopted by the NERC BOT and FERC become mandatory and enforceable on the declared effective date(s). There is no need for Part R4.3 to reinforce the compliance enforcement dictated by the established NERC Rules of Procedure.2. Requirement R4: The requirement is clear to notify the appropriate control center regarding conditions that might cause a fault on a transmission facility. The requirement should be clear, this for the Transmission Owners applicable lines and recommend the SDT modify the language in R4 to that end. In addition, there is no action other than notification in regards to this operating condition. Highly recommend the SDT consider adding language to take “immediate actions” to remedy the vegetation condition and remove the threat.3. Requirements R5 & R7 are not clear in that they are for the Transmission Owners applicable lines. This has been a common theme throughout this Standard and by the omission of this language, it is not clear that the intended scope of the requirements do not go beyond the applicable lines.
	Response:		

	Organization	Yes or No	Question 8 Comment
	1. Thank you for your comment. NERC staff will address this concern. **2. The SDT feels that the applicability of lines is sufficiently clear in R4. However, it is not appropriate for this Standard to specify any particular action for the TOP to take; this is the realm of TOP-006.** **3. The SDT feels that the applicability of lines is sufficiently clear in R5 and R6.**		
21	American Transmission Company	Yes	1.) Rationale boxes associated with R1, R2 and R3 within the standard include reference Tables and Figures in the “Guidelines and Technical Basis” without specifying where they are located. ATC recommends inserting this information as applicable.2.) ATC raises a previous draft concern on including Rationale Boxes plus Guidelines and Technical Basis as part of the NERC Reliability Standard. ATC recommends that the SDT either remove these sections or make them separate from the formal standard to eliminate any risk that these may be construed as requirements. An alternative method is to very clearly identify which parts of the standard are subject to compliance and considered mandatory and which are not considered requirements and are only for guidance in meeting the requirements. 3.) ATC believes the Measurements are well written and provide guidance on acceptable compliance evidence related to the requirement.4.) Measurement M2 related to R2 states that outages related to encroachments have records confirming no Real-Time observations of any MVCD encroachments. ATC feels this would be hard to prove as a negative. It could require one to show every single patrol or inspection has documentation stating no real time encroachments were observed.5.) Editorial Comment on Draft SDT VSLs for R2: To clarify the statements made for the Moderate, High and Severe VSLs. please add the verbiage, “into the MVCD” after “The TO had an encroachment.......”
	Response: **1) The formatting of these Rationale boxes is not set and will be addressed by NERC as the results-based standard-making procedural document is finalized.** **2) This issue will be addressed by NERC as the results-based standard-making procedural document is finalized.**		

	Organization	Yes or No	Question 8 Comment
	3) Thank you for your comments. **4) As stated in the Measure, an attestation serves as adequate evidence.** **5) Thank you for noticing this oversight. It will be corrected.**		
22	MRO's NERC Standards Review Subcommittee (nsrs)	Yes	1.) The NSRS notices that a previous draft concern on including Rationale Boxes plus Guidelines and Technical Basis as part of the NERC Reliability Standard. The NSRS recommends that the SDT either remove these sections or make them separate from the formal standard to eliminate any risk that these may be construed as requirements. An alternative method is to very clearly identify which parts of the standard are subject to compliance and considered mandatory and which are not considered requirements and are only for guidance in meeting the requirements. Such as; State within in the text that this information "Is not subject to enforcement". 2.) The NSRS believes the Measurements are well written and provide guidance on acceptable compliance evidence related to the requirement.3.) Measurement M2 related to R2 states that outages related to encroachments have records confirming no Real-Time observations of any MVCD encroachments. The NSRS feels this would be hard to prove as a negative. It could require one to show every single patrol or inspection has documentation stating no real time encroachments were observed.4.) Editorial Comment on Draft SDT VSLs for R2: To clarify the statements made for the Moderate, High and Severe VSLs. please add the verbiage, "into the MVCD" after "The TO had an encroachment......."
	Response: **1. This issue will be addressed by NERC as the results-based standard-making procedural document is finalized.** **2. Thank you for your comments.** **3. As stated in the Measure, an attestation serves as adequate evidence.** **4. Thank you for noticing this oversight. It will be corrected.**		

	Organization	Yes or No	Question 8 Comment
23	BGE Forestry Management	Yes	4.2.4 States that the Standard is not applicable to “...to Facilities .... located inside the fenced area of a switchyard, station or substation”. This implies that anything within the fenced area of a switchyard, substation or power plant does not fall within the jurisdiction of FAC-003-2. Some fenced in areas could be very large and susceptible to vegetation encroachments issues. Suggest reference to “inside the fence” be removed.Disagree with R6. - Inspection Frequency. Very prescriptive. Please consider allowing TO’s to select an annual frequency that best fits their requirements, such as calendar year, every growing season, every non-growing season, etc. BGE currently defines their inspection frequency as annually during the non-growing season, October 1 to May 1. BGE believes inspecting during the dormant season is a best practice due to the ability of the inspector to identify vegetation defects, especially off the ROW, which could be hidden during the growing season due to foliage, canopy cover, etc. Also, if a utility elects to leverage an advance technology, such as LiDAR, it provides the most effective results when LiDAR is utilize during the growing season, therefore allowing the results of the advance technology to enhance the fall to spring inspection cycle. Table 1 - Time Horizons, Violation Risk Factors, and Violation Severity Levels The VSL’s for R7 all include “the Transmission Owner failed to complete.....% of its annual work plan (including modifications if any)”. This is not clear to BGE. R7. allows plans to be modified due to changing conditions, for example ROW maintenance could be deferred to the following year due to mutual assistance agreements if the deferment does not violate the encroachment within the MVCD. The VSL implies this is a violation since the “modification” deferred a certain percentage of the planned worked to the following year, therefore 100% of the planned worked wasn’t completed. If the modification was excluded, than 100% of the planned work would have been completed.
	Response: **1. Regarding station boundaries, overall industry consensus is that line-based vegetation programs do not apply inside the station boundary. The SDT believes that “fence” is the best overall term for a station boundary.** **2. While the SDT lauds BGE’s approach, it feels that a calendar year basis affords sufficient flexibility for BGE and other TOs to schedule their inspections.**		

	Organization	Yes or No	Question 8 Comment
	3. The Standard suggests that the TO will begin with an original plan which may then be modified; it is implicit that measurements of plan completion are against the modified plan, not against the original plan.		
24	MidAmerican Energy	Yes	Any references to "observed in real time" should be removed. Vegetation contacts must be verified and references to real time are inappropriate. This causes difficulties in proving a negative in real time.
	Response: The SDT believes that the commenter has misinterpreted the requirement. It is not necessary for the TO to continuously observe; rather, a violation can only be reported if observed in real time.		
25	NERC Staff	Yes	**Effective Dates** • The first item should be re-written to "First calendar day of the first calendar quarter one year after the date of the order approving the standard from applicable regulatory authorities where such explicit approval is required." • The second item is not needed and should be removed. • The third item is okay but the phrase "where explicit regulatory approval is not required" should be removed. **Exceptions** • Identifying a critical line and then waiting 12 months to perform vegetation management is counter to the risk avoidance strategy that the standard is attempting to accomplish. In effect, this standard permits an entity to identify a major WECC path or an IROL just prior to peak season and then not complete any vegetation management activities until just before the next season 12 months later. This is wholly inappropriate. The Planning Coordinator will identify these lines sufficiently far in advance that the 12-month window will prevent encroachments

	Organization	Yes or No	Question 8 Comment
			• Using the phrase "an element of an IROL" seems confusing because "Element" is a term defined in the glossary. Further, IROL is an identified limit, not a physical component. This should be reworded to say "a facility that is identified to be part of an interface or path impacting an IROL." This is also seen in R1 and R2 and needs to be adjusted there as well. The industry has reviewed this language and has found it to be sufficiently clear. • For newly acquired assets, the 12 month window may be appropriate, but there needs to be a much nearer term inspection undertaken to identify "risky" vegetation. **Definition** • The modified definition assumes the ROW is maintained, which may not be the case (for instance, if a newly acquired asset has not yet been acted upon). An entity could interpret the new definition to indicate that the new owner cannot be performing an initial vegetation inspection if the ROW has not yet been maintained. The phrase "maintained transmission line" should be changed to "applicable transmission line." • The inclusion of the phrase "which may be combined with a general line inspection" is unnecessary and should be removed. In fact, the current definition does not restrict combining the inspection with other field visits, while in the proposed definition that vegetation inspection can only be combined with a general line inspection. **Objectives (Section 3)** • NERC staff is concerned that the purpose states "that could lead to Cascading." This qualifier limits the purpose of the standard, which should be to prevent vegetation-related outages. The more outages there are, the less the overall system reliability; it does not necessarily have to lead to

	Organization	Yes or No	Question 8 Comment
			Cascading to be significant and represent a reasonable risk to the BES. • The term “maintain” might be better than “improve.” **Applicability (Section 4)** • 4.1 Functional Entities • Noticeably absent from the standard is coverage for transmission facilities that connect generators to the interconnected bulk power system. As such, the team should add Generator Owners to the applicability and include such language that was proposed by the ad hoc team: transmission facilities that connect generators to the bulk power system that exceed two spans from the fence-line of the generating plant; coupled with the previous discussion, this provides complete coverage for all transmission facilities and switchyards and substations. This is what is needed to ensure no gaps in vegetation management coverage. • 4.2 Facilities o The identification of critical facilities herein does not recognize the overarching criteria that are being developed in support of the PRC-023 order, and in some respects, in response to Order 693 directives to define the criteria for “critical facilities.” The FAC-003-2 SDT should work in conjunction with the PRC-023 team, which is establishing a set of criteria for identifying critical facilities such that the outcome across all NERC standards is consistent. • “Transmission line” should be capitalized as a NERC-defined term. o 4.2.4: This exclusion seems strange. It would appear that there are no expectations for vegetation management in switchyards, which is unacceptable. We should be able to develop language that requires that a Transmission Owner or Generator Owner maintain vegetation within fenced areas of the

	Organization	Yes or No	Question 8 Comment
			switchyard, station, or substation to the same clearances as one does for the ROWs, without necessarily obligating them to an annual cycle of inspection or management. o **Requirement R4** • "Qualified personnel" should be defined. In the Rationale, some examples are listed, but who else counts as "qualified field personnel"? This was intended to be an incomplete partial list. • "At any moment" is an unnecessary qualifier and should be removed (same for M4). • With respect to the phrase "intentional time delay," intent is a tricky thing to prove. Most standards set clear timelines which kick in regardless of intent, because it diminishes reliability to base a standard on intent. The SDT should consider doing so here. **Requirement R5** • NERC staff is confused by the overall purpose of this requirement. It appears to be a defense to a possible violation for failure to perform some planned vegetation work, but it flips it around and makes it a requirement. A better approach would be to just deal with this in addressing the mitigating/aggravating factors under a violation of R1 and R2. This concept is already part (R1.4) of the existing in-force FERC-approved FAC-003-1, but has been renamed to avoid conflict with terminology in the current NERC compliance guidelines. • The team should be more specific with respect to expectations for "corrective action." There needs to be an expectation that the corrective action needs to maintain an equivalent level of performance consistent with the intent of the vegetation management program. This could include, for example re-

	Organization	Yes or No	Question 8 Comment
			rating lines to reduce max sag until the condition is rectified, enhanced inspection cycles to monitor conditions, etc. It would be useful to define a metric for the success of corrective actions. • The team should be clearer on what constitutes a "constraint." Is it only legal constraints? One interpretation could be resource constraints, which would certainly not be appropriate in this context. The phrase "due to constraints" is also used in the Rationale section. In this context, "constraint" appears to mean congestion on a transmission line. This seems very different from being "constrained from performing planned vegetation work." In fact, the existence of congestion on a line does not necessarily create risk. We would not want entities to make the economic determination that they will put off required vegetation work because it would cost too much in energy sales profits. **Requirement R6** • It would appear necessary to require the use of the inspection information to guide or modify program development as is identified in the Rationale box accompanying the requirement. This is referred to in R7 but is not identified as an expectation from R6. • What are "all applicable transmission lines"? Are those lines covered by both R1 and R2? Clarify this. • "Once per calendar year" requires more guidance. Would two inspections on 12/31/2010 and 1/1/2011 satisfy this requirement? Shouldn't there be a requirement to space these inspections out? Recommend: once per calendar year with no more than 15 months between inspections. • The last sentence of R6's Rationale states that "Transmission Owners should consider local and environmental factors that could warrant more frequent inspection." But the way the

	Organization	Yes or No	Question 8 Comment
			requirement is written, there is no basis for requiring anything more frequent than once per calendar year. If the intent is to have stricter timelines for different registered entities, then the standard would need to be revised. **Compliance** • Additional Compliance Information o Categories of Sustained Outages ▪ Category 3 (Fall-ins from outside the ROW) should be reinstated. Even if it is not required by the standards, Category 3 reporting should be kept. The SDT believes that the current NERC TADS process captures such information adequately. ▪ There is currently a public bulletin to encourage Transmission Owners to report Category 1 and 2 outages within 48 hours. The SDT should consider adding this as a requirement and including it in the new standard as such. The SDT has considered your suggestion and believes that the recognized requirement to promptly self-report any potential violations is sufficient. **VSLs** • The VSL for R3 should be shifted to an approach that simply counts the missing elements: Thanks for your comments. The SDT has modified the VSLs for R3. o lower = missing one element o moderate = missing two elements o high= missing three elements o severe = not having documents • The VSL for R4 uses the phrase “vegetation threat,” which needs to either be conformed to the text of the drafting team or defined. This VSL also uses the phrase “intentional delay” A

	Organization	Yes or No	Question 8 Comment
			truly intentional delay should be labeled as severe, not just high. (And as already stated, intent is a very tricky thing to prove.) In the context of the requirement, Measure and VSL, the term “vegetation threat” is self-evident. Refer to the SDT’s earlier reply regariding “intentional delay”. • For the VSL for R5, there may be ways to differentiate violations based on whether the entity identified appropriate corrective actions (versus missing obvious alternatives), attempted corrective actions but failed, considered alternative corrective action, etc. The SDT has considered this but has not identified a good means of differentiation. Additionally, industry stakeholders have not offered any means of differentiation. The SDT would welcome a proposal. • For the VSL for R6, the SDT should differentiate between the criticality of different lines. At the very least, a failure to inspect R1 lines should be a more severe violation than a failure to inspect R2 lines. The risk to the system is properly addressed by the VRFs, not by the VSLs. • The VSL for R7 should perhaps be differentiated based on whether the incomplete work related to critical versus non-critical or less critical lines (i.e., R1 lines vs. R2 lines). The risk to the system is properly addressed by the VRFs, not by the VSLs. **Guidelines and Technical Basis** • R1/R2 o “If an investigation of a fault by a qualified person confirms that a vegetation encroachment within the MVCD occurred, then it shall be considered a Real-time observation”: This is an important statement and should be included as part of the requirement itself. The SDT feels that this is really more of a “Measure” issue than a “Requirement” issue, and is adequately captured in M1. • R3

	Organization	Yes or No	Question 8 Comment
			o With respect to the phrase "an adequate transmission vegetation management program," the standard talks about factors to consider, but the requirement does not include any provisions on which to base a determination of adequacy. NERC staff believes it should. With NERC's movement to the results-based standard-making techniques, this is an outstanding issue that can best be resolved once RBS techniques are firmly established. o The guideline states, "This approach provides the basis for evaluating the intent, allocation of appropriate resources and the competency of the Transmission Owner in managing vegetation," but nothing in the requirements actually provide explicitly for such evaluations. The SDT asserts that with the totality of R3, M3 and associated VSLs, it is possible for the auditor to assess the TO's intent, competency, etc. • R4 o "Cellular service or two-way radio disabled" should not be considered an acceptable unintentional delay. This seems to be within the entity's control: there may be a difference between whether the cell service problems are due to network problems as opposed to the entity failing to charge the phone or pay the bill. The SDT has considered the comments, but believes the verbiage is adequate. o "Remote field locations" should not be considered an acceptable unintentional delay. This is not entirely beyond the registered entity's control. There may be a difference between a work site that is isolated from radio or cellular networks versus the fact that the employee simply left the radio in the truck. The SDT has considered the comments, but believes the verbiage is adequate. o "Vegetation-related conditions that warrant a response" should be defined in the standard. Qualified personnel

	Organization	Yes or No	Question 8 Comment
			are ab;le to assess the conditions as called for in the Requirement. o It is not clear to NERC staff that a lineman or an arborist is capable of completing “an assessment of the possible sag or movement of the conductor” out in the field in real time. However, if this is the expectation, it should be written into the requirements. The SDT believes it is necessary to rely on field personnel for routine decisions in the field, and that it is impractical and unworkable for engineering or survey teams to examine every questionable site. The SDT has considered the comments, but believes the verbiage is adequate. o The fourth paragraph states that the “Transmission Owner has the responsibility to ensure the proper communication…” Earlier in this section, however, it says that the condition of the communication system is not considered to be intentional delay. This inconsistency needs to be addressed. This sentence should also include a requirement for correcting the vegetation encroachment. The SDT agrees with your observation and will clarify the wording to indicate communication “processes” between field personnel and control centers are the issue being addressed. o The phrase “minutes or hours” is used in the final sentence of the fourth paragraph of this sentence. This detail should be written more clearly and written into the standards. Is 24 hours still hours? What about 48 hours? The SDT has conceived of cases where a 10-hour or more delay may be perfectly acceptable, but others where a 10- or 20-minute delay is inexcusable. The SDT believes that no rigid timeline is appropriate. • R6 o With respect to the following sentence, beginning with “Therefore it is expected,” NERC staff is concerned that

	Organization	Yes or No	Question 8 Comment
			nothing in the requirement actually makes this expectation enforceable. It would be best to require each TO that experiences a vegetation related sustained outage to investigate the outage and make revisions to its TVMP if the investigation shows that the growth rates of vegetation under the TO's control do not match those anticipated in the TVMP. The primary definition of "expected" is "looking forward to a probably occurrence", not a "required activity," and so the SDT believes that the verbiage is appropriate. • R7 o The second paragraph states that "recent line inspections may identify unanticipated high priority work." But the fifth bullet in R7 does not indicate that the higher priority work was identified in a recent line inspection. R7 should be revised to make that caveat clear. The SDT suggests that it is unnecessary to state that the TO will use all information available to it (including inspection results) in identifying unanticipated high-priority work. o The second paragraph references "Modifications to the annual work plan." Presumably, these modifications would not excuse compliance with R1, R2, and R6. That should be made clearer in the requirements. Thank you for the comments. **Table 3** • None of the requirements actually reference this table. That should be modified. Thank you. The Table will be removed. •
	Response:		

	Organization	Yes or No	Question 8 Comment
	Effective Dates **The SDT assumes that NERC staff will correct implementation timetable conflicts.** **Exceptions** **The SDT considered such language, but ultimately determined that it was unnecessary, partly because the response to “hot-spot”-type conditions is not part of this standard.** **Definition** • **Thank you for your excellent comments. The SDT has made changes to meet this concern.** • **Previous overwhelming industry comments have dictated the need for the SDT to clarify this language as it exists in the current draft. The current definition offers no restrictions that the vegetation restriction may only be combined with a general line inspection.** **Objectives (Section 3)** • **The Purpose as currently stated reflects broad industry consensus that earlier Purpose statements were over-reaching.** • **The Purpose as currently stated reflects broad industry consensus.** **Applicability (Section 4)** • **Re: generators - There is a NERC GO/TO team established to address this issue.** • **Re: critical facilities - While the SDT is aware of the interest in FERC to consolidate tests or criteria for so-called “critical” facilities, NERC leadership have indicated to FERC staff its commitment to separate efforts for use by PRC-023 and this standard.** • **Re: capitalizing Transmission Line - The SDT agrees and thanks you for your comments.** • **Re: 4.2.4 - Wide industry consensus is that line-based vegetation programs should not apply inside the station boundary. Also, as previously mentioned, another NERC team is examining the TO/GO issue.** **Requirement R4** • **Re: qualified personnel - The SDT changed the language to confirmation by the Transmission Operator.** • **Re: “At any moment” - The SDT believes that “at any moment” is a necessary but sufficient qualifier.** • **Re: “intentional time delay,” - The SDT has considered this. FERC has already approved other standards with the same language.**		

	Organization	Yes or No	Question 8 Comment
	Requirement R5 • **Re: corrective action - Past and recent industry comments indicate little confusion on this portion of the Standard.** • **Re: constraints - Past and recent industry comments indicate little confusion on this portion of the Standard.** **Requirement R6** • **Re: inspection information - The SDT suggests that it is unnecessary to state that the TO will use all information available to it (including inspection results) in developing its annual plan.** • **Re: "all applicable transmission lines" - Please refer to section 4 ("Applicability") of the draft.** • **Re: calendar year - The SDT posed the question of inspection frequency to the overall industry in an earlier posting and received general consensus that a one-year interval would be appropriate.** • **Re: Rationale - The SDT does not intend that stricter timelines be rigidly defined or employed.** **Compliance** • **Re: Category 3 (Fall-ins from outside the ROW) - The SDT added this back in.** • **Re: Public bulletin - The SDT has considered your suggestion and believes that the recognized requirement to promptly self-report any potential violations is sufficient.** **VSLs** • **Re: VSL for R3 - The SDT has modified the VSLs for R3.** • **Re: VSL for R4 - In the context of the requirement, Measure and VSL, the term "vegetation threat" is self-evident. Table 3 • Thank you. Table 3 has been removed.		
26	FirstEnergy	Yes	FE has the following additional comments:1. In the SDT consideration of

	Organization	Yes or No	Question 8 Comment
			comments from Draft 3, it was indicated that "The subcommittee will ask that NERC's legal department write a statement for addition to each standard to clarify which parts/elements of the standard are mandatory and enforceable and which are provided only as information". We would appreciate this statement be placed into the standard before the final ballot so stakeholders have an opportunity to review and comment on the wording.2. We cannot comment on the Technical Reference Document since the latest draft was not posted for review. Does NERC intend to post this at a later time? If so, we ask that NERC give the industry enough time to adequately review the document so that we can provide quality feedback.3. In the Guidelines and Technical Basis Section, in the first paragraph of Requirement R5, second sentence, the word "temporarily" should be removed since it was removed from the requirement.
	Response: **The SDT thanks you for your comments.** **1) The NERC legal department has been contacted to provide a statement to clarify which parts/elements of a standard are mandatory and enforceable and which are provided only as information. This statement is nearing finalization and when completed will be posted as a separate document when the next draft of FAC-003-2 is posted.** **2) The Technical Reference Document is not a mandatory and enforceable document but your feedback is definitely appreciated once the document is finalized. The Technical Reference will be updated during the next ballot which will start during early August. The SDT will finalize the Technical Reference document at the August meeting in Toronto, ON which is scheduled from 8/17-8/19/10 and will post for comment.** **The word 'temporarily' has been removed from the Guidelines and Technical Basis as requested. Thank you for your comment.**		
27	Ameren	Yes	Funding Adjustments (increase or decrease) - need more description to imply only when planned vegetation work is "over and above".
	Response: Thank you for your comment. The SDT believes your observation and question is the same as voiced in Question 5. As stated in the SDT's response to Ameren's Question 5, we reviewed the Funding Adjustment example for R7 and feels this is a valid reason for modifying the Annual Plan keeping in mind that a modification must not place the transmission system at risk of vegetation encroachment into the		

	Organization	Yes or No	Question 8 Comment
	MVCD.		
28	Hydro One	Yes	Hydro One wants to thank the SDT for the effort that has gone into developing this proposed revision to FAC-003. Overall the new version is consistent with FERC Order 693 and will be a straightforward, workable, and auditable standard. One item requiring clarification and change is the Active ROW definition. The recent addition of a centerline distance to edge of Active ROW is not acceptable. In many areas design standards allow a smaller ROW width with no compromise to “cleared width” or tree related reliability of the line. The SDT needs to address this issue. In R5, the phrase 'where a transmission line is put at potential risk due to the constraint' should be better defined. This is vague and could lead to inconsistent practices between utilities. All undesirable species on the full width of the ROW are defined as 'potential risks to the transmission line' regardless of height or location at the time of vegetation management. Interim corrective action should only be required when the potential risk is approaching the imminent threat classification.
	Response: The SDT thanks you for your response. Your objection to our attempt to define a minimum width of the Active Transmission Right of Way was very similar to many other commenters. The SDT has subsequently revised the definition of ROW. **The issue you mention with R5 and “potential risk to the system” is understandable. The SDT changed this.**		
29	Idaho Power Company	Yes	I would like to see something more from NERC to clear the way for utilities to do vegetation management on federal lands that will allow timely vegetation management without delays from these federal entities.
	Response: **Thank you for your comments. This Standard places requirements on the Transmission Owners, not on landowners. There is no legal mechanism for this Standard to take rights from property owners and assign them to the Transmission Owner. There is joint UAA/EEI Task Force that is working on an MOU with the Federal Agencies to address these issues which are outside the purview of NERC Reliability Standards.**		
30	Idaho Power	Yes	I'd like to see language or NERC support to encourage federal agencies to expedite vegetation management maintenance requests and minimize the

	Organization	Yes or No	Question 8 Comment
			barriers to perform work on federal lands.
	Response: **Thank you for your comments. This Standard places requirements on the Transmission Owners, not on landowners. There is no legal mechanism for this Standard to take rights from property owners and assign them to the Transmission Owner. There is joint UAA/EEI Task Force that is working on an MOU with the Federal Agencies to address these issues which are outside the purview of NERC Reliability Standards.**		
31	Dominion	Yes	In R4 and M4, the phrase "without any intentional time delay" has been added. We recommend removing this language from the requirement as it is not possible to measure intent.
	Response: **Thank you for your comment. Please refer to the SDT response to NERC staff above regarding R4.**		
32	Consolidated Edison Company of New York Inc	Yes	In R5, the SDT should better define the phrase 'where a transmission line is put at potential risk due to the constraint.' This is rather vague and could lead to inconsistent practices between utilities. Con Edison defines all undesirable species on the full width of the ROW as 'potential risks to the transmission line' regardless of height or location at the time of vegetation management. Interim corrective action should only be required when the potential risk is approaching the imminent threat classification.
	Response: **The SDT thanks you for your comments. As described in the Technical Reference document (See Page 30), R5 is not intended to address situations where the transmission line is not at potential risk, meaning risk of a Sustained Outage, and the work event can be rescheduled or re-planned using an alternate work methodology. For example, a land owner may prevent the planned use of chemicals on non-threatening, low growth vegetation but agree to the use of mechanical clearing. In this case the Transmission Owner is not under any immediate time constraint for achieving the management objective, can easily reschedule work using an alternate approach, and therefore does not need to take interim corrective action. However, in situations where transmission line reliability is potentially at risk due to a constraint, the Transmission Owner is required to take an interim corrective action to mitigate the potential risk to the transmission line.**		

	Organization	Yes or No	Question 8 Comment
33	Orange and Rockland Utilities, Inc.	Yes	In R5, the SDT should better define the phrase 'where a transmission line is put at potential risk due to the constraint.' This is rather vague and could lead to inconsistent practices between utilities. Orange and Rockland Utilities, Inc. defines all undesirable species on the full width of the ROW as 'potential risks to the transmission line' regardless of height or location at the time of vegetation management. Interim corrective action should only be required when the potential risk is approaching the imminent threat classification.
	Response: The SDT thanks you for your comments. As described in the Technical Reference document (See Page 30), R5 is not intended to address situations where the transmission line is not at potential risk, meaning risk of a Sustained Outage, and the work event can be rescheduled or re-planned using an alternate work methodology. For example, a land owner may prevent the planned use of chemicals on non-threatening, low growth vegetation but agree to the use of mechanical clearing. In this case the Transmission Owner is not under any immediate time constraint for achieving the management objective, can easily reschedule work using an alternate approach, and therefore does not need to take interim corrective action. However, in situations where transmission line reliability is potentially at risk due to a constraint, the Transmission Owner is required to take an interim corrective action to mitigate the potential risk to the transmission line.		
34	Entergy Services	Yes	ITEMS of concern listed below:ITEM 1: Page 13 of the Standard Draft 4 under Add'l Compliance Information - Periodic Data Submittal......Clarify if Immediate Reporting is expected for outages in Outage Categories 1A, 1B, 2, or 4........or if Quarterly Reporting is all that is expected. It does not specifically say that IMMEDIATE Reporting is Required for any outage type. It is assumed that IMMEDIATE reporting is required for some outages, but is unclear.ITEM 2: Agree that text boxes being used for additional clarity is a benefit if used in a correct and clear manner, but it needs to be specifically stated in the document that the text boxes are to be used for reference only, we will not be required to specifically follow the language in the rationale, and that and each utility should specify their own exact process for addressing each Requirement.ITEM 3: Language should be added to the Guideline and Technical Basis Section to clarify or re-state that this section that this section is for assisting entities in understanding how to comply with the standard but does not contain mandatory actions/activities.ITEM 4: Please clarify defining factors that constitute "wind shear or fresh gale" as referenced in Section 4.4 Other. This is a very unclear interpretation and will most likely be interpreted

	Organization	Yes or No	Question 8 Comment
			differently by all involved if not specified.
	Response: Thank you for your comments. **ITEM 1: There is no requirement in this Standard for immediate reporting of any vegetation outage to the TO's RE. The TO's RE may require more frequent reporting or immediate reporting of any vegetation related outage. There may be other standards that apply to any transmission line outage that require immediate notification to the RE, NERC FERC, FBI, DOT and/or DOE. The SDT has considered your suggestion and believes that the recognized requirement to promptly self-report any potential violations is sufficient.** **ITEM 2: The Rationale boxes are intended to provide clarity and foundation behind each requirement. They are not a part of the requirement and are not sanctionable, as such. You are correct that every TO is required to structure its TVMP to comply with the standard as vegetation conditions exist. The NERC legal department has been contacted to provide a statement to clarify which parts/elements of a standard are mandatory and enforceable and which are provided only as information. This statement is nearing finalization and when completed will be posted as a separate document when the next draft of FAC-003-2 is posted.** **ITEM 3: The Guideline and Technical Reference paper Disclaimer on Page 6 of the document clearly states that the supporting document is supplemental to the reliability standard FAC-003-2 – Transmission Vegetation Management and does not contain mandatory requirements subject to compliance review.** **ITEM 4: Wind Shear and Fresh Gale are defined terms by the National Oceanic Atmospheric Administration (NOAA). Fresh gale is defined as straight line winds of between 39-46 mph. Wind Shear according to NOAA is a complicated formula that no one will ever use. Wind Shear definition according to NOAA Glossary is "The rate at which wind velocity changes from point to point in a given direction (as, vertically). The shear can be speed shear (where speed changes between the two points, but not direction_, direction shear (where direction changes between the two points, but not speed) or a combination of the two.**		
35	Northeast Power Coordinating Council	Yes	NPCC wants to thank the SDT for the effort that has gone into developing this proposed revision to FAC-003. Overall the new version is consistent with FERC Order 693 and will be a straightforward, workable, and auditable standard. One item requiring clarification and change is the Active ROW definition. The recent addition of a centerline distance to edge of Active ROW is not acceptable. In many areas design standards allow a smaller

	Organization	Yes or No	Question 8 Comment
			ROW width with no compromise to "cleared width" or tree related reliability of the line. The SDT needs to address this issue. In R5, the phrase 'where a transmission line is put at potential risk due to the constraint' should be better defined. This is vague and could lead to inconsistent practices between utilities. All undesirable species on the full width of the ROW are defined as 'potential risks to the transmission line' regardless of height or location at the time of vegetation management. Interim corrective action should only be required when the potential risk is approaching the imminent threat classification.
	Response: The SDT thanks you for your response. Your objection to our attempt to define a minimum width of the Active Transmission Right of Way was very similar to many other commenters. The SDT has revised the definition of ROW. **The issue you mention with R5 and "potential risk to the system" is understandable. The SDT amended the language.**		
36	Arizona Public Service Company	Yes	Qualifications needs to be put back in the standard. There needs to be a clearance 1 requirement.
	Response: Thank you for your comments. Training and qualifications are best addressed in the NERC PER standards. Additionally please refer to the SDT response to question 8, comment 42, regarding the issue of Clearance 1.		
37	Xcel Energy	Yes	R1 & R2 states that "types of encroachments include:" - is the way this is worded intended to imply there can be other types of encroachments that are not listed? If not, then rephrase the leading sentence to be definitive and indicate that the types are the only categories to be considered. We suggest that the wording from the prior draft, i.e., " . . . limited to".MCVD should be a defined term in the glossary, not in a "Rationale" box.R1 "1" should Real-time be capitalized to reflect the glossary definition? The term is used as "real time", "Real time" and "Real Time" throughout the standard. This seems to be just a drafting issue, but the same term should be used consistently. Need to establish somewhere that the entity defines what constitutes a "qualified" person. Further, some portions of the standard use the term "qualified person" (e.g., see M1) and others reference "qualified field personnel" (e.g., see the Rational Box near M3). It seems that all references should be to

	Organization	Yes or No	Question 8 Comment
			“qualified field personnel.”R1 & R2 are duplicative. It appears the only reason for the separation is so that different VRFs can be assigned. Why not just have 1 requirement and indicate that the VRF is High for one set of lines and Med for others?In general, the “Rationale” boxes force the requirement language into a difficult to read format.R5/M5 - the measures identified do not constitute “corrective actions”, they merely identify documentation that work was attempted. Corrective actions should be “actions”, such as establish an increased monitoring plan, re-rating of the line, removal from service, etc.R6 - Xcel Energy still believes the requirement in R6 that mandates an annual inspection is too onerous and is at odds with the results-based approach of these revisions. Xcel Energy urges the retention of the provision in the existing standard that allows the Transmission Owner to set the frequency of inspection. In some areas of the country, annual inspections may not be adequate. Yet in other areas, a longer inspection frequency may be perfectly reasonable and practical. Our point is that inspection frequency should not be treated as if it were “one size fits all”. If treated this way, we feel this could pose a risk to reliability and is not likely to be cost-effective. The Transmission Owner should be allowed some flexibility. However, if the drafting team disagrees and determines that an annual inspection is to be mandated, Xcel Energy believes that an exception to the annual inspection is appropriate when a non-subjective advanced technology such as LIDAR is utilized to achieve actual clearance distances. This places the Transmission Owner in a situation where it can rationally determine that the objectively measured distances result in a situation where an inspection need not be performed within the next year. It is suggested that R6 be revised to read as follows: Each Transmission Owner shall perform a Vegetation Inspection of all applicable transmission lines at least once per calendar year, unless the Transmission Owner, based on a non-subjective advanced technology, such as LIDAR, determines that a longer inspection period is appropriate.The Effective Dates section is confusing - exactly when would this standard be in effect? It lists 3 approvals...do all three have to be met or just one?The reference to Major WECC transfer paths in the requirements introduces a weak element. The WECC major path designation and elements that comprise those paths should be controlled through a robust process and easily available to WECC members. Currently, there are some concerns around that process in general.NERC’s concerns regarding reporting vegetation related outages within 48 hours

	Organization	Yes or No	Question 8 Comment
			should be addressed or clarified in the Compliance section. (i.e., incorporate or indicate that this supersedes that recommendation). Ref: Public Notice - NERC Compliance Process #2008 - 001
	Response: Thank you for your comments. The yellow highlighting refers to commenter issues. The SDT response follows. **R1 & R2 states that "types of encroachments include:": To address your concern, there are only (4) types of failure- to- manage types of encroachment as defined in R1 and R2 as it relates to compliance with FAC-003-2. The SDT appreciates your perspective but believes the requirement as written is clear to the point of only four encroachment types.** **MCVD should be a defined term in the glossary, not in a "Rationale": This term refers to a Table of values that is clearly defined within the standard itself.** **The term is used as "real time", "Real time" and "Real Time" throughout the standard. : Thanks for identifying this inconsistency and the SDT will review and address as appropriate.** **Need to establish somewhere that the entity defines what constitutes a "qualified" person.: This was replaced with confirmed by the Transmission Owner.** **Further, some portions of the standard use the term "qualified person" (e.g., see M1) and others reference "qualified field personnel" (e.g., see the Rational Box near M3).: Thanks for recognizing this inconsistency. The term "qualified" was replaced with confirmed by the Transmission Owner.** **R1 & R2 are duplicative. It appears the only reason for the separation is so that different VRFs can be assigned. Why not just have 1 requirement and indicate that the VRF is High for one set of lines and Med for others?: The SDT is following the VSL and VRF Guidelines which required us to designate two requirements since the VRFs are different for the applicable lines in the two requirements.** **R5/M5 - the measures identified do not constitute "corrective actions", they merely identify documentation that work was attempted.: The measures in R5 are evidence that appropriate corrective action was taken by the TO. Trying to identify very specific actions would be prescriptive in nature and difficult to cover a broad spectrum of potential corrective actions.** **R6 that mandates an annual inspection is too onerous and is at odds with the results-based approach of these revisions: As stated in previous comment responses, the SDT was directed by Order 693 to set a minimum inspection criteria and the SDT feels that an annual inspection is a reasonable minimum frequency.** **Effective Dates section is confusing - exactly when would this standard be in effect? The SDT has revised the effective date language for clarity. Please refer to change in revised draft.**		

	Organization	Yes or No	Question 8 Comment
	WECC major path designation and elements that comprise those paths should be controlled through a robust process and easily available to WECC members. Currently, there are some concerns around that process in general. : This is an issue that needs to be directed to WECC rather than the SDT. **48 hours should be addressed or clarified in the Compliance section. (i.e., incorporate or indicate that this supersedes that recommendation). Ref: Public Notice - NERC Compliance Process #2008 – 001: This Public Notice is a requirement for a Regional Entity to report to NERC.**		
38	BC Hydro	Yes	1. R4 - There will likely be issues of definition over what constitutes an “intentional delay” in notification. The time for reasonable reporting needs to be quantified. 2. The standard references Tables 2 and 3 but there is no Table 1 in the document. This is confusing and should be renumbered. This is likely a carry over from an earlier draft where a Table 1 has been renamed or dropped. 3. As noted earlier in Q1, table 3 is poorly developed and should be revisited.C 4. How does one objectively measure compliance to MVCD distances? Use of LiDAR technology, laser rangefinders, etc. should be used and evidence of potential violations should be empirical and not based solely on subjective observations, even if they are performed by “qualified personnel”. 5. The technical document should include a glossary of all the acronyms used throughout the document as it has some excessive jargon and does not always read smoothly, especially compared to FAC-003- The use of explanation boxes is helpful.
	Response: **1 The SDT debated a set time limit. The team could not find a time that would fit all situations. Intentional would apply if a TO withheld notification after having confirmed that risk conditions exist.** **2 The standard has been revised** **3 The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of ROW.**		

	Organization	Yes or No	Question 8 Comment
	4 The determination of a potential violation should employ any technology available 5 SDT has defined unusual terms not found within the industry. 6 Thank you		
39	The United Illuminating Company	Yes	R4:In R4 the phrase: without any intentional time delay, is a concern. There is a time line between identification and reporting of an imminent hazard that represents the minimal time required to complete this Requirement. Any situation where the time between observation and reporting is greater than this minimal time line indicates a time delay occurred. It will be left to the compliance enforcement authority to determine if this delay was intentional or not. It is not proper for the test to be based on Intentional versus Non-Intentional. Using other synonyms such as reasonable, expeditious, prompt, immediate or without hesitation all introduce a qualitative not a quantitative attribute to the measurement. The Supplemental Reference for R4 indicates that the imminent threat requirement is measured in minutes or hours; again no guidance for enforcement. R4 would be improved with an explicit time requirement of 6 hours between observation and report. This is measurable and clear.R4 should be: Each Transmission Owner shall notify the control center holding switching authority for the associated transmission line no more than 6 hours of a qualified personnel confirm the existence of a vegetation condition that is likely to cause a Fault at any moment.Other commenter's will argue that 6 hours is arbitrary or unduly prescriptive. I believe it is in line with the Supplemental Reference and adds clarity to the enforcement process.M4 becomes Each Transmission Owner that has a vegetation condition likely to cause a Fault at any moment, as confirmed by qualified personnel, will have evidence that it notified the control center holding switching authority for the associated transmission line within 6 hours of observation.The Transmission Owner can use the inspection as evidence of the time of observation.Effective Dates: The effective dates in the implementation Plan is in a different form then UI was expecting. Effective Date 1 UI has no comment.Effective date number 2 implies that if the BOT approves the standard and FERC takes no action (neither approves, remands or withholds approval of the standard) then the standard will become effective in one year. This seems to create the possibility of an effective standard without enforceability.Effective Date number 3 implies that regardless of any action by FERC the standard will become effective at least

	Organization	Yes or No	Question 8 Comment
			one year following BOT approval. Again this creates an effective standard without enforceability. Also the use of "at least one year" does not add any clarity to when the Standard would be effective any way.
	Response: **Thank you for your comments. The SDT considered a fixed time as you offer. We rejected that alternative as the situations under which conditions are found that can cause a Fault at any moment vary widely based on the terrain, weather and available transportation and communication methods. This Requirement is directing the TO to communicate the condition as soon as the above mentioned constraints will allow.** **We have addressed your concerns by revising the effective date language.**		
40	FPL Corporate Compliance	Yes	R5 as written is vague. It leads to confusion in interpretation. FPL recommends the following wording.R5. The Transmission Owner shall certify each corridor or line section that it meets the standards it set forth under R3 until the next planned management cycle when it is completed. If a location in known to not meet the criteria defined under R3, a mitigation plan must be in place to prevent a violation of R1 or R2.R1 and R2 are too inclusive. They equate vegetation growing in to conductors from below the same as vegetation falling or blowing into the conductors from within the Active ROW. There is no evidence that a cascading event has ever been caused by the latter two events. This standard should concentrate on vegetation growing from below the conductor. Suggested wording of R1 and R2 is as follows.R1. Each Transmission Owner shall manage vegetation to prevent encroachment into the Minimum Vegetation Clearance Distance (MVCD) as shown in Table 2 from within the active ROW on of any line identified as an element of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions). Encroachments are determined by: 1. An encroachment, observed in real time, 4. An encroachment due to a grow-in from below the conductor in the active ROW that caused a Fault.R1. Each Transmission Owner shall manage vegetation to prevent encroachment into the Minimum Vegetation Clearance Distance (MVCD) as shown in Table 2 from within the active ROW on of any line that is not an element of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions). Encroachments are determined by:

	Organization	Yes or No	Question 8 Comment
			1. An encroachment, observed in real time, 4. An encroachment due to a grow-in from below the conductor in the active ROW that caused a Fault.
	Response: The STD recognizes that defining any risk is subjective. Removing the term does not change the fact that each TO must determine the risk and respond accordingly. **The SDT has placed reference to the different severity of the respective violations into R1 and R2. Both NERC and FERC are on record that fall-in and blow-in interruptions place sufficient risk to the system that they should be part of the standard.**		
41	MWDSC (METROPOLITAN WATER DISTRICT OF SOUTHERN CALIFORNIA)	Yes	Requirement R4.uses the phrase "notify the control center holding switching authority for the associated transmission line" when a vegetation condition is confirmed which is likely to cause a Fault. Switching jurisdiction may be assigned to a manned substation located closer to a line rather than a remote 24/7 manned control center. However, the switching substation will notify its control center. The control center may need to notify and coordinate with its Balancing Authority or neighboring control centers. Suggest changing the phrase as follows: "notify the appropriate control center(s)for the associated transmission line"
	Response: The SDT thanks you for your comments. The example you provided in your comment is in compliance with the Requirement as written. The local procedure developed by a Transmission Owner may involve multiple notification steps but, as long as the proper operating personnel holding switching authority for that associated line is notified without any intentional delay, the Requirement is met. Due to multiple variations in utility notification procedures across North America, the SDT has decided to retain the existing language in the current draft.		
42	Southern California Edison Company	Yes	SCE questions the need for including the “Guidelines and Technical Basis” section within the body of the standard and is also curious as to the criteria used in developing new Table 3.SCE finds this Draft (4) to be the best work product thus far, and commends the SDT for its efforts and continued dedication to crafting a best-in-class standard.
	Response: The SDT thanks you for your comment. The ‘Guidelines and Technical Basis” is part of the format change with a “results based” standard. The idea is to bring some of the technical reference documentation into the Standard. This will hopefully make the entire Standard a more complete document and will reduce the need to have both the Standard and the Technical Reference Document in hand.		

	Organization	Yes or No	Question 8 Comment
	Table 3 was an attempt to define a "minimum width" of the Active Transmission Right of Way. This table, along with the footnote, has been removed from the Standard. The definition of Right of Way has been changed in the Glossary.		
43	Bonneville Power Administration	Yes	The basis of managing vegetation to MVCD in Table 2 (essentially withstand distances) will likely prove problematic. BPA believes NERC should develop an additional table that calls out minimum "buffers" based on attributes such as line voltage, line rating etc. This table should be a companion to Table 2. It is NERC's responsibility to regulate and we believe that they should do so. In this case, the loss of flexibility for the owners is not necessarily a bad thing.
	Response: The SDT thanks you for your comments. As described in the Background Section of the Standard, FAC-003-2 is being drafted utilizing a Results Based Standard approach. One component of this type of Standard is that requirements within a standard are not too prescriptive allowing for flexibility. An additional Table would be considered overly prescriptive and in direct conflict with our guidance. It is the Transmission Owner's responsibility to identify the 'buffers' that you mention, not NERC. Since conditions vary significantly across North America, maintaining this specific buffer distance may not be feasible for all utilities.		
44	Southern Company Transmission	Yes	The NERC Glossary of Terms provides a definition for Flashover. The Rationale boxes for R1 and R2 use the term "spark-over". This is inconsistent with other references in the Standard. Note that the term Flashover is used in footnote No.4. Please resolve the inconsistency between these terms.We are concerned FAC-003-2 is being developed under a zero tolerance philosophy, while other NERC standards do not adopt a zero tolerance philosophy. Industry performance under FAC-003-1 indicates the standard is working and that industry is responding to ensure reliability of the electric Transmission system.We would like to thank the SDT for the work they have put into developing the proposed draft.
	Response: **The SDT thanks you for your response. The technically correct term for the electric discharge through air is "spark-over". In the Technical Reference Document this term is used. The technical definition of "flash-over" refers to the electric discharge over the surface of insulation when the "withstand" of the air is less than the "withstand" of the insulation and the insulator "flashes over".**		

	Organization	Yes or No	Question 8 Comment
	However, the commonly used term in industry for both phenomena is "flash over". The NERC Glossary definition has actually rolled the technical definition of both terms together into one definition. **The SDT has decided to use the term "flash-over" in all sections of the Standard except for the derivation of the Gallet equations in the appendix of the Technical Reference Document. Hopefully this will alleviate any confusion.** **The SDT recognizes that the current version of the Standard is zero tolerance and believes it is compelled to write the new version it that way. FERC staff and NERC assert that a revised standard cannot result in less reliability than the one it replaces, and, their belief is the current Standard is zero tolerance.**		
45	ITC Transmission	Yes	We were beginning to except Version 3 to the standard but with the addition of "Table 3, Minimum Distance from the Centerline of the Circuit to the edge of the active transmission line ROW" is totally unacceptable. This entire reference should be stricken from the standard. ITC can not support this table #3 and Version 4 is unacceptable.
	Response: The SDT thanks you for your comments. Based on your comment and others, the SDT has revised the definition of ROW in the NERC Glossary.		

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed

1. SC approved SAR for initial posting (January 11, 2007).
2. SAR posted for comment (January 15–February 14, 2007).
3. SAR posted for comment (April 10–May 9, 2007).
4. SC authorized moving the SAR forward to standard development (June 27, 2007).
5. First draft of proposed standard posted (October 27, 2008-November 25, 2008)).
6. Second draft of revised standard posted (September 10, 20-October 24, 2009).
7. Third draft of revised standard posted (March 1, 2010-March 31, 2010).
8. Forth draft of revised standard posted (June 17, 2010-July 17, 2010).

Proposed Action Plan and Description of Current Draft

This is the third posting of the proposed revisions to the standard in accordance with Results-Based Criteria and the fifth draft overall.

Future Development Plan

Anticipated Actions	Anticipated Date
Recirculation ballot of standards.	January 2011
Receive BOT approval	February 2011

Effective Dates

First calendar day of the first calendar quarter one year after the date of the order approving the standard from applicable regulatory authorities where such explicit approval is required.

Exceptions:

A line operated below 200kV, designated by the Planning Coordinator as an element of an IROL or as a Major WECC transfer path, becomes subject to this standard 12 months after the date the Planning Coordinator or WECC initially designates the line as being subject to this standard.

An existing transmission line operated at 200kV or higher that is newly acquired by an asset owner and was not previously subject to this standard, becomes subject to this standard 12 months after the acquisition date of the line.

Version History

Version	Date	Action	Change Tracking
1	TBA	1. Added "Standard Development Roadmap." 2. Changed "60" to "Sixty" in section A, 5.2. 3. Added "Proposed Effective Date: April 7, 2006" to footer. 4. Added "Draft 3: November 17, 2005" to footer.	01/20/06
1	April 4, 2007	Regulatory Approval — Effective Date	New
2			

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary. When this standard has received ballot approval, the text boxes will be moved to the Guideline and Technical Basis Section.

Right-of-Way (ROW)

The corridor of land under a transmission line(s) needed to operate the line(s). The width of the corridor is established by engineering or construction standards as documented in either construction documents, pre-2007 vegetation maintenance records, or by the blowout standard in effect when the line was built. The ROW width in no case exceeds the Transmission Owner's legal rights but may be less based on the aforementioned criteria.

> The current glossary definition of this NERC term is modified to address the issues set forth in Paragraph 734 of FERC Order 693.

Vegetation Inspection

The systematic examination of vegetation conditions on a Right-of-Way and those vegetation conditions under the Transmission Owner's control that are likely to pose a hazard to the line(s) prior to the next planned maintenance or inspection. This may be combined with a general line inspection.

> The current glossary definition of this NERC term is modified to allow both maintenance inspections and vegetation inspections to be performed concurrently.
>
> Current definition of Vegetation Inspection: The systematic examination of a transmission corridor to document vegetation conditions.

Introduction

1. **Title:** Transmission Vegetation Management

2. **Number:** FAC-003-2

3. **Objectives:** To maintain a reliable electric transmission system by using a defense-in-depth strategy to manage vegetation located on transmission rights of way (ROW) and minimize encroachments from vegetation located adjacent to the ROW, thus preventing the risk of those vegetation-related outages that could lead to Cascading.

4. **Applicability**

4.1. Functional Entities:

Transmission Owners

4.2. Facilities: Defined below (referred to as "applicable lines"), including but not limited to those that cross lands owned by federal[1], state, provincial, public, private, or tribal entities:

4.2.1. Overhead transmission lines operated at 200kV or higher.

4.2.2. Overhead transmission lines operated below 200kV having been identified as included in the definition of an Interconnection Reliability Operating Limit (IROL) under NERC Standard FAC-014 by the Planning Coordinator.

4.2.3. Overhead transmission lines operated below 200 kV having been identified as included in the definition of one of the *Major WECC Transfer Paths in the Bulk Electric System*.

4.2.4. This standard applies to overhead transmission lines identified above (4.2.1 through 4.2.3) located outside the fenced area of the switchyard, station or substation and any portion of the span of the transmission line that is crossing the substation fence.

4.3. Enforcement: *The reliability obligations of the applicable entities and facilities are*

Rationale

-The areas excluded in 4.2.4 were excluded based on comments from industry for reasons summarized as follows: 1) There is a very low risk from vegetation in this area. Based on an informal survey, no TOs reported such an event. 2) Substations, switchyards, and stations have many inspection and maintenance activities that are necessary for reliability. Those existing process manage the threat. As such, the formal steps in this standard are not well suited for this environment. 3) The standard was written for Transmission Owners. Rolling the excluded areas into this standard will bring GO and DP into the standard, even though NERC has an initiative in place to address this bigger registry issue. 4) Specifically addressing the areas where the standard applies or doesn't makes the standard stronger as it relates to clarity.

[1] EPAct 2005 section 1211c: *"Access approvals by Federal agencies"*.

contained within the technical requirements of this standard. [Straw proposal]

5. Background:

This NERC Vegetation Management Standard ("Standard") uses a defense-in-depth approach to improve the reliability of the electric Transmission System by preventing those vegetation related outages that could lead to Cascading. This Standard is not intended to address non-preventable outages such as those due to vegetation fall-ins or blow-ins from outside the Right-of-Way, vandalism, human activities and acts of nature. Operating experience indicates that trees that have grown out of specification have contributed to Cascading, especially under heavy electrical loading conditions.

With a defense-in-depth strategy, this Standard utilizes three types of requirements to provide layers of protection to prevent vegetation related outages that could lead to Cascading:

a) Performance-based — defines a particular reliability objective or outcome to be achieved.

b) Risk-based — preventive requirements to reduce the risks of failure to acceptable tolerance levels.

c) Competency-based — defines a minimum capability an entity needs to have to demonstrate it is able to perform its designated reliability functions.

The defense-in-depth strategy for reliability standards development recognizes that each requirement in a NERC reliability standard has a role in preventing system failures, and that these roles are complementary and reinforcing. Reliability standards should not be viewed as a body of unrelated requirements, but rather should be viewed as part of a portfolio of requirements designed to achieve an overall defense-in-depth strategy and comport with the quality objectives of a reliability standard. For this Standard, the requirements have been developed as follows:

- Performance-based: Requirements 1 and 2
- Competency-based: Requirement 3
- Risk-based: Requirements 4, 5, 6 and 7

Thus the various requirements associated with a successful vegetation program could be viewed as using R1, R2 and R3 as first levels of defense; while R4 could be a subsequent or final level of defense. R6 depending on the particular vegetation approach may be either an initial defense barrier or a final defense barrier.

Major outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations. Adherence to the Standard requirements for applicable lines on any kind of land or easement, whether they are Federal Lands, state or provincial lands, public or private lands, franchises, easements or lands owned in fee, will reduce and manage this risk. For the purpose of the Standard the term “public lands” includes municipal lands, village lands, city lands, and a host of other governmental entities.

This Standard addresses vegetation management along applicable overhead lines and does not apply to underground lines, submarine lines or to line sections inside an electric station boundary.

This Standard focuses on transmission lines to prevent those vegetation related outages that could lead to Cascading. It is not intended to prevent customer outages due to tree contact with lower voltage distribution system lines. For example, localized customer service might be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. However, this Standard is not written to address such isolated situations which have little impact on the overall electric transmission system.

Since vegetation growth is constant and always present, unmanaged vegetation poses an increased outage risk, especially when numerous transmission lines are operating at or near their Rating. This can present a significant risk of multiple line failures and Cascading. Conversely, most other outage causes (such as trees falling into lines, lightning, animals, motor vehicles, etc.) are statistically intermittent. These events are not any more likely to occur during heavy system loads than any other time. There is no cause-effect relationship which creates the probability of simultaneous occurrence of other such events. Therefore these types of events are highly unlikely to cause large-scale grid failures. Thus, this Standard’s emphasis is on vegetation grow-ins.

Requirements and Measures

R1. Each Transmission Owner shall manage vegetation to prevent encroachments of the types shown below, into the Minimum Vegetation Clearance Distance (MVCD) of any of its applicable line(s) identified as an element of an Interconnection Reliability Operating Limit (IROL) in the planning horizon by the Planning Coordinator; or Major Western Electricity Coordinating Council (WECC) transfer path(s); operating within its Rating and all Rated Electrical Operating Conditions.[2]

1. An encroachment into the MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage,
2. An encroachment due to a fall-in from inside the Right-of-Way (ROW) that caused a vegetation-related Sustained Outage,
3. An encroachment due to blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained Outage,
4. An encroachment due to a grow-in that caused a vegetation-related Sustained Outage.

[VRF – High] [Time Horizon – Real-time]

Rationale
The MVCD is a calculated minimum distance stated in feet (meters) to prevent flash-over between conductors and vegetation, for various altitudes and operating voltages. The distances in Table 2 were derived using a proven transmission design method. The types of failure to manage vegetation are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a TO's vegetation maintenance program since the encroachments listed require different and increasing levels of skills and knowledge and thus constitute a logical progression of how well, or poorly, a TO manages vegetation relative to this Requirement.

M1. Each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R1. Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-time observations of any MVCD encroachments.

If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation.

Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period. (R1)

[2] This requirement does not apply to circumstances that are beyond the control of a Transmission Owner subject to this reliability standard, including natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods; human or animal activity such as logging, animal severing tree, vehicle contact with tree, arboricultural activities or horticultural or agricultural activities, or removal or digging of vegetation. Nothing in this footnote should be construed to limit the Transmission Owner's right to exercise its full legal rights on the ROW.

R2. Each Transmission Owner shall manage vegetation to prevent encroachments of the types shown below, into the MVCD of any of its applicable line(s) that is not an element of an IROL; or Major WECC transfer path; operating within its Rating and all Rated Electrical Operating Conditions.[2]

1. An encroachment into the MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage,
2. An encroachment due to a fall-in from inside the ROW that caused a vegetation-related Sustained Outage,
3. An encroachment due to blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained Outage,
4. An encroachment due to a grow-in that caused a vegetation-related Sustained Outage.

[VRF – Medium] [Time Horizon – Real-time]

Rationale

The MVCD is a calculated minimum distance stated in feet (meters) to prevent flash-over between conductors and vegetation, for various altitudes and operating voltages. The distances in Table 2 were derived using a proven transmission design method. The types of failure to manage vegetation are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a TO's vegetation maintenance program since the encroachments listed require different and increasing levels of skills and knowledge and thus constitute a logical progression of how well, or poorly, a TO manages vegetation relative to this Requirement.

M2. Each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R2. Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-time observations of any MVCD encroachments.

If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation.

Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period. (R2)

R3. Each Transmission Owner shall have documented maintenance strategies or procedures or processes or specifications it uses to prevent the encroachment of vegetation into the MVCD of its applicable transmission lines that include(s) the following:

3.1 Accounts for the movement of applicable transmission line conductors under their Facility Rating and all Rated Electrical Operating Conditions;

3.2 Accounts for the inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency.

Rationale

The documentation provides a basis for evaluating the competency of the Transmission Owner's vegetation program. There may be many acceptable approaches to maintain clearances. Any approach must demonstrate that the Transmission Owner avoids vegetation-to-wire conflicts under all Rated Electrical Operating Conditions. See Figure 1 for an illustration of possible conductor locations.

[VRF – Lower] [Time Horizon – Long Term Planning]

M3. The maintenance strategies or procedures or processes or specifications provided demonstrate that the Transmission Owner can prevent encroachment into the MVCD considering the factors identified in the requirement. (R3)

R4. Each Transmission Owner, without any intentional time delay, shall notify the control center holding switching authority for the associated applicable transmission line when the Transmission Owner has confirmed the existence of a vegetation condition that is likely to cause a Fault at any moment.

Rationale

To ensure expeditious communication between the Transmission Owner and the control center when a critical situation is confirmed.

[VRF – Medium] [Time Horizon – Real-time]

M4. Each Transmission Owner that has a confirmed vegetation condition likely to cause a Fault at any moment will have evidence that it notified the control center holding switching authority for the associated transmission line without any intentional time delay. Examples of evidence may include control center logs, voice recordings, switching orders, clearance orders and subsequent work orders. (R4)

R5. When a Transmission Owner is constrained from performing vegetation work, and the constraint may lead to a vegetation encroachment into the MVCD of its applicable transmission lines prior to the implementation of the next annual work plan then the Transmission Owner shall take corrective action to ensure continued vegetation management to prevent encroachments.

[VRF – Medium] [Time Horizon – Operations Planning]

Rationale

Legal actions and other events may occur which result in constraints that prevent the Transmission Owner from performing planned vegetation maintenance work.

In cases where the transmission line is put at potential risk due to constraints, the intent is for the Transmission Owner to put interim measures in place, rather than do nothing.

The corrective action process is intended to address situations where a planned work methodology cannot be performed but an alternate work methodology can be used.

M5. Each Transmission Owner has evidence of the corrective action taken for each constraint where an applicable transmission line was put at potential risk. Examples of acceptable forms of evidence may include initially-planned work orders, documentation of constraints from landowners, court orders, inspection records of increased monitoring, documentation of the de-rating of lines, revised work orders, invoices, and evidence that a line was de-energized. (R5)

R6. Each Transmission Owner shall perform a Vegetation Inspection of 100% of its applicable transmission lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.) at least once per calendar year and with no more than 18 months between inspections on the same ROW.[3]

[VRF – Medium] [Time Horizon – Operations Planning]

M6. Each Transmission Owner has evidence that it conducted Vegetation Inspections of the transmission line ROW for all applicable transmission lines at least once per calendar year but with no more than 18 months between inspections on the same ROW. Examples of acceptable

Rationale

Inspections are used by Transmission Owners to assess the condition of the entire ROW. The information from the assessment can be used to determine risk, determine future work and evaluate recently-completed work. This requirement sets a minimum Vegetation Inspection frequency of once per calendar year but with no more than 18 months between inspections on the same ROW. Based upon average growth rates across North America and on common utility practice, this minimum frequency is reasonable. Transmission Owners should consider local and environmental factors that could warrant more frequent inspections.

[3] When the Transmission Owner is prevented from performing a Vegetation Inspection within the timeframe in R6 due to a natural disaster, the TO is granted a time extension that is equivalent to the duration of the time the TO was prevented from performing the Vegetation Inspection.

forms of evidence may include completed and dated work orders, dated invoices, or dated inspection records. (R6)

R7. Each Transmission Owner shall complete 100% of its annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made (provided they do not put the transmission system at risk of a vegetation encroachment) and must be documented. The percent completed calculation is based on the number of units actually completed divided by the number of units in the final amended plan (measured in units of choice - circuit, pole line, line miles or kilometers, etc.) Examples of reasons for modification to annual plan may include:

- Change in expected growth rate/ environmental factors
- Circumstances that are beyond the control of a Transmission Owner[4]
- Rescheduling work between growing seasons
- Crew or contractor availability/ Mutual assistance agreements
- Identified unanticipated high priority work
- Weather conditions/Accessibility
- Permitting delays
- Land ownership changes/Change in land use by the landowner
- Emerging technologies

[VRF – Medium] [Time Horizon – Operations Planning]

Rationale

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. An annual vegetation work plan allows for work to be modified for changing conditions, taking into consideration anticipated growth of vegetation and all other environmental factors, provided that the changes do not violate the encroachment within the MVCD.

M7. Each Transmission Owner has evidence that it completed its annual vegetation work plan. Examples of acceptable forms of evidence may include a copy of the completed annual work plan (including modifications if any), dated work orders, dated invoices, or dated inspection records. (R7)

[4] Circumstances that are beyond the control of a Transmission Owner include but are not limited to natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, major storms as defined either by the TO or an applicable regulatory body, ice storms, and floods; arboricultural, horticultural or agricultural activities.

Compliance

Compliance Enforcement Authority

- Regional Entity

Compliance Monitoring and Enforcement Processes:

- Compliance Audits
- Self-Certifications
- Spot Checking
- Compliance Violation Investigations
- Self-Reporting
- Complaints
- Periodic Data Submittals

Evidence Retention

The Transmission Owner retains data or evidence to show compliance with Requirements R1, R2, R3, R5, R6 and R7, Measures M1, M2, M3, M5, M6 and M7 for three calendar years unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

The Transmission Owner retains data or evidence to show compliance with Requirement R4, Measure M4 for most recent 12 months of operator logs or most recent 3 months of voice recordings or transcripts of voice recordings, unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

If a Transmission Owner is found non-compliant, it shall keep information related to the non-compliance until found compliant or for the time period specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

Additional Compliance Information

Periodic Data Submittal: The Transmission Owner will submit a quarterly report to its Regional Entity, or the Regional Entity's designee, identifying all Sustained Outages of applicable transmission lines determined by the Transmission Owner to have been caused by vegetation, except as excluded in footnote 2, which includes as a minimum, the following:

- The name of the circuit(s), the date, time and duration of the outage; the voltage of the circuit; a description of the cause of the outage; the category associated with the Sustained Outage; other pertinent comments; and any countermeasures taken by the Transmission Owner.

A Sustained Outage is to be categorized as one of the following:

- Category 1A — Grow-ins: Sustained Outages caused by vegetation growing into applicable transmission lines, that are identified as an element of an IROL or Major WECC Transfer Path, by vegetation inside and/or outside of the ROW;

- Category 1B — Grow-ins: Sustained Outages caused by vegetation growing into applicable transmission lines, but are not identified as an element of an IROL or Major WECC Transfer Path, by vegetation inside and/or outside of the ROW;
- Category 2A — Fall-ins: Sustained Outages caused by vegetation falling into applicable transmission lines that are identified as an element of an IROL or Major WECC Transfer Path, from within the ROW;
- Category 2B — Fall-ins: Sustained Outages caused by vegetation falling into applicable transmission lines, but are not identified as an element of an IROL or Major WECC Transfer Path, from within the ROW;
- Category 3 — Fall-ins: Sustained Outages caused by vegetation falling into applicable transmission lines from outside the ROW;
- Category 4A — Blowing together: Sustained Outages caused by vegetation and applicable transmission lines that are identified as an element of an IROL or Major WECC Transfer Path, blowing together from within the ROW.
- Category 4B — Blowing together: Sustained Outages caused by vegetation and applicable transmission lines, but are not identified as an element of an IROL or Major WECC Transfer Path, blowing together from within the ROW.

The Regional Entity will report the outage information provided by Transmission Owners, as per the above, quarterly to NERC, as well as any actions taken by the Regional Entity as a result of any of the reported Sustained Outages.

Time Horizons, Violation Risk Factors, and Violation Severity Levels

Table 1

R#	Time Horizon	VRF	Violation Severity Level			
			Lower	Moderate	High	Severe
R1	Real-time	High	The Transmission Owner had an encroachment into the MVCD observed in Real-time, absent a Sustained Outage.	The Transmission Owner had an encroachment into the MVCD due to a fall-in from inside the ROW that caused a vegetation-related Sustained Outage.	The Transmission Owner had an encroachment into the MVCD due to blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained Outage.	The Transmission Owner had an encroachment into the MVCD due to a grow-in that caused a vegetation-related Sustained Outage.
R2	Real-time	Medium	The Transmission Owner had an encroachment into the MVCD observed in Real-time, absent a Sustained Outage.	The Transmission Owner had an encroachment into the MVCD due to a fall-in from inside the ROW that caused a vegetation-related Sustained Outage.	The Transmission Owner had an encroachment into the MVCD due to blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained Outage.	The Transmission Owner had an encroachment into the MVCD due to a grow-in that caused a vegetation-related Sustained Outage.
R3	Long-Term Planning	Lower		The Transmission Owner has maintenance strategies or documented procedures or processes or specifications but has not accounted for the inter-relationships between	The Transmission Owner has maintenance strategies or documented procedures or processes or specifications but has not accounted for the	The Transmission Owner does not have any maintenance strategies or documented procedures or processes or specifications used to prevent the

				vegetation growth rates, vegetation control methods, and inspection frequency, for the Transmission Owner's applicable lines.	movement of transmission line conductors under their Rating and all Rated Electrical Operating Conditions, for the Transmission Owner's applicable lines.	encroachment of vegetation into the MVCD, for the Transmission Owner's applicable lines.
R4	Real-time	Medium			The Transmission Owner experienced a confirmed vegetation threat and notified the control center holding switching authority for that transmission line, but there was intentional delay in that notification.	The Transmission Owner experienced a confirmed vegetation threat and did not notify the control center holding switching authority for that transmission line.
R5	Operations Planning	Medium				The Transmission Owner did not take corrective action when it was constrained from performing planned vegetation work where a transmission line was put at potential risk.
R6	Operations Planning	Medium	The Transmission Owner failed to inspect 5% or less of its applicable transmission lines (measured in units of choice - circuit, pole line, line miles or	The Transmission Owner failed to inspect more than 5% up to and including 10% of its applicable transmission lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.).	The Transmission Owner failed to inspect more than 10% up to and including 15% of its applicable transmission lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.).	The Transmission Owner failed to inspect more than 15% of its applicable transmission lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.).

			kilometers, etc.)			
R7	Operations Planning	Medium	The Transmission Owner failed to complete up to 5% of its annual vegetation work plan (including modifications if any).	The Transmission Owner failed to complete more than 5% and up to 10% of its annual vegetation work plan (including modifications if any).	The Transmission Owner failed to complete more than 10% and up to 15% of its annual vegetation work plan (including modifications if any).	The Transmission Owner failed to complete more than 15% of its annual vegetation work plan (including modifications if any).

Guideline and Technical Basis

Requirements R1 and R2:
R1 and R2 are performance-based requirements. The reliability objective or outcome to be achieved is the prevention of vegetation encroachments within a minimum distance of transmission lines. Content-wise, R1 and R2 are the same requirements; however, they apply to different Facilities. Both R1 and R2 require each Transmission Owner to manage vegetation to prevent encroachment within the Minimum Vegetation Clearance Distance ("MVCD") of transmission lines. R1 is applicable to lines "identified as an element of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions) to avoid a Sustained Outage". R2 applies to all other applicable lines that are not an element of an IROL or Major WECC Transfer Path.

The separation of applicability (between R1 and R2) recognizes that an encroachment into the MVCD of an IROL or Major WECC Transfer Path transmission line is a greater risk to the electric transmission system. Applicable lines that are not an element of an IROL or Major WECC Transfer Path are required to be clear of vegetation but these lines are comparatively less operationally significant. As a reflection of this difference in risk impact, the Violation Risk Factors (VRFs) are assigned as High for R1 and Medium for R2.

These requirements (R1 and R2) state that if vegetation encroaches within the distances in Table 1 in Appendix 1 of this supplemental Transmission Vegetation Management Standard FAC-003-2 Technical Reference document, it is in violation of the standard. Table 2 tabulates the distances necessary to prevent spark-over based on the Gallet equations as described more fully in Appendix 1 below.

These requirements assume that transmission lines and their conductors are operating within their Rating. If a line conductor is intentionally or inadvertently operated beyond its Rating (potentially in violation of other standards), the occurrence of a clearance encroachment may occur. For example, emergency actions taken by a Transmission Operator or Reliability Coordinator to protect an Interconnection may cause the transmission line to sag more and come closer to vegetation, potentially causing an outage. Such vegetation-related outages are not a violation of these requirements.

Evidence of violation of Requirement R1 and R2 include real-time observation of a vegetation encroachment into the MVCD (absent a Sustained Outage), or a vegetation-related encroachment resulting in a Sustained Outage due to a fall-in from inside the ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to blowing together of applicable lines and vegetation located inside the ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to a grow-in. If an investigation of a Fault by a Transmission Owner confirms that a vegetation encroachment within the MVCD occurred, then it shall be considered the equivalent of a Real-time observation.

With this approach, the VSLs were defined such that they directly correlate to the severity of a failure of a Transmission Owner to manage vegetation and to the corresponding performance level of the Transmission Owner's vegetation program's ability to meet the goal of "preventing a Sustained Outage that could lead to Cascading." Thus violation severity increases with a Transmission Owner's inability to meet this goal and its potential of leading to a Cascading event. The additional benefits of such a combination are that it simplifies the standard and clearly defines performance for compliance. A performance-based requirement of this nature will promote high quality, cost effective vegetation management programs that will deliver the overall end result of improved reliability to the system.

Multiple Sustained Outages on an individual line can be caused by the same vegetation. For example, a limb may only partially break and intermittently contact a conductor. Such events are considered to be a single vegetation-related Sustained Outage under the Standard where the Sustained Outages occur within a 24 hour period.

The MVCD is a calculated minimum distance stated in feet (or meters) to prevent spark-over, for various altitudes and operating voltages that is used in the design of Transmission Facilities. Keeping vegetation from entering this space will prevent transmission outages.

Requirement R3:
Requirement R3 is a competency based requirement concerned with the maintenance strategies, procedures, processes, or specifications, a Transmission Owner uses for vegetation management.

An adequate transmission vegetation management program formally establishes the approach the Transmission Owner uses to plan and perform vegetation work to prevent transmission Sustained Outages and minimize risk to the Transmission System. The approach provides the basis for evaluating the intent, allocation of appropriate resources and the competency of the Transmission Owner in managing vegetation. There are many acceptable approaches to manage vegetation and avoid Sustained Outages. However, the Transmission Owner must be able to state what its approach is and how it conducts work to maintain clearances.

An example of one approach commonly used by industry is ANSI Standard A300, part 7. However, regardless of the approach a utility uses to manage vegetation, any approach a Transmission Owner chooses to use will generally contain the following elements:

1. *the maintenance strategy used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that MVCD clearances are never violated.*
2. *the work methods that the Transmission Owner uses to control vegetation*
3. *a stated Vegetation Inspection frequency*
4. *an annual work plan*

The conductor’s position in space at any point in time is continuously changing as a reaction to a number of different loading variables. Changes in vertical and horizontal conductor positioning are the result of thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation. Physical loading applied to the conductor affects sag and sway by combining physical factors such as ice and wind loading. The movement of the transmission line conductor and the MVCD is illustrated in Figure 1 below.

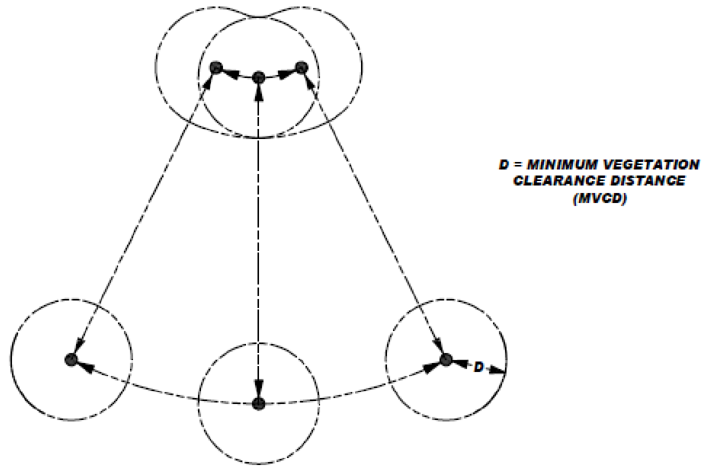

Figure 1

Cross-section view of a single conductor at a given point along the span showing six possible conductor positions due to movement resulting from thermal and mechanical loading.

Requirement R4:

R4 is a risk-based requirement. It focuses on preventative actions to be taken by the Transmission Owner for the mitigation of Fault risk when a vegetation threat is confirmed. R4 involves the notification of potentially threatening vegetation conditions, without any intentional delay, to the control center holding switching authority for that specific transmission line. Examples of acceptable unintentional delays may include communication system problems (for example, cellular service or two-way radio disabled), crews located in remote field locations with no communication access, delays due to severe weather, etc.

Confirmation is key that a threat actually exists due to vegetation. This confirmation could be in the form of a Transmission Owner's employee who personally identifies such a threat in the field. Confirmation could also be made by sending out an employee to evaluate a situation reported by a landowner.

Vegetation-related conditions that warrant a response include vegetation that is near or encroaching into the MVCD (a grow-in issue) or vegetation that could fall into the transmission conductor (a fall-in issue). A knowledgeable verification of the risk would include an assessment of the possible sag or movement of the conductor while operating between no-load conditions and its rating.

The Transmission Owner has the responsibility to ensure the proper communication between field personnel and the control center to allow the control center to take the appropriate action until the vegetation threat is relieved. Appropriate actions may include a temporary reduction in the line loading, switching the line out of service, or positioning the system in recognition of the increasing risk of outage on that circuit. The notification of the threat should be communicated in terms of minutes or hours as opposed to a longer time frame for corrective action plans (see R5).

All potential grow-in or fall-in vegetation-related conditions will not necessarily cause a Fault at any moment. For example, some Transmission Owners may have a danger tree identification program that identifies trees for removal with the potential to fall near the line. These trees would not require notification to the control center unless they pose an immediate fall-in threat.

Requirement R5:
R5 is a risk-based requirement. It focuses upon preventative actions to be taken by the Transmission Owner for the mitigation of Sustained Outage risk when temporarily constrained from performing vegetation maintenance. The intent of this requirement is to deal with situations that prevent the Transmission Owner from performing planned vegetation management work and, as a result, have the potential to put the transmission line at risk. Constraints to performing vegetation maintenance work as planned could result from legal injunctions filed by property owners, the discovery of easement stipulations which limit the Transmission Owner's rights, or other circumstances.

This requirement is not intended to address situations where the transmission line is not at potential risk and the work event can be rescheduled or re-planned using an alternate work methodology. For example, a land owner may prevent the planned use of chemicals on non-threatening, low growth vegetation but agree to the use of mechanical clearing. In this case the Transmission Owner is not under any immediate time constraint for achieving the management objective, can easily reschedule work using an alternate approach, and therefore does not need to take interim corrective action.

However, in situations where transmission line reliability is potentially at risk due to a constraint, the Transmission Owner is required to take an interim corrective action to mitigate the potential risk to the transmission line. A wide range of actions can be taken to address various situations. General considerations include:

- Identifying locations where the Transmission Owner is constrained from performing planned vegetation maintenance work which potentially leaves the transmission line at risk.
- Developing the specific action to mitigate any potential risk associated with not performing the vegetation maintenance work as planned.
- Documenting and tracking the specific action taken for each location.
- In developing the specific action to mitigate the potential risk to the transmission line the Transmission Owner could consider location specific measures such as modifying the inspection and/or maintenance intervals. Where a legal constraint would not allow any vegetation work, the interim corrective action could include limiting the loading on the transmission line.
- The Transmission Owner should document and track the specific corrective action taken at each location. This location may be indicated as one span, one tree or a combination of spans on one property where the constraint is considered to be temporary.

Requirement R6:
R6 is a risk-based requirement. This requirement sets a minimum time period for completing Vegetation Inspections that fits general industry practice. In addition, the fact that Vegetation Inspections can be performed in conjunction with general line inspections further facilitates a Transmission Owner's ability to meet this requirement. However, the Transmission Owner may determine that more frequent inspections are needed to maintain reliability levels, dependent upon such factors as anticipated growth rates of the local vegetation, length of the growing season for the geographical area, limited ROW width, and rainfall amounts. Therefore it is expected that some transmission lines may be designated with a higher frequency of inspections.

The VSL for Requirement R6 has VSL categories ranked by the percentage of the required ROW inspections completed. To calculate the percentage of inspection completion, the Transmission Owner may choose units such as: line miles or kilometers, circuit miles or kilometers, pole line miles, ROW miles, etc.

For example, when a Transmission Owner operates 2,000 miles of 230 kV transmission lines this Transmission Owner will be responsible for inspecting all 2,000 miles of 230 kV transmission lines at least once during the calendar year. If one of the included lines was 100 miles long, and if it was not inspected during the year, then the amount failed to inspect would be 100/2000 = 0.05 or 5%. The "Low VSL" for R6 would apply in this example.

Requirement R7:
R7 is a risk-based requirement. The Transmission Owner is required to implement an annual work plan for vegetation management to accomplish the purpose of this standard. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made and documented provided they do not put the transmission system at risk. The annual work plan requirement is not intended to necessarily require a "span-by-span", or even a "line-by-line" detailed description of all work to be performed. It is only intended to require that the Transmission Owner provide evidence of annual planning and execution of a vegetation management maintenance approach which successfully prevents encroachment of vegetation into the MVCD.

The ability to modify the work plan allows the Transmission Owner to change priorities or treatment methodologies during the year as conditions or situations dictate. For example recent line inspections may identify unanticipated high priority work, weather conditions (drought) could make herbicide application ineffective during the plan year, or a major storm could require redirecting local resources away from planned maintenance. This situation may also include complying with mutual assistance agreements by moving resources off the Transmission Owner's system to work on another system. Any of these examples could result in acceptable deferrals or additions to the annual work plan. Modifications to the annual work plan must always ensure the reliability of the electric Transmission system.

In general, the vegetation management maintenance approach should use the full extent of the Transmission Owner's easement, fee simple and other legal rights allowed. A comprehensive approach that exercises the full extent of legal rights on the ROW is superior to incremental management in the long term because it reduces the overall potential for encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient.

When developing the annual work plan the Transmission Owner should allow time for procedural requirements to obtain permits to work on federal, state, provincial, public, tribal lands. In some cases the lead time for obtaining permits may necessitate preparing work plans more than a year prior to work start dates. Transmission Owners may also need to consider those special landowner requirements as documented in easement instruments.

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. Therefore, deferrals or relevant changes to the annual plan shall be documented. Depending on the planning and documentation format used by the Transmission Owner, evidence of successful annual work plan execution could consist of signed-off work orders, signed contracts, printouts from work management systems, spreadsheets of planned versus completed work, timesheets, work inspection reports, or paid invoices. Other evidence may include photographs, and walk-through reports.

FAC-003 — TABLE 2 — Minimum Vegetation Clearance Distances (MVCD)[5]

For **Alternating Current** Voltages

(AC) Nominal System Voltage (kV)	(AC) Maximum System Voltage (kV)	MVCD feet (meters) sea level	MVCD feet (meters) 3,000ft (914.4m)	MVCD feet (meters) 4,000ft (1219.2m)	MVCD feet (meters) 5,000ft (1524m)	MVCD feet (meters) 6,000ft (1828.8m)	MVCD feet (meters) 7,000ft (2133.6m)	MVCD feet (meters) 8,000ft (2438.4m)	MVCD feet (meters) 9,000ft (2743.2m)	MVCD feet (meters) 10,000ft (3048m)	MVCD feet (meters) 11,000ft (3352.8m)

<u>Notes:</u>

The SDT determined that the use of IEEE 516-2003 in version 1 of FAC-003 was a misapplication. The SDT consulted specialists who advised that the Gallet Equation would be a technically justified method. The explanation of why the Gallet approach is more appropriate is explained in the paragraphs below.

The drafting team sought a method of establishing minimum clearance distances that uses realistic weather conditions and realistic maximum transient over-voltages factors for in-service transmission lines.

The SDT considered several factors when looking at changes to the minimum vegetation to conductor distances in FAC-003-1:

- avoid the problem associated with referring to tables in another standard (IEEE-516-2003)
- transmission lines operate in non-laboratory environments (wet conditions)
- transient over-voltage factors are lower for in-service transmission lines than for inadvertently re-energized transmission lines with trapped charges.

FAC-003-1 uses the minimum air insulation distance (MAID) without tools formula provided in IEEE 516-2003 to determine the minimum distance between a transmission line conductor and vegetation. The equations and methods provided in IEEE 516 were developed by an IEEE Task Force in 1968 from test data provided by thirteen independent laboratories. The distances provided in IEEE 516 Tables 5 and 7 are based on the withstand voltage of a dry rod-rod air gap, or in other words, dry laboratory conditions. Consequently, the validity of using these distances in an outside environment application has been questioned.

FAC-003-01 allowed Transmission Owners to use either Table 5 or Table 7 to establish the minimum clearance distances. Table 5 could be used if the Transmission Owner knew the maximum transient over-voltage factor for its system. Otherwise, Table 7 would have to be used. Table 7 represented minimum air insulation distances under the worst possible case for transient over-voltage factors. These worst case transient over-voltage factors were as follows: 3.5 for voltages up to 362 kV phase to phase; 3.0 for 500 - 550 kV phase to phase; and 2.5 for 765 to 800 kV phase to phase. These worst case over-voltage factors were also a cause for concern in this particular application of the distances.

In general, the worst case transient over-voltages occur on a transmission line that is inadvertently re-energized immediately after the line is de-energized and a trapped charge is still present. The intent of FAC-003 is to keep a transmission line that is *in service* from becoming de-energized (i.e. tripped out) due to spark-over from the line conductor to nearby vegetation. Thus, the worst case transient overvoltage assumptions are not appropriate for this application. Rather, the appropriate over voltage values are those that occur only while the line is energized.

Typical values of transient over-voltages of in-service lines, as such, are not readily available in the literature because they are negligible compared with the maximums. A conservative value for the maximum transient over-voltage that can occur anywhere along the length of an in-service ac line is approximately 2.0 per unit. This value is a conservative estimate of the transient over-voltage that is created at the point of application (e.g. a substation) by switching a capacitor bank without pre-insertion devices (e.g. closing resistors). At voltage levels where capacitor banks are not very common (e.g. 362 kV), the maximum transient over-voltage of an in-service ac line are created by fault initiation on adjacent ac lines and shunt reactor bank switching. These transient voltages are usually 1.5 per unit or less.

Even though these transient over-voltages will not be experienced at locations remote from the bus at which they are created, in order to be conservative, it is assumed that all nearby ac lines are subjected to this same level of over-voltage. Thus, a maximum transient over-voltage factor of 2.0 per unit for transmission lines operated at 242 kV and below is considered to be a realistic maximum in this application. Likewise, for ac transmission lines operated at 362 kV and above a transient over-voltage factor of 1.4 per unit is considered a realistic maximum.

The Gallet Equations are an accepted method for insulation coordination in tower design. These equations are used for computing the required strike distances for proper transmission line insulation coordination. They were developed for both wet and dry applications and can be used with any value of transient over-voltage factor. The Gallet Equation also can take into account various air gap geometries. This approach was used to design the first 500 kV and 765 kV lines in North America [1].

If one compares the MAID using the IEEE 516-2003 Table 7 (table D.5 for English values) with the critical spark-over distances computed using the Gallet wet equations, for each of the nominal voltage classes and identical transient over-voltage factors, the Gallet equations yield a more conservative (larger) minimum distance value.

Distances calculated from either the IEEE 516 (dry) formulas or the Gallet “wet” formulas are not vastly different when the same transient overvoltage factors are used; the “wet” equations will consistently produce slightly larger distances than the IEEE 516 equations when the same transient overvoltage is used. While the IEEE 516 equations were only developed for dry conditions the Gallet equations have provisions to calculate spark-over distances for both wet and dry conditions.

While EPRI is currently trying to establish empirical data for spark-over distances to live vegetation, there are no spark-over formulas currently derived expressly for vegetation to conductor minimum distances. Therefore the SDT chose a proven method that has been used in other EHV applications. The Gallet equations relevance to wet conditions and the selection of a Transient Overvoltage Factor that is consistent with the absence of trapped charges on an in-service transmission line make this methodology a better choice.

The following table is an example of the comparison of distances derived from IEEE 516 and the Gallet equations using various transient overvoltage values.

Comparison of spark-over distances computed using Gallet wet equations
vs.
IEEE 516-2003 MAID distances
using various transient over-voltage factors

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed

1. SC approved SAR for initial posting (January 11, 2007).
2. SAR posted for comment (January 15–February 14, 2007).
3. SAR posted for comment (April 10–May 9, 2007).
4. SC authorized moving the SAR forward to standard development (June 27, 2007).
5. First draft of proposed standard posted (October 27, 2008-November 25, 2008)).
6. Second draft of revised standard posted (September 10, 20-October 24, 2009).
7. Third draft of revised standard posted (March 1, 2010-March 31, 2010).
8. Forth draft of revised standard posted (June 17, 2010-July 17, 2010).

Proposed Action Plan and Description of Current Draft

This is the ~~second~~third posting of the proposed revisions to the standard in accordance with Results-Based Criteria and the fifth draft overall.

Future Development Plan

Anticipated Actions	Anticipated Date
~~Drafting team considers comments, makes conforming changes, and requests SC approval to proceed to formal comment and ballot.~~	~~June - July 2010~~
Recirculation ballot of standards.	~~July-August 2010~~January 2011
Receive BOT approval	~~August 2010~~February 2011

Effective Dates

~~1.~~ First calendar day of the first calendar quarter one year after the date of the order approving the standard from applicable regulatory ~~authority~~authorities where such explicit approval ~~for all requirements~~
~~2. First calendar day of the first calendar quarter one year following Board of Trustees adoption unless governmental authority withholds approval~~
~~First calendar day of the first calendar quarter that~~ is ~~at least one year following Board of Trustees adoption~~required.

Exceptions:

A line operated below 200kV, designated by the Planning Coordinator as an element of an IROL or as a Major WECC transfer path, becomes subject to this standard 12 months after the date the Planning Coordinator or WECC initially designates the ~~lines~~line as being subject to this standard.

An existing transmission line operated at 200kV or higher that is newly acquired by an asset owner and was not previously subject to this standard, becomes subject to this standard 12 months after the acquisition date of the line.

Version History

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary. When this standard has received ballot approval, the text boxes will be moved to the Guideline and Technical Basis Section.

Right-of-Way (ROW)

The corridor of land under a transmission line(s) needed to operate the line(s). The width of the corridor is established by engineering or construction standards as documented in either construction documents, pre-2007 vegetation maintenance records, or by the blowout standard in effect when the line was built. The ROW width in no case exceeds the Transmission Owner's legal rights but may be less based on the aforementioned criteria.

> ~~The current glossary definition of this NERC term is modified to allow both maintenance inspections and vegetation inspections to be performed concurrently.~~
>
> ~~Current definition of Vegetation Inspection: The systematic examination of a transmission corridor to document vegetation conditions.~~

Vegetation Inspection

The systematic examination of vegetation conditions on a ~~maintained transmission line Right-of-Way which~~Right-of-Way and those vegetation conditions under the Transmission Owner's control that are likely to pose a hazard to the line(s) prior to the next planned maintenance or inspection. This may be combined with a general line inspection.

> The current glossary definition of this NERC term is modified to allow both maintenance inspections and vegetation inspections to be performed concurrently.
>
> Current definition of Vegetation Inspection: The systematic examination of a transmission corridor to document vegetation conditions.

Introduction

1. **Title:** Transmission Vegetation Management

2. **Number:** FAC-003-2

3. **Objectives:** To ~~improve the reliability of the~~ maintain a reliable electric transmission system by using a defense-in-depth strategy to manage vegetation located on transmission rights of way (ROW) and minimize encroachments from vegetation located adjacent to the ROW, thus preventing the risk of those vegetation-related outages that could lead to Cascading.

4. **Applicability**

4.1. Functional Entities:

Transmission Owners

4.2. Facilities: Defined below~~,~~ (referred to as "applicable lines"), including but not limited to those that cross lands owned by federal[1], state, provincial, public, private, or tribal entities:

4.2.1. Overhead transmission lines operated at 200kV or higher.

4.2.2. Overhead transmission lines operated below 200kV having been identified as included in the definition of an Interconnection Reliability Operating Limit (IROL) under NERC Standard FAC-014 by the Planning Coordinator.

4.2.3. Overhead transmission lines operated below 200 kV having been identified as included in the definition of one of the *Major WECC Transfer Paths in the Bulk Electric System*.

4.2.4. This standard ~~does not apply~~applies to ~~Facilities~~overhead transmission lines identified above (4.2.1 through 4.2.3) located ~~in~~outside the fenced area of ~~a~~the switchyard, station or substation and any portion of the span of the transmission line that is crossing the substation fence.

Rationale

-The areas excluded in 4.2.4 were excluded based on comments from industry for reasons summarized as follows: 1) There is a very low risk from vegetation in this area. Based on an informal survey, no TOs reported such an event. 2) Substations, switchyards, and stations have many inspection and maintenance activities that are necessary for reliability. Those existing process manage the threat. As such, the formal steps in this standard are not well suited for this environment. 3) The standard was written for Transmission Owners. Rolling the excluded areas into this standard will bring GO and DP into the standard, even though NERC has an initiative in place to address this bigger registry issue. 4) Specifically addressing the areas where the standard applies or doesn't makes the standard stronger as it relates to clarity.

4.3. Enforcement: *The reliability obligations of*

[1] EPAct 2005 section 1211c: *"Access approvals by Federal agencies"*.

the applicable entities and facilities are contained within the technical requirements of this standard. [Straw proposal]

~~**4.4. Other:**~~

~~This Standard does not apply to any occurrence, non-occurrence, or other set of circumstances that are beyond the control of a Transmission Owner subject to this reliability standard, including acts of God, flood, drought, earthquake, major storms, fire, hurricane, tornado, landslides, ice storms, vehicle contact with tree, human activity involving: removal of, installation of, or digging around vegetation, animals severing trees, lightning, epidemic, strike, war, riot, civil disturbance, sabotage, vandalism, terrorism, wind shear, or fresh gale (or higher wind speed) that restricts or prevents performance to comply with this reliability standard's requirements. Nothing in this section should be construed to limit the Transmission Owner's right to exercise its full legal rights on the active transmission line ROW[2].~~

5. Background:

This NERC Vegetation Management Standard ("Standard") uses a defense-in-depth approach to improve the reliability of the electric Transmission System by preventing those vegetation related outages that could lead to Cascading. This Standard is not intended to address non-preventable outages such as those due to vegetation fall-ins or blow-ins from outside the ~~Active Transmission Line~~ Right-of-Way, vandalism, human activities and acts of nature. Operating experience indicates that trees that have grown out of specification have contributed to Cascading, especially under heavy electrical loading conditions.

With a defense-in-depth strategy, this Standard utilizes three types of requirements to provide layers of protection to prevent vegetation related outages that could lead to Cascading:

a) Performance-based — defines a particular reliability objective or outcome to be achieved.

b) Risk-based — preventive requirements to reduce the risks of failure to acceptable tolerance levels.

c) Competency-based — defines a minimum capability an entity needs to have to demonstrate it is able to perform its designated reliability functions.

The defense-in-depth strategy for reliability standards development recognizes that each requirement in a NERC reliability standard has a role in preventing system failures, and that these roles are complementary and reinforcing. Reliability standards should not be viewed as a body of unrelated requirements, but rather should be viewed as part of a portfolio of requirements designed to achieve an overall defense-in-depth strategy and comport with the quality objectives of a reliability standard. For this Standard, the requirements have been developed as follows:

~~[2] A strip or corridor of land that is occupied by active transmission facilities. This corridor does not include the parts of the Right-of-Way that are unused or intended for other facilities. However, it is not to be less than the width of the easement itself unless the easement exceeds distances as shown in Table 3 for various voltage classes.~~

- Performance-based: Requirements 1 and 2
- Competency-based: Requirement 3
- Risk-based: Requirements 4, 5, 6 and 7

Thus the various requirements associated with a successful vegetation program could be viewed as using R1, R2 and R3 as first levels of defense; while R4 could be a subsequent or final level of defense. R6 depending on the particular vegetation approach may be either an initial defense barrier or a final defense barrier.

Major outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations. Adherence to the Standard requirements for applicable lines on any kind of land or easement, whether they are Federal Lands, state or provincial lands, public or private lands, franchises, easements or lands owned in fee, will reduce and manage this risk. For the purpose of the Standard the term “public lands” includes municipal lands, village lands, city lands, and a host of other governmental entities.

This Standard addresses vegetation management along applicable overhead lines and does not apply to underground lines, submarine lines or to line sections inside an electric station boundary.

This Standard focuses on transmission lines to prevent those vegetation related outages that could lead to Cascading. It is not intended to prevent customer outages due to tree contact with lower voltage distribution system lines. For example, localized customer service might be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. However, this Standard is not written to address such isolated situations which have little impact on the overall electric transmission system.

Since vegetation growth is constant and always present, unmanaged vegetation poses an increased outage risk, especially when numerous transmission lines are operating at or near their Rating. This can present a significant risk of multiple line failures and Cascading. Conversely, most other outage causes (such as trees falling into lines, lightning, animals, motor vehicles, etc.) are statistically intermittent. These events are not any more likely to occur during heavy system loads than any other time. There is no cause-effect relationship which creates the probability of simultaneous occurrence of other such events. Therefore these types of events are highly unlikely to cause large-scale grid failures. Thus, this Standard’s emphasis is on vegetation grow-ins.

Requirements and Measures

R1. Each Transmission Owner shall manage vegetation to prevent ~~encroachment that could result in a Sustained Outage~~encroachments of the types shown below, into the Minimum Vegetation Clearance Distance (MVCD) of any of its applicable line(s) identified as an element of an Interconnection Reliability Operating Limit (IROL) in the planning horizon by the Planning Coordinator; or Major Western Electricity Coordinating Council (WECC) transfer path ~~(~~(s); operating within its Rating and all Rated Electrical Operating Conditions~~). Types of encroachment include:~~.[3]

1. An encroachment into the ~~Minimum Vegetation Clearance Distance (MVCD)~~ MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage,
2. An encroachment due to a fall-in from inside the ~~active transmission line~~ Right-of-Way (ROW) that caused a vegetation-related Sustained Outage,
3. An encroachment due to blowing together of applicable lines and vegetation located inside the ~~active transmission line~~ ROW that caused a vegetation-related Sustained Outage,
4. An encroachment due to a grow-in that caused a vegetation-related Sustained Outage.

[VRF – High] [Time Horizon – Real-time]

Rationale

The MVCD is a calculated minimum distance stated in feet (meters) to prevent ~~spark~~flash-over between conductors and vegetation, for various altitudes and operating voltages. The distances in Table 2 were derived using a proven transmission design method. The types of failure to manage vegetation are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a TO's vegetation maintenance program since the encroachments listed require different and increasing levels of skills and knowledge and thus constitute a logical progression of how well, or poorly, a TO manages vegetation relative to this Requirement.

M1. Each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R1. Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-time observations of any MVCD encroachments.

If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation.

Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-

[3] This requirement does not apply to circumstances that are beyond the control of a Transmission Owner subject to this reliability standard, including natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods; human or animal activity such as logging, animal severing tree, vehicle contact with tree, arboricultural activities or horticultural or agricultural activities, or removal or digging of vegetation. Nothing in this footnote should be construed to limit the Transmission Owner's right to exercise its full legal rights on the ROW.

hour period.~~ If an investigation of a Fault by a qualified person confirms that a vegetation encroachment within the MVCD occurred, then it shall be considered a Real-time observation.~~ (R1)

R2. Each Transmission Owner shall manage vegetation to prevent ~~encroachment that could result in a Sustained Outage of~~encroachments of the types shown below, into the MVCD of any of its applicable ~~lines~~line(s) that ~~are~~is not ~~elements~~an element of an ~~Interconnection Reliability Operating Limit (~~IROL~~)~~; or Major ~~Western Electricity Coordinating Council (~~WECC~~)~~ transfer path~~ (~~; operating within its Rating and all Rated Electrical Operating Conditions~~). Types of encroachment include:~~.[3]

1. An encroachment into the ~~Minimum Vegetation Clearance Distance (MVCD)~~MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage,
2. An encroachment due to a fall-in from inside the~~ active transmission line~~ ROW that caused a vegetation-related Sustained Outage,
3. An encroachment due to blowing together of applicable lines and vegetation located inside the ~~active transmission line~~ ROW that caused a vegetation-related Sustained Outage,
4. An encroachment due to a grow-in that caused a vegetation-related Sustained Outage. *[VRF – Medium] [Time Horizon – Real-time]*

Rationale

The MVCD is a calculated minimum distance stated in feet (meters) to prevent flash-over between conductors and vegetation, for various altitudes and operating voltages. The distances in Table 2 ... a logical progression of how well, or poorly, a TO manages vegetation relative to this Requirement.

~~**Rationale**~~

~~The MVCD is a calculated minimum distance stated in feet (meters) to prevent spark-over between conductors and vegetation, for various altitudes and operating voltages. The distances in Table 2 were derived using a proven transmission design method.~~

M2. Each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R2. Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-time observations of any MVCD encroachments.

If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation.

Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period. ~~If an investigation of a Fault by a qualified person confirms that a vegetation encroachment within the MVCD occurred, then it shall be considered a Real-time observation.~~(R2)

R3. Each Transmission Owner shall ~~document the~~ have documented maintenance strategies or procedures~~,~~ or processes~~,~~ or specifications it uses to prevent the encroachment of vegetation into the MVCD~~. Such documentation will incorporate~~ of its applicable transmission lines that include(s) the following:

3.1 Accounts for the ~~dynamics~~movement of ~~a~~applicable transmission line ~~conductor's movement throughout its~~ conductors under their Facility Rating and all Rated Electrical Operating Conditions ~~and~~;

3.2 Accounts for the inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency~~, for the Transmission Owner's applicable lines.~~.

[VRF – Lower] [Time Horizon – Long Term Planning]

Rationale

The documentation provides a basis for evaluating the competency of the Transmission Owner's vegetation program. There may be many acceptable approaches to maintain clearances. Any approach must demonstrate that the Transmission Owner avoids vegetation-to-wire conflicts under all Rated Electrical Operating Conditions. See Figure 1 for an illustration of possible conductor locations.

~~**Rationale**~~

~~Provide a basis for evaluation on the intent and competency of the Transmission Owner in maintaining vegetation. There may be many acceptable approaches to maintain clearances. However, the Transmission Owner should be able to state what its approach is and how it conducts work to maintain clearances. See Figure 1 for an illustration of possible conductor locations.~~

M3. The maintenance strategies or procedures~~,~~ or processes~~,~~ or specifications provided demonstrate that the Transmission Owner can prevent encroachment into the MVCD considering the factors identified in the requirement. (R3)

R4. Each Transmission Owner, without any intentional time delay, shall notify the control center holding switching authority for the associated applicable transmission line when ~~qualified personnel confirm~~the Transmission Owner has confirmed the existence of a vegetation condition that is likely to cause a Fault at any moment.

[VRF – Medium] [Time Horizon – Real-time]

~~**Rationale**~~

~~To ensure expeditious communication between qualified field personnel and proper operating personnel when a critical situation is confirmed. Qualified field personnel may include lineworkers and utility arborists.~~

M4. Each Transmission Owner that has a confirmed vegetation condition likely to cause a Fault at any moment~~, as confirmed by qualified personnel,~~ will have evidence that it notified the control center holding switching authority for the associated transmission line without any intentional time delay. Examples of evidence may include control center logs, voice recordings, switching orders, clearance orders and subsequent work orders. (R4)

R5. ~~Each~~When a Transmission Owner ~~shall take corrective action when it~~ is constrained from performing ~~planned~~ vegetation work, ~~where a transmission line is put at potential risk due to~~ and the constraint may lead to a vegetation encroachment into the MVCD of its applicable transmission lines prior to the implementation of the next annual work plan then the Transmission Owner shall take corrective action to ensure continued vegetation management to prevent encroachments.

[VRF – Medium] [Time Horizon – Operations Planning]

M5. Each Transmission Owner has evidence of the corrective action taken for each constraint where ~~a~~an applicable transmission line was put at potential risk. Examples of acceptable forms of evidence may include initially-planned work orders, documentation of constraints from landowners, court orders, inspection records of increased monitoring, documentation of the de-rating of lines, revised work orders, invoices, and evidence that a line was de-energized. (R5)

Rationale

Legal actions and other events may occur which result in constraints that prevent the Transmission Owner from performing planned vegetation maintenance work.

In cases where the transmission line is put at potential risk due to constraints, the intent is for the Transmission Owner to put interim measures in place, rather than do nothing.

The corrective action process is intended to

~~**Rationale**~~

~~Legal actions and other events may occur which result in constraints that prevent the Transmission Owner from performing planned vegetation maintenance work.~~

~~In cases where the transmission line is put at potential risk due to constraints, the intent is for the Transmission Owner to put interim measures in place, rather than do nothing.~~

~~For example, in the 2003 NE blackout a Transmission Owner was prevented by a court order from performing planned work. However, when the court order expired, the TO failed to take action to maintain the vegetation resulting in a sustained outage that contributed to the cascade.~~

~~The corrective action process is not intended to address situations where a planned work methodology cannot be performed but an alternate work methodology can be used.~~

R6. Each Transmission Owner shall perform a Vegetation Inspection of ~~all~~100% of its applicable transmission lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.) at least once per calendar year~~.~~ and with no more than 18 months between inspections on the same ROW.[4]

Rationale

Inspections are used by Transmission Owners to assess the condition of the entire ROW. The information from the assessment can be used to determine risk, determine future work and evaluate recently-completed work. This requirement sets a minimum Vegetation Inspection frequency of once per calendar year~~.~~ but with no more than 18 months between inspections on the same ROW. Based upon average growth rates across North America and on common utility practice, this minimum frequency is reasonable. Transmission Owners should consider local and environmental factors that could warrant more frequent inspections.

[4] When the Transmission Owner is prevented from performing a [...] due to a natural disaster, the TO is granted a time extension that i[...] prevented from performing the Vegetation Inspection.

[VRF – Medium] [Time Horizon – Operations Planning]

~~*[VRF – Medium] [Time Horizon – Operations Planning]*~~

M6. Each Transmission Owner has evidence that it conducted Vegetation Inspections ~~at least once per calendar year~~ of the transmission line ROW for all applicable transmission lines at least once per calendar year but with no more than 18 months between inspections on the same ROW. Examples of acceptable forms of evidence may include completed and dated work orders, dated invoices, or dated inspection records. (R6)

R7. Each Transmission Owner shall complete ~~the work in an~~100% of its annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made ~~and documented (~~provided they do not put the transmission system at risk of a vegetation encroachment~~.~~) and must be documented. The percent completed calculation is based on the number of units actually completed divided by the number of units in the final amended plan (measured in units of choice - circuit, pole line, line miles or kilometers, etc.) Examples of reasons for modification to annual plan may include:

~~**Rationale**~~
~~This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. An annual vegetation work plan allows for work to be modified for changing conditions, taking into consideration anticipated growth of vegetation and all other environmental factors, provided that the changes do not violate the encroachment within the MVCD.~~

- Change in expected growth rate/ environmental factors
- ~~Major storms~~
- Circumstances that are beyond the control of a Transmission Owner[5]
- Rescheduling work between growing seasons
- Crew or contractor availability/ Mutual assistance agreements
- Identified unanticipated high priority work
- Weather conditions/Accessibility
- Permitting delays
- Land ownership changes/Change in land use by the landowner
- ~~Funding adjustments (increase or decrease)~~
- Emerging technologies

[VRF – Medium] [Time Horizon – Operations Planning]

[5] Circumstances that are beyond the control of a Transmission Owner include but are not limited to natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, major storms as defined either by the TO or an applicable regulatory body, ice storms, and floods; arboricultural, horticultural or agricultural activities.

~~*[VRF – Medium] [Time Horizon – Operations Planning]*~~

M7. Each Transmission Owner has evidence that it completed its annual vegetation work plan. Examples of acceptable forms of evidence may include a copy of the completed annual work plan (including modifications if any), dated work orders, dated invoices, or dated inspection records. (R7)

Compliance

Compliance Enforcement Authority

- Regional Entity

Compliance Monitoring and Enforcement Processes:

- Compliance Audits
- Self-Certifications
- Spot Checking
- Compliance Violation Investigations
- Self-Reporting
- Complaints
- Periodic Data Submittals

Evidence Retention

The Transmission Owner retains data or evidence ~~of~~to show compliance with Requirements R1~~ through~~, R2, R3, R5, R6 and R7, Measures M1~~ through~~, M2, M3, M5, M6 and M7 for three calendar years ~~to show compliance~~unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

The Transmission Owner retains data or evidence to show compliance with Requirement R4, Measure M4 for most recent 12 months of operator logs or most recent 3 months of voice recordings or transcripts of voice recordings, unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

If a Transmission Owner is found non-compliant, it shall keep information related to the non-compliance until found compliant~~,~~ or for the ~~duration~~time period specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

Additional Compliance Information

Periodic Data Submittal: The Transmission Owner will submit a quarterly report to its Regional Entity, or the Regional Entity's designee, identifying all Sustained Outages of applicable transmission lines determined by the Transmission Owner to have been caused by vegetation~~ that~~, except as excluded in footnote 2, which includes~~,~~ as a minimum, the following:

- o The name of the circuit(s), the date, time and duration of the outage; the voltage of the circuit; a description of the cause of the outage; the category associated with the Sustained Outage; other pertinent comments; and any countermeasures taken by the Transmission Owner.

A Sustained Outage is to be categorized as one of the following:

- o Category 1A — Grow-ins: Sustained Outages caused by vegetation growing into applicable transmission lines, that are identified as an element of an IROL or

Major WECC Transfer Path, by vegetation inside and/or outside of the ~~active transmission line~~ ROW;

- Category 1B — Grow-ins: Sustained Outages caused by vegetation growing into applicable transmission lines, but are not identified as an element of an IROL or Major WECC Transfer Path, by vegetation inside and/or outside of the ~~active transmission line~~ ROW;
- Category ~~2~~2A — Fall-ins: Sustained Outages caused by vegetation falling into applicable transmission lines that are identified as an element of an IROL or Major WECC Transfer Path, from within the ~~active transmission line~~ ROW;
- Category[6] ~~4~~ 2B — Fall-ins: Sustained Outages caused by vegetation falling into applicable transmission lines, but are not identified as an element of an IROL or Major WECC Transfer Path, from within the ROW;
- Category 3 — Fall-ins: Sustained Outages caused by vegetation falling into applicable transmission lines from outside the ROW;
- Category 4A — Blowing together: Sustained Outages caused by vegetation and applicable transmission lines that are identified as an element of an IROL or Major WECC Transfer Path, blowing together from within the ~~active transmission line~~ROW.
- Category 4B — Blowing together: Sustained Outages caused by vegetation and applicable transmission lines, but are not identified as an element of an IROL or Major WECC Transfer Path, blowing together from within the ROW.

The Regional Entity will report the outage information provided by Transmission Owners, as per the above, quarterly to NERC, as well as any actions taken by the Regional Entity as a result of any of the reported Sustained Outages.

[6] ~~Category 3 reporting is eliminated.~~

~~At the request of the Standards Committee, stakeholders are asked to review and comment on the proposed VSLs for R1 and R2. Following the comment period and nonbinding poll, only one set of VSLs will move forward for R1 and R2.~~

~~Guidelines~~Guideline and Technical Basis

Requirements R1 and R2:
R1 and R2 are performance-based requirements. The reliability objective or outcome to be achieved is the prevention of vegetation encroachments within a minimum distance of transmission lines. Content-wise, R1 and R2 are the same requirements; however, they apply to different Facilities. Both R1 and R2 require each Transmission Owner to ~~prevent~~manage vegetation ~~from encroaching~~to prevent encroachment within the Minimum Vegetation Clearance Distance ("MVCD") of transmission lines. R1 is applicable to lines "identified as an element of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions) to avoid a Sustained Outage". R2 applies to all other applicable lines that are not an element of an IROL or Major WECC Transfer Path.

The separation of applicability (between R1 and R2) recognizes that an encroachment into the MVCD of an IROL or Major WECC Transfer Path transmission line is a greater risk to the electric transmission system. Applicable lines that are not an element of an IROL or Major WECC Transfer Path are required to be clear of vegetation but these lines are comparatively less operationally significant. As a reflection of this difference in risk impact, the Violation Risk Factors (VRFs) are assigned as High for R1 and Medium for R2.

These requirements (R1 and R2) state that if vegetation encroaches within the distances ~~prescribed~~ in Table 1 in Appendix 1 of this supplemental Transmission Vegetation Management Standard FAC-003-2 Technical Reference document, it is in violation of the standard. Table 2 ~~delineates~~tabulates the distances necessary to prevent spark-over based on the Gallet equations as described more fully in ~~a supplemental *Transmission Vegetation Management Standard FAC-003-2 Technical Reference*.~~Appendix 1 below.

These requirements assume that transmission lines and their conductors are operating within their Rating. If a line conductor is intentionally or inadvertently operated beyond its Rating (potentially in violation of other standards), the occurrence of a clearance encroachment may occur. For example, emergency actions taken by a Transmission Operator or Reliability Coordinator to protect an Interconnection may cause the transmission line to sag more and come closer to vegetation, potentially causing an outage. Such vegetation-related outages are not a violation of these requirements.

Evidence of violation of Requirement R1 and R2 include real-time observation of a vegetation encroachment into the MVCD (absent a Sustained Outage), or a vegetation-related encroachment resulting in a Sustained Outage due to a fall-in from inside the ~~active transmission line~~ ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to blowing together of applicable lines and vegetation located inside the ~~active transmission line~~ ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to a grow-in. If an investigation of a Fault by a ~~qualified person~~Transmission Owner confirms that a vegetation encroachment within the MVCD occurred, then it shall be considered the equivalent of a Real-time observation.

With this approach, the VSLs were defined such that they directly correlate to the severity of a failure of a Transmission Owner to ~~keep~~manage vegetation ~~away from conductors~~ and to the corresponding performance level of the Transmission Owner's vegetation program's ability to meet the goal of "preventing a Sustained Outage that could lead to Cascading." Thus violation severity increases with a Transmission Owner's inability to meet this goal and its potential of leading to a Cascading event. The additional benefits of such a combination are that it simplifies the standard and clearly defines performance for compliance. A performance-based requirement of this nature will promote high quality, cost effective vegetation management programs that will deliver the overall end result of improved reliability to the system.

Multiple Sustained Outages on an individual line can be caused by the same vegetation~~,~~. For example, a limb ~~that~~may only partially ~~breaks~~break and intermittently ~~contacts~~contact a conductor. Such events are considered to be a single vegetation-related Sustained Outage under the Standard where the Sustained Outages occur within a 24 hour period.

The MVCD is a calculated minimum distance stated in feet (or meters) to prevent spark-over, for various altitudes and operating voltages that is used in the design of Transmission Facilities. Keeping vegetation from entering this space will ~~help~~ prevent transmission outages.

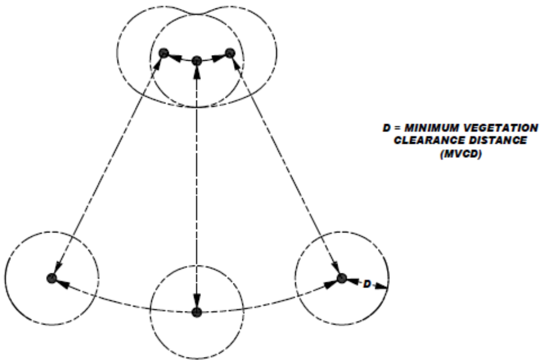
Requirement R3:
Requirement R3 is a competency based requirement concerned with the maintenance strategies, procedures, processes, or specifications, a Transmission Owner uses for vegetation management.

An adequate transmission vegetation management program formally establishes the approach the Transmission Owner uses to plan and perform vegetation work to prevent transmission Sustained Outages and minimize risk to the Transmission System. The approach provides the basis for evaluating the intent, allocation of appropriate resources and the competency of the Transmission Owner in managing vegetation. There are many acceptable approaches to manage vegetation and avoid Sustained Outages. However, the Transmission Owner must be able to state what its approach is and how it conducts work to maintain clearances.

An example of one approach commonly used by industry is ANSI Standard A300, part 7. However, regardless of the approach a utility uses to manage vegetation, any approach a Transmission Owner chooses to use will generally contain the following elements:

1. *the maintenance strategy used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that MVCD clearances are never violated.*
2. *the work methods that the Transmission Owner uses to control vegetation*
3. *a stated Vegetation Inspection frequency*
4. *an annual work plan*

The conductor's position in space at any point in time is continuously changing as a reaction to a number of different loading variables. Changes in vertical and horizontal conductor positioning are the result of thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation. Physical loading applied to the conductor affects sag and sway by combining physical factors such as ice and wind loading. The movement of the transmission line conductor and the MVCD is illustrated in Figure 1 below.



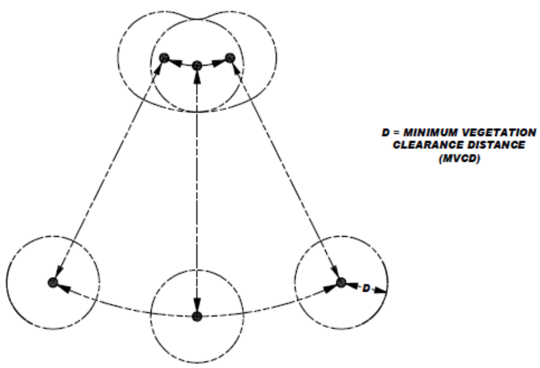


Figure 1
Cross-section view of a single conductor at a given point along the span showing six possible conductor positions due to movement resulting from thermal and mechanical loading.

Requirement R4:
R4 is a risk-based requirement. It focuses on preventative actions to be taken by the Transmission Owner for the mitigation of Fault risk when a vegetation threat is confirmed. R4 involves the notification of potentially threatening vegetation conditions, without any intentional delay, to the control center holding switching authority for that specific transmission line. Examples of acceptable unintentional delays may include communication system problems (for example, cellular service or two-way radio disabled), crews located in remote field locations with no communication access, delays due to severe weather, etc.

Confirmation is key that a threat actually exists due to vegetation. This confirmation could be in the form of a ~~qualified~~Transmission Owner's employee who personally identifies such a threat in the field. Confirmation could also be made by sending out ~~a qualified person~~an employee to evaluate a situation reported by a landowner~~ or an unqualified employee~~.

Vegetation-related conditions that warrant a response include vegetation that is near or encroaching into the MVCD (a grow-in issue) or vegetation that could fall into the transmission conductor (a fall-in issue). A knowledgeable verification of the risk would include an assessment of the possible sag or movement of the conductor while operating between no-load conditions and its rating.

The Transmission Owner has the responsibility to ensure the proper communication between field personnel and the control center to allow the control center to take the appropriate action until the vegetation threat is relieved. Appropriate actions may include a temporary reduction in the line loading, switching the line out of service, or positioning the system in recognition of the increasing risk of outage on that circuit. The notification of the threat should be communicated in terms of minutes or hours as opposed to a longer time frame for corrective action plans (see R5).

All potential grow-in or fall-in vegetation-related conditions will not necessarily cause a Fault at any moment. For example, some Transmission Owners may have a danger tree identification program that identifies trees for removal with the potential to fall near the line. These trees would not require notification to the control center unless they pose an immediate fall-in threat.

Requirement R5:
R5 is a risk-based requirement. It focuses upon preventative actions to be taken by the Transmission Owner for the mitigation of Sustained Outage risk when temporarily constrained from performing vegetation maintenance. The intent of this requirement is to deal with situations that prevent the Transmission Owner from performing planned vegetation management work and, as a result, have the potential to put the transmission line at risk. Constraints to performing vegetation maintenance work as planned could result from legal injunctions filed by property owners, the discovery of easement stipulations which limit the Transmission Owner's rights, or other circumstances.

This requirement is not intended to address situations where the transmission line is not at potential risk and the work event can be rescheduled or re-planned using an alternate work methodology. For example, a land owner may prevent the planned use of chemicals on non-threatening, low growth vegetation but agree to the use of mechanical clearing. In this case the Transmission Owner is not under any immediate time constraint for achieving the management objective, can easily reschedule work using an alternate approach, and therefore does not need to take interim corrective action.

However, in situations where transmission line reliability is potentially at risk due to a constraint, the Transmission Owner is required to take an interim corrective action to mitigate the potential risk to the transmission line. A wide range of actions can be taken to address various situations. General considerations include:

- Identifying locations where the Transmission Owner is constrained from performing planned vegetation maintenance work which potentially leaves the transmission line at risk.
- Developing the specific action to mitigate any potential risk associated with not performing the vegetation maintenance work as planned.
- Documenting and tracking the specific action taken for each location.
- In developing the specific action to mitigate the potential risk to the transmission line the Transmission Owner could consider location specific measures such as modifying the inspection and/or maintenance intervals. Where a legal constraint would not allow any vegetation work, the interim corrective action could include limiting the loading on the transmission line.
- The Transmission Owner should document and track the specific corrective action taken at each location. This location may be indicated as one span, one tree or a combination of spans on one property where the constraint is considered to be temporary.

Requirement R6:
R6 is a risk-based requirement. This requirement sets a minimum time period for completing Vegetation Inspections that fits general industry practice. In addition, the fact that Vegetation Inspections can be performed in conjunction with general line inspections further facilitates a Transmission Owner's ability to meet this requirement. However, the Transmission Owner may determine that more frequent inspections are needed to maintain reliability levels, dependent upon such factors as anticipated growth rates of the local vegetation, length of the growing season for the geographical area, limited ~~Active Transmission~~ ROW width, and rainfall amounts. Therefore it is expected that some transmission lines may be designated with a higher frequency of inspections.

The VSL for Requirement R6 has VSL categories ranked by the percentage of the required ROW inspections completed. To calculate the percentage of inspection completion, the Transmission Owner may choose units such as: line miles or kilometers, circuit miles or kilometers, pole line miles, ROW miles, etc.

For example, when a Transmission Owner operates 2,000 miles of 230 kV transmission lines this Transmission Owner will be responsible for inspecting all 2,000 miles of 230 kV transmission lines at least once during the calendar year. If one of the included lines was 100 miles long, and if it was not inspected during the year, then the amount failed to inspect would be 100/2000 = 0.05 or 5%. The "Low VSL" for R6 would apply in this example.

Requirement R7:
R7 is a risk-based requirement. The Transmission Owner is required to implement an annual work plan for vegetation management to accomplish the purpose of this standard. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections

may be made and documented provided they do not put the transmission system at risk. The annual work plan requirement is not intended to necessarily require a “span-by-span”, or even a “line-by-line” detailed description of all work to be performed. It is only intended to require that the Transmission Owner provide evidence of annual planning and execution of a vegetation management maintenance approach which successfully prevents encroachment of vegetation into the MVCD.

The ability to modify the work plan allows the Transmission Owner to change priorities or treatment methodologies during the year as conditions or situations dictate. For example recent line inspections may identify unanticipated high priority work, weather conditions (drought) could make herbicide application ineffective during the plan year, or a major storm could require redirecting local resources away from planned maintenance. This situation may also include complying with mutual assistance agreements by moving resources off the Transmission Owner’s system to work on another system. Any of these examples could result in acceptable deferrals or additions to the annual work plan. Modifications to the annual work plan must always ensure the reliability of the electric Transmission system.

In general, the vegetation management maintenance approach should use the full extent of the Transmission Owner’s easement, fee simple and other legal rights allowed. A comprehensive approach that exercises the full extent of legal rights on the ~~active transmission line~~ ROW is superior to incremental management in the long term because it reduces the overall potential for encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient.

When developing the annual work plan the Transmission Owner should allow time for procedural requirements to obtain permits to work on federal, state, provincial, public, tribal lands. In some cases the lead time for obtaining permits may necessitate preparing work plans more than a year prior to work start dates. Transmission Owners may also need to consider those special landowner requirements as documented in easement instruments.

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. Therefore, deferrals or relevant changes to the annual plan shall be documented. Depending on the planning and documentation format used by the Transmission Owner, evidence of successful annual work plan execution could consist of signed-off work orders, signed contracts, printouts from work management systems, spreadsheets of planned versus completed work, timesheets, work inspection reports, or paid invoices. Other evidence may include photographs, and walk-through reports.

~~Table 3 – Minimum Distance from the Centerline of the Circuit to the edge of the active transmission line ROW~~

Notes:

The SDT determined that the use of IEEE 516-2003 in version 1 of FAC-003 was a misapplication. The SDT consulted specialists who advised that the Gallet Equation would be a technically justified method. The explanation of why the Gallet approach is more appropriate is explained in the paragraphs below.

The drafting team sought a method of establishing minimum clearance distances that uses realistic weather conditions and realistic maximum transient over-voltages factors for in-service transmission lines.

The SDT considered several factors when looking at changes to the minimum vegetation to conductor distances in FAC-003-1:

- avoid the problem associated with referring to tables in another standard (IEEE-516-2003)
- transmission lines operate in non-laboratory environments (wet conditions)
- transient over-voltage factors are lower for in-service transmission lines than for inadvertently re-energized transmission lines with trapped charges.

FAC-003-1 uses the minimum air insulation distance (MAID) without tools formula provided in IEEE 516-2003 to determine the minimum distance between a transmission line conductor and vegetation. The equations and methods provided in IEEE 516 were developed by an IEEE Task Force in 1968 from test data provided by thirteen independent laboratories. The distances provided in IEEE 516 Tables 5 and 7 are based on the withstand voltage of a dry rod-rod air gap, or in other words, dry laboratory conditions. Consequently, the validity of using these distances in an outside environment application has been questioned.

FAC-003-01 allowed Transmission Owners to use either Table 5 or Table 7 to establish the minimum clearance distances. Table 5 could be used if the Transmission Owner knew the maximum transient over-voltage factor for its system. Otherwise, Table 7 would have to be used. Table 7 represented minimum air insulation distances under the worst possible case for transient over-voltage factors. These worst case transient over-voltage factors were as follows: 3.5 for voltages up to 362 kV phase to phase; 3.0 for 500 - 550 kV phase to phase; and 2.5 for 765 to 800 kV phase to phase. These worst case over-voltage factors were also a cause for concern in this particular application of the distances.

In general, the worst case transient over-voltages occur on a transmission line that is inadvertently re-energized immediately after the line is de-energized and a trapped charge is still present. The intent of FAC-003 is to keep a transmission line that is *in service* from becoming de-energized (i.e. tripped out) due to spark-over from the line conductor to nearby vegetation. Thus, the worst case transient overvoltage assumptions are not appropriate for this application. Rather, the appropriate over voltage values are those that occur only while the line is energized.

Typical values of transient over-voltages of in-service lines, as such, are not readily available in the literature because they are negligible compared with the maximums. A conservative value for the maximum transient over-voltage that can occur anywhere along the length of an in-service ac line is approximately 2.0 per unit. This value is a conservative estimate of the transient over-voltage that is created at the point of application (e.g. a substation) by switching a capacitor bank without pre-insertion devices (e.g. closing resistors). At voltage levels where capacitor banks are not very common (e.g. 362 kV), the maximum transient over-voltage of an in-service ac line are created by fault initiation on adjacent ac lines and shunt reactor bank switching. These transient voltages are usually 1.5 per unit or less.

Even though these transient over-voltages will not be experienced at locations remote from the bus at which they are created, in order to be conservative, it is assumed that all nearby ac lines are subjected to this same level of over-voltage. Thus, a maximum transient over-voltage factor of 2.0 per unit for transmission lines operated at 242 kV and below is considered to be a realistic maximum in this application. Likewise, for ac transmission lines operated at 362 kV and above a transient over-voltage factor of 1.4 per unit is considered a realistic maximum.

The Gallet Equations are an accepted method for insulation coordination in tower design. These equations are used for computing the required strike distances for proper transmission line insulation coordination. They were developed for both wet and dry applications and can be used with any value of transient over-voltage factor. The Gallet Equation also can take into account various air gap geometries. This approach was used to design the first 500 kV and 765 kV lines in North America [1].

If one compares the MAID using the IEEE 516-2003 Table 7 (table D.5 for English values) with the critical spark-over distances computed using the Gallet wet equations, for each of the nominal voltage classes and identical transient over-voltage factors, the Gallet equations yield a more conservative (larger) minimum distance value.

Distances calculated from either the IEEE 516 (dry) formulas or the Gallet “wet” formulas are not vastly different when the same transient overvoltage factors are used; the “wet” equations will consistently produce slightly larger distances than the IEEE 516 equations when the same transient overvoltage is used. While the IEEE 516 equations were only developed for dry conditions the Gallet equations have provisions to calculate spark-over distances for both wet and dry conditions.

While EPRI is currently trying to establish empirical data for spark-over distances to live vegetation, there are no spark-over formulas currently derived expressly for vegetation to conductor minimum distances. Therefore the SDT chose a proven method that has been used in other EHV applications.   The Gallet equations relevance to wet conditions and the selection of a Transient Overvoltage Factor that is consistent with the absence of trapped charges on an in-service transmission line make this methodology a better choice.

The following table is an example of the comparison of distances derived from IEEE 516 and the Gallet equations using various transient overvoltage values.

Comparison of spark-over distances computed using Gallet wet equations
vs.
IEEE 516-2003 MAID distances

Implementation Plan for FAC-003-2

Prerequisite Approvals
There are no other Reliability Standards or Standard Authorization Requests (SARs), in progress or approved, that must be implemented before this standard can be implemented.

FAC-003-2 – Vegetation Management

Revision to Sections of Approved Standards and Definitions
There are no proposed revisions to requirements in other already approved standards. There are two revised definitions in the proposed standard. FAC-003-1 will be retired when FAC-003-2 becomes effective.

Compliance with Standard
The standard applies to Transmission Owners.

Effective Date
The effective date is the date entities are expected to meet the performance identified in this standard. The effective date allows entities time to make revisions to their existing transmission vegetation management programs to comply with the new requirements.

First calendar day of the first calendar quarter one year after the date of the order approving the standard from applicable regulatory authorities where such explicit approval is required.

Exceptions:

A line operated below 200kV, designated by the Planning Coordinator as an element of an IROL or as a Major WECC transfer path, becomes subject to this standard 12 months after the date the Planning Coordinator or WECC initially designates the line as being subject to this standard.

An existing transmission line operated at 200kV or higher that is newly acquired by an asset owner and was not previously subject to this standard, becomes subject to this standard 12 months after the acquisition date of the line.

A. Introduction

1. **Title:** **Transmission Vegetation Management Program**

2. **Number:** FAC-003-1

3. **Purpose:** To improve the reliability of the electric transmission systems by preventing outages from vegetation located on transmission rights-of-way (ROW) and minimizing outages from vegetation located adjacent to ROW, maintaining clearances between transmission lines and vegetation on and along transmission ROW, and reporting vegetation-related outages of the transmission systems to the respective Regional Reliability Organizations (RRO) and the North American Electric Reliability Council (NERC).

4. **Applicability:**

   4.1. Transmission Owner.

   4.2. Regional Reliability Organization.

   4.3. This standard shall apply to all transmission lines operated at 200 kV and above and to any lower voltage lines designated by the RRO as critical to the reliability of the electric system in the region.

5. **Effective Dates:**

   5.1. One calendar year from the date of adoption by the NERC Board of Trustees for Requirements 1 and 2.

   5.2. Sixty calendar days from the date of adoption by the NERC Board of Trustees for Requirements 3 and 4.

B. Requirements

R1. The Transmission Owner shall prepare, and keep current, a formal transmission vegetation management program (TVMP). The TVMP shall include the Transmission Owner's objectives, practices, approved procedures, and work specifications[1].

R1.1. The TVMP shall define a schedule for and the type (aerial, ground) of ROW vegetation inspections. This schedule should be flexible enough to adjust for changing conditions. The inspection schedule shall be based on the anticipated growth of vegetation and any other environmental or operational factors that could impact the relationship of vegetation to the Transmission Owner's transmission lines.

R1.2. The Transmission Owner, in the TVMP, shall identify and document clearances between vegetation and any overhead, ungrounded supply conductors, taking into consideration transmission line voltage, the effects of ambient temperature on conductor sag under maximum design loading, and the effects of wind velocities on conductor sway. Specifically, the Transmission Owner shall establish clearances to be achieved at the time of vegetation management work identified herein as Clearance 1, and shall also establish and maintain a set of clearances identified herein as Clearance 2 to prevent flashover between vegetation and overhead ungrounded supply conductors.

R1.2.1. Clearance 1 — The Transmission Owner shall determine and document appropriate clearance distances to be achieved at the time of transmission vegetation management work based upon local conditions and the expected time frame in which the Transmission Owner plans to return for future

[1] ANSI A300, Tree Care Operations – Tree, Shrub, and Other Woody Plant Maintenance – Standard Practices, while not a requirement of this standard, is considered to be an industry best practice.

vegetation management work. Local conditions may include, but are not limited to: operating voltage, appropriate vegetation management techniques, fire risk, reasonably anticipated tree and conductor movement, species types and growth rates, species failure characteristics, local climate and rainfall patterns, line terrain and elevation, location of the vegetation within the span, and worker approach distance requirements. Clearance 1 distances shall be greater than those defined by Clearance 2 below.

R1.2.2. Clearance 2 — The Transmission Owner shall determine and document specific radial clearances to be maintained between vegetation and conductors under all rated electrical operating conditions. These minimum clearance distances are necessary to prevent flashover between vegetation and conductors and will vary due to such factors as altitude and operating voltage. These Transmission Owner-specific minimum clearance distances shall be no less than those set forth in the Institute of Electrical and Electronics Engineers (IEEE) Standard 516-2003 (*Guide for Maintenance Methods on Energized Power Lines*) and as specified in its Section 4.2.2.3, Minimum Air Insulation Distances without Tools in the Air Gap.

R1.2.2.1 Where transmission system transient overvoltage factors are not known, clearances shall be derived from Table 5, IEEE 516-2003, phase-to-ground distances, with appropriate altitude correction factors applied.

R1.2.2.2 Where transmission system transient overvoltage factors are known, clearances shall be derived from Table 7, IEEE 516-2003, phase-to-phase voltages, with appropriate altitude correction factors applied.

R1.3. All personnel directly involved in the design and implementation of the TVMP shall hold appropriate qualifications and training, as defined by the Transmission Owner, to perform their duties.

R1.4. Each Transmission Owner shall develop mitigation measures to achieve sufficient clearances for the protection of the transmission facilities when it identifies locations on the ROW where the Transmission Owner is restricted from attaining the clearances specified in Requirement 1.2.1.

R1.5. Each Transmission Owner shall establish and document a process for the immediate communication of vegetation conditions that present an imminent threat of a transmission line outage. This is so that action (temporary reduction in line rating, switching line out of service, etc.) may be taken until the threat is relieved.

R2. The Transmission Owner shall create and implement an annual plan for vegetation management work to ensure the reliability of the system. The plan shall describe the methods used, such as manual clearing, mechanical clearing, herbicide treatment, or other actions. The plan should be flexible enough to adjust to changing conditions, taking into consideration anticipated growth of vegetation and all other environmental factors that may have an impact on the reliability of the transmission systems. Adjustments to the plan shall be documented as they occur. The plan should take into consideration the time required to obtain permissions or permits from landowners or regulatory authorities. Each Transmission Owner shall have systems and procedures for documenting and tracking the planned vegetation management work and ensuring that the vegetation management work was completed according to work specifications.

R3. The Transmission Owner shall report quarterly to its RRO, or the RRO's designee, sustained transmission line outages determined by the Transmission Owner to have been caused by vegetation.

R3.1. Multiple sustained outages on an individual line, if caused by the same vegetation, shall be reported as one outage regardless of the actual number of outages within a 24-hour period.

R3.2. The Transmission Owner is not required to report to the RRO, or the RRO's designee, certain sustained transmission line outages caused by vegetation: (1) Vegetation-related outages that result from vegetation falling into lines from outside the ROW that result from natural disasters shall not be considered reportable (examples of disasters that could create non-reportable outages include, but are not limited to, earthquakes, fires, tornados, hurricanes, landslides, wind shear, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods), and (2) Vegetation-related outages due to human or animal activity shall not be considered reportable (examples of human or animal activity that could cause a non-reportable outage include, but are not limited to, logging, animal severing tree, vehicle contact with tree, arboricultural activities or horticultural or agricultural activities, or removal or digging of vegetation).

R3.3. The outage information provided by the Transmission Owner to the RRO, or the RRO's designee, shall include at a minimum: the name of the circuit(s) outaged, the date, time and duration of the outage; a description of the cause of the outage; other pertinent comments; and any countermeasures taken by the Transmission Owner.

R3.4. An outage shall be categorized as one of the following:

R3.4.1. Category 1 — Grow-ins: Outages caused by vegetation growing into lines from vegetation inside and/or outside of the ROW;

R3.4.2. Category 2 — Fall-ins: Outages caused by vegetation falling into lines from inside the ROW;

R3.4.3. Category 3 — Fall-ins: Outages caused by vegetation falling into lines from outside the ROW.

R4. The RRO shall report the outage information provided to it by Transmission Owner's, as required by Requirement 3, quarterly to NERC, as well as any actions taken by the RRO as a result of any of the reported outages.

C. Measures

M1. The Transmission Owner has a documented TVMP, as identified in Requirement 1.

M1.1. The Transmission Owner has documentation that the Transmission Owner performed the vegetation inspections as identified in Requirement 1.1.

M1.2. The Transmission Owner has documentation that describes the clearances identified in Requirement 1.2.

M1.3. The Transmission Owner has documentation that the personnel directly involved in the design and implementation of the Transmission Owner's TVMP hold the qualifications identified by the Transmission Owner as required in Requirement 1.3.

M1.4. The Transmission Owner has documentation that it has identified any areas not meeting the Transmission Owner's standard for vegetation management and any mitigating measures the Transmission Owner has taken to address these deficiencies as identified in Requirement 1.4.

M1.5. The Transmission Owner has a documented process for the immediate communication of imminent threats by vegetation as identified in Requirement 1.5.

M2. The Transmission Owner has documentation that the Transmission Owner implemented the work plan identified in Requirement 2.

M3. The Transmission Owner has documentation that it has supplied quarterly outage reports to the RRO, or the RRO's designee, as identified in Requirement 3.

M4. The RRO has documentation that it provided quarterly outage reports to NERC as identified in Requirement 4.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

RRO

NERC

1.2. Compliance Monitoring Period and Reset

One calendar Year

1.3. Data Retention

Five Years

1.4. Additional Compliance Information

The Transmission Owner shall demonstrate compliance through self-certification submitted to the compliance monitor (RRO) annually that it meets the requirements of NERC Reliability Standard FAC-003-1. The compliance monitor shall conduct an on-site audit every five years or more frequently as deemed appropriate by the compliance monitor to review documentation related to Reliability Standard FAC-003-1. Field audits of ROW vegetation conditions may be conducted if determined to be necessary by the compliance monitor.

2. Levels of Non-Compliance

2.1. Level 1:

2.1.1. The TVMP was incomplete in one of the requirements specified in any subpart of Requirement 1, or;

2.1.2. Documentation of the annual work plan, as specified in Requirement 2, was incomplete when presented to the Compliance Monitor during an on-site audit, or;

2.1.3. The RRO provided an outage report to NERC that was incomplete and did not contain the information required in Requirement 4.

2.2. Level 2:

2.2.1. The TVMP was incomplete in two of the requirements specified in any subpart of Requirement 1, or;

2.2.2. The Transmission Owner was unable to certify during its annual self-certification that it fully implemented its annual work plan, or documented deviations from, as specified in Requirement 2.

2.2.3. The Transmission Owner reported one Category 2 transmission vegetation-related outage in a calendar year.

2.3. Level 3:

2.3.1. The Transmission Owner reported one Category 1 or multiple Category 2 transmission vegetation-related outages in a calendar year, or;

2.3.2. The Transmission Owner did not maintain a set of clearances (Clearance 2), as defined in Requirement 1.2.2, to prevent flashover between vegetation and overhead ungrounded supply conductors, or;

2.3.3. The TVMP was incomplete in three of the requirements specified in any subpart of Requirement 1.

2.4. Level 4:

2.4.1. The Transmission Owner reported more than one Category 1 transmission vegetation-related outage in a calendar year, or;

2.4.2. The TVMP was incomplete in four or more of the requirements specified in any subpart of Requirement 1.

E. Regional Differences

None Identified.

Version History

Version	Date	Action	Change Tracking
Version 1	TBA	1. Added “Standard Development Roadmap.” 2. Changed “60” to “Sixty” in section A, 5.2. 3. Added “Proposed Effective Date: April 7, 2006” to footer. 4. Added “Draft 3: November 17, 2005” to footer.	01/20/06

Unofficial Comment Form for 5th Draft of FAC-003-2 Transmission Vegetation Management —Project 2007-07 Vegetation Management

Please **DO NOT** use this form to submit comments. Please use the electronic form located at the site below to submit comments on the 5th Draft of FAC-003-2 Transmission Vegetation Management. Comments must be submitted by February 28, 2011.

If you have questions please contact Doug Keegan or by telephone at 404-446-2576.

Draft 5 Information

On November 4, 2010 NERC staff provided a Quality Review of FAC-003-2 to the Standards Committee (SC). In November, 2010 the SC requested the VMSDT to work with NERC staff in addressing the items identified in the Quality Review, and approved posting of the revised documents. The SDT conducted several conference calls and acted in good faith to produce this Draft 5 of FAC-003-2. The VMSDT considered the feedback provided in the Quality Review by NERC staff and reached consensus in the following areas:

1. Elaborated upon the Purpose Statement to encompass more of the standard's content.
2. Added a Rationale text box to the 4.2 Facilities section, to explain the exclusion of substation facilities. Clarified 4.2.4 by adding specific boundary details.
3. Updated Requirement R1 and R2 to emphasize the "planning" time horizon as the applicable temporal context.
4. Elaborated upon the explanation in the Rationale text boxes for R1 and R2, to highlight the range of non-compliant performance.
5. Re-organized the content of Requirement R3 for improved readability.
6. Augmented Requirement R5 to include a "reliability objective."
7. Modified Requirement R6 and the associated VSLs for improved enforceability and for consistency in the units of measure between the Requirement and the associated VSLs.
8. Modified Requirement R7 and the associated VSLs for improved enforceability and for consistency in the units of measure between the Requirement and the associated VSLs.
9. Updated the Evidence Retention section in accordance with current guidelines.

Modification incorporated into this Draft 5 of FAC-003-2 in response to stakeholder comments include:

A. Removed reference to Active Transmission Line ROW.
B. Redefined the Glossary term for ROW to address Paragraph 734 of FERC Order 693 addressing the width of ROW to be maintained.
C. Redefined the Glossary term for Vegetation Inspection to include identifying hazards to the line inside the ROW.
D. Included the term referred to as "applicable lines" under 4.2 Facilities.
E. Removed 4.4 addressing "force majeure" under Applicability to Footnotes 2, 3 and 4.
F. In R1./R2 – M1/M2
   - Added reference "into the MVCD" into the text.

- Eliminated "types of encroachment" and added "The four types of failure to manage vegetation, in order of increasing severity."
- In M1/M2 Added a paragraph defining "later confirmation of a Fault by the TO as a real-time observation."
- Added Footnote 2
- Added to the Rationale box types of failures to manage vegetation.

G. In R4. Changed "qualified personnel" to TO.

H. In R5. Added the term "is constrained from performing vegetation work" and referenced MVCD.
   - Removed reference to 2003 NE blackout from Rationale box

I. In R6. added the phrase " but no more than 18 months between inspections" also added Footnote 3.

J. In R7. Replaced major storms bullet with "circumstances that are beyond the control of a Transmission Owner". Added Footnote 4 to this requirement.

K. In Additional Compliance Information
   - Category 2 was split into two parts recognizing IROL's and Major WECC Transfer Paths
   - Added Category 3 for Fall-ins from outside the ROW.
   - Category 4 was split into two parts recognizing IROL's and Major WECC Transfer Paths

L. Removed alternate versions of VSL's for R1./R2.

M. Deleted Table 3 from the Guidelines and Technical Basis section

Background Information

The purpose of Project 2007-07 Vegetation Management is to:

- Assist in providing an adequate level of reliability for the North American electric Transmission System by verifying that the FAC-003-2 Transmission Vegetation Management standard is complete and that its requirements are set at an appropriate level to ensure reliability.

- Incorporate other general improvements described in the Standard Review Guidelines to bring FAC-003-2 Transmission Vegetation Management into conformance with the latest version of the Reliability Standards Development Procedure and the ERO Sanctions Guidelines.

- Consider comments received from ERO regulatory authorities and stakeholders on FAC-003-1 Transmission Vegetation Management as noted in the NERC Standards Issues Database.

- Satisfy the requirement for review of FAC-003-2 Transmission Vegetation Management within five-year review cycle.

In addition, on January 14, 2010, the NERC Standards Committee endorsed the use of Project 2007-07 Vegetation Management as the prototype for the proof-of-concept for using the results-based criteria for developing a reliability standard. The results-based initiative is intended to focus the collective effort of NERC and industry participants on improving the clarity and quality of NERC reliability standards by developing performance-based, risk-based and competency-based requirements that accomplish a reliability objective through a defense-in-depth strategy, while eliminating documentation-driven requirements that do not have an impact on bulk power system reliability.

The Standards Committee also directed the standard drafting team for Project 2007-07 Vegetation Management to do so with a target for final industry ballot of draft FAC-003-2 Transmission Vegetation Management by August 31, 2010.

The criteria for developing a results-based reliability standard include:

1. Strive to achieve a portfolio of performance-based, risk-based, and competency-based mandatory reliability requirements that provide an effective defense-in-depth strategy for achieving an adequate level of reliability of the bulk power system.

    a) **Performance-based** — defines a particular reliability objective or outcome to be achieved. In its simplest form, a results-based requirement has four components: *who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome*?

    b) **Risk-based** — preventive requirements to reduce the risks of failure to acceptable tolerance levels. A risk-based reliability requirement should be framed as: *who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome <u>that reduces a stated risk to the reliability of the bulk power system</u>?*

    c) **Competency-based** — defines a minimum capability an entity needs to have to demonstrate it is able to perform its designated reliability functions.

2. The defense-in-depth strategy for reliability standards development should recognize that each requirement in a NERC reliability standard has a role in preventing system failures, and that these roles are complementary and reinforcing. Reliability standards should not be viewed as a body of unrelated requirements, but rather should be viewed as part of a portfolio of requirements designed to achieve an overall defense-in-depth strategy and comport with the quality objectives of a reliability standard.

3. Each requirement should identify a clear and measurable expected outcome, such as: i) a stated level of reliability performance, ii) a reduction in a specified reliability risk, or iii) a necessary competency.

4. Strive to minimize prescriptive, administrative (document something), and commercial requirements within the set of NERC reliability standards (i.e., these types of requirements are permissible in standards but should be the exception rather than the rule).

5. A requirement should not prescribe commercial business practices which do not contribute directly to reliability.

The Vegetation Management Standard Drafting Team worked with Ivy Hooks of Compliance Automation, Inc. to apply the "results-based" approach to developing requirements that are clear and enforceable. Ivy is the CEO of Compliance Automation and has shared a wealth of knowledge and expertise with the drafting team. The "look and feel" of the proposed standard contains much more information than we have been including in previous standards, thus the look and feel of the draft FAC-003-2 Transmission Vegetation Management standard is quite different from the look of our existing standards. One of the more obvious changes is the addition of information to aid end users in reading the requirements from a common understanding of the standard's objective and the rationale for including each requirement. During the Three-year Performance Assessment, stakeholders indicated that they wanted more information to assist in applying standards – and the additional details provided in the proposed Vegetation Management standard provide an example of one way to fill that void.

On February 11, 2010 the Standards Committee authorized the standard drafting team for Project 2007-07 Vegetation Management to take the following actions relative to the development of draft FAC-003-2 Transmission Vegetation Management:

- Discontinue work in developing a complete Consideration of Comments Report for the comments received in response to the posting of the second draft of the draft FAC-003-2 Transmission Vegetation Management standard that was posted in August 2009; however, post the comments received along with a summary of the actions taken by the team in response to those comments but without an individual response to each comment provided.
- Use informal comment periods to collect comments on future "drafts" of the standard, post the comments received during the informal comment periods along with a summary of how the team used the comments received and a redline version of the standard showing the changes made based on the comments received.
- Conduct a 45-day formal comment period in parallel with the formation of the ballot pool and the initial ballot of the standard; post the comments from the formal comment period as they are received for at least the first 30 days of the comment period.
- Use a standard template that is different from the template stipulated in the Reliability Standard Development Procedure as provided by the Standards Committee's Process Subcommittee.

With respect to the first bullet above, that work was completed with the March 1, 2010 posting. With respect to the second bullet above, this current posting is the second informal posting for comments, and the current plans are for the next posting to be a formal posting. A summary of the SDT considerations for the responses to the March 1, 2010 submittal has been posted on the NERC website in lieu of a full Consideration of Comments Report.

The following questions will assist the SDT in finalizing the development of FAC-003-2 Transmission Vegetation Management. For questions where you agree with indicated statement, please state that you agree. If you disagree with the statement, please explain why you disagree and provide a rationale, or alternate language, to support your position. We would appreciate answers to as many of the following questions as possible.

1. The SDT proposes a revised NERC Glossary definition for Right-of-Way (ROW). This revised definition will be used in lieu of the Active Transmission Line ROW. Do you agree? If answer is no, please explain.

   ☐ Yes
   ☐ No
   Comments:

2. In R1 and R2 and their associated VSLs, the SDT added the phrase *"in order of increasing severity"* and added the sentence, *"The types of encroachments are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a TO's vegetation maintenance program."* to the Rationale boxes for R1/R2. Do you agree? If answer is no, please explain.

   ☐ Yes

☐ No

Comments:

3. In response to comments received regarding t*he term "investigation" in M1/M2,* the SDT substituted *"confirmation…by the Transmission Owner..." in its place, among other minor edits to these measures.* Do you agree? If answer is no, please explain.

☐ Yes

☐ No

Comments:

4. In response to comments received that requirement R3 is unclear with respect to intent, the SDT added "maintenance strategies." Do you agree this clarifies the intent? If answer is no, please offer alternative language.

☐ Yes

☐ No

Comments:

5. The SDT added clarifying language in M7 to explain how the annual work plan percentage complete calculation is to be performed. Is this adequate? If no, please provide improved examples.

☐ Yes

☐ No

Transmission Vegetation Management
Standard FAC-003-2 Technical Reference

Prepared by the

North American Electric Reliability Corporation

Vegetation Management Standard Drafting Team

December 17, 2010

Introduction

This document is intended to provide supplemental information and guidance for complying with the requirements of Reliability Standard FAC-003-2.

The purpose of the Standard is to improve the reliability of the electric transmission system by preventing those vegetation related outages that could lead to Cascading.

Compliance with the Standard is mandatory and enforceable.

Special Note: The Application of Results-Based Approach to FAC-003-2

In its three-year assessment as the ERO, NERC acknowledged stakeholder comments and committed to:

i) addressing quality issues to ensure each reliability standard has a clear statement of purpose, and has outcome-focused requirements that are clear and measurable; and
ii) eliminating requirements that do not have an impact on bulk power system reliability.

In 2010, the Standards Committee approved a recommendation to use Project 2007-07 Vegetation Management as a first proof of concept for developing results-based standards.

The Standard Drafting Team (SDT) employed a defense-in-depth[1] strategy for FAC-003-2, where each requirement has a role in preventing those vegetation related outages that could lead to Cascading. This portfolio of requirements was designed to achieve an overall defense-in-depth strategy and to comply with the quality objectives identified in the *Acceptance Criteria of a Reliability Standard* document.

The SDT developed a portfolio of performance, risk, and competency-based mandatory reliability requirements to support an effective defense-in-depth strategy. Each Requirement was developed using one of the following requirement types:

a) Performance-based - defines a particular reliability objective or outcome to be achieved. In its simplest form, a results-based requirement has four components: who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome?
b) Risk-based - preventive requirements to reduce the risks of failure to acceptable tolerance levels. A risk-based reliability requirement should be framed as: who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome that reduces a stated risk to the reliability of the bulk power system?
c) Competency-based - defines a minimum set of capabilities an entity needs to have to demonstrate it is able to perform its designated reliability functions. A competency-based reliability requirement should be framed as: who, under what conditions (if any), shall have what capability, to achieve what particular result or outcome to perform an action to achieve a result or outcome or to reduce a risk to the reliability of the bulk power system?

The drafting team reviewed and edited version 1 of FAC-003-1 to remove prescriptive and administrative language in order to distill the technical requirements down to their

[1] A defense-in-depth strategy for reliability standards recognizes that each requirement in the NERC standards has a role in preventing system failures, and that these roles are complementary and reinforcing. These prevention measures should be arranged in a series of defensive layers or walls. No single defensive layer provides complete protection from failure by itself. But taken together, with well-designed layers including performance, risk, and competency-based requirements, a defense-in-depth approach can be very effective in preventing future large scale power system failures.

essential reliability content. Text that is explanatory in nature is placed in a special section of the standard entitled Guideline and Technical Basis to aid in the understanding of the requirements. Furthermore, Rationale text boxes are inserted alongside each requirement to communicate the foundation for the requirement.

Disclaimer

This supporting document is supplemental to the reliability standard FAC-003-2 — Transmission Vegetation Management and does not contain mandatory requirements subject to compliance review.

Preface

The NERC Vegetation Management Standard Drafting Team (VM SDT) acknowledges those across the industry who contributed to the development of this Standard and companion Technical Reference document. The Technical Reference document is intended to provide supplemental explanatory background and guidance related to requirements contained in the Standard but does not in itself contain requirements subject to compliance review.

The VM SDT believes that a well-designed and executed Transmission Vegetation Management Program (TVMP) will have few problems meeting the requirements of this Standard. While the Standard requires a TVMP to contain certain elements, it allows the Transmission Owner flexibility in designing a TVMP to meet local needs provided it also meets the purpose of the Standard.

While there are many approaches to vegetation management, the VMSDT supports industry best practices contained in ANSI A300 (Part 7) – Integrated Vegetation Management (IVM) practices on Utility Rights-of-way, as well as the companion publication Best Management Practices – Integrated Vegetation Management, as an effective strategy to maintain compliance with this Standard. ANSI A300 (Part 7), approved by industry consensus in 2006, contains many elements needed for an effective TVMP as required by this Standard. One key element is the “wire zone – border zone” concept. Supported by over 50 years of continuous research, wire zone – border zone is a proven method to manage vegetation on transmission rights-of-ways and is an industry accepted best practice to help ensure electric system reliability.

The VM SDT believes that Transmission Owners who adopt and effectively implement IVM principles, particularly the “wire zone – border zone” concept, are far less likely to experience a vegetation caused outage than those who do not.

Definition of Terms

Right-of-Way (ROW)*

The corridor of land under a transmission line(s) needed to operate the line(s). The width of the corridor is established by engineering or construction standards as documented in either construction documents, pre-2007 vegetation maintenance records, or by the blowout standard in effect when the line was built. The ROW width in no case exceeds the Transmission Owner's legal rights but may be less based on the aforementioned criteria.

The current glossary definition of this NERC term is modified to address the issues set forth in Paragraph 734 of FERC Order 693.

The current NERC glossary definition of Right of Way has been modified to address the matter set forth in Paragraph 734 of FERC Order 693. The Order pointed out that Transmission Owners may in some cases own more property or rights than are needed to reliably operate transmission lines. This modified definition represents a slight but significant departure from the strict legal definition of "right of way" in that this definition is based on engineering and construction considerations that establish the width of a corridor from a technical basis.

Vegetation Inspection*

The systematic examination of vegetation conditions on a Right-of-Way and those vegetation conditions under the Transmission Owner's control that are likely to pose a hazard to the line(s) prior to the next planned maintenance or inspection. This may be combined with a general line inspection.

The current glossary definition of this NERC term is modified to allow both maintenance inspections and vegetation inspections to be performed concurrently.

Current definition of Vegetation Inspection: The systematic examination of a transmission corridor to document vegetation conditions.

The inspection includes the identification of any vegetation that may pose a threat to reliability prior to the next planned maintenance or inspection work, considering the current location of the conductor and other possible locations of the conductor due to sag and sway for rated conditions.

This definition allows both maintenance inspections and vegetation inspections to be performed concurrently.

* This is a modification to a defined term in the NERC glossary and will be incorporated into the NERC glossary of terms with final approval of this standard revision

Applicability of the Standard

4. Applicability

4.1. Functional Entities:
Transmission Owners

4.2. Facilities: *Defined below (referred to as "applicable lines"), including but not limited to those that cross lands owned by federal*[1]*, state, provincial, public, private, or tribal entities:*

4.2.1 *Overhead transmission lines operated at 200kV or higher.*
4.2.2 *Overhead transmission lines operated below 200kV having been identified as included in the definition of an Interconnection Reliability Operating Limit (IROL) under NERC Standard FAC 014 by the Planning Coordinator.*
4.2.3 *Overhead transmission lines operated below 200 kV having been identified as included in the definition of one of the Major WECC Transfer Paths in the Bulk Electric System.*
4.2.4 *This standard applies to overhead transmission lines identified above (4.2.1 through 4.2.3) located outside the fenced area of the switchyard, station or substation and any portion of the span of the transmission line that is crossing the substation fence.*

4.3. Enforcement: *The reliability obligations of the applicable entities and facilities are contained within the technical requirements of this standard. [Straw proposal]*

Rationale

-The areas excluded in 4.2.4 were excluded based on comments from industry for reasons summarized as follows: 1) There is a very low risk from vegetation in this area. Based on an informal survey, no TOs reported such an event. 2) Substations, switchyards, and stations have many inspection and maintenance activities that are necessary for reliability. Those existing process manage the threat. As such, the formal steps in this standard are not well suited for this environment. 3) The standard was written for Transmission Owners. Rolling the excluded areas into this standard will bring GO and DP into the standard, even though NERC has an initiative in place to address this bigger registry issue. 4) Specifically addressing the areas where the standard applies or doesn't makes the standard stronger as it relates to clarity.

In Order 693, FERC discussed the 200 kV bright-line test of applicability. While FERC did not change the 200 kV bright line, the Commission remained concerned that there may be some transmission lines operating at lesser voltages that could have significant impact on the Bulk Electric System that should therefore be subject to this standard.

NERC Standard FAC-014 has the stated purpose, "*To ensure that System Operating Limits (SOLs) used in the reliable planning and operation of the Bulk Electric System (BES) are determined based on an established methodology or methodologies.*" FAC-014 requires Reliability Coordinators, Planning Coordinators, and Transmission Planners to have a methodology to identify all lines that might comprise an IROL. Thus, these entities would identify sub-200 kV lines that qualify as part of an IROL and should be subject to FAC-003-2.

[1] EPAct 2005 section 1211c: "*Access approvals by Federal agencies*".

Although all three entities may prepare the list of elements, FAC-003-2 presently does not specify that it is the list from the Planning Coordinator that should be used by Transmission Owners for FAC-003. However, the Time Horizon needed to plan vegetation management work does not lend itself to the operating horizon of a Reliability Coordinator. Additionally, the Planning Coordinator has a wider-area view than the Transmission Planner and could thus identify any elements of importance to a sub-set of its area that might be missed by a Transmission Planner.

Transmission Owners, who do not already get the list of circuits included in the definition of an IROL, can get them from the Planning Coordinator. Specifically R5 of FAC-014 specifies that "*The Reliability Coordinator, Planning Authority (Coordinator) and Transmission Planner shall each provide its SOLs and IROLs to those entities that have a reliability-related need for those limits and provide a written request that includes a schedule for delivery of those limits*"

Vegetation-related Sustained Outages that occur due to natural disasters are beyond the control of the Transmission Owner. These events are not classified as vegetation-related Sustained Outages and are therefore exempt from the Standard. Transmission lines are not designed to withstand the impacts of natural disasters such as flood, drought, earthquake, major storms, fire, hurricane, tornado, landslides, ice storms, etc. In the aftermath of catastrophic system damage from natural disasters the Transmission Owner's focus is on electric system restoration for public safety and critical support infrastructure.

Sustained Outages due to human or animal activity are beyond the control of the Transmission Owner. These outages are not classified as vegetation-related Sustained Outages and are therefore exempt from the Standard. Examples of these events may include new plantings by outside parties of tall vegetation under the transmission line planted since the last Vegetation Inspection, tree contacts with line initiated by vehicles, logging activities, etc.

The foregoing exemptions are addressed in a new footnote 2. Referred to collectively as force majeure events and activities, this footnote applies to requirements R1 and R2 in FAC-003-2.

The reliability objective of this NERC Vegetation Management Standard ("Standard") is to prevent vegetation-related outages which could lead to Cascading by effective vegetation maintenance while recognizing that certain outages such as those due to vandalism, human errors and acts of nature are not preventable. Operating experience clearly indicates that trees that have grown out of specification could contribute to a cascading grid failure, especially under heavy electrical loading conditions.

Serious outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations. To properly reduce and manage this risk, it is necessary to apply the Standard to applicable lines on any kind of land or easement, whether they are Federal Lands, state or provincial lands, public or private lands, franchises, easements or lands owned in fee. For the purposes of the Standard and this Technical Reference document, the term "public lands" includes municipal lands, village lands, city lands, and land owned by a host of other governmental entities.

The Standard addresses vegetation management along applicable overhead lines that serve to connect one electric station to another. However, it is not intended to be applied to lines sections inside the electric station fence or other boundary of an electric station, submarine or underground lines.

The Standard is intended to reduce the risk of Cascading involving vegetation. It is not intended to prevent customer outages from occurring due to tree contact with all transmission lines and voltages. For example, localized customer service might be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. However, this Standard is not written to address such isolated situations which have little impact on the overall Bulk Electric System.

Vegetation growth is constant and always present. Unmanaged vegetation poses an increased outage risk when numerous transmission lines are operating at or near their Rating. This poses a significant risk of multiple line failures and Cascading. On the other hand, most other outage causes (such as trees falling into lines, lightning, animals, motor vehicles, etc.) are statistically intermittent. The probability of occurrence of these events is not dependent on heavy loads. There is no cause-effect relationship which creates the probability of simultaneous occurrence of other such events. Therefore these types of events are highly unlikely to cause large-scale grid failures.

In preparing the original vegetation management standard in 2005, industry stakeholders set the threshold for applicability of the standard at 200kV. This was because an unexpected loss of lines operating at above 200kV has a higher probability of initiating a widespread blackout or cascading outages compared with lines operating at less than 200kV.

The original NERC Standard FAC-003-1 also allowed for application of the standard to “critical” circuits (critical from the perspective of initiating widespread blackouts or cascading outages) operating below 200kV. While the percentage of these circuits is relatively low, it remains a fact that there are sub-200kV circuits whose loss could contribute to a widespread outage. Given the very limited exposure and unlikelihood of a major event related to these lower-voltage lines, it would be an imprudent use of resources to apply the Standard to all sub-200kV lines. The drafting team, after evaluating several alternatives, selected the IROL and WECC Major Transfer Path criteria to determine applicable lines below 200 kV that are subject to this standard.

Requirements R1 and R2

Rationale

Rationale

The MVCD is a calculated minimum distance stated in feet (meters) to prevent flash-over between conductors and vegetation, for various altitudes and operating voltages. The distances in Table 2 were derived using a proven transmission design method. The types of failure to manage vegetation are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a TO's vegetation maintenance program since the encroachments listed require different and increasing levels of skills and knowledge and thus constitute a logical progression of how well, or poorly, a TO manages vegetation relative to this Requirement.

R1. *Each Transmission Owner shall manage vegetation to prevent encroachments of the types shown below, into the Minimum Vegetation Clearance Distance (MVCD) of any of its applicable line(s) identified as an element of an Interconnection Reliability Operating Limit (IROL) in the planning horizon by the Planning Coordinator; or Major Western Electricity Coordinating Council (WECC) transfer path(s); operating within its Rating and all Rated Electrical Operating Conditions.*[2]

1. *An encroachment into the MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage,*
2. *An encroachment due to a fall-in from inside the Right-of-Way (ROW) that caused a vegetation-related Sustained Outage,*
3. *An encroachment due to blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained Outage,*
4. *An encroachment due to a grow-in that caused a vegetation-related Sustained Outage. [VRF – High] [Time Horizon – Real-time]*

R2. *Each Transmission Owner shall manage vegetation to prevent encroachments of the types shown below, into the MVCD of any of its applicable line(s) that is not an element of an IROL; or Major WECC transfer path; operating within its Rating and all Rated Electrical Operating Conditions.*Error! Bookmark not defined.

1. *An encroachment into the MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage,*
2. *An encroachment due to a fall-in from inside the ROW that caused a vegetation-related Sustained Outage,*
3. *An encroachment due to blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained Outage,*

[2] This requirement does not apply to circumstances that are beyond the control of a Transmission Owner subject to this reliability standard, including natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods; human or animal activity such as logging, animal severing tree, vehicle contact with tree, arboricultural activities or horticultural or agricultural activities, or removal or digging of vegetation. Nothing in this footnote should be construed to limit the Transmission Owner's right to exercise its full legal rights on the ROW.

4. *An encroachment due to a grow-in that caused a vegetation-related Sustained Outage.* *[VRF – Medium] [Time Horizon – Real-time]*

M1. Each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R1. Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-time observations of any MVCD encroachments.

If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation.

Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period. (R1)

M2. Each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R2. Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-time observations of any MVCD encroachments.

If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation.

Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period. (R2)

R1 and R2 are performance-based requirements. The reliability objective or outcome to be achieved is the prevention of vegetation encroachments within a minimum distance of transmission lines. Content-wise, R1 and R2 are the same requirements; however, they apply to different Facilities. Both R1 and R2 require each Transmission Owner to manage vegetation to prevent encroachment within the Minimum Vegetation Clearance Distance ("MVCD") of transmission lines. R1 is applicable to lines "identified as an element of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions) to avoid a Sustained Outage". R2 applies to all other applicable lines that are not an element of an IROL or Major WECC Transfer Path.

The separation of applicability (between R1 and R2) recognizes that an encroachment into the MVCD of an IROL or Major WECC Transfer Path transmission line is a greater risk to the electric transmission system. Applicable lines that are not an element of an IROL or Major WECC Transfer Path are required to be clear of vegetation but these lines are comparatively less operationally significant. As a reflection of this difference in risk impact, the Violation Risk Factors (VRFs) are assigned as High for R1 and Medium for R2.

These requirements (R1 and R2) state that if vegetation encroaches within the distances in Table 1 in Appendix 1 of this supplemental Transmission Vegetation Management Standard FAC-003-2 Technical Reference document, it is in violation of the standard. Table 2 tabulates the distances necessary to prevent spark-over based on the Gallet equations as described more fully in Appendix 1 below.

These requirements assume that transmission lines and their conductors are operating within their Rating. If a line conductor is intentionally or inadvertently operated beyond its Rating (potentially in violation of other standards), the occurrence of a clearance encroachment may occur. For example, emergency actions taken by a Transmission Operator or Reliability Coordinator to protect an Interconnection may cause the transmission line to sag more and come closer to vegetation, potentially causing an outage. Such vegetation-related outages are not a violation of these requirements.

Evidence of violation of Requirement R1 and R2 include real-time observation of a vegetation encroachment into the MVCD (absent a Sustained Outage), or a vegetation-related encroachment resulting in a Sustained Outage due to a fall-in from inside the ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to blowing together of applicable lines and vegetation located inside the ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to a grow-in. If an investigation of a Fault by a Transmission Owner confirms that a vegetation encroachment within the MVCD occurred, then it shall be considered the equivalent of a Real-time observation.

With this approach, the VSLs were defined such that they directly correlate to the severity of a failure of a Transmission Owner to manage vegetation and to the corresponding performance level of the Transmission Owner's vegetation program's ability to meet the goal of "preventing a Sustained Outage that could lead to Cascading." Thus violation severity increases with a Transmission Owner's inability to meet this goal and its potential of leading to a Cascading event. The additional benefits of such a combination are that it simplifies the standard and clearly defines performance for compliance. A performance-based requirement of this nature will promote high quality, cost effective vegetation management programs that will deliver the overall end result of improved reliability to the system.

Multiple Sustained Outages on an individual line can be caused by the same vegetation. For example, a limb may only partially break and intermittently contact a conductor. Such events are considered to be a single vegetation-related Sustained Outage under the Standard where the Sustained Outages occur within a 24 hour period.

The MVCD is a calculated minimum distance stated in feet (or meters) to prevent spark-over, for various altitudes and operating voltages that is used in the design of Transmission Facilities. Keeping vegetation from entering this space will prevent transmission outages.

Requirement R3

Rationale

The documentation provides a basis for evaluating the competency of the Transmission Owner's vegetation program. There may be many acceptable approaches to maintain clearances. Any approach must demonstrate that the Transmission Owner avoids vegetation-to-wire conflicts under all Rated Electrical Operating Conditions. See Figure 1 for an illustration of possible conductor locations.

R3. *Each Transmission Owner shall have documented maintenance strategies or procedures or processes or specifications it uses to prevent the encroachment of vegetation into the MVCD of its applicable transmission lines that include(s) the following:*

3.1 *Accounts for the movement of applicable transmission line conductors under their Facility Rating and all Rated Electrical Operating Conditions;*

3.2 *Accounts for the inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency.*

[VRF – Lower] [Time Horizon – Long Term Planning]

M3. *The maintenance strategies or procedures or processes or specifications provided demonstrate that the Transmission Owner can prevent encroachment into the MVCD considering the factors identified in the requirement. (R3)*

Requirement R3 is a competency based requirement concerned with the maintenance strategies, procedures, processes, or specifications, a Transmission Owner uses for vegetation management.

An adequate transmission vegetation management program formally establishes the approach the Transmission Owner uses to plan and perform vegetation work to prevent transmission Sustained Outages and minimize risk to the Transmission System. The approach provides the basis for evaluating the intent, allocation of appropriate resources and the competency of the Transmission Owner in managing vegetation. There are many acceptable approaches to manage vegetation and avoid Sustained Outages. However, the Transmission Owner must be able to state what its approach is and how it conducts work to maintain clearances.

An example of one approach commonly used by industry is ANSI Standard A300, part 7. However, regardless of the approach a utility uses to manage vegetation, any approach a Transmission Owner chooses to use will generally contain the following elements:

1. *the maintenance strategy used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that MVCD clearances are never violated.*
2. *the work methods that the Transmission Owner uses to control vegetation*
3. *a stated Vegetation Inspection frequency*
4. *an annual work plan*

The conductor's position in space at any point in time is continuously changing as a reaction to a number of different loading variables. Changes in vertical and horizontal conductor positioning are the result of thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation. Physical loading applied to the conductor affects sag and sway by combining physical factors such as ice and wind loading. The movement of the transmission line conductor and the MVCD is illustrated in Figures 2 and 3 below.

Conductor Dynamics

In order for a Transmission Owner to develop a specific maintenance approach, it is important to understand the dynamics of a line conductor's movement. This paper will first address the complexities inherent in observing and predicting conductor movement, particularly for field personnel. It will then present some examples of maintenance approaches which Transmission Owners may consider that take into account these complexities, while resulting in practical approaches for field personnel.

Additionally, it is important the Transmission Owner consider all conductor locations, the MVCD, and vegetation growth between maintenance activities when developing a maintenance approach.

Understanding Conductor Position and Movement

The conductor's position in space at any point in time is continuously changing as a reaction to a number of different loading variables. Changes in vertical and horizontal conductor positioning are the result of thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation. Physical loading applied to the conductor affects sag and sway by combining physical factors such as ice and wind loading.

As a consequence of these loading variables, the conductor's position in space is dynamic and moving. When calculating the range of conductor positions, the Transmission Owner should use the same design criteria and assumptions that the Transmission Owner uses when establishing Ratings and SOL, as described in other standards. Typically, the greatest conductor movement would be at mid-span. As the conductor moves through various positions, a spark-over zone surrounding the conductor moves with it. The radius of the spark-over zone may be found by referring to Table 1 ("Minimum Vegetation Clearance Distances") in the standard. For illustrations of this zone and conductor movements, Figures 1 through 3 below demonstrate these concepts. At the time of making a field observation, however, it is very difficult to precisely know where the conductor is in relation to its wide range of all possible positions. Therefore, Transmission Owners must adopt maintenance approaches that account for this dynamic situation.

For Consideration in Developing a Maintenance Approach

Figure 3

Selecting a Maintenance Approach

In order to maintain adequate separation between vegetation and transmission line conductors, the Transmission Owner must craft a maintenance strategy that keeps vegetation well away from the spark-over zone mentioned above. In fact, it is generally necessary to incorporate a variety of maintenance strategies. For example, one Transmission Owner may utilize a combination of routine cycles, traditional IVM techniques and long-term planning. Another Transmission Owner may place a higher reliance on frequent inspections and quick remediation as opposed to a cyclical approach. This variation of approaches is further warranted when factors, such as terrain, legal and other constraints, vegetation types, and climates, are considered in developing a Transmission Owner's specific approach to satisfying this requirement.

The following is a sample description of one combination of strategies which may be utilized by a Transmission Owner. A Transmission Owner's basic maintenance approach could be to remove all incompatible vegetation from the right of way if it has the right to do so and has no constraints. In mountainous terrain, however, this strategy could change to one where the Transmission Owner manages vegetation based on vegetation-to-conductor clearances, since it might not be necessary to remove vegetation in a valley that is far below.
If faced with constraints and assuming a line design with sufficient ground clearance, the Transmission Owner 's approach could then be to allow vegetation such as fruit trees, but perhaps only up to a given height at maturity (perhaps 10 feet from the ground). If constraints cannot be overcome and if design clearances are sufficient, an exception to the Transmission Owner's 10-foot guideline might be made. Finally, if the Transmission Owner has chosen to utilize vegetation-to-conductor clearance distance methods, the Transmission Owner could have an inspection regimen in place to regularly ensure that any impending clearance problems are identified early for rectification.

ANSI A300 – Best Management Practices for Tree Care Operations

A description of ANSI A-300, part 7, is offered below to illustrate another maintenance approach that could be used in developing a comprehensive transmission vegetation management program.

Introduction

Integrated Vegetation Management (IVM) is a best management practice conveyed in the American National Standard for Tree Care Operations, Part 7 (ANSI 2006) and the International Society of Arboriculture *Best Management Practices: Integrated Vegetation Management* (Miller 2007). IVM is consistent with the requirements in FAC-003-02, and it provides practitioners with what industry experts consider to be appropriate techniques to apply to electric right-of-way projects in order to meet or exceed the Standard.

IVM is a system of managing plant communities whereby managers set objectives; identify compatible and incompatible vegetation; consider action thresholds; and evaluate, select and implement the most appropriate control method or methods to achieve set objectives. The choice of control method or methods should be based on the environmental impact and anticipated effectiveness; along with site characteristics, security, economics, current land use and other factors.

Planning and Implementation

Best management practices provide a systematic way of planning and implementing a vegetation management program. While designed primarily with transmission systems in mind, it is also

applicable to distribution projects. As presented in ANSI A300 part 7 and the ISA best management practices, IVM consists of 6 elements:

1) Set Objectives
2) Evaluate the Site
3) Define Action Thresholds
4) Evaluate and Select Control Methods
5) Implement IVM
6) Monitor Treatment and Quality Assurance

The setting of objectives, defining action thresholds, and evaluating and selecting control methods all require decisions. The planning and implementation process is cyclical and continuous, because vegetation is dynamic and managers must have the flexibility to adjust their plans. Adjustments may be made at each stage as new information becomes available and circumstances evolve.

Set Objectives

Objectives should be clearly defined and documented. Examples of objectives can include promoting safety, preventing sustained outages caused by vegetation growing into electric facilities, maintaining regulatory compliance, protecting structures and security, restoring electric service during emergencies, maintaining access and clear lines of sight, protecting the environment, and facilitating cost effectiveness.

Objectives should be based on site factors, such as workload and vegetation type, in addition to human, equipment and financial resources. They will vary from utility to utility and project to project, depending on line voltage and criticality, as well as topographical, environmental, fiscal and political considerations. However, where it is appropriate, the overriding focus should be on environmentally-sound, cost effective control of species that potentially conflict with the electric facility, while promoting compatible, early successional, sustainable plant communities.

Work Load Evaluations

Work-load evaluations are inventories of vegetation that could have a bearing on management objectives. Work load assessments can capture a variety of vegetation characteristics, such as location, height, species, size and condition, hazard status, density and clearance from conductors. Assessments should be conducted considering voltage, conductor sag from ambient temperatures and loading, and the potential influence of wind on line sway.

Evaluate and Select Control Methods

Control methods are the process through which managers achieve objectives. The most suitable control method best achieves management objectives at a particular site. Many cases call for a combination of methods. Managers have a variety of controls from which to choose, including manual, mechanical, herbicide and tree growth regulators, biological, and cultural options.

Manual Control Methods

Manual methods employ workers with hand-carried tools, including chainsaws, handsaws, pruning shears and other devices to control incompatible vegetation. The advantage of manual techniques is that they are selective and can be used where others may not be. On the other hand, manual techniques can be inefficient and expensive compared to other methods.

Mechanical Control Methods

Mechanical controls are done with machines. They are efficient and cost effective, particularly for clearing dense vegetation during initial establishment, or reclaiming neglected or overgrown right of way. On the other hand, mechanical control methods can be non-selective and disturb sensitive sites.

Tree Growth Regulator and Herbicide Control Methods

Tree growth regulators and herbicides can be effective for vegetation management. Tree growth regulators (TGRs) are designed to reduce growth rates by interfering with natural plant processes. TGRs can be helpful where removals are prohibited or impractical by reducing the growth rates of some fast-growing species.

Herbicides control plants by interfering with specific botanical biochemical pathways. Herbicide use can control individual plants that are prone to re-sprout or sucker after removal. When trees that re-sprout or sucker are removed without herbicide treatment, dense thickets develop, impeding access, swelling workloads, increasing costs, blocking lines-of-site, and deteriorating wildlife habitat. Treating suckering plants allows early successional, compatible species to dominate the right-of-way and out-compete incompatible species, ultimately reducing work.

Cultural Control Methods

Cultural methods modify habitat to discourage incompatible vegetation and establish and manage desirable, early successional plant communities. Cultural methods take advantage of seed banks of native, compatible species lying dormant on site. In the long run, cultural control is the most desirable method where it is applicable.

A cultural control known as cover-type conversion provides a competitive advantage to short-growing, early successional plants, allowing them to thrive and eventually out-compete unwanted tree species for sunlight, essential elements and water. The early successional plant community is relatively stable, tree-resistant and reduces the amount of work, including herbicide application, with each successive treatment.

Wire-Border Zone

The wire-border zone technique is a management philosophy that can be applied through cultural control. W.C. Bramble and W.R. Byrnes developed it in the mid-1980s out of research begun in 1952 on a transmission right-of-way in the Pennsylvania State Game Lands 33 Research and Demonstration project (Yahner and Hutnik (2004).

The wire zone is the section of a utility transmission right-of-way directly under the wires and extending outward about 10 feet on each side. The wire zone is managed to promote a low-growing plant community dominated by grasses, herbs and small shrubs (under 3 feet in height at maturity). The border zone is the remainder of the right-of-way. It is managed to establish small trees and tall shrubs (under 25 feet in height at maturity). When properly managed, diverse, tree-resistant plant communities develop in wire and border zones. The communities not only protect the electric facility and reduce long-term maintenance, but also enhance wildlife habitat, forest ecology and aesthetic values.

Although the wire-border zone is a best practice in many instances, it is not necessarily universally suitable. For example, standard wire-border zone prescriptions may be unnecessary where lines are high off the ground, such as across low valleys or canyons, so the technique can be modified without sacrificing reliability.

One way to accommodate variances in topography is to establish different regions based on wire height. For example, over canyon bottoms or other areas where conductors are 100 feet or more above the ground, only a few trees are likely to be tall enough to conflict with the lines. In those cases, trees that potentially interfere with the transmission lines can be removed selectively on a case-by-case basis.

In areas where the wire is lower, perhaps between 50-100 feet from the ground, a border zone community can be developed throughout the right-of-way. Note that in many cases, conductor attachment points are more than 50 feet off the ground, so a border zone community can be cultivated near structures. Where the line is less than 50 feet off the ground, managers could apply a full wire-border zone prescription.

An environmental advantage of this type of modification is stream protection. Streams often course through the valleys and canyons where lines are likely to be elevated. Leaving timber or border zone communities in canyon bottoms helps shelter this valuable habitat, enabling managers to achieve environmentally sensitive objectives.

Implement IVM

All laws and regulations governing IVM practices and specifications written by qualified vegetation managers must be followed. Integrated vegetation management control methods should be implemented on regular work schedules, which are based on established objectives and completed assessments. Work should progress systematically, using control measures determined to be best for varying conditions at specific locations along a right-of-way. Some considerations used in developing schedules include the importance and type of line, vegetation clearances, work loads, growth rate of predominant vegetation, geography, accessibility, and in some cases, time lapsed since the last scheduled work.

Clearances Following Work

Clearances following work should be sufficient to meet management objectives, including preventing trees from entering the Minimum Vegetation Clearance Distance, electric safety risks, service-reliability threats and cost.

Monitor Treatment and Quality Assurance

An effective program includes documented processes to evaluate results. Evaluations can involve quality assurance while work is underway and after it is completed. Monitoring for quality assurance should begin early to correct any possible miscommunication or misunderstanding on the part of crewmembers. Early and consistent observation and evaluation also provides an opportunity to modify the plan, if need be, in time for a successful outcome.

Utility vegetation management programs should have systems and procedures in place for documenting and verifying that vegetation management work was completed to specifications. Post-control reviews can be comprehensive or based on a statistically representative sample. This final review points back to the first step and the planning process begins again.

Summary of A-300 example
Integrated Vegetation Management offers among others, a systematic way of planning and implementing a vegetation management program as presented in ANSI A300 Part 7. This methodology enables a program to comply with the NERC *Transmission Vegetation Management Program* standard (FAC-003-2). Managers should select control options to best promote management objectives.

Vegetation Inspections
As with the ANSI A-300 example, The Transmission Owner's transmission vegetation management program (TVMP) establishes the frequency of vegetation inspections based upon many factors. Such local and environmental factors may include anticipated growth rates of the local vegetation, length of the growing season for the geographical area, limited Rights of Way width, rainfall amounts, etc.

Annual Work Plan
Requirement R7 of the Standard addresses the execution of the annual work plan. A comprehensive approach that exercises the full extent of legal rights is superior to incremental management in the long term because it reduces overall encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient at all locations on the Right of Way. Removal is superior to pruning. Removal minimizes the possibility of conflicts between energized conductors and vegetation. Since this is not always possible, the Transmission Owner's approach should be to use its prescribed vegetation maintenance methods to work towards or achieve the maximum use of the Right of Way.

Requirement R4

R4. *Each Transmission Owner, without any intentional time delay, shall notify the control center holding switching authority for the associated applicable transmission line when the Transmission Owner has confirmed the existence of a vegetation condition that is likely to cause a Fault at any moment.*

[VRF – Medium] [Time Horizon – Real-time]

Rationale
To ensure expeditious communication between the Transmission Owner and the control center when a critical situation is confirmed.

M4. *Each Transmission Owner that has a confirmed vegetation condition likely to cause a Fault at any moment will have evidence that it notified the control center holding switching authority for the associated transmission line without any intentional time delay. Examples of evidence may include control center logs, voice recordings, switching orders, clearance orders and subsequent work orders. (R4)*

R4 is a risk-based requirement. It focuses on preventative actions to be taken by the Transmission Owner for the mitigation of Fault risk when a vegetation threat is confirmed. R4 involves the notification of potentially threatening vegetation conditions, without any intentional delay, to the control center holding switching authority for that specific transmission line. Examples of acceptable unintentional delays may include communication system problems (for example, cellular service or two-way radio disabled), crews located in remote field locations with no communication access, delays due to severe weather, etc.

Confirmation is key that a threat actually exists due to vegetation. This confirmation could be in the form of a Transmission Owner's employee who personally identifies such a threat in the field. Confirmation could also be made by sending out an employee to evaluate a situation reported by a landowner.

Vegetation-related conditions that warrant a response include vegetation that is near or encroaching into the MVCD (a grow-in issue) or vegetation that could fall into the transmission conductor (a fall-in issue). A knowledgeable verification of the risk would include an assessment of the possible sag or movement of the conductor while operating between no-load conditions and its rating.

The Transmission Owner has the responsibility to ensure the proper communication between field personnel and the control center to allow the control center to take the appropriate action until the vegetation threat is relieved. Appropriate actions may include a temporary reduction in the line loading, switching the line out of service, or positioning the system in recognition of the increasing risk of outage on that circuit. The notification of the threat should be communicated in terms of minutes or hours as opposed to a longer time frame for corrective action plans (see R5).

All potential grow-in or fall-in vegetation-related conditions will not necessarily cause a Fault at any moment. For example, some Transmission Owners may have a danger tree identification

program that identifies trees for removal with the potential to fall near the line. These trees would not require notification to the control center unless they pose an immediate fall-in threat.

Requirement R5

R5. *When a Transmission Owner is constrained from performing vegetation work, and the constraint may lead to a vegetation encroachment into the MVCD of its applicable transmission lines prior to the implementation of the next annual work plan then the Transmission Owner shall take corrective action to ensure continued vegetation management to prevent encroachments. [VRF – Medium] [Time Horizon – Operations Planning]*

M5. *Each Transmission Owner has evidence of the corrective action taken for each constraint where an applicable transmission line was put at potential risk. Examples of acceptable forms of evidence may include initially-planned work orders, documentation of constraints from landowners, court orders, inspection records of increased monitoring, documentation of the de-rating of lines, revised work orders, invoices, and evidence that a line was de-energized. (R5)*

> **Rationale**
> Legal actions and other events may occur which result in constraints that prevent the Transmission Owner from performing planned vegetation maintenance work.
> In cases where the transmission line is put at potential risk due to constraints, the intent is for the Transmission Owner to put interim measures in place, rather than do nothing.
> The corrective action process is not intended to address situations where a planned work methodology cannot be performed but an alternate work methodology can be used.

R5 is a risk-based requirement. It focuses upon preventative actions to be taken by the Transmission Owner for the mitigation of Sustained Outage risk when temporarily constrained from performing vegetation maintenance. The intent of this requirement is to deal with situations that prevent the Transmission Owner from performing planned vegetation management work and, as a result, have the potential to put the transmission line at risk. Constraints to performing vegetation maintenance work as planned could result from legal injunctions filed by property owners, the discovery of easement stipulations which limit the Transmission Owner's rights, or other circumstances.

This requirement is not intended to address situations where the transmission line is not at potential risk and the work event can be rescheduled or re-planned using an alternate work methodology. For example, a land owner may prevent the planned use of chemicals on non-threatening, low growth vegetation but agree to the use of mechanical clearing. In this case the Transmission Owner is not under any immediate time constraint for achieving the management objective, can easily reschedule work using an alternate approach, and therefore does not need to take interim corrective action.

However, in situations where transmission line reliability is potentially at risk due to a constraint, the Transmission Owner is required to take an interim corrective action to mitigate the potential risk to the transmission line. A wide range of actions can be taken to address various situations. General considerations include:

- Identifying locations where the Transmission Owner is constrained from performing planned vegetation maintenance work which potentially leaves the transmission line at risk.
- Developing the specific action to mitigate any potential risk associated with not performing the vegetation maintenance work as planned.
- Documenting and tracking the specific action taken for each location.
- In developing the specific action to mitigate the potential risk to the transmission line the Transmission Owner could consider location specific measures such as modifying the inspection and/or maintenance intervals. Where a legal constraint would not allow any vegetation work, the interim corrective action could include limiting the loading on the transmission line.
- The Transmission Owner should document and track the specific corrective action taken at each location. This location may be indicated as one span, one tree or a combination of spans on one property where the constraint is considered to be temporary.

Requirement R6

R6. *Each Transmission Owner shall perform a Vegetation Inspection of 100% of its applicable transmission lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.) at least once per calendar year and with no more than 18 months between inspections on the same ROW.*[3]

[VRF – Medium] [Time Horizon – Operations Planning]

M6. *Each Transmission Owner has evidence that it conducted Vegetation Inspections of the transmission line ROW for all applicable transmission lines at least once per calendar year but with no more than 18 months between inspections on the same ROW. Examples of acceptable forms of evidence may include completed and dated work orders, dated invoices, or dated inspection records. (R6)*

Rationale

Inspections are used by Transmission Owners to assess the condition of the entire ROW. The information from the assessment can be used to determine risk, determine future work and evaluate recently-completed work. This requirement sets a minimum Vegetation Inspection frequency of once per calendar year but with no more than 18 months between inspections on the same ROW. Based upon average growth rates across North America and on common utility practice, this minimum frequency is reasonable. Transmission Owners should consider local and environmental factors that could warrant more frequent inspections.

R6 is a risk-based requirement. This requirement sets a minimum time period for completing Vegetation Inspections that fits general industry practice. In addition, the fact that Vegetation Inspections can be performed in conjunction with general line inspections further facilitates a Transmission Owner's ability to meet this requirement. However, the Transmission Owner may determine that more frequent inspections are needed to maintain reliability levels, dependent upon such factors as anticipated growth rates of the local vegetation, length of the growing season for the geographical area, limited ROW width, and rainfall amounts. Therefore it is expected that some transmission lines may be designated with a higher frequency of inspections.

The SDT added footnote 3 to address the situation where a Transmission Owner through no fault of its own, would be unable to complete the vegetation inspection within the allotted time period. This would include the situation of mutual aid as well as disasters to the Transmission Owner's own system.

The VSL for Requirement R6 has VSL categories ranked by the percentage of the required ROW inspections completed. To calculate the percentage of inspection completion, the Transmission Owner may choose units such as: line miles or kilometers, circuit miles or kilometers, pole line miles, ROW miles, etc.

[3] When the Transmission Owner is prevented from performing a Vegetation Inspection within the timeframe in R6 due to a natural disaster, the TO is granted a time extension that is equivalent to the duration of the time the TO was prevented from performing the Vegetation Inspection.

For example, when a Transmission Owner operates 2,000 miles of 230 kV transmission lines this Transmission Owner will be responsible for inspecting all 2,000 miles of 230 kV transmission lines at least once during the calendar year. If one of the included lines was 100 miles long, and if it was not inspected during the year, then the amount failed to inspect would be 100/2000 = 0.05 or 5%. The “Low VSL” for R6 would apply in this example.

Requirement R7

Rationale

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. An annual vegetation work plan allows for work to be modified for changing conditions, taking into consideration anticipated growth of vegetation and all other environmental factors, provided that the changes do not violate the encroachment within the MVCD.

R7. *Each Transmission Owner shall complete 100% of its annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made (provided they do not put the transmission system at risk of a vegetation encroachment) and must be documented. The percent completed calculation is based on the number of units actually completed divided by the number of units in the final amended plan (measured in units of choice - circuit, pole line, line miles or kilometers, etc.) Examples of reasons for modification to annual plan may include:*

- Change in expected growth rate/ environmental factors
- Circumstances that are beyond the control of a Transmission Owner[4]
- Rescheduling work between growing seasons
- Crew or contractor availability/ Mutual assistance agreements
- Identified unanticipated high priority work
- Weather conditions/Accessibility
- Permitting delays
- Land ownership changes/Change in land use by the landowner
- Emerging technologies

  [VRF – Medium] [Time Horizon – Operations Planning]

M7. *Each Transmission Owner has evidence that it completed its annual vegetation work plan. Examples of acceptable forms of evidence may include a copy of the completed annual work plan (including modifications if any), dated work orders, dated invoices, or dated inspection records. (R7)*

R7 is a risk-based requirement. The Transmission Owner is required to implement an annual work plan for vegetation management to accomplish the purpose of this Standard. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made and documented provided they do not put the transmission system at risk. The annual work plan requirement is not intended to necessarily require a “span-by-span”, or even a “line-by-line” detailed description of all work to be performed. It is only intended to require that the Transmission Owner provide evidence of annual planning and execution of a vegetation management maintenance approach which successfully prevents encroachment of vegetation into the MVCD.

[4] circumstances that are beyond the control of a Transmission Owner include but are not limited to natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, major storms as defined either by the TO or an applicable regulatory body, ice storms, and floods; arboricultural, horticultural or agricultural activities.

The ability to modify the work plan allows the Transmission Owner to change priorities or treatment methodologies during the year as conditions or situations dictate. For example recent line inspections may identify unanticipated high priority work, weather conditions (drought) could make herbicide application ineffective during the plan year, or a major storm could require redirecting local resources away from planned maintenance or work may be deferred to a subsequent year because of slower-than-expected growth. This situation may also include complying with mutual assistance agreements by moving resources off the Transmission Owner's system to work on another system. Any of these examples could result in acceptable deferrals or additions to the annual work plan. Modifications to the annual work plan must always ensure the reliability of the electric Transmission system.

In general, the vegetation management maintenance approach should use the full extent of the Transmission Owner's legal rights on the ROW. A comprehensive approach that exercises the full extent of legal rights on the ROW is superior to incremental management in the long term because it reduces the overall potential for encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient.

When developing the annual work plan, the Transmission Owner should allow time for reasonable and predictable procedural requirements to obtain permits to work on federal, state, provincial, public, tribal lands. In some cases, the lead time for obtaining permits may necessitate preparing work plans more than a year prior to the start of work. Transmission Owners may also need to consider those special landowner requirements.

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. Therefore, deferrals or relevant changes to the annual plan shall be documented. Depending on the planning and documentation format used by the Transmission Owner, evidence of successful annual work plan execution could consist of signed-off work orders, signed contracts, printouts from work management systems, spreadsheets of planned versus completed work, timesheets, work inspection reports, or paid invoices. Other evidence may include photographs and walk-through reports.

Appendix 1: Clearance Distance Derivation by the Gallet Equation

The Gallet Equation is a well-known method of computing the required strike distance for proper insulation coordination, and has the ability to take into account various air gap geometries, as well as non-standard atmospheric conditions. When the Gallet Equation and conservative probabilistic methods are combined, i.e. deterministic design, sparkover probabilities of 10^{-6} or less are achieved. This approach is well known for its conservatism and was used to design the first 500 kV and 765 kV lines in North America [1]. Thus, the deterministic design approach using the Gallet Equation is used for the standard to compute the minimum strike distance between transmission lines and the vegetation that may be present in or along the transmission corridor.

Method Explanation (Gallet Equation)

In 1975 G. Gallet published a benchmark paper that provided a method to compute the critical flashover voltage (CFO) of various air gap geometries [4]. The Gallet Equation uses various "gap factors" to take into account various air gap geometries. Various gap factor values are provided in [1]. If the vegetation in a transmission corridor, e.g. a tree, is assumed electrically to be a large structure then the CFO of such an air gap geometry can be computed for dry or wet conditions using a well established equation proposed by Gallet [1],[2],[4],

$$CFO_A = k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\dfrac{8}{D}} \tag{1}$$

where,

k_w is defined as the factor that takes into account wet or dry conditions (dry = 1.0 and wet = 0.96) and phase arrangement (multiply by 1.08 for outside phase), e.g. outside phase and wet conditions = (0.96)(1.08) = 1.037,

k_g is defined as the gap factor (1.3 for conductor to large structure),

D is the strike distance (m),

CFO_A is the CFO for the relative air density (kV).

δ is defined as the relative air density and is approximately equal to (2) where A is the altitude in km,

$$\delta = e^{-\frac{A}{8.6}} \tag{2}$$

$$m = 1.25G_0\left(G_0 - 0.2\right) \tag{3}$$

$$G_0 = \frac{CFO_s}{500 \cdot D} \tag{4}$$

$$CFO_s = k_w \cdot k_g \cdot \frac{3400}{1+\frac{8}{D}} \tag{5}$$

where CFO_S is the CFO for standard atmospheric conditions (kV). Using (1)-(5), the required CFO_A can be computed using an iterative process.

Once the CFO_A is known, deterministic methods can be used to determine the required clearance distance. If we let the maximum switching overvoltage be equal to the withstand voltage of the air gap (CFO_A - 3σ) then the CFO_A can be written as (6).

$$CFO_A = \frac{V_m}{1-3\left(\frac{\sigma}{CFO_A}\right)} \tag{6}$$

where

V_m is equal to the maximum switching overvoltage, i.e. the value that has a 0.135% chance of being exceeded,

σ is the standard deviation of the air gap insulation,

CFO_A is the critical flashover voltage of the air gap insulation under non-standard atmospheric conditions.

The ratio of σ to the CFO_A given in (6) can be assumed to be 0.05 (5%) [1]. Thus, (6) can be written as (7).

$$CFO_A = \frac{V_m}{0.85} \tag{7}$$

Substituting (7) into (1) we arrive at (8).

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} \tag{8}$$

Equation 8 relates the maximum transient overvoltage, V_m, to the air gap distance, D. Using (8) to compute the required clearance distance for the specified air gap geometry (conductor to large structure) results in a probability of flashover in the range of 10^{-6}.

Transient Overvoltage

In general, the worst case transient overvoltages occurring on a transmission line are caused by energizing or re-energizing the line with the latter being the extreme case if trapped charge is present. The intent of FAC-003 is to keep a transmission line that is *in service* from becoming de-energized (i.e. tripped out) due to sparkover from the line conductor to nearby vegetation. Thus, the worst case scenarios that are typically analyzed for insulation coordination purposes (e.g. line energization and re-energization) can be ignored. For the purposes of FAC-003-2, the worst case transient overvoltage then becomes the maximum value that can occur with the line energized. Determining a realistic value of transient overvoltage for this situation is difficult because the maximum transient overvoltage factors listed in the literature are based on a

switching operation of the line in question. In other words, these maximum overvoltage values (e.g. the values listed in [2], [3] and [5]) are based on the assumption that the subject line is being energized, re-energized or de-energized. These operations, by their very nature, will create the largest transient overvoltages. Typical values of transient overvoltages of in-service lines, as such, are not readily available in the literature because the resulting level of overvoltage is negligible compared with the maximum (e.g. re-energizing a transmission line with trapped charge). A conservative value for the maximum transient overvoltage that can occur anywhere along the length of an in-service ac line is approximately 2.0 p.u.[2]. This value is a conservative estimate of the transient overvoltage that is created at the point of application (e.g. a substation) by switching a capacitor bank without a pre-insertion device (e.g. closing resistors). At voltage levels where capacitor banks are not very common (e.g. 362 kV), the maximum transient overvoltage of an “in-service” ac line are created by fault initiation on adjacent ac lines and shunt reactor bank switching. These transient voltages are usually 1.5 p.u. or less [2]. It is well known that these theoretical transient overvoltages will not be experienced at locations remote from the bus at which they were created; however, in order to be conservative, it will be assumed that all nearby ac lines are subjected to this same level of overvoltage. Thus, a maximum transient overvoltage factor of 2.0 p.u. for 242 kV and below and 1.4 p.u. for ac transmission lines 362 kV and above is used to compute the required clearance distances for vegetation management purposes.

The overvoltage characteristics of dc transmission lines vary somewhat from their ac counterparts. The referenced empirically derived transient overvoltage factor used to calculate the minimum clearance distances from dc transmission lines to vegetation for the purpose of FAC-003-2 will be 1.8 p.u.[3].

Example Calculation

An example calculation is presented below using the proposed method of computing the vegetation clearance distances. It is assumed that the line in question has a maximum operating voltage of 550 kV_{rms} line-to-line. Using a per unit transient overvoltage factor of 1.4, the result is a peak transient voltage of 629 kV_{crest}. It is further assumed that the line in question operates at a maximum altitude of 7000 feet (2.134 km) above sea level.

The required withstand voltage of the air gap must be equal to or greater than 629 kV_{crest}. Since the altitude is above sea level, (1) - (5) have to be iterated on to achieve the desired result. Equation (9) can be used as an initial guess for the clearance distance.

$$D_i = \frac{8}{\dfrac{3400 \cdot k_w \cdot k_g}{\left(\dfrac{V_m}{0.85}\right)} - 1} \tag{9}$$

For our case here, V_m is equal to 629 kV, k_w = 1.037 and k_g = 1.3. Thus,

$$D_i = \frac{8}{\dfrac{3400 \cdot k_w \cdot k_g}{\left(\dfrac{V_m}{0.85}\right)} - 1} = \frac{8}{\dfrac{3400 \cdot 1.037 \cdot 1.3}{\left(\dfrac{629}{0.85}\right)} - 1} = 1.535m \tag{10}$$

Using (2)-(5) and (8) the withstand voltage of the air gap is next computed. This value will then be compared to the maximum transient overvoltage.

$$CFO_S = k_w \cdot k_g \cdot \frac{3400}{1+\frac{8}{D}} = 1.037 \cdot 1.3 \cdot \frac{3400}{1+\frac{8}{1.535}} = 737.7kV \tag{11}$$

$$\delta = e^{-\frac{A}{8.6}} = e^{-\frac{2.134}{8.6}} = 0.78 \tag{12}$$

$$G_O = \frac{CFO_S}{500 \cdot D} = \frac{737.7}{(500)\cdot(1.535)} = 0.961 \tag{13}$$

$$m = 1.25 \cdot G_O(G_O - 0.2) = 1.25 \cdot 0.961(0.961 - 0.2) = 0.915 \tag{14}$$

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} = (0.85)(1.037)(1.3)(0.78)^{0.915}\left(\frac{3400}{1+\frac{8}{1.535}}\right) = 499.8kV \tag{15}$$

The calculated V_m is less than 629 kV; thus, the clearance distance must be increased. A few iterations using (2)-(5) and (8) are required until the computed $V_m \geq 629$ kV. For this case it was found that D = 1.978 m (6.49 feet) yielded V_m = 629.3 kV. Using this clearance distance the following values were computed for the final iteration.

$$CFO_S = k_w \cdot k_g \cdot \frac{3400}{1+\frac{8}{D}} = 1.037 \cdot 1.3 \cdot \frac{3400}{1+\frac{8}{1.978}} = 908.5kV \tag{16}$$

$$\delta = e^{-\frac{A}{8.6}} = e^{-\frac{2.134}{8.6}} = 0.78 \tag{17}$$

$$G_O = \frac{CFO_S}{500 \cdot D} = \frac{908.5}{(500)\cdot(1.978)} = 0.919 \tag{18}$$

$$m = 1.25 \cdot G_O(G_O - 0.2) = 1.25 \cdot 0.919(0.919 - 0.2) = 0.825 \tag{19}$$

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} = (0.85)(1.037)(1.3)(0.78)^{0.825}\left(\frac{3400}{1+\frac{8}{1.978}}\right) = 629.3kV \tag{20}$$

Therefore, the minimum vegetation clearance distance for a maximum line to line ac operating voltage of 550 kV at 7000 feet above sea level is 1.978 m (6.49 feet). Table 1 provides calculated distances for various altitudes and maximum system operating ac voltages.

TABLE 1 — Minimum Vegetation Clearance Distances (MVCD)[6]
For **Alternating Current** Voltages

(AC) Nominal System Voltage (kV)	(AC) Maximum System Voltage (kV)	MVCD feet (meters) sea level	MVCD feet (meters) 3,000ft (914.4m)	MVCD feet (meters) 4,000ft (1219.2m)	MVCD feet (meters) 5,000ft (1524m)	MVCD feet (meters) 6,000ft (1828.8m)	MVCD feet (meters) 7,000ft (2133.6m)	MVCD feet (meters) 8,000ft (2438.4m)	MVCD feet (meters) 9,000ft (2743.2m)	MVCD feet (meters) 10,000ft (3048m)	MVCD feet (meters) 11,000ft (3352.8m)

Transmission Vegetation Management
Standard FAC-003-2 Technical Reference

Prepared by the

North American Electric Reliability Corporation

Vegetation Management Standard Drafting Team

~~June 28~~December 17, 2010

~~Table of Contents~~

Introduction

This document is intended to provide supplemental information and guidance for complying with the requirements of Reliability Standard FAC-003-2.

The purpose of the Standard is to improve the reliability of the electric transmission system by preventing those vegetation related outages that could lead to Cascading.

Compliance with the Standard is mandatory and enforceable.

Special Note: The Application of Results-Based Approach to FAC-003-2

In its three-year assessment as the ERO, NERC acknowledged stakeholder comments and committed to:

i) addressing quality issues to ensure each reliability standard has a clear statement of purpose, and has outcome-focused requirements that are clear and measurable; and
ii) eliminating requirements that do not have an impact on bulk power system reliability.

In 2010, the Standards Committee approved a recommendation to use Project 2007-07 Vegetation Management as a first proof of concept for developing results-based standards.

The Standard Drafting Team (SDT) employed a defense-in-depth[1] strategy for FAC-003-2, where each requirement has a role in preventing those vegetation related outages that could lead to Cascading. This portfolio of requirements was designed to achieve an overall defense-in-depth strategy and to comply with the quality objectives identified in the *Acceptance Criteria of a Reliability Standard* document.

The SDT developed a portfolio of performance, risk, and competency-based mandatory reliability requirements to support an effective defense-in-depth strategy. Each Requirement was developed using one of the following requirement types:

a) Performance-based - defines a particular reliability objective or outcome to be achieved. In its simplest form, a results-based requirement has four components: who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome?
b) Risk-based - preventive requirements to reduce the risks of failure to acceptable tolerance levels. A risk-based reliability requirement should be framed as: who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome that reduces a stated risk to the reliability of the bulk power system?
c) Competency-based - defines a minimum set of capabilities an entity needs to have to demonstrate it is able to perform its designated reliability functions. A competency-based reliability requirement should be framed as: who, under what conditions (if any), shall have what capability, to achieve what particular result or outcome to perform an action to achieve a result or outcome or to reduce a risk to the reliability of the bulk power system?

The drafting team reviewed and edited version 1 of FAC-003-1 to remove prescriptive and administrative language in order to distill the technical requirements down to their

[1] A defense-in-depth strategy for reliability standards recognizes that each requirement in the NERC standards has a role in preventing system failures, and that these roles are complementary and reinforcing. These prevention measures should be arranged in a series of defensive layers or walls. No single defensive layer provides complete protection from failure by itself. But taken together, with well-designed layers including performance, risk, and competency-based requirements, a defense-in-depth approach can be very effective in preventing future large scale power system failures.

essential reliability content. Text that is explanatory in nature is placed in a special section of the standard entitled Guideline and Technical Basis to aid in the understanding of the requirements. Furthermore, Rationale text boxes are inserted alongside each requirement to communicate the foundation for the requirement.

Disclaimer

This supporting document is supplemental to the reliability standard FAC-003-2 — Transmission Vegetation Management and does not contain mandatory requirements subject to compliance review.

Preface

The NERC Vegetation Management Standard Drafting Team (VM SDT) acknowledges those across the industry who contributed to the development of this Standard and companion Technical Reference document. The Technical Reference document is intended to provide supplemental explanatory background and guidance related to requirements contained in the Standard but does not in itself contain requirements subject to compliance review.

The VM SDT believes that a well-designed and executed Transmission Vegetation Management Program (TVMP) will have few problems meeting the requirements of this Standard. While the Standard requires a TVMP to contain certain elements, it allows the Transmission Owner flexibility in designing a TVMP to meet local needs provided it also meets the purpose of the Standard.

While there are many approaches to vegetation management, the VMSDT supports industry best practices contained in ANSI A300 (Part 7) – Integrated Vegetation Management (IVM) practices on Utility Rights-of-way, as well as the companion publication Best Management Practices – Integrated Vegetation Management, as an effective strategy to maintain compliance with this Standard. ANSI A300 (Part 7), approved by industry consensus in 2006, contains many elements needed for an effective TVMP as required by this Standard. One key element is the "wire zone – border zone" concept. Supported by over 50 years of continuous research, wire zone – border zone is a proven method to manage vegetation on transmission rights-of-ways and is an industry accepted best practice to help ensure electric system reliability.

The VM SDT believes that Transmission Owners who adopt and effectively implement IVM principles, particularly the "wire zone – border zone" concept, are far less likely to experience a vegetation caused outage than those who do not.

Definition of Terms

Right-of-Way (ROW)*

The corridor of land under a transmission line(s) needed to operate the line(s). The width of the corridor is established by engineering or construction standards as documented in either construction documents, pre-2007 vegetation maintenance records, or by the blowout standard in effect when the line was built. The ROW width in no case exceeds the Transmission Owner's legal rights but may be less based on the aforementioned criteria.

The current glossary definition of this NERC term is modified to address the issues set forth in Paragraph 734 of FERC Order 693.

The current NERC glossary definition of Right of Way has been modified to address the matter set forth in Paragraph 734 of FERC Order 693. The Order pointed out that Transmission Owners may in some cases own more property or rights than are needed to reliably operate transmission lines. This modified definition represents a slight but significant departure from the strict legal definition of "right of way" in that this definition is based on engineering and construction considerations that establish the width of a corridor from a technical basis.

Vegetation Inspection~~ —~~ ***

The systematic examination of vegetation conditions on ~~an Active Transmission Line Right-of-Way which~~a Right-of-Way and those vegetation conditions under the Transmission Owner's control that are likely to pose a hazard to the line(s) prior to the next planned maintenance or inspection. This may be combined with a general line inspection.

The current glossary definition of this NERC term is modified to allow both maintenance inspections and vegetation inspections to be performed concurrently.

Current definition of Vegetation Inspection: The systematic examination of a transmission corridor to document vegetation conditions.

The inspection includes the identification of any vegetation that may pose a threat to reliability prior to the next planned ~~inspection or~~ maintenance or inspection work, considering the current location of the conductor and other possible locations of the conductor due to sag and sway for rated conditions.

This definition allows both maintenance inspections and vegetation inspections to be performed concurrently.

~~*To~~

* This is a modification to a defined term in the NERC glossary and will be ~~added to~~incorporated into the NERC glossary of terms with final approval of this standard revision
~~** This is a modification to a defined term in the NERC glossary.~~

Applicability of the Standard

4. Applicability

4.1. Functional Entities:
Transmission Owners

4.2. Facilities: *Defined below~~,~~ (referred to as "applicable lines"), including but not limited to those that cross lands owned by federal*[1]*, state, provincial, public, private, or tribal entities:*

4.2.1 *Overhead transmission lines operated at 200kV or higher.*
4.2.2 *Overhead transmission lines operated below 200kV having been identified as included in the definition of an Interconnection Reliability Operating Limit (IROL) under NERC Standard FAC 014 by the Planning Coordinator.*
4.2.3 *Overhead transmission lines operated below 200 kV having been identified as included in the definition of one of the Major WECC Transfer Paths in the Bulk Electric System.*
4.2.4 *This standard ~~does not apply~~applies to ~~Facilities~~overhead transmission lines identified above (4.2.1 through 4.2.3) located ~~in~~outside the fenced area of ~~a~~the switchyard, station or substation~~.~~ and any portion of the span of the transmission line that is crossing the substation fence.*

4.3. Enforcement: *The reliability obligations of the applicable entities and facilities are contained within the technical requirements of this standard. [Straw proposal]*

Rationale
-The areas excluded in 4.2.4 were excluded based on comments from industry for reasons summarized as follows: 1) There is a very low risk from vegetation in this area. Based on an informal survey, no TOs reported such an event. 2) Substations, switchyards, and stations have many inspection and maintenance activities that are necessary for reliability. Those existing process manage the threat. As such, the formal steps in this standard are not well suited for this environment. 3) The standard was written for Transmission Owners. Rolling the excluded areas into this standard will bring GO and DP into the standard, even though NERC has an initiative in place to address this bigger registry issue. 4) Specifically addressing the areas where the standard applies or doesn't makes the standard stronger as it relates to clarity.

~~***4.4. Other:***~~
~~*This Standard does not apply to any occurrence, non-occurrence, or other set of circumstances that are beyond the control of a Transmission Owner subject to this reliability standard, including acts of God, flood, drought, earthquake, major storms, fire, hurricane, tornado, landslides, ice storms, vehicle contact with tree, human activity involving: removal of, installation of, or digging around vegetation, animals severing trees, lightning, epidemic, strike, war, riot, civil disturbance, sabotage, vandalism, terrorism, wind shear, or fresh gale (or higher wind speed) that restricts or prevents performance to comply with this reliability standard's*~~

[1] EPAct 2005 section 1211c: *"Access approvals by Federal agencies"*.

~~*requirements. Nothing in this section should be construed to limit the Transmission Owner's right to exercise its full legal rights on the Active Transmission Line ROW.*~~

In Order 693, FERC discussed the 200 kV bright-line test of applicability. While FERC did not change the 200 kV bright ~~-~~line, the Commission remained concerned that there may be some transmission lines operating at lesser voltages that could have significant impact on the Bulk Electric System that should therefore be subject to this standard.

NERC Standard FAC-014 has the stated purpose, "*To ensure that System Operating Limits (SOLs) used in the reliable planning and operation of the Bulk Electric System (BES) are determined based on an established methodology or methodologies.*" FAC-014 requires Reliability Coordinators, Planning Coordinators, and Transmission Planners to have a methodology to identify all lines that might comprise an IROL. Thus, these entities would identify sub-200 kV lines that qualify as part of an IROL and should be subject to FAC-003-2.

Although all three entities may prepare the list of elements, FAC-003-2 presently does not specify that it is the list from the Planning Coordinator that should be used by Transmission Owners for FAC-003. However, the Time Horizon needed to plan vegetation management work does not lend itself to the operating horizon of a Reliability Coordinator. Additionally, the Planning Coordinator has a wider-area view than the Transmission Planner and could thus identify any elements of importance to a sub-set of its area that might be missed by a Transmission Planner.

Transmission Owners, who do not already get the list of circuits included in the definition of an IROL, can get them from the Planning Coordinator. Specifically R5 of FAC-014 specifies that "*The Reliability Coordinator, Planning Authority (Coordinator) and Transmission Planner shall each provide its SOLs and IROLs to those entities that have a reliability-related need for those limits and provide a written request that includes a schedule for delivery of those limits*"

Vegetation-related Sustained Outages that occur due to natural disasters are beyond the control of the Transmission Owner. These events are not classified as vegetation-related Sustained Outages and are therefore exempt from the Standard. Transmission lines are not designed to withstand the impacts of natural disasters such as flood, drought, earthquake, major storms, fire, hurricane, tornado, landslides, ice storms, etc. In the aftermath of catastrophic system damage from natural disasters the Transmission Owner's focus is on electric system restoration for public safety and critical support infrastructure.

Sustained Outages due to human or animal activity are beyond the control of the Transmission Owner. These outages are not classified as vegetation-related Sustained Outages and are therefore exempt from the Standard. Examples of these events may include new plantings by outside parties of tall vegetation under the transmission line planted since the last Vegetation Inspection, tree contacts with line initiated by vehicles, logging activities, etc.

The foregoing exemptions are addressed in a new ~~subsection, 4.4 Other, of the Applicability section.~~footnote 2. Referred to collectively as force majeure events and activities, this ~~section~~footnote applies to ~~all~~ requirements R1 and R2 in FAC-003-2.

The reliability objective of this NERC Vegetation Management Standard ("Standard") is to prevent vegetation-related outages which could lead to Cascading by effective vegetation maintenance while recognizing that certain outages such as those due to vandalism, human errors and acts of nature are not preventable. Operating experience clearly indicates that trees that have grown out of specification could contribute to a cascading grid failure, especially under heavy electrical loading conditions.

Serious outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations. To properly reduce and manage this risk, it is necessary to apply the Standard to applicable lines on any kind of land or easement, whether they are Federal Lands, state or provincial lands, public or private lands, franchises, easements or lands owned in fee. For the purposes of the Standard and this Technical Reference document, the term “public lands” includes municipal lands, village lands, city lands, and land owned by a host of other governmental entities.

The Standard addresses vegetation management along applicable overhead lines that serve to connect one electric station to another. However, it is not intended to be applied to lines sections inside the electric station fence or other boundary of an electric station, submarine or underground lines.

The Standard is intended to reduce the risk of Cascading involving vegetation. It is not intended to prevent customer outages from occurring due to tree contact with all transmission lines and voltages. For example, localized customer service might be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. However, this Standard is not written to address such isolated situations which have little impact on the overall Bulk Electric System.

Vegetation growth is constant and always present. Unmanaged vegetation poses an increased outage risk when numerous transmission lines are operating at or near their Rating. This poses a significant risk of multiple line failures and Cascading. On the other hand, most other outage causes (such as trees falling into lines, lightning, animals, motor vehicles, etc.) are statistically intermittent. The probability of occurrence of these events is not dependent on heavy loads. There is no cause-effect relationship which creates the probability of simultaneous occurrence of other such events. Therefore these types of events are highly unlikely to cause large-scale grid failures.

In preparing the original vegetation management standard in 2005, industry stakeholders set the threshold for applicability of the standard at 200kV. This was because an unexpected loss of lines operating at above 200kV has a higher probability of initiating a widespread blackout or cascading outages compared with lines operating at less than 200kV.

The original NERC Standard FAC-003-1 also allowed for application of the standard to “critical” circuits (critical from the perspective of initiating widespread blackouts or cascading outages) operating below 200kV. While the percentage of these circuits is relatively low, it remains a fact that there are sub-200kV circuits whose loss could contribute to a widespread outage. Given the very limited exposure and unlikelihood of a major event related to these lower-voltage lines, it would be an imprudent use of resources to apply the Standard to all sub-200kV lines. The drafting team, after evaluating several alternatives, selected the IROL and WECC Major Transfer Path criteria to determine applicable lines below 200 kV that are subject to this standard.

~~*Active Transmission Line ROW*~~

~~The term "Active Transmission Line Right of Way" is defined in the Standard in a footnote repeated for convenience below:~~

> ~~*A strip or corridor of land that is occupied by active transmission facilities. This corridor does not include the parts of the Right-of-Way that are unused or intended for other facilities. However, it is not to be less than the width of the easement itself unless the easement exceeds distances as shown in Table 3 for various voltage classes.*~~

~~The term Right of Way (ROW) can be used in reference to many situations. This is partially because some lines are built on the land that is owned fee simple by the transmission owner, other lines are built across federal or provincial lands with only limited rights under a permit or agreement, and many other lines cross lands with only limited easement rights to construct, operate and maintain the line. Transmission line configurations on ROWs are present in many combinations of multiple circuits on various tower types. The number of circuits and configurations change along the length of the ROW due to circuits departing to other locations or terminating at nearby substations. Figures 1, 2 and 3 on the following pages depict several typical transmission line configurations on typical rights of way.~~

~~A Transmission Owner may plan for a nominal width along the entire length of a line during planning using its design specifications for a particular circuit configuration and voltage. The actual acquired ROW width at the time a circuit is constructed is however impacted in many cases, by other considerations. Those considerations include other future circuits that may be built adjacent to the subject line, or property parcels with unusual 'extra" widths due to special property owner demands during initial acquisition, or other existing lines adjacent to the subject line (which may be retired or abandoned at a future date). Refer to Figures 1 and 3 for common examples of such situations.~~

~~This Standard requires the Transmission Owner to prevent sustained outages due to vegetation "growing into" or "blowing together" with line conductors if that vegetation is under the line or growing beside the line (provided the Transmission Owner has the legal right to remove or trim the vegetation growing beside the line). Transmission Owners are also required to prevent sustained outages due to fall-ins from trees that, before falling, were standing inside the limits established in footnote 2 and associated "Table 3" (see below).~~

~~However it is recognized that any requirement in this standard to impose violations for sustained outages due to "fall-ins" must consider the impact of forcing the clearing of ROWs to the legal edge or to widths wider than they are typically managed. Therefore the standard drafting team inserted the subject footnote "active transmission line ROW" to provide a distance for a Transmission Owner to use if they do not already have a codified ROW width for a particular circuit or voltage". This approach of defining "active" and "inactive" right of way is intended to clarify the confusion created by the current standard which simply states that a fall-in from within the ROW is a violation. This provides the Transmission Owner with a means to define a right of way width that is applicable to fall-ins, provided it is not less than those limits in "Table 3".~~

Requirements R1 and R2

R1. *Each Transmission Owner shall manage vegetation to prevent ~~encroachment that could result in a Sustained Outage of any line~~encroachments of the types shown below, into the Minimum Vegetation Clearance Distance (MVCD) of any of its applicable line(s) identified as an element of an Interconnection Reliability Operating Limit (IROL) in the planning horizon by the Planning Coordinator; or Major Western Electricity Coordinating Council (WECC) transfer path ~~(~~(s); operating within its Rating and all Rated Electrical Operating Conditions~~). Types of encroachment include:~~.[2]*

1. *An encroachment into the ~~Minimum Vegetation Clearance Distance (MVCD)~~ MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage,*
2. *An encroachment due to a fall-in from inside the ~~Active Transmission Line ROW~~Right-of-Way (ROW) that caused a vegetation-related Sustained Outage,*
3. *An encroachment due to blowing together of applicable lines and vegetation located inside the ~~Active Transmission Line~~ ROW that caused a vegetation-related Sustained Outage,*
4. *An encroachment due to a grow-in that caused a vegetation-related Sustained Outage.*
   [VRF – High] [Time Horizon – Real-time]

~~Rationale~~

~~The MVCD is a calculated minimum distance stated in feet (meters) to prevent spark-over between conductors and vegetation, for various altitudes and operating voltages. The distances in Table 2 were derived using a proven transmission design method.~~

e 2

manage vegetation are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a TO's vegetation maintenance program since the encroachments listed require different and increasing levels of skills and knowledge and thus constitute a logical progression of how well, or poorly, a TO manages vegetation relative to this Requirement.

[2] This requirement does not apply to circumstances that are beyond the control of a Transmission Owner subject to this reliability standard, including natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods; human or animal activity such as logging, animal severing tree, vehicle contact with tree, arboricultural activities or horticultural or agricultural activities, or removal or digging of vegetation. Nothing in this footnote should be construed to limit the Transmission Owner's right to exercise its full legal rights on the ROW.

R2. *Each Transmission Owner shall manage vegetation to prevent ~~**encroachment that could result in a Sustained Outage**~~encroachments of the types shown below, into the MVCD of any of its applicable ~~**lines**~~line(s) that ~~**are**~~is not ~~**elements of**~~ an ~~**Interconnection Reliability Operating Limit (**~~element of an IROL~~)~~; or Major ~~**Western Electricity Coordinating Council (**~~WECC~~)~~ transfer path ~~(~~; operating within its Rating and all Rated Electrical Operating Conditions~~). Types of encroachment include:~~.*Error! Bookmark not defined.

1. *An encroachment into the ~~Minimum Vegetation Clearance Distance (MVCD)~~MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage,*
2. *An encroachment due to a fall-in from inside the ~~Active Transmission Line~~ ROW that caused a vegetation-related Sustained Outage,*
3. *An encroachment due to blowing together of applicable lines and vegetation located inside the ~~Active Transmission Line~~ ROW that caused a vegetation-related Sustained Outage,*
4. *An encroachment due to a grow-in that caused a vegetation-related Sustained Outage. [VRF – Medium] [Time Horizon – Real-time]*

M1. Each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R1. Examples of acceptable forms of evidence may include dated attestations, ~~*reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-Time observations of any MVCD encroachments.*~~

dated~~Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period.~~ ~~*If an investigation of a Fault by a qualified person confirms that a vegetation encroachment within the MVCD occurred, then it shall be considered a Real-time observation.*~~

~~***M2.*** *Each Transmission Owner has evidence that it managed vegetation as described in R2. Examples of acceptable forms of evidence may include attestations,*~~ reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-time observations of any MVCD encroachments.

If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation.

Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period. (R1)

M2. Each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R2. Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained

Outages associated with encroachment types 2 through 4 above, or records confirming no Real-time observations of any MVCD encroachments.

If ~~*an investigation*~~a later confirmation of a Fault by ~~*a qualified person confirms*~~the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred~~*, then it*~~ from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation.

Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period. (R2)

R1 and R2 are performance-based requirements. The reliability objective or outcome to be achieved is the prevention of vegetation encroachments within a minimum distance of transmission lines. Content-wise, R1 and R2 are the same requirements; however, they apply to different Facilities. Both R1 and R2 require each Transmission Owner to ~~prevent~~manage vegetation ~~from encroaching~~to prevent encroachment within the Minimum Vegetation Clearance Distance ("MVCD") of transmission lines. R1 is applicable to lines "identified as an element of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions) to avoid a Sustained Outage". R2 applies to all other applicable lines that are not an element of an IROL or Major WECC Transfer Path.

The separation of applicability (between R1 and R2) recognizes that an encroachment into the MVCD of an IROL or Major WECC Transfer Path transmission line is a greater risk to the electric transmission system. Applicable lines that are not an element of an IROL or Major WECC Transfer Path are required to be clear of vegetation but these lines are comparatively less operationally significant. As a reflection of this difference in risk impact, the Violation Risk Factors (VRFs) are assigned as High for R1 and Medium for R2.

These requirements (R1 and R2) state that if vegetation encroaches within the distances in Table 1 in Appendix 1 of this supplemental Transmission Vegetation Management Standard FAC-003-2 Technical Reference document, it is in violation of the standard. Table ~~1~~2 tabulates the distances necessary to prevent spark-over based on the Gallet equations as described more fully in Appendix 1 below.

These requirements assume that transmission lines and their conductors are operating within their Rating. If a line conductor is intentionally or inadvertently operated beyond its Rating (potentially in violation of other standards), the occurrence of a clearance encroachment may occur. For example, emergency actions taken by a Transmission Operator or Reliability Coordinator to protect an Interconnection may cause the transmission line to sag more and come closer to vegetation, potentially causing an outage. Such vegetation-related outages are not a violation of these requirements.

Evidence of violation of Requirement R1 and R2 include real-time observation of a vegetation encroachment into the MVCD (absent a Sustained Outage), or a vegetation-related encroachment resulting in a Sustained Outage due to a fall-in from inside the ~~Active Transmission Line~~ ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to blowing together of applicable lines and vegetation located inside the ~~Active Transmission Line~~ ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to a grow-in. If an investigation of a Fault by a ~~qualified person~~Transmission Owner confirms that a vegetation encroachment within the MVCD occurred, then it shall be considered the equivalent of a Real-time observation.

With this approach, the VSLs were defined such that they directly correlate to the severity of a failure of a Transmission Owner to ~~keep~~manage vegetation~~ away from conductors~~ and to the corresponding performance level of the Transmission Owner's vegetation program's ability to meet the goal of "preventing a Sustained Outage that could lead to Cascading." Thus violation severity increases with a Transmission Owner's inability to meet this goal and its potential of leading to a Cascading event. The additional benefits of such a combination are that it simplifies the standard and clearly defines performance for compliance. A performance-based requirement of this nature will promote high quality, cost effective vegetation management programs that will deliver the overall end result of improved reliability to the system.

Multiple Sustained Outages on an individual line can be caused by the same vegetation~~,~~. For example, a limb ~~that~~may only partially ~~breaks~~break and intermittently ~~contacts~~contact a conductor. Such events are considered to be a single vegetation-related Sustained Outage under the Standard where the Sustained Outages occur within a 24 hour period.

The MVCD is a calculated minimum distance stated in feet (or meters) to prevent spark-over, for various altitudes and operating voltages that is used in the design of Transmission Facilities. Keeping vegetation from entering this space will ~~help~~ prevent transmission outages.

Requirement R3

> **Rationale**
> ~~Provide~~The documentation provides a basis for ~~evaluation on~~evaluating the ~~intent and~~ competency of the Transmission ~~Owner in maintaining~~Owner's vegetation program. There may be many acceptable approaches to maintain clearances. ~~However,~~Any approach must demonstrate that the Transmission Owner ~~should be able~~ avoids vegetation-to ~~state what its approach is and how it conducts work to maintain clearances.~~-wire conflicts under all Rated Electrical Operating Conditions. See Figure 1 *~~[in Standard FAC-003-2]~~* for an illustration of possible conductor locations.

R3. *Each Transmission Owner shall ~~document the~~ have documented maintenance strategies or procedures~~,~~ or processes~~,~~ or specifications it uses to prevent the encroachment of vegetation into the MVCD~~. Such documentation will incorporate~~ of its applicable transmission lines that include(s) the following:*

3.1 Accounts for the ~~dynamics~~movement of ~~a~~applicable transmission line ~~conductor's movement throughout its~~ conductors under their Facility Rating and all Rated Electrical Operating Conditions ~~and~~;

[VRF – Lower] [Time Horizon – Long Term Planning]

M3. *The maintenance strategies or procedures~~,~~ or processes~~,~~ or specifications provided demonstrate that the Transmission Owner can prevent encroachment into the MVCD considering the factors identified in the requirement. (R3)*

Requirement R3 is a competency based requirement concerned with the maintenance strategies, procedures, processes, or specifications, a Transmission Owner uses for vegetation management.

An adequate transmission vegetation management program formally establishes the approach the Transmission Owner uses to plan and perform vegetation work to prevent transmission Sustained Outages and minimize risk to the Transmission System. The approach provides the basis for evaluating the intent, allocation of appropriate resources and the competency of the Transmission Owner in managing vegetation. There are many acceptable approaches to manage vegetation and avoid Sustained Outages. However, the Transmission Owner must be able to state what its approach is and how it conducts work to maintain clearances.

An example of one approach commonly used by industry is ANSI Standard A300, part 7. However, regardless of the approach a utility uses to manage vegetation, any approach a Transmission Owner chooses to use will generally contain the following elements:

1. *the maintenance strategy used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that MVCD clearances are never violated.*
2. *the work methods that the Transmission Owner uses to control vegetation*
3. *a stated Vegetation Inspection frequency*
4. *an annual work plan*

The conductor's position in space at any point in time is continuously changing as a reaction to a number of different loading variables. Changes in vertical and horizontal conductor positioning are the result of thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation. Physical loading applied to the conductor affects sag and sway by combining physical factors such as ice and wind loading. The movement of the transmission line conductor and the MVCD is illustrated in ~~Figure 5~~Figures 2 and 3 below.

Conductor Dynamics

In order for a Transmission Owner to develop a specific maintenance approach, it is important to understand the dynamics of a line conductor's movement. This paper will first address the complexities inherent in observing and predicting conductor movement, particularly for field personnel. It will then present some examples of maintenance approaches which Transmission Owners may consider that take into account these complexities, while resulting in practical approaches for field personnel.

Additionally, it is important the Transmission Owner consider all conductor locations, the MVCD, and vegetation growth between maintenance activities when developing a maintenance approach.

Understanding Conductor Position and Movement

The conductor's position in space at any point in time is continuously changing as a reaction to a number of different loading variables. Changes in vertical and horizontal conductor positioning are the result of thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation. Physical loading applied to the conductor affects sag and sway by combining physical factors such as ice and wind loading.

As a consequence of these loading variables, the conductor's position in space is dynamic and moving. When calculating the range of conductor positions, the Transmission Owner should use the same design criteria and assumptions that the Transmission Owner uses when establishing Ratings and SOL, as described in other standards. Typically, the greatest conductor movement would be at mid-span. As the conductor moves through various positions, a spark-over zone surrounding the conductor moves with it. The radius of the spark-over zone may be found by referring to Table 1 ("Minimum Vegetation Clearance Distances") in the standard. For illustrations of this zone and conductor movements, Figures ~~4~~1 through ~~6~~3 below demonstrate these concepts. At the time of making a field observation, however, it is very difficult to precisely know where the conductor is in relation to its wide range of all possible positions. Therefore, Transmission Owners must adopt maintenance approaches that account for this dynamic situation.

For Consideration in Developing a Maintenance Approach

Figure ~~6~~3

Selecting a Maintenance Approach

In order to maintain adequate separation between vegetation and transmission line conductors, the Transmission Owner must craft a maintenance strategy that keeps vegetation well away from the spark-over zone mentioned above. In fact, it is generally necessary to incorporate a variety of maintenance strategies. For example, one Transmission Owner may utilize a combination of routine cycles, traditional IVM techniques and long-term planning. Another Transmission Owner may place a higher reliance on frequent inspections and quick remediation as opposed to a cyclical approach. This variation of approaches is further warranted when factors, such as terrain, legal and other constraints, vegetation types, and climates, are considered in developing a Transmission Owner's specific approach to satisfying this requirement.

The following is a sample description of one combination of strategies which may be utilized by a Transmission Owner. A Transmission Owner's basic maintenance approach could be to remove all incompatible vegetation from the right of way if it has the right to do so and has no constraints. In mountainous terrain, however, this strategy could change to one where the Transmission Owner manages vegetation based on vegetation-to-conductor clearances, since it might not be necessary to remove vegetation in a valley that is far below.
If faced with constraints and assuming a line design with sufficient ground clearance, the Transmission Owner 's approach could then be to allow vegetation such as fruit trees, but perhaps only up to a given height at maturity (perhaps 10 feet from the ground). If constraints cannot be overcome and if design clearances are sufficient, an exception to the Transmission Owner's 10-foot guideline might be made. Finally, if the Transmission Owner has chosen to utilize vegetation-to-conductor clearance distance methods, the Transmission Owner could have an inspection regimen in place to regularly ensure that any impending clearance problems are identified early for rectification.

ANSI A300 – Best Management Practices for Tree Care Operations

A description of ANSI A-300, part 7, is offered below to illustrate another maintenance approach that could be used in developing a comprehensive transmission vegetation management program.

Introduction

Integrated Vegetation Management (IVM) is a best management practice conveyed in the American National Standard for Tree Care Operations, Part 7 (ANSI 2006) and the International Society of Arboriculture *Best Management Practices: Integrated Vegetation Management* (Miller 2007). IVM is consistent with the requirements in FAC-003-02, and it provides practitioners with what industry experts consider to be appropriate techniques to apply to electric right-of-way projects in order to meet or exceed the Standard.

IVM is a system of managing plant communities whereby managers set objectives; identify compatible and incompatible vegetation; consider action thresholds; and evaluate, select and implement the most appropriate control method or methods to achieve set objectives. The choice of control method or methods should be based on the environmental impact and anticipated effectiveness; along with site characteristics, security, economics, current land use and other factors.

Planning and Implementation

Best management practices provide a systematic way of planning and implementing a vegetation management program. While designed primarily with transmission systems in mind, it is also

applicable to distribution projects. As presented in ANSI A300 part 7 and the ISA best management practices, IVM consists of 6 elements:

1) Set Objectives
2) Evaluate the Site
3) Define Action Thresholds
4) Evaluate and Select Control Methods
5) Implement IVM
6) Monitor Treatment and Quality Assurance

The setting of objectives, defining action thresholds, and evaluating and selecting control methods all require decisions. The planning and implementation process is cyclical and continuous, because vegetation is dynamic and managers must have the flexibility to adjust their plans. Adjustments may be made at each stage as new information becomes available and circumstances evolve.

Set Objectives

Objectives should be clearly defined and documented. Examples of objectives can include promoting safety, preventing sustained outages caused by vegetation growing into electric facilities, maintaining regulatory compliance, protecting structures and security, restoring electric service during emergencies, maintaining access and clear lines of sight, protecting the environment, and facilitating cost effectiveness.

Objectives should be based on site factors, such as workload and vegetation type, in addition to human, equipment and financial resources. They will vary from utility to utility and project to project, depending on line voltage and criticality, as well as topographical, environmental, fiscal and political considerations. However, where it is appropriate, the overriding focus should be on environmentally-sound, cost effective control of species that potentially conflict with the electric facility, while promoting compatible, early successional, sustainable plant communities.

Work Load Evaluations

Work-load evaluations are inventories of vegetation that could have a bearing on management objectives. Work load assessments can capture a variety of vegetation characteristics, such as location, height, species, size and condition, hazard status, density and clearance from conductors. Assessments should be conducted considering voltage, conductor sag from ambient temperatures and loading, and the potential influence of wind on line sway.

Evaluate and Select Control Methods

Control methods are the process through which managers achieve objectives. The most suitable control method best achieves management objectives at a particular site. Many cases call for a combination of methods. Managers have a variety of controls from which to choose, including manual, mechanical, herbicide and tree growth regulators, biological, and cultural options.

Manual Control Methods

Manual methods employ workers with hand-carried tools, including chainsaws, handsaws, pruning shears and other devices to control incompatible vegetation. The advantage of manual techniques is that they are selective and can be used where others may not be. On the other hand, manual techniques can be inefficient and expensive compared to other methods.

Mechanical Control Methods

Mechanical controls are done with machines. They are efficient and cost effective, particularly for clearing dense vegetation during initial establishment, or reclaiming neglected or overgrown right of way. On the other hand, mechanical control methods can be non-selective and disturb sensitive sites.

Tree Growth Regulator and Herbicide Control Methods

Tree growth regulators and herbicides can be effective for vegetation management. Tree growth regulators (TGRs) are designed to reduce growth rates by interfering with natural plant processes. TGRs can be helpful where removals are prohibited or impractical by reducing the growth rates of some fast-growing species.

Herbicides control plants by interfering with specific botanical biochemical pathways. Herbicide use can control individual plants that are prone to re-sprout or sucker after removal. When trees that re-sprout or sucker are removed without herbicide treatment, dense thickets develop, impeding access, swelling workloads, increasing costs, blocking lines-of-site, and deteriorating wildlife habitat. Treating suckering plants allows early successional, compatible species to dominate the right-of-way and out-compete incompatible species, ultimately reducing work.

Cultural Control Methods

Cultural methods modify habitat to discourage incompatible vegetation and establish and manage desirable, early successional plant communities. Cultural methods take advantage of seed banks of native, compatible species lying dormant on site. In the long run, cultural control is the most desirable method where it is applicable.

A cultural control known as cover-type conversion provides a competitive advantage to short-growing, early successional plants, allowing them to thrive and eventually out-compete unwanted tree species for sunlight, essential elements and water. The early successional plant community is relatively stable, tree-resistant and reduces the amount of work, including herbicide application, with each successive treatment.

Wire-Border Zone

The wire-border zone technique is a management philosophy that can be applied through cultural control. W.C. Bramble and W.R. Byrnes developed it in the mid-1980s out of research begun in 1952 on a transmission right-of-way in the Pennsylvania State Game Lands 33 Research and Demonstration project (Yahner and Hutnik (2004).

The wire zone is the section of a utility transmission right-of-way directly under the wires and extending outward about 10 feet on each side. The wire zone is managed to promote a low-growing plant community dominated by grasses, herbs and small shrubs (under 3 feet in height at maturity). The border zone is the remainder of the right-of-way. It is managed to establish small trees and tall shrubs (under 25 feet in height at maturity). When properly managed, diverse, tree-resistant plant communities develop in wire and border zones. The communities not only protect the electric facility and reduce long-term maintenance, but also enhance wildlife habitat, forest ecology and aesthetic values.

Although the wire-border zone is a best practice in many instances, it is not necessarily universally suitable. For example, standard wire-border zone prescriptions may be unnecessary where lines are high off the ground, such as across low valleys or canyons, so the technique can be modified without sacrificing reliability.

One way to accommodate variances in topography is to establish different regions based on wire height. For example, over canyon bottoms or other areas where conductors are 100 feet or more above the ground, only a few trees are likely to be tall enough to conflict with the lines. In those cases, trees that potentially interfere with the transmission lines can be removed selectively on a case-by-case basis.

In areas where the wire is lower, perhaps between 50-100 feet from the ground, a border zone community can be developed throughout the right-of-way. Note that in many cases, conductor attachment points are more than 50 feet off the ground, so a border zone community can be cultivated near structures. Where the line is less than 50 feet off the ground, managers could apply a full wire-border zone prescription.

An environmental advantage of this type of modification is stream protection. Streams often course through the valleys and canyons where lines are likely to be elevated. Leaving timber or border zone communities in canyon bottoms helps shelter this valuable habitat, enabling managers to achieve environmentally sensitive objectives.

Implement IVM

All laws and regulations governing IVM practices and specifications written by qualified vegetation managers must be followed. Integrated vegetation management control methods should be implemented on regular work schedules, which are based on established objectives and completed assessments. Work should progress systematically, using control measures determined to be best for varying conditions at specific locations along a right-of-way. Some considerations used in developing schedules include the importance and type of line, vegetation clearances, work loads, growth rate of predominant vegetation, geography, accessibility, and in some cases, time lapsed since the last scheduled work.

Clearances Following Work

Clearances following work should be sufficient to meet management objectives, including preventing trees from entering the Minimum Vegetation Clearance Distance, electric safety risks, service-reliability threats and cost.

Monitor Treatment and Quality Assurance

An effective program includes documented processes to evaluate results. Evaluations can involve quality assurance while work is underway and after it is completed. Monitoring for quality assurance should begin early to correct any possible miscommunication or misunderstanding on the part of crewmembers. Early and consistent observation and evaluation also provides an opportunity to modify the plan, if need be, in time for a successful outcome.

Utility vegetation management programs should have systems and procedures in place for documenting and verifying that vegetation management work was completed to specifications. Post-control reviews can be comprehensive or based on a statistically representative sample. This final review points back to the first step and the planning process begins again.

Summary of A-300 example
Integrated Vegetation Management offers among others, a systematic way of planning and implementing a vegetation management program as presented in ANSI A300 Part 7. This methodology enables a program to comply with the NERC *Transmission Vegetation Management Program* standard (FAC-003-2). Managers should select control options to best promote management objectives.

Vegetation Inspections
As with the ANSI A-300 example, The Transmission Owner's transmission vegetation management program (TVMP) establishes the frequency of vegetation inspections based upon many factors. Such local and environmental factors may include anticipated growth rates of the local vegetation, length of the growing season for the geographical area, limited ~~Active Transmission~~ Rights of Way width, rainfall amounts, etc.

Annual Work Plan
Requirement R7 of the Standard addresses the execution of the annual work plan. A comprehensive approach that exercises the full extent of legal rights is superior to incremental management in the long term because it reduces overall encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient at all locations on the ~~Active Transmission Line~~ Right of Way. Removal is superior to pruning. Removal minimizes the possibility of conflicts between energized conductors and vegetation. Since this is not always possible, the Transmission Owner's approach should be to use its prescribed vegetation maintenance methods to work towards or achieve the maximum use of the ~~Active Transmission Line~~ Right of Way.

Requirement R4

R4. *Each Transmission Owner, without any intentional time delay, shall notify the control center holding switching authority for the associated applicable transmission line when ~~qualified personnel confirm~~the Transmission Owner has confirmed the existence of a vegetation condition that is likely to cause a Fault at any moment.*

Rationale
To ensure expeditious communication between ~~qualified field personnel~~the Transmission Owner and ~~proper operating personnel~~the control center when a critical situation is confirmed.
~~Qualified field personnel may include~~

[VRF – Medium] [Time Horizon – Real-time]

M4. *Each Transmission Owner that has a confirmed vegetation condition likely to cause a Fault at any moment~~, as confirmed by qualified personnel,~~ will have evidence that it notified the control center holding switching authority for the associated transmission line without any intentional time delay. Examples of evidence may include control center logs, voice recordings, switching orders, clearance orders and subsequent work orders. (R4)*

R4 is a risk-based requirement. It focuses on preventative actions to be taken by the Transmission Owner for the mitigation of Fault risk when a vegetation threat is confirmed. R4 involves the notification of potentially threatening vegetation conditions, without any intentional delay, to the control center holding switching authority for that specific transmission line. Examples of acceptable unintentional delays may include communication system problems (for example, cellular service or two-way radio disabled), crews located in remote field locations with no communication access, delays due to severe weather, etc.

Confirmation is key that a threat actually exists due to vegetation. This confirmation could be in the form of a ~~qualified~~Transmission Owner's employee who personally identifies such a threat in the field. Confirmation could also be made by sending out ~~a qualified person~~an employee to evaluate a situation reported by a landowner~~ or an unqualified employee.~~.

Vegetation-related conditions that warrant a response include vegetation that is near or encroaching into the MVCD (a grow-in issue) or vegetation that could fall into the transmission conductor (a fall-in issue). A knowledgeable verification of the risk would include an assessment of the possible sag or movement of the conductor while operating between no-load conditions and its rating.

The Transmission Owner has the responsibility to ensure the proper communication between field personnel and the control center to allow the control center to take the appropriate action until the vegetation threat is relieved. Appropriate actions may include a temporary reduction in the line loading, switching the line out of service, or positioning the system in recognition of the increasing risk of outage on that circuit. The notification of the threat should be communicated in terms of minutes or hours as opposed to a longer time frame for corrective action plans (see R5).

All potential grow-in or fall-in vegetation-related conditions will not necessarily cause a Fault at any moment. For example, some Transmission Owners may have a danger tree identification

program that identifies trees for removal with the potential to fall near the line. These trees would not require notification to the control center unless they pose an immediate fall-in threat.

Requirement R5

R5. *~~Each~~ When a Transmission Owner ~~shall take corrective action when it~~ is constrained from performing ~~planned~~ vegetation work, ~~where a transmission line is put at potential risk due to~~ and the constraint~~.~~ may lead to a vegetation encroachment into the MVCD of its applicable transmission lines prior to the implementation of the next annual work plan then the Transmission Owner shall take corrective action to ensure continued vegetation management to prevent encroachments. [VRF – Medium] [Time Horizon – Operations Planning]*

Rationale

Legal actions and other events may occur which result in constraints that prevent the Transmission Owner from performing planned vegetation maintenance work.

In cases where the transmission line is put at potential risk due to constraints, the intent is for the Transmission Owner to put interim measures in place, rather than do nothing. ~~For example, in the 2003 NE blackout a Transmission Owner was prevented by a court order from performing planned work. However, when the court order expired, the TO failed to take action to maintain the~~

M5. *Each Transmission Owner has evidence of the corrective action taken for each constraint where ~~a~~an applicable transmission line was put at potential risk. Examples of acceptable forms of evidence may include initially-planned work orders, documentation of constraints from landowners, court orders, inspection records of increased monitoring, documentation of the de-rating of lines, revised work orders, invoices, and evidence that a line was de-energized. (R5)*

R5 is a risk-based requirement. It focuses upon preventative actions to be taken by the Transmission Owner for the mitigation of Sustained Outage risk when temporarily constrained from performing vegetation maintenance. The intent of this requirement is to deal with situations that prevent the Transmission Owner from performing planned vegetation management work and, as a result, have the potential to put the transmission line at risk. Constraints to performing vegetation maintenance work as planned could result from legal injunctions filed by property owners, the discovery of easement stipulations which limit the Transmission Owner's rights, or other circumstances.

This requirement is not intended to address situations where the transmission line is not at potential risk and the work event can be rescheduled or re-planned using an alternate work methodology. For example, a land owner may prevent the planned use of chemicals on non-threatening, low growth vegetation but agree to the use of mechanical clearing. In this case the Transmission Owner is not under any immediate time constraint for achieving the management objective, can easily reschedule work using an alternate approach, and therefore does not need to take interim corrective action.

However, in situations where transmission line reliability is potentially at risk due to a constraint, the Transmission Owner is required to take an interim corrective action to mitigate the potential risk to the transmission line. A wide range of actions can be taken to address various situations. General considerations include:

- Identifying locations where the Transmission Owner is constrained from performing planned vegetation maintenance work which potentially leaves the transmission line at risk.
- Developing the specific action to mitigate any potential risk associated with not performing the vegetation maintenance work as planned.
- Documenting and tracking the specific action taken for each location.
- In developing the specific action to mitigate the potential risk to the transmission line the Transmission Owner could consider location specific measures such as modifying the inspection and/or maintenance intervals. Where a legal constraint would not allow any vegetation work, the interim corrective action could include limiting the loading on the transmission line.
- The Transmission Owner should document and track the specific corrective action taken at each location. This location may be indicated as one span, one tree or a combination of spans on one property where the constraint is considered to be temporary.

Requirement R6

R6. *Each Transmission Owner shall perform a Vegetation Inspection of ~~all~~100% of its applicable transmission lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.) at least once per calendar year~~.~~ and with no more than 18 months between inspections on the same ROW.*[3]

[VRF – Medium] [Time Horizon – Operations Planning]

M6. *Each Transmission Owner has evidence that it conducted Vegetation Inspections ~~at least once per calendar year for applicable~~of the transmission ~~lines~~line ROW for all applicable transmission lines at least once per calendar year but with no more than 18 months between inspections on the same ROW. Examples of acceptable forms of evidence may include completed and dated work orders, dated invoices, or dated inspection records. (R6)*

> ~~**Rationale**~~
> ~~Inspections are used by Transmission Owners to prevent the encroachment of vegetation into the MVCD and provide a basis for assessing risk. This requirement sets a minimum vegetation inspection frequency of once per calendar year. Based upon average growth rates across North America and on common utility practice, this minimum frequency is reasonable. Transmission Owners should consider local and environmental factors that could warrant more frequent inspections.~~
> frequency is reasonable. Transmission Owners should consider local and environmental factors that could warrant more frequent inspections.

R6 is a risk-based requirement. This requirement sets a minimum time period for completing Vegetation Inspections that fits general industry practice. In addition, the fact that Vegetation Inspections can be performed in conjunction with general line inspections further facilitates a Transmission Owner's ability to meet this requirement. However, the Transmission Owner may determine that more frequent inspections are needed to maintain reliability levels, dependent upon such factors as anticipated growth rates of the local vegetation, length of the growing season for the geographical area, limited ~~Active Transmission~~ ROW width, and rainfall amounts. Therefore it is expected that some transmission lines may be designated with a higher frequency of inspections.

The SDT added footnote 3 to address the situation where a Transmission Owner through no fault of its own, would be unable to complete the vegetation inspection within the allotted time period. This would include the situation of mutual aid as well as disasters to the Transmission Owner's own system.

The VSL for Requirement R6 has VSL categories ranked by the percentage of the required ROW inspections completed. To calculate the percentage of inspection completion, the Transmission Owner may choose units such as: line miles or kilometers, circuit miles or kilometers, pole line miles, ROW miles, etc.

[3] When the Transmission Owner is prevented from performing a Vegetation Inspection within the timeframe in R6 due to a natural disaster, the TO is granted a time extension that is equivalent to the duration of the time the TO was prevented from performing the Vegetation Inspection.

For example, when a Transmission Owner operates 2,000 miles of 230 kV transmission lines this Transmission Owner will be responsible for inspecting all 2,000 miles of 230 kV transmission lines at least once during the calendar year. If one of the included lines was 100 miles long, and if it was not inspected during the year, then the amount failed to inspect would be 100/2000 = 0.05 or 5%. The “Low VSL” for R6 would apply in this example.

Requirement R7

R7. *Each Transmission Owner shall complete ~~the work in an~~100% of its annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made ~~and documented~~ (provided they do not put the transmission system at risk of a vegetation encroachment~~.~~) and must be documented. The percent completed calculation is based on the number of units actually completed divided by the number of units in the final amended plan (measured in units of choice - circuit, pole line, line miles or kilometers, etc.) Examples of reasons for modification to annual plan may include:*

- Change in expected growth rate/ environmental factors
- ~~*Major storms*~~
- Circumstances that are beyond the control of a Transmission Owner[4]
- Rescheduling work between growing seasons
- Crew or contractor availability/ Mutual assistance agreements
- Identified unanticipated high priority work
- Weather conditions/Accessibility
- Permitting delays
- Land ownership changes/Change in land use by the landowner
- ~~*Funding adjustments (increase or decrease)*~~
- Emerging technologies

  [VRF – Medium] [Time Horizon – Operations Planning]

Rationale
This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. An annual vegetation work plan allows for work to be modified for changing conditions, taking into consideration anticipated growth of vegetation and all other environmental factors, provided that the changes do not violate the encroachment within the MVCD.

M7. *Each Transmission Owner has evidence that it completed its annual vegetation work plan. Examples of acceptable forms of evidence may include a copy of the completed annual work plan (including modifications if any), dated work orders, dated invoices, or dated inspection records. (R7)*

R7 is a risk-based requirement. The Transmission Owner is required to implement an annual work plan for vegetation management to accomplish the purpose of this Standard. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made and documented provided they do not put the transmission system at risk. The annual work plan requirement is not intended to necessarily require a “span-by-span”, or even a “line-by-line” detailed description of all work to be performed. It is only intended to require that the Transmission Owner provide evidence of annual planning and execution of a vegetation

[4] circumstances that are beyond the control of a Transmission Owner include but are not limited to natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, major storms as defined either by the TO or an applicable regulatory body, ice storms, and floods; arboricultural, horticultural or agricultural activities.

management maintenance approach which successfully prevents encroachment of vegetation into the MVCD.

The ability to modify the work plan allows the Transmission Owner to change priorities or treatment methodologies during the year as conditions or situations dictate. For example recent line inspections may identify unanticipated high priority work, weather conditions (drought) could make herbicide application ineffective during the plan year, or a major storm could require redirecting local resources away from planned maintenance~~.~~ or work may be deferred to a subsequent year because of slower-than-expected growth. This situation may also include complying with mutual assistance agreements by moving resources off the Transmission Owner's system to work on another system. Any of these examples could result in acceptable deferrals or additions to the annual work plan. Modifications to the annual work plan must always ensure the reliability of the electric Transmission system.

In general, the vegetation management maintenance approach should use the full extent of the Transmission Owner's ~~easement, fee simple and other~~ legal rights ~~allowed.~~ on the ROW. A comprehensive approach that exercises the full extent of legal rights on the ~~Active Transmission Line~~ ROW is superior to incremental management in the long term because it reduces the overall potential for encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient.

When developing the annual work plan, the Transmission Owner should allow time for reasonable and predictable procedural requirements to obtain permits to work on federal, state, provincial, public, tribal lands. In some cases, the lead time for obtaining permits may necessitate preparing work plans more than a year prior to ~~work~~the start ~~dates~~of work. Transmission Owners may also need to consider those special landowner requirements ~~as documented in easement instruments~~.

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. Therefore, deferrals or relevant changes to the annual plan shall be documented. Depending on the planning and documentation format used by the Transmission Owner, evidence of successful annual work plan execution could consist of signed-off work orders, signed contracts, printouts from work management systems, spreadsheets of planned versus completed work, timesheets, work inspection reports, or paid invoices. Other evidence may include photographs~~,~~ and walk-through reports.

Appendix 1: Clearance Distance Derivation by the Gallet Equation

The Gallet Equation is a well-known method of computing the required strike distance for proper insulation coordination, and has the ability to take into account various air gap geometries, as well as non-standard atmospheric conditions. When the Gallet Equation and conservative probabilistic methods are combined, i.e. deterministic design, sparkover probabilities of 10^{-6} or less are achieved. This approach is well known for its conservatism and was used to design the first 500 kV and 765 kV lines in North America [1]. Thus, the deterministic design approach using the Gallet Equation is used for the standard to compute the minimum strike distance between transmission lines and the vegetation that may be present in or along the transmission corridor.

Method Explanation (Gallet Equation)

In 1975 G. Gallet published a benchmark paper that provided a method to compute the critical flashover voltage (CFO) of various air gap geometries [4]. The Gallet Equation uses various "gap factors" to take into account various air gap geometries. Various gap factor values are provided in [1]. If the vegetation in a transmission corridor, e.g. a tree, is assumed electrically to be a large structure then the CFO of such an air gap geometry can be computed for dry or wet conditions using a well established equation proposed by Gallet [1],[2],[4],

$$CFO_A = k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} \quad (1)$$

where,

k_w is defined as the factor that takes into account wet or dry conditions (dry = 1.0 and wet = 0.96) and phase arrangement (multiply by 1.08 for outside phase), e.g. outside phase and wet conditions = (0.96)(1.08) = 1.037,

k_g is defined as the gap factor (1.3 for conductor to large structure),

D is the strike distance (m),

CFO_A is the CFO for the relative air density (kV).

δ is defined as the relative air density and is approximately equal to (2) where A is the altitude in km,

$$\delta = e^{-\frac{A}{8.6}} \quad (2)$$

$$m = 1.25 G_0 \left(G_0 - 0.2\right) \quad (3)$$

$$G_0 = \frac{CFO_s}{500 \cdot D} \quad (4)$$

$$CFO_s = k_w \cdot k_g \cdot \frac{3400}{1+\frac{8}{D}} \tag{5}$$

where CFO_S is the CFO for standard atmospheric conditions (kV). Using (1)-(5), the required CFO_A can be computed using an iterative process.

Once the CFO_A is known, deterministic methods can be used to determine the required clearance distance. If we let the maximum switching overvoltage be equal to the withstand voltage of the air gap (CFO_A - 3σ) then the CFO_A can be written as (6).

$$CFO_A = \frac{V_m}{1-3\left(\frac{\sigma}{CFO_A}\right)} \tag{6}$$

where

V_m is equal to the maximum switching overvoltage, i.e. the value that has a 0.135% chance of being exceeded,

σ is the standard deviation of the air gap insulation,

CFO_A is the critical flashover voltage of the air gap insulation under non-standard atmospheric conditions.

The ratio of σ to the CFO_A given in (6) can be assumed to be 0.05 (5%) [1]. Thus, (6) can be written as (7).

$$CFO_A = \frac{V_m}{0.85} \tag{7}$$

Substituting (7) into (1) we arrive at (8).

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} \tag{8}$$

Equation 8 relates the maximum transient overvoltage, V_m, to the air gap distance, D. Using (8) to compute the required clearance distance for the specified air gap geometry (conductor to large structure) results in a probability of flashover in the range of 10^{-6}.

Transient Overvoltage

In general, the worst case transient overvoltages occurring on a transmission line are caused by energizing or re-energizing the line with the latter being the extreme case if trapped charge is present. The intent of FAC-003 is to keep a transmission line that is *in service* from becoming de-energized (i.e. tripped out) due to sparkover from the line conductor to nearby vegetation. Thus, the worst case scenarios that are typically analyzed for insulation coordination purposes (e.g. line energization and re-energization) can be ignored. For the purposes of FAC-003-2, the worst case transient overvoltage then becomes the maximum value that can occur with the line energized. Determining a realistic value of transient overvoltage for this situation is difficult because the maximum transient overvoltage factors listed in the literature are based on a

switching operation of the line in question. In other words, these maximum overvoltage values (e.g. the values listed in [2], [3] and [5]) are based on the assumption that the subject line is being energized, re-energized or de-energized. These operations, by their very nature, will create the largest transient overvoltages. Typical values of transient overvoltages of in-service lines, as such, are not readily available in the literature because the resulting level of overvoltage is negligible compared with the maximum (e.g. re-energizing a transmission line with trapped charge). A conservative value for the maximum transient overvoltage that can occur anywhere along the length of an in-service ac line is approximately 2.0 p.u.[2]. This value is a conservative estimate of the transient overvoltage that is created at the point of application (e.g. a substation) by switching a capacitor bank without a pre-insertion device (e.g. closing resistors). At voltage levels where capacitor banks are not very common (e.g. 362 kV), the maximum transient overvoltage of an "in-service" ac line are created by fault initiation on adjacent ac lines and shunt reactor bank switching. These transient voltages are usually 1.5 p.u. or less [2]. It is well known that these theoretical transient overvoltages will not be experienced at locations remote from the bus at which they were created; however, in order to be conservative, it will be assumed that all nearby ac lines are subjected to this same level of overvoltage. Thus, a maximum transient overvoltage factor of 2.0 p.u. for 242 kV and below and 1.4 p.u. for ac transmission lines 362 kV and above is used to compute the required clearance distances for vegetation management purposes.

The overvoltage characteristics of dc transmission lines vary somewhat from their ac counterparts. The referenced empirically derived transient overvoltage factor used to calculate the minimum clearance distances from dc transmission lines to vegetation for the purpose of FAC-003-2 will be 1.8 p.u.[3].

Example Calculation

An example calculation is presented below using the proposed method of computing the vegetation clearance distances. It is assumed that the line in question has a maximum operating voltage of 550 kV_{rms} line-to-line. Using a per unit transient overvoltage factor of 1.4, the result is a peak transient voltage of 629 kV_{crest}. It is further assumed that the line in question operates at a maximum altitude of 7000 feet (2.134 km) above sea level.

The required withstand voltage of the air gap must be equal to or greater than 629 kV_{crest}. Since the altitude is above sea level, (1) - (5) have to be iterated on to achieve the desired result. Equation (9) can be used as an initial guess for the clearance distance.

$$D_i = \frac{8}{\dfrac{3400 \cdot k_w \cdot k_g}{\left(\dfrac{V_m}{0.85}\right)} - 1} \tag{9}$$

For our case here, V_m is equal to 629 kV, k_w = 1.037 and k_g = 1.3. Thus,

$$D_i = \frac{8}{\dfrac{3400 \cdot k_w \cdot k_g}{\left(\dfrac{V_m}{0.85}\right)} - 1} = \frac{8}{\dfrac{3400 \cdot 1.037 \cdot 1.3}{\left(\dfrac{629}{0.85}\right)} - 1} = 1.535m \tag{10}$$

Using (2)-(5) and (8) the withstand voltage of the air gap is next computed. This value will then be compared to the maximum transient overvoltage.

$$CFO_S = k_w \cdot k_g \cdot \frac{3400}{1+\frac{8}{D}} = 1.037 \cdot 1.3 \cdot \frac{3400}{1+\frac{8}{1.535}} = 737.7kV \tag{11}$$

$$\delta = e^{-\frac{A}{8.6}} = e^{-\frac{2.134}{8.6}} = 0.78 \tag{12}$$

$$G_O = \frac{CFO_S}{500 \cdot D} = \frac{737.7}{(500)\cdot(1.535)} = 0.961 \tag{13}$$

$$m = 1.25 \cdot G_O(G_O - 0.2) = 1.25 \cdot 0.961(0.961 - 0.2) = 0.915 \tag{14}$$

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} = (0.85)(1.037)(1.3)(0.78)^{0.915}\left(\frac{3400}{1+\frac{8}{1.535}}\right) = 499.8kV \tag{15}$$

The calculated V_m is less than 629 kV; thus, the clearance distance must be increased. A few iterations using (2)-(5) and (8) are required until the computed $V_m \geq 629$ kV. For this case it was found that D = 1.978 m (6.49 feet) yielded V_m = 629.3 kV. Using this clearance distance the following values were computed for the final iteration.

$$CFO_S = k_w \cdot k_g \cdot \frac{3400}{1+\frac{8}{D}} = 1.037 \cdot 1.3 \cdot \frac{3400}{1+\frac{8}{1.978}} = 908.5kV \tag{16}$$

$$\delta = e^{-\frac{A}{8.6}} = e^{-\frac{2.134}{8.6}} = 0.78 \tag{17}$$

$$G_O = \frac{CFO_S}{500 \cdot D} = \frac{908.5}{(500)\cdot(1.978)} = 0.919 \tag{18}$$

$$m = 1.25 \cdot G_O(G_O - 0.2) = 1.25 \cdot 0.919(0.919 - 0.2) = 0.825 \tag{19}$$

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} = (0.85)(1.037)(1.3)(0.78)^{0.825}\left(\frac{3400}{1+\frac{8}{1.978}}\right) = 629.3kV \tag{20}$$

Therefore, the minimum vegetation clearance distance for a maximum line to line ac operating voltage of 550 kV at 7000 feet above sea level is 1.978 m (6.49 feet). Table 1 provides calculated distances for various altitudes and maximum system operating ac voltages.

Standards Announcement

Successive Ballot and Non-binding Poll Open
Project 2007-07 – Vegetation Management
February 18 – February 28, 2011

Now available at: https://standards.nerc.net/CurrentBallots.aspx

Project 2007-07 – Vegetation Management

A successive ballot window for FAC-003-2 – Transmission Vegetation Management and its associated implementation plan is open through **8 p.m. on February 28, 2011**.

In addition, members of this ballot pool will be able to vote in a concurrent non-binding poll on the standard's Violation Risk Factors (VRFs) and Violation Severity Levels (VSLs). Members who joined the ballot pool to vote on the standard were automatically entered in a separate pool to participate in the non-binding poll for the VRFs and VSLs. The non-binding poll will appear in the list of current ballots, and is labeled accordingly.

Instructions

Members of the ballot pool associated with this project may log in and submit their votes from the following page: https://standards.nerc.net/CurrentBallots.aspx

Background

FAC-003-1 is being revised to address several fill-in-the-blank requirements, directives from Order 693, and issues raised by stakeholders. An initial ballot closed in July 2010 and achieved a quorum of 86.18 % and an approval of 65.93 %. The drafting team has posted its consideration of comments received, both those submitted with a ballot as well as those submitted with a comment form. In addition, a Quality Review was conducted in November 2010, and the drafting team revised the draft standard and technical reference in response to comments and input from the Quality Review.

Documents for this project, including clean and redline to the last posted versions of the standard, implementation plan, and technical reference and an unofficial copy of the questions listed in the comment forms are posted on the project web page at:
http://www.nerc.com/filez/standards/Vegetation-Management_Project_2007-7.html

Next Steps

Voting results will be posted and announced after the ballot window closes, and the drafting team will consider all comments, including those submitted with a comment form and those submitted with a ballot.

Standards Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

Project 2007-07 Transmission Vegetation Management
Successive Formal Comment Period Open
January 27, 2010 – February 28, 2011

Now available at:
http://www.nerc.com/filez/standards/Vegetation-Management_Project_2007-7.html

A 30-day formal comment period for the proposed standard, FAC-003-2 – Transmission Vegetation Management, its associated implementation plan, and supporting technical reference paper is now open **until 8 p.m. Eastern on February 28, 2011**.

Background

FAC-003-1 is being revised to address several fill-in-the-blank requirements, directives from Order 693, and issues raised by stakeholders. An initial ballot closed in July 2010. The ballot achieved a quorum of 86.18 % and an approval of 65.93 %. The drafting team has posted its Consideration of Comments received (those submitted with a ballot as well as those submitted with a comment form). A Quality Review was conducted in November 2010 and the drafting team has revised the draft standard and technical reference in response to comments and input from the Quality Review.

Documents for this project, including clean and redline to the last posted versions of the standard, implementation plan, and technical reference and an unofficial copy of the questions listed in the comment forms are posted at the following site:
http://www.nerc.com/filez/standards/Vegetation-Management_Project_2007-7.html

Instructions

Please use this electronic form to submit comments on FAC-003-2, its associated implementation plan, and supporting technical reference paper. If you experience any difficulties in using the electronic form, please contact Monica Benson at monica.benson@nerc.net.

Next Steps – Successive Ballot and Non-binding Poll of VRFs and VSLs

A successive ballot will be conducted during the last 10 days of the formal comment period, from 8 a.m. Eastern on Friday, February 18, 2011 until 8p.m. Eastern on Monday, February 28, 2011. All members of the ballot pool must cast a new ballot since the votes and comments from the last ballot will not be carried over. In addition, members of the ballot pool will need to cast a new opinion on the revised VRFs and VSLs. The drafting team will consider all comments (those submitted with a comment form, and those submitted with a ballot or with the non-binding poll) and will determine whether to make additional changes to the standard and its implementation plan.

Standards Development Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate. For more information or assistance, please contact Monica Benson at monica.benson@nerc.net.

For more information or assistance, please contact Monica Benson,
Standards Process Administrator, at monica.benson@nerc.net or at 609.452.8060.

Standards Announcement

Project 2007-07 Transmission Vegetation Management
Successive Ballot Results

Now available at: https://standards.nerc.net/Ballots.aspx

Ballot Results for Revisions to FAC-003

A successive ballot on revisions to FAC-003 - Transmission Vegetation Management, and a concurrent non-binding poll of associated VRFs and VSLs concluded on February 28, 2011.

Voting statistics are listed below, and the Ballot Results Web page provides a link to the detailed results:

Quorum: 79.28 %
Approval: 79.34 %

Violation Risk Factor (VRF) and Violation Severity Level (VSL) Non-binding Poll Results

For the non-binding poll of VRFs and VSLs, 77% of those who registered to participate provided an opinion; 79% of those who provided an opinion indicated support for the VRFs and VSLs that were proposed.

Next Steps

The drafting team will post its consideration of all comments (those submitted with a comment form, and those submitted with a ballot).

Background:

FAC-003-1 is being revised to address several fill-in-the-blank requirements, directives from Order 693, and issues raised by stakeholders. An initial ballot closed in July 2010 and achieved a quorum of 86.18 % and an approval of 65.93 %. The drafting team has posted its consideration of comments received, both those submitted with a ballot as well as those submitted with a comment form. In addition, a Quality Review was conducted in November 2010, and the drafting team revised the draft standard and technical reference in response to comments and input from the Quality Review.

Further details are available on the project page: http://www.nerc.com/filez/standards/Vegetation-Management_Project_2007-7.html

Standards Process

The Standard Processes Manual contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

For more information or assistance, please contact Monica Benson, Standards Process Administrator, at monica.benson@nerc.net or at 404-446-2560.

	The minimum frequency of Vegetation Inspection should be based upon an average growth rates of smaller regions than all North America. Example, above the latitude of about 50 degrees North, the vegetation growth rates is limited. We think that Vegetation Inspection frequency should be relaxed to 3 years for those areas in Canada. As indicator of the minimum frequency requested in R6, we suggest to use a global vegetation index like the Normalized Difference Vegetation Index (NDVI). The NDVI has been in use for many years to measure the vigor of vegetation growth among other things. http://earthobservatory.nasa.gov/Features/MeasuringVegetation/

	These proposed Requirements, Measures and Violation Severity Levels as written do not give credit to the Transmission Owners for effectively monitoring their systems and taking appropriate actions in regard to vegetation clearing. Why does it make sense to punish and penalize a Transmission Owner for discovering an encroachment when they take the appropriate actions to remedy the condition before any facility outage occurs that results in compromising the reliability of the Bulk Electric System? These Requirements, Measures and VSL's should recognize the good practices of effective response to a vegetation condition and penalize ineffective response. Recommend the SDT consider including appropriate language to recognize effective remedial actions by Transmission Owners and by doing so, recognize effective efforts instead of punishing them. In addition, proving encroachments have not occurred will pose audit challenges in determining that encroachments have not occurred for the Auditors as well as Registered Entities. If no encroachments occur, then there is nothing to report or record. This is a weak platform to stand compliance on. Facility interruption events caused by vegetation contacts is definitively measurable and recordable. Recommend the SDT reconsider the concept of compliance with FAC-003 on the basis of sustained outages and remove the references regarding encroachments only. Recommend the SDT remove the LOWER VSL language from Requirements R1 and R2 and revise the Requirements and Measures to reflect the same.
	Yes
	Yes
	No
	1) R7 states "Each Transmission Owner shall complete 100% of its annual vegetation work plan...". We suggest to be consistent with all other sections of the rule that it should read, "Each Transmission Owner shall complete 100% of its annual vegetation work plan for all applicable lines...". Otherwise, leaves room for interpretation to include all lines including those not defined as applicable. Also require these same revisions to row R7 of the table "Time Horizons, Violation Risk Factors, and Violation Severity Levels". 2) In the "Additional Compliance Information" section Categories 1, 2, and 4 are each defined to have an A & B component to recognize the severity level difference for "applicable transmission lines" identified versus not identified "as an element of an IROL or Major WECC Transfer Path". However, Category 3 does not separate these two scenarios however it appears that the same distinction should apply. Additional comments: Vegetation Inspection Definition Recommend the SDT consider removing the conditional language, "that are likely to pose a hazard to the line(s) prior to the next". Vegetation inspections are not dependent on a predisposed condition of vegetation. Suggest the SDT remove that phrase and consider the following definition: The systematic examination of vegetation conditions on a maintained transmission line Right-of-Way under the Transmission Owner's control under a planned maintenance or inspection which may be combined with a general line inspection.

We agree with the proposed definition as a replacement for active transmission ROW, however, in a review of NERC standards, the term ROW is not used except in FAC-003. It is therefore recommended that the term be removed from the NERC glossary.

This is a reliability standard and the TO should know what its clearance needs are at all rated conditions, especially considering today’s technology. If the TO manages to this standard there is no need for R1 and R2.
No
The TO should be managing for reliability. The system is not static, like vegetation it moves and changes over time and that fluctuation should be taken into account to maintain reliability at all rated conditions.
No
The TVMP shall demonstrate the TO’s ability to manage the system at all rated conditions to maintain reliability.

	The definition does not define transmission owner responsibility for areas covered by “danger tree” rights. This area is outside the maintained width but for economic and social reasons the transmission owner can not remove all danger trees. Utilities have procedures in place to remove the hazard trees but it is not practical to remove all danger trees that have the potential to violate the MVCD should they fail. This area of the definition requires clarification.

	The revised definition of ROW is unclear in regards to the application of standards and/or historic records as a means of determining ROW width; is it necessary for a TO to select one method to apply in all cases, or can each span be treated in the manner deemed most appropriate by the TO? Additionally “blowout Standard” has not been defined in the document or in the technical paper, and therefore it is not clear exactly how this method would be applied, and subsequently defended under scrutiny.

	You could also include the term “maintenance standards”.
	Yes
	You could also include other documentation such as monthly financial and program variance reports. Additional Comments Table 1: R6 definitions could be clearer. Suggested clarification: VSL Lower – Greater than 95% of annual inspections complete but less than 100% complete. VSL Moderate – Greater than 90 % of annual inspections complete but less than 95% complete VSL High – Greater than 85% of annual inspections complete but less than 90% complete VSL Severe – Less than 85% of annual inspections completed Table 1 R7 definitions could be clearer. Suggested clarification: VSL Lower – Greater than 95% of annual work plan complete but less than 100% complete. VSL Moderate – Greater than 90 % of annual work plan complete but less than 95% complete VSL High – Greater than 85% of annual work plan complete but less than 90% complete VSL Severe – Less than 85% of annual work plan completed Table 2: This table includes a number of common nominal system voltages vs MVCD distances by altitude. However, some utilities have other non-standard voltages, in our case 287 kV, which forms a significant part of their system. It may be worthwhile for the standard to state what a utility should follow when a standard voltage class is not present – i.e. go to the next higher voltage MVCD if a particular voltage isn’t in the table, or direct the utility to do its own Gallett Equation calcuations for their unique voltage class. Otherwise, different utilities may create a non-standard solution that wouldn’t address the risk.

	There was no definition of ROW listed in FAC-003-1. The revised definition of ROW in FAC-003-2 is unclear regarding the application of standards and/or historic records as a means of determining ROW width. Is it necessary for a TO to select one method to apply in all cases, or can each span be treated in the manner deemed most appropriate by the TO? “Blowout standard” has not been defined in the document, technical paper, or NERC Glossary and it is not clear what this method is, and exactly how it would be applied. It could not be defended under scrutiny. It is still unclear whether Danger Tree rights are included in this definition. In the NERC Glossary of Terms, Right-of-Way (ROW) is defined as “A corridor of land on which electric lines may be located. The Transmission Owner may own the land in fee, own an easement, or have certain franchise, prescription, or license rights to construct and maintain lines.” Propose keeping this definition. Is encroachment into the MVCD, or (MVCD plus additional distance as defined by the TO)? MVCD, as specified within the body of FAC-003-2 "is a calculated minimum distance stated in feet (meters) to prevent flashover between conductors and vegetation, for various altitudes and operating voltages." MVCD should be “formally” defined in this document, and the NERC Glossary. Can a list/database be established in 2011 that lists the widths for the pre-2007 vegetation management records?
	Yes

	American Electric Power
	Yes
	No
	American Electric Power believes that the phrase "arboricultural activities or horticultural or agricultural activities" was mistakenly introduced into Footnotes 2 and 4, and should be deleted from both footnotes. If the phrase remains in the Standard, it may empower orchard growers, landowners and others to plant trees on the right of way and challenge Transmission Owners' rights to perform maintenance on the presumption that the standard will exempt the TO from violating the outage or encroachment requirements.
	No
	For increased clarity, AEP offers the following change to the second paragraph of M1, as well as the second paragraph of M2. The original text “If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation” should be replaced with ““If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation growing into or blowing together with the conductor within the ROW, this shall be considered the equivalent of a Real-time observation. A brief encroachment caused by falling vegetation passing through the MVCD is not considered an encroachment in this requirement”.

	Yes
	Yes
	No
	M1 & M2 bullet: “Real-time observation of any MVCD encroachments.” implies that real-time observation of vegetation encroachment ensures reliable operation the Bulk Electric System. The reliability standard objective states; “To improve the reliability of the electric Transmission system by preventing those vegetation related outages that could lead to Cascading.” However, real time observation of current operating conditions provides no assurance that vegetation will not lead to outages since it doesn’t take into consideration the full conductor range of

	motion including maximum sag. BGE recommends removing the language. If an inspector finds vegetation encroaching into the MVCD during a visual inspection he / she should immediately initiate an Immediate Threat Notification. Therefore, this measure has no value.

	Yes
	Yes
	No
	There is currently no percentage language in M7. If they are referring to R7, then YES it is adequate.
	Individual
	Michael Pakeltis
	CenterPoint Energy
	No
	CenterPoint Energy agrees with the removal of “Active Transmission Line ROW” as a defined term. The change in the NERC Glossary definition for Right-of-Way (ROW) alone, however, does not address all of the remaining interpretation issues within the Standard that still exist. The following issues still require resolution: 1. The “force majeure” was moved from the Applicability section to a footnote, and is no longer an encompassing exception for each Requirement. Therefore, the “force majeure” footnote needs to be applied not only to R1, R2, R6, and R7 but also R4 and R5. For R4, notification to the control center would likely be restricted during a natural disaster. For R5, correction action by the control center may not be possible during a natural disaster. 2. The exception for

	applicability beyond the "Rating and all Rated Electrical Operating Conditions" should be included not only in R1, R2, and R3, but also R5 and R7. For R5 and R7, the encroachment into the MVCD should consider whether the line is operating within its design limits. 3. The use of the term "Fault" in M1 and M2 should be revised to "Sustained Outage". A "Fault" can be associated with a Momentary Outage or a Sustained Outage. The scope of R1 and R2 is specific to Sustained Outages only. The Periodic Data Submittal is specific to Sustained Outages only as well. If a later confirmation of a "Fault" by the Transmission Owner indicates that a vegetation encroachment into the MVCD was due to a fall-in from inside the ROW, yet caused only a Momentary Outage, the Transmission Owner would be in violation of R1 because M1 considers it to be the equivalent of a Real-time observation. The current scope of the Standard is not intended to include Momentary Outages. If it was, the Periodic Data Submittal would capture this type of outage, which it does not. 4. In the Introduction Section 5 - Background, fall-ins are characterized as "statistically intermittent" and "these types of events are highly unlikely to cause large-scale grid failures". CenterPoint Energy agrees and therefore recommends that fall-ins be excluded from the Requirements R1, R2, and Periodic Data Submittal of outages. This would negate the need for determining the limits of the ROW, thus simplifying the Standard to a great margin while not sacrificing the emphasis of the Standard. The Draft 5 Background Information states the criteria for developing a results-based reliability standard such that "each requirement should identify a clear and measurable expected outcome." When the determination of the limits of the ROW goes beyond the interpretation of the legal limits of the ROW, it adds a level of complexity that may be unclear and not deterministically measurable. 5. For R6, CenterPoint Energy believes the detailed rationale and studies used for the determination of the required one year inspection cycle should be included in the Guidelines and Technical Basis. The explanation provided in the Rationale that it is "based upon average growth rates across North America and on common utility practice" are unfounded and arbitrary without a specific reference to a North American study. 6. R7 contains the phrase, "provided they do not put the transmission system at risk of a vegetation encroachment". CenterPoint Energy recommends this phrase be replaced with the more specific terminology used in the Rationale for R7 and R3: "provided they do not allow encroachment of vegetation into the MVCD." 7. CenterPoint Energy believes the Periodic Data Submittal should be clarified as to the specific conditions under which Sustained Outages are reported. There is a reference to footnote 2 regarding the exclusion for the "force majeure"; however, the exclusion for lines operating outside their design limits as mentioned in R1, R2, and R3 is missing. CenterPoint Energy believes the wording should be changed to include all applicable exclusions for added clarity and recommends the following wording: "The Transmission Owner will submit a quarterly report to its Regional Entity, or Regional Entity's designee, identifying all Sustained Outages of applicable transmission lines operating within their Facility Rating and all Rated Electrical Operating Conditions as determined by the Transmission Owner to have been caused by vegetation, except as excluded in footnote 2, which includes as a minimum, the following:" 8. The Guidelines and Technical Basis and the Technical Reference with the Gallet Equation should be combined into one document as a supplement to the Standard to avoid duplication in wording and misinterpretation of context. 9. The Guideline and Technical Basis under Requirement R6 refers to the "percentage of the required ROW inspections completed" and should be revised to match the wording of R6 and the VSL for R6 as the "percentage of applicable transmission line inspections completed." 10. CenterPoint Energy agrees that the Rationale test boxes should be deleted from the Standard and applicable explanatory text be included within the Guidelines and Technical Basis. 11. The Guidelines and Technical Basis should contain specific examples for determining if a fall-in is considered inside or outside the ROW. 12. CenterPoint Energy recommends modifying the Technical Reference section regarding "Selecting a Maintenance Approach" to delete the sentences beginning with, "If constraints cannot be overcome and if design clearances are sufficient…" and continuing through to, "identified early for rectification." This example may lead the public to inappropriately ask the utilities for exceptions to allow vegetation beneath the transmission lines, and it also does not address the dynamics of future modifications to the transmission lines (e.g. higher operating temperatures or new conductors) that may necessitate reduced clearances to ground, thus requiring removal of now mature vegetation. The example should not be included in a Standard intended to reduce vegetation risks to the transmission system. It is also in conflict with later statements in the Technical Reference regarding Set Objectives which emphasize maintaining access and clear lines of sight. 13. In general, CenterPoint Energy strongly believes the proposed FAC-003-2 has gone far beyond what was contemplated by the Commission in FERC Order 693. The Commission's determination dealt with the following areas: (1) applicability; (2) inspection cycles; and (3) minimum clearances on National Forest Service lands. For instance, in Paragraph 729, the Commission states, "As proposed in the NOPR, the Commission approves Reliability Standard FAC-003-1 with no proposed modification on the issue of clearances. The Commission reaffirms its interpretation that FAC-003-1 requires sufficient clearances to prevent outages due to vegetation management practices under all applicable conditions…." Rewriting the minimum clearances introduces a new set of confusing definitions, and further burdens the Transmission Owners with new documentation requirements while providing little, if any, benefit when compared to the Clearance 2 concept in the existing Standard. A preferred approach would be to incorporate the following few items into the existing Standard FAC-003-1: (1) the RC versus the RRO; (2) the designation of a specific inspection frequency; (3) the Gallet equation; and (4) the applicability to National Forest Service lands.
	Yes
	Yes

	Yes
	No
	CenterPoint Energy could not find any reference to an example percentage complete calculation for the annual work plan in the Standard for M7, in the Guideline and Technical Basis for M7, nor in the Technical Reference for M7. There was such an example for M6 which was helpful. CenterPoint Energy recommends such an example be included for M7.

	We agree with the drafting team's approach, and also agree with reinstating reporting of Category 3 (Fall-ins from outside the ROW) in the Additional Compliance Information section. The SDT responded to comments submitted with the last ballot that: "Zero tolerance for vegetation caused outages is a stated goal of FERC and NERC as it relates to this standard. This policy is part of FAC-003-1 and in concept did not change with the proposed version. The SDT recognizes this concern and has developed gradation taking into account line criticality in VRF's and type of outage not contained in the current version FAC-003-1. Finally, it is also important to note that each and every incident or potential violation is investigated and addressed based on the specific circumstances surrounding the particular event. These investigations should necessarily take into consideration and recognize the utility's individual efforts in responding to an encroachment situation." In addition, we believe that clarifying changes need to be made to footnotes 2 and 4. Clarify footnote 2 by removing the phrase "arboricultural activities or horticultural or agricultural activities" and replacing it with the phrase "installation of". Similarly, clarify footnote 4 by removing the phrase "arboricultural, horticultural or agricultural activities", and replacing it with the phrase "or human activities such as installation, or removal or digging of vegetation."
	Yes
	However, this change was not completely made in paragraph five of the Guideline and Technical Basis document. There the phrase "an investigation" should be replaced by the phrase "a later confirmation"

	We agree that the ROW width in no case exceeds the TO's legal rights but may be less. We do not agree that the revised NERC Glossary definition for Right-of-Way addresses paragraph 734 of FERC Order 693 "that rights-of-way be defined to encompass the required clearance areas instead of the corresponding legal rights, and that the standards should not require clearing the entire right-of-way when the required clearance for an existing line does not take up the entire right-of-way". The engineering or construction standards for establishing the width of the corridor outlined in the definition are in most cases not useful. We will continue to rely on our easements and legal rights with this definition. We believe the Active Transmission Line ROW definition in the previous version more clearly addressed paragraph 734 of FERC Order 693.

	Yes
	BPA prefers the stratified levels of violation severity presented in the table for R1 and R2. Foot note #2 on page 8 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. What specifically does this phrase refer to? Foot note #4 on page 12 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. What specifically does this phrase refer to?
	Yes
	Yes
	The TO procedures / policies and specifications shall demonstrate the TO's ability to manage the system at all rated conditions to maintain reliability. BPA believes that the intent is clear, but the fundamental approach of using the MVCD (table 2) to manage a vegetation program is still problematic. These values are flashover distances and are way too close. This is acknowledged in a footnote to table 2 but no identification of allowable buffers/distances between energized phase conductors at rated temperatures and vegetation is discussed (this is left up the transmission owners). Clarity is needed on this topic. Setting a finite distance limit based on recognized standards, good science and risk avoidance should be done for the industry. BPA previously made this comment during the drafting of the standard. It was not addressed then, nor has it been addressed now.

	Although NextEra Energy Inc. (NextEra), including Florida Power & Light Company, agrees with the changes referenced for R1 and R2, NextEra is concerned that the exemptions identified in footnote 2 for “…arboricultural activities or horticultural or agricultural activities…,” and similar language in footnote 4, are too broad. For example, this language appears to include an exemption for a landowner, who, during arboricultural activities or horticultural or agricultural activities, causes a vegetation contact with a transmission line (e.g., cutting or lifting a tree into a transmission line). This places the Transmission Owner in the difficult position of a landowner arguing it is exempt from a controllable risk. Thus, the “…arboricultural activities or horticultural or agricultural activities…” references should be removed from footnote 2, and the similar language in footnote 4

	My Comments do not relate to the question asked, however, I saw no other place to add my comment. I would like to thank NERC for allowing the public to participate in the process of improving the reliability standard FAC-003-1. I became interested in Vegetation Management requirements for Transmission Lines, after Con Edison clear cut the ROW behind my home. I appreciate the importance of safe and reliable electrical service, and recognize how an effective TVMP contributes to this goal. In this whole process, what has dispirited me the most, is the inaccurate information being conveyed about why the clear cutting was necessary and, the causes of the August 14th, 2003 blackout. The narrative goes something like..”a tree falling onto transmission lines caused the black out of 2003.” I find it harmful because it misdirects the focus from the grid’s short fallings, and impedes upgrading the system to improve reliability. I found this same philosophy in the initial pages of CN Utility’s document, UTILITY VEGETATION MANAGEMENT FINAL REPORT MARCH 2004. It suggests that had the trees been adequately maintained, the blackout would have most “likely” not happened. Now I am aware of the qualification of the word “likely,” but the document is heavily weighted on the contribution of tree contact to the blackout. We know that de-regulation and the physical nature of A.C. current had more to do with the causes of the blackout, than tree contact. The timeline shows a range of cascading system failures that created the catastrophic event. The trouble began at 1:58 p.m. when First Energy generating plant in Eastlake, Ohio, shuts down. At 3:06 p.m. a First Energy 345-kV transmission line fails. As a result, at 3:17 p.m voltage dips temporarily on the Ohio portion of the grid. Controllers take no action, but power shifted onto another power line, overloading it and, causing it to sag into a tree and go offline at 3:32 p.m. Mid West ISO and First Energy controllers fail to inform system controllers in nearby states. At 3:41 and 3:46 p.m., two breakers connecting First Energy□s grid with American Electric Power are tripped. 4:05 p.m., a sustained power surge on some Ohio lines signals more trouble building. At 4:09:02 p.m., voltage sags deeply, as Ohio draws 2 GW of power from Michigan. 4:10:34 p.m., many transmission lines trip out, beginning in Michigan and then in Ohio, blocking the eastward flow of power. Generators go down, creating a huge power deficit, in seconds, power surges out of the East, tripping East coast generators, and the rest is history. The U.S.-Canada Power System Outage Task Force: Final Report on Implementation of Recommendations, September 2006, states that “Inadequate reactive supply was a factor in most of the events.” and “the assumed contribution of dynamic reactive output of system generators was greater than the generators actually produced, resulting in more significant voltage problems.” The backup generators were not adequate to handle the amperage load or voltage needed. A lack of coordination of System Protection Programs(relays tripping), inadequate communication between Utilities/TOs, and lack of "training of operating personnel in dealing with severe system disturbances" are all the causes for the blackout. With respect to vegetation management, the findings from The U.S.-Canada Power System Outage Task Force: Final Report on Implementation of Recommendations, September 2006, clearly did not intend for transmission owners to develop a one-size-fits-all standard. The Energy Policy Act of 2005, initiated NERC to draft and adopt the standard FAC-003-1. When I read through the standard, it all seems very reasonable. I can understand the stiff penalties for noncompliance because it seems, like an easy fix, compared to the necessary, major changes in infrastructure. The principles further outlined in ANSI A300 VII, and “Best Practices” IVM, seem very reasonable too. There is mention of the environment, property owners, even proper pruning techniques. The wire zone clearance of 10 feet and, allowing low growing compatible vegetation in the boarder zone, seems to retain more vegetation, than remove. However, in practice, the TOs are simply clear cutting the ROW, with no regard for the enviroment, the trees that they are cutting, or the abutting properties. It took Con Edison 2 1/2 half days to clear 450 tress form behind our home. We are now forced to see and hear 93,000 cars a day from the Sprain Parkway. Following the clearing, our real estate broker dropped the asking price by 30%. The house remains empty and unsold. Apparently, no one is interested in spending 32,000K a year in property taxes to look at transmission towers/lines and live on a highway. This has been devastating to our family, and thousands of others in Westchester County. They removed a buffer of trees that were 150 feet away from wires and towers, on a downward slope. These trees would have never made contact with conductors. Con Edison’s defense is that they did it because it was in their right to. Moreover, they use the NERC fine structure to defend their behavior. I went through the Notice of Penalties that NERC has issued from 6/2/08-2/01/11. Out of 646 Notice of Penalties, 1700 violations were sited, 36 out of 1700 penalties were issued for violations to the FAC- 003-1 standard. Some NOPs had multiple violations-18 R1 violations were cited and 29 penalties were issued for R2 violations. Out of the 29 R2 penalties, 20 involved tree contact. Some outages were caused by sagging wires, some were caused by arcing electricity looking for a ground fault, but none were caused by a tree falling onto the transmissions wires. The numbers should put into perspective how immaterial the problem of tree contact really is. Think about it... 20 out of

	1700 involved tree contact, and none of then resulted in a sustained outage. That means 1680 violations were issued due to other system failures. To use these penalties as an excuse is a complete over exaggeration. What is missing from the standard and the fine structure, are penalties for over cutting and violations to other stipulations, such as proper communication, training, and aftercare of the affected areas. The problems that have arisen from current TVMP activities being executed nationally on our ROWs, is not a public perception problem. Rather, TOs are not complying with standards that are meant protect the environment and they are not respecting the property rights of the neighboring homeowners. I appreciate the opportunity to share my views, and would take any opportunity to further participate in protecting the rights of property owners, and the environment, while working to secure safe and reliable electrical service. Most respectfully, Amy M Kupferberg Utility Whisperer

	The added language for the annual work plan percentage complete calculation is shown in R7 not M7 as stated in the question. In the Guideline and Technical Basis Section for Requirement R6, there is a sample calculation shown for the amount of lines the TO failed to inspect. An example should also be included for Requirement R7 since there is some confusion regarding how modifications to the work plan affect the calculation. In the Lower VSL column for R7, it states that the TO failed to complete up to 5% of its annual vegetation work plan (including modifications if any). If a TO operates 100 lines and submits a justified modification that affects 10 miles of lines, the total number of units in the final amended plan is 90 miles. When you read the VSL, it is somewhat confusing since the information in parenthesis says that the calculation 'includes' the modifications. Should it state 'excludes modifications if any' or the VSLs can simply be re-written to state that ..The TO failed to complete up to x% of the final amended plan.' Also, the VSLs in R6 and R7 should be consistent with each other: R6 says '...TO failed to inspect 5% or less.....' and R7 says '...TO failed to complete up to 5%....' They both should use the same verbiage in each VSL whether it is 'x% or less' or 'up to and including x%.'

	Suggested Modification to the Measure - "If an after-the-fact analysis of a Fault by the Transmission Owner determines that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of observing an encroachment in Real-Time." CECD would also like to comment on the Evidence Retention section, as it relates to Measures. The Evidence Retention section states that the Transmission Owner retains data or evidence to show compliance with Requirement R1, R2, R3, R5, and R7, Measures M1, M2, M3, M5, M6 and M7 for three calendar years...." Measures provide examples of evidence that a Transmission Owner can produce to show compliance with the associated Requirement but are not separate Requirements to be managed so reference to Measures should be deleted from the Evidence Retention section of the standard.
	Yes
	Because Requirement 5 and 7 use the phrase annual work plan, and there is not a Requirement to develop a work plan, this Requirement should include a relationship between the document that is developed for maintenance strategies and the annual work plan.

	Yes
	Yes
	Yes
	The actual clarifying language seems to have been added to R7 instead of M7 (as stated above). The clarifying language provides benefit as added to R7, and should remain in R7. Additionally, we feel that, in an effort to promote consistency with the other 6 Requirements, the term "on applicable Transmission lines" should be added at the end of the first sentence of R7, as it is listed in all other R's. The first sentence of R7 currently reads: "Each Transmission Owner shall complete 100% of its annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD". We feel the first sentence should read "Each Transmission Owner shall complete 100% of its annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD on applicable transmission lines".

	NERC Staff
	Doug Keegan
	NERC
	No
	NERC supports a revised definition and prefers the definition in Draft 5 over the Active Transmission Line ROW definition used in Draft 4. NERC believes the use of the term “pre-2007 vegetation maintenance records” in the proposed definition is ambiguous and will likely be interpreted differently throughout the industry. Therefore, NERC supports this change subject to removing the aforementioned term.
	No
	The sentence was added to the rationale but the phrase “in order of increasing severity” is not in the requirement or their associated VSLs. NERC staff does not support the language in the rationale box which differentiates the VSL based on skill level of maintenance personnel rather than the impact to reliability of the encroachment. The VSL should be based on whether or not the owner managed the vegetation to prevent encroachment and therefore be binary. See additional comments submitted separately regarding combining R1 and R2.
	No
	Concur with restating as mentioned above. Other issues remain regarding data reports indicating no sustained outages or real-time observations. These measures appear to indicate that if the outages or real-time observations are not documented then an encroachment didn’t occur. What will compel an entity to document these occurrences? In addition, the last two paragraphs of the Measure are not really measures. They would be better served as part of the Requirement.
	No
	Adding the term “maintenance strategies” is not helpful in the requirement. NERC staff recommends the following: “Each Transmission Owner shall have a documented vegetation management plan that includes maintenance strategies, procedures, processes, and specifications it uses to prevent the encroachment of vegetation into the MVCD of its applicable lines that include(s) the following:”
	Yes
	Actually, R7 contains the clarifying language. It should be noted that although R7 indicates the TO shall complete 100% of the VM work plan, there is no requirement in this draft that a plan is actually developed.

	Saurabh Saksena
	National Grid
	No
	The revised ROW definition emphasizes the ROW width needed to operate the transmission line(s). It is National Grid’s interpretation that the width established when the line was constructed is the width to be maintained. This width is documented in engineering drawings, per-2007 vegetation records or blow-out standards. This definition does not imply that danger tree rights beyond the constructed and maintained width are incorporated in the definition; therefore fallins - from outside the ROW but within within an area with danger tree rights would not be considered fallin-ins from within the ROW. National Grid would like the SDT to comment on this interpretation in its response to these comments.

Although for the most part we agree with the changes to the definition of ROW, we suggest the following changes. 1. The last sentence of the definition states "The ROW width in no case exceeds the Transmission Owner's legal rights but may be less based on the aforementioned criteria." We do not agree with the phrase "in no case exceeds the Transmission Owner's legal rights" because there could be instances where special permission has been granted by landowners to the TO. We suggest revising this statement to "The ROW width may be less than the Transmission Owner’s granted rights based on the aforementioned criteria." 2. Regarding the phrase "blowout standard" used in the definition, we are assuming this is in reference to the company specific calculations for sag and sway on not on any one specific industry standard. We suggest clarification such as "Transmission Owner's specific blowout or sag and sway analysis in effect when the line was built".
No
For the Requirement R1 and R2 VSLs, we suggest that the proposed Moderate (fall-ins) and High (blowing together) VSL be interchanged. We believe that fall-ins are more severe encroachments than blowing together and the categories listed in the compliance section support this point. Category 1 (grow-ins) is most severe, followed by Category 2 & 3 (fall-ins) and Category 4 (blowing together).
Yes
Yes
Yes
Although we generally agree with Requirements R7 and its measure M7, we suggest adding clarifying wording to bullet 4 which states "Crew or contractor availability/ Mutual assistance agreements". In addition to availability, contractor performance may be another issue that requires modification to the work plan. We suggest adding

	another bullet that reads "Crew or contractor performance". The rationale behind this addition is to address poor safety, productivity and/or quality issues with a crew or contractor assigned to perform vegetation management. FirstEnergy provides the following additional comments and suggestions not related to the specific questions asked in this posting: 1. Requirement R5 – We appreciate this requirement which recognizes that the TO may face situations in which it is constrained from performing its vegetation management and are permitted to seek alternative methods. However, there may be instances where the TO has exhausted all course of action to perform vegetation and must utilize other means to prevent vegetation encroachment into the MVCD. Therefore, in these instances, "continued vegetation management" as stated in the requirement is not possible, but other methods such as line deratings and deenergizing of lines may have to be used. We ask that the phrase "to ensure continued vegetation management to prevent encroachments" be changed to read “to ensure continued reliability of the BES”. 2. Compliance Section – Category 3 – We suggest removing this category from the standard. Since fall-ins from outside the ROW are not considered a violation of this standard per Requirements R1 and R2, the entity should not have to report these fall-ins. 3. Objectives – We do not believe that is necessary for the Objectives statement to include the "defense-in-depth" concept which is actually an overarching goal of results-based standards in general and not specific to FAC-003-2. We suggest removing this phrase. 4. Background Section 5 – Similar to our comment above regarding defense-in-depth in the objectives statement, this is an overarching goal of results based standard and not specific to FAC-003-2. Therefore, we suggest removing the explanation of defense-in-depth from the background section. 5. Vegetation Inspection Definition – We suggest replacing the word "hazard" with "risk". 6. Requirement R4 – We do not agree with the phrase "without any intentional time delay" and suggest it be removed. This phrase is not measurable. Also, other drafting teams have attempted to incorporate this statement but industry comments have persuaded them to remove it; for example, the Reliability Coordination drafting team (Project 2006-06) initially proposed the same phrase but later removed it in their development of the COM/IRO standards. At the very least standards development should be consistent throughout the NERC standards drafting teams. We suggest the following as wording for Requirement R7: "Each Transmission Owner shall ensure the control center holding switching authority for the applicable transmission line is promptly notified when the Transmission Owner has confirmed the existence of a vegetation condition that can potentially cause a Fault."

	We support the clarifying languae in M7 However, since there is no generic "Any other Comments" section associated with this on-line comment form, we raise a question here. On December 24, 2008, NERC issued an e-mail to all Transmission Owners in which it referenced its December 17, 2008 Public Notice – NERC Compliance Process #2008- 001, Vegetation-related Transmission Outage Reporting. The notice stated that: "Due to the potential severity of transmission outages caused by vegetation associated with Standard FAC-003-1, NERC is encouraging each Transmission Owner to self-report all Category 1 and Category 2 transmission outages related to vegetation to the Regional Entity within 48 hours utilizing the 48-hour vegetation reporting notice form provided by your appropriate Regional Entity." We do not see any reference to a 48-hour reporting notice in Ithis version of the standard. Is this still a requirement? The only reference to reporting is in the Additional Compliance Information section and references quarterly reporting only.

	The red-line revision does not indicated changes to M7; therefore, Dominion is unable to evaluate the clarifying language identified in this question. If the SDT meant to reference R7, we agree that the clarification is adequate.

	We would recommend the middle paragraph of M1 and M2 be revised as follows: "If a later confirmation of a Fault by the TO shows that vegetation encroachment within the MVCD has occurred from vegetation growing into or blowing into the conductor within the ROW, this shall be considered the equivalent of a Real-time observation. Brief encroachments caused by a falling tree going through the MVCD is not considered an encroachment."

	While there are some enhancements to the organization and content of the standard such as the addition of the Guidelines and Technical Basis section, clarification of what constitutes evidence of compliance, and tailoring of VSL severity levels for the requirements based on the risk each poses to the likelihood of contributing to a cascade.

	too many elements present in FAC-003-1 and which are vital to preventing vegetation caused outages and maximizing system reliability, have been eliminated from FAC-003-2. Specifically, the elimination of concrete, declared and audited clearance standards between vegetation and conductors (the existing Clearance 1 and Clearance 2 (R1.2)) Requirements) in the revised standard is a major defect that will decrease system reliability. It has been indispensable for NIPSCO when communicating with stake holders (governments, interest groups, land owners, the public, etc.) to point to these clearance standards to give credibility and support to the kind of tree removal and trimming that is necessary to achieve the stated objective of zero preventable tree caused outages. Without these declared clearance standards in the NERC standard, utility vegetation managers will constantly be challenged by stake holders to show them that such work is required rather than an elective choice on the utility's part. One of the key lessons learned from the 2003 blackout and First Energy's overgrown ROW tree problem was that individual land owners, local governments, and interest groups will exert pressure on the utility to only do the minimum amount of vegetation management. Without external and enforceable Vegetation Clearance Standards and by returning to a pre-2003 regime where the extent of vegetation clearing is left to the individual discretion and pressures at each utility, there is no doubt that tree clearance conditions will deteriorate over time and put system reliability at greater risk of vegetation contact.

FAC-003-2 Vegetation Management Draft 5
NERC Staff Comments in Addition To Those Submitted On Comment Form
2.28.11

In addition to the comments NERC submitted to the five questions on the official comment form, NERC staff has numerous other comments to make with regard to this Draft 5. Before that, NERC staff first wants to acknowledge the significant effort and talent that the industry brought to attempt to improve upon Reliability Standard FAC-003-1 – Vegetation Management. This Draft 5 of FAC-003-2 – Vegetation Management entailed significant industry work towards understanding the issue, compromising on proposals and attempting to reach consensus utilizing the NERC Standards Development Process. While NERC staff believes this draft represents some improvements to the existing standard, it does not believe the draft in its totality represents an improvement to the existing standard. FERC Order 693 approved the existing Vegetation Management Standard and it provided a number of directives for NERC with regard to further developing the Standard in order to improve it. Such directives and NERC comments regarding how the directives were addressed included:

- FERC Directive - Develop compliance audit procedures, using relevant industry experts, which would identify appropriate inspection cycles based on local factors. The Commission is dissuaded from requiring the ERO to create a backstop inspection cycle at this time.

  NERC Comment – Compliance audit procedures are outside the scope of the SDT and this Draft 5. Although not required by the Commission, the SDT added an annual inspection cycle to the Standard, with a maximum of 18 months between inspections. NERC believes this requirement represents an improvement to the existing Standard and does not believe it is overly burdensome on utilities.

- FERC Directive - Remove the general limitation on lines 200kV and above to include lines that have an impact on reliability.
  - Do not reduce facilities included
  - Develop an acceptable definition for the applicability of this Reliability Standard that covers facilities that impact reliability while not unreasonably increasing the burden on transmission owners.
  - Evaluate the suggestions proposed by LPPC, APPA and Avista that regional entities should determine which facilities this standard applies to

  NERC Comment – NERC believes Draft 5 partially addresses this issue by increasing applicable facilities to IROL lines under 200kV. NERC staff is also concerned about

  - The possibility that this very addition could limit a regional entity's desire to include additional lines.

- The exclusion of facilities inside the fenced area of switching stations, stations and substations. These excluded areas still pose a vegetation related outage risk and the rationale for excluding them is not compelling enough.
- The separation of IROL (any voltage level) and non-IROL (200 kV and above) Transmission Lines into separate requirements with different VRFs. NERC believes all Transmission Lines subject to this standard should be under the same requirement and associated VRFs. IROL lines are relatively few and do not warrant their own requirement. By having lower VRFs for non-IROL lines, this version of the standard is weaker than the existing standard. These two requirements should be a single requirement with high VRFs

- FERC Directive - Develop a Reliability Standard that defines the minimum clearance needed as an improvement to IEEE 516 which FERC does not believe is appropriately used for purposes of reliability and/or safety.

  NERC Comment – Draft 5 makes a change from IEEE 516 and utilizes Gallet equations for industry clearances. While NERC believes these equations are technically accurate, NERC is concerned about the usefulness of the clearances determined under this methodology as put forth in this draft. NERC is not aware of any utility which would maintain clearances as specified in this draft as it has no built in safety factor. NERC is further concerned that utilities could be mandated by courts of law to reduce existing maintained clearances to values much closer to those determined by the methodology in this draft.

- FERC Directive - Define rights-of-way to encompass the required clearance areas instead of the corresponding legal rights, and the standards should not require clearing the entire right-of-way when the required clearance for an existing line does not take up the entire right-of-way.

  NERC Comment – NERC staff believes this directive was met and is addressed in question 1 of the comment form.

- FERC Directive – NERC should address the proposed modifications through its Reliability Standards development process.

  NERC Comment – NERC staff believes this directive was met in preparing this draft standard.

- FERC Directive - Collect outage data for transmission outages, analyze it, and use the results of this analysis and information in the development of the Reliability Standard.

  NERC Comment – NERC staff believes more work needs to be done in this area. NERC staff believes the drafting team should consider modifying the Periodic Data Submittal to include if outages occur on Federal land.

Other Draft 5 Issues

- Removal of a formal transmission vegetation management program, of Clearance 1 and of a documented vegetation management plan.

  NERC Comment – NERC does not support the removal of these items. NERC does not believe these changes represent an improvement to the standard and does not believe this existing requirement is overly burdensome to utilities. NERC does not understand why industry would not be willing to be held accountable to their vegetation management plans. NERC is concerned that the removal of these items could make it difficult for utilities to obtain permissions needed to maintain clearances between inspection cycles which are prudent for reliability and safety due to intervener or landowners exercising their rights and then pointing to this new standard as a the basis for smaller clearances. . Requirement 3 in this draft needs to include a documented plan and to clearly identify the specifics to be included in the plan and provide clarity of expectations. The SDT may not support such specifics as not being consistent with results-based standards development but NERC staff believes otherwise.

- Objectives**:** A qualifier in the standard Objective that it should apply to preventing the risk of vegetation related outages *that could lead to cascading outages.*

  NERC Comment – This qualifier limits the purpose of the standard, which should be to prevent vegetation related outages, not cascading outages. The more outages there are, the less the overall system reliability. An outage does not necessarily have to lead to a cascading outage to be significant and represent a reasonable risk to the BES. References to cascading outages should be removed.

- Background**:** This section excludes vegetations fall-ins and blow-ins from outside the ROW on the basis that they are not preventable.

  NERC Comment – Many fall-ins and blow-ins from outside the ROW are preventable. Trees outside the ROW must be managed adequately to prevent outages on the BES. The work to remove and/or prune trees outside the ROW may be more difficult and costly than such work inside the ROW, but that is not sufficient reason to exclude this work. In addition, utilities wishing to perform such work might be prevented from doing so by regulatory bodies based upon the lack of a specific requirement in this standard.

- Requirement 1 & 2: These requirements discuss preventing encroachments into the MVCD of an applicable line that is operating within its Rating.

  NERC Comments –NERC staff would like confirmation that "Rating" is intended to include all published ratings issued by the facility owner, such as Normal, Emergency, etc.

- Requirement 4: R4 states that "Each Transmission Owner, without any intentional time delay, shall notify…"

  NERC Comments: The previous version of the standard included a time limit of 15 minutes once communications became available. This should be reinstated.

- Requirement 7: R7 sets the requirement for each Transmission Owner to complete 100 percent of its annual vegetation work plan.

  NERC Comments – NERC is concerned that the draft doesn't have a requirement for a Transmission Owner to have a documented annual plan making Requirement 7 unenforceable. In addition, Requirement 7 has a number of other qualifiers that would seem to allow manipulation of the annual plan to ensure compliance.

- Draft 5 document quality

  NERC Comments – this draft has some typographical errors which need to be fixed. For example, on page 28, reference to use of Table 5 versus Table 7 based on knowledge of maximum transient over-voltage factor is reversed. These edits could probably be handled through a recirculation ballet.

- Previously raised NERC issues

  NERC Comments – NERC staff posted several comments on the Draft 4 version of this standard in July 2010. NERC believes most of the concerns it raised in those comments are not addressed in Draft 5 and continue to be a concern for NERC.
- General compliance and audit issues

  NERC Comments –

  - The whole "sustained outage" concept in R1 (for fall ins and blow ins) is unworkable from an enforcement perspective.
  - The difference between a violation and a non-violation in Draft 5 is whether the registered entity was fortunate with regard to an encroachment. This part should be rewritten to say that any tree contact is a violation. VRFs and VSLs could then be used to address whether the violation was minor or serious.
  - There could be a lot of litigation over whether "circumstances" were really "beyond the control" of the TO. NERC had previously objected to the implementation of a force majeure clause in the standard. If an entity failed to carry out its annual plan, that should be treated as a violation, and any excuses for failing to do so or for changing the plan mid-year all go to whether the penalty should be $0 or substantial.
  - For the evidence retention period, the entity really should retain evidence of compliance until the next compliance audit. Since some TOs may be on a 6 year audit schedule, the 3 year retention period is not sufficient.

Successive Ballot (February 18-28, 2011) Consideration of Comments Report

Project 2007-07 Vegetation Management — September 30, 2011

Summary Consideration:
In order to be consistent with the latest version of NERC's Results Based Standards template, the heading "Objective" was replaced with "Purpose," and the numbering, headings, and sections were reformatted as necessary.

Several entities expressed concern with the use of the Minimum Vegetation Clearance Distance (MVCD) and elimination of Clearance 1. With respect to comments about the MVCD, R3 does not suggest the MVCD be used as a distance to manage vegetation. The MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD. In a performance-based standard, requirements are focused on "what" needs to be accomplished to achieve desired results and avoids prescriptive requirements of "how" to achieve that result. TO's are in the best position to determine the appropriate management approach suited for their system, rather than a "one size fits all" or "fill in the blank" requirement that could suppress best practices for vegetation management.

Other entities questioned whether the goal of the standard was to "prevent outages" or to "manage vegetation." In Order 693, FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way by maintaining safe clearances between transmission lines and vegetation." The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct inspections in which clearances are evaluated.

Some entities expressed concern with the mandatory inspection intervals proposed in the standard. The SDT recognizes that a number of Transmission Owners in North America may prefer to set their own inspection intervals. Because there is substantial industry support for an annual inspection interval the SDT believes that the industry is best served with this approach.

Several entities suggested making minor changes to clarify the footnotes. The team did so.

If you feel that the drafting team overlooked your comments, please let us know immediately. Our goal is to give every comment serious consideration in this process. If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herb Schrayshuen, at 404-446-2563 or at herb.scrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

Voter	Entity	Segment	Vote	Comment
Paul B. Johnson	American Electric Power	1	Affirmative	American Electric Power believes that the phrase "arboricultural activities or horticultural or agricultural activities" was mistakenly introduced into Footnotes 2 and 4, and should be deleted from both footnotes. If the phrase remains in the Standard, it may empower orchard growers, landowners and others to plant trees on the right of way and challenge Transmission Owners' rights to perform maintenance on the presumption that the standard will exempt the TO from violating the outage or encroachment requirements. For increased clarity, AEP offers the following change to the second paragraph of M1, as well as the second paragraph of M2. The original text "If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation" should be replaced

[1] The appeals process is in the Reliability Standards Development Procedure: http://www.nerc.com/files/RSDP_V6_1_12Mar07.pdf.

Voter	Entity	Segment	Vote	Comment
				with “If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation growing into or blowing together with the conductor within the ROW, this shall be considered the equivalent of a Real-time observation. A brief encroachment caused by falling vegetation passing through the MVCD is not considered an encroachment in this requirement”.
Response: Thank you for your comments. The SDT made suggested changes to the footnotes as proposed. Regarding the issue of fall-ins, the SDT is sympathetic to your concern. In fact, the SDT had originally crafted language similar to that which you suggested. However, due to concerns expressed by regulators and others, the exemption for encroachment violations due to falling vegetation from inside the right of way was removed.				
Robert D Smith	Arizona Public Service Co.	1	Negative	Overall comment: The objective, as written, is about outages that can lead to cascading and not about reliability. Recommended change to Standard Objective: To maintain a reliable electric transmission system, implement a defense-in-depth strategy to manage vegetation located on transmission rights of way (ROW) and minimize encroachments from vegetation located adjacent to the ROW.
Response: The SDT thanks you for your comment. With respect to the Purpose as written in the proposed standard, the language clearly states “To improve the reliability of the electric Transmission system…” The SDT made it a point to keep the Purpose as concise as possible without getting into issues that are covered further in the body of the standard.				
John Bussman	Associated Electric Cooperative, Inc.	1	Negative	R1 - “Each Transmission Owner shall manage vegetation to prevent encroachments of the types shown below, into the Minimum Vegetation Clearance Distance (MVCD) of any of its applicable line(s) identified as an element of an Interconnection Reliability Operating Limit (IROL) in the planning horizon by the Planning Coordinator; or Major Western Electricity Coordinating Council (WECC) transfer

Voter	Entity	Segment	Vote	Comment
				path(s); operating within its Rating and all Rated Electrical Operating Conditions...” The following is my preliminary comment on this requirement. R1 - Associated Electric Cooperative Inc wants to thank the SDT for their hard work and all the effort associated with this standard. However we currently disagrees with the inclusion in this requirement of any and all IROLs identified within the entire planning horizon (typically 10 years or more). Associated Electric certainly agrees that in real time and in the near term sub 200 kV elements of an IROL should be subject to R1. It seems unreasonable, however, to include a sub 200 kV transmission line that might become an IROL element 10 years in the future. Perhaps the time frame could be limited to the Transmission Owner’s planned maintenance cycle.
Response: The SDT thanks you for your comment, and has revised the Standard’s effective dates (exceptions) accordingly.				
Gregory S Miller	Baltimore Gas & Electric Company	1	Affirmative	There seems to be a marginal level of improvement over the previous drafts.
Response: The SDT thanks you for your comment.				
Joseph S. Stonecipher	Beaches Energy Services	1	Negative	R1 and R2 Requirement reads: "Each Transmission Owner shall manage to prevent encroachment ....". The results of manage would be invoices of tree trimming actually performed, documentation of a vegetation management program that would be managed to, etc. However, the Measures proposed are all actual outages which are neither

Voter	Entity	Segment	Vote	Comment
				evidence of management nor evidence of encroachment since there can be encroachment without an outage, and in fact, many if not most encroachments do not result in outages. Hence, the Measures are inconsistent with the Requirements. Further, there is ambiguity of the action required in requirements R1 and R2 - e.g., do entities need evidence that they: 1) "manage", or 2) "prevent encroachment"; or 3) as implied by the Measures, prevent vegetation related outages? In other words, what needs to be proven through evidence? Certainly the third, prevent vegetation related outages, is not in the Requirement; yet, that us what is proposed for the Measures, highlighting the inconsistency between Requirements and Measures. But, how would the ambiguity between "manage" and "prevent encroachment" be resolved? One auditor could interpret that the Requirement is to "manage" and accept a vegetation management program and plan and proof that the plan was executed as appropriate evidence. Another auditor could interpret that "prevent" is the key word and look for evidence proving that there was never a vegetation encroachment. How would evidence be produced to provide the auditor that vegetation never encroached? Would video cameras and other surveillance measures need to operate 24 hours a day? Would we cause an entity to survey the lines periodically? One can easily see that "prevent encroachment" is inappropriate here since it is infeasible to create evidence of compliance.

Response: The SDT thanks you for your comments. In Order 693, FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances**

Voter	Entity	Segment	Vote	Comment
between transmission lines and vegetation" (emphasis added). The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct inspections in which clearances are evaluated.				
Donald S. Watkins	Bonneville Power Administration	1	Affirmative	R2. Do you agree? If answer is no, please explain. BPA prefers the stratified levels of violation severity presented in the table for R1 and R2. Foot note # 2 on page 8 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. Foot note # 4 on page 12 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. In response to comments received that requirement R3 is unclear with respect to intent, the SDT added "maintenance strategies." Do you agree this clarifies the intent? If answer is no, please offer alternative language. The TO procedures / policies and specifications shall demonstrate the TO's ability to manage the system at all rated conditions to maintain reliability. BPA believes that the intent is clear, but the fundamental approach of using the MVCD (table 2) to manage a vegetation program is still problematic. These values are flashover distances and are way too close. This is acknowledged in a footnote to table 2 but no identification of allowable buffers/distances between energized phase conductors at rated temperatures and vegetation is discussed (this is left up the transmission owners). Clarity is needed on this topic. Setting a finite distance limit based on recognized standards, good science and risk avoidance should be done for the industry. BPA has previously made this comment during the drafting of the

Voter	Entity	Segment	Vote	Comment
				standard. It was not addressed then, nor has it been addressed now.
Response: The SDT thanks you for your comments. The footnotes were changed to conform with your suggestions. With respect to comments about the MVCD, R3 does not suggest the MVCD be used as a distance to manage vegetation. The MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD In a performance based standard, requirements are focused on "what" needs to be accomplished to achieve desired results and avoids prescriptive requirements of "how" to achieve that result. TO's are in the best position to determine the appropriate management approach suited for their system, rather than a "one size fits all" that could suppress best practices for vegetation management.				
Randall McCamish	City of Vero Beach	1	Negative	Vero Beach's concern is that entities may not be able prove compliance with the standard. R1 and R2 say that: "Each Transmission Owner shall manage vegetation to prevent encroachments ...". If the requirements were interpreted such that "manage" is the operative word, then, we are OK because we can provide evidence of managing a program, such as a vegetation management plan and evidence of executing that plan (which does not align with the Measures). However, that 1) would cause the standard to not be performance based, and 2) it would be duplicative of the other requirements of the standard. If the requirements were interpreted with "prevent encroachment" as the operative phrase (which would be an

Voter	Entity	Segment	Vote	Comment
				incorrect interpretation from the construct of the sentence) there is no way to provide sufficient evidence that encroachment was prevented during the audit-period. The suggested Measures are not sufficient evidence to prove compliance with that interpretation of the requirement. For instance, most encroachments do not result in outages; hence, lack of outages cannot prove that there were no encroachments, and real time observations are insufficient because it is a spot-check that does not cover the audit period. There are other weaknesses in the standard, such as R4 being un-measurable therefore unenforceable. However, in the guilty until proven innocent paradigm we live in, FMPA's primary concern is that industry could be put into a no-win situation of not being able to prove compliance with the standard if R1 and R2 are interpreted as "prevent encroachment", and if R1 and R2 are interpreted as "manage" then it is not a performance based standard as advertised. Vero Beach suggests one of two approaches: 1. Performance based focused on preventing vegetation related outages. For instance: "Each Transmission Owner shall prevent vegetation related outages (except as noted in Footnote 2) of any of its applicable line(s) ..." Evidence of outages is practical to gather and provide, evidence of encroachment is not. 2. Modify the standard to be similar to the currently mandatory non-results based standard and focus on the word "manage". This would essentially mean eliminating R1

Voter	Entity	Segment	Vote	Comment
				and R2 since the rest of the standard focuses on having a plan and managing to that plan.
Response: The SDT thanks you for your comments. In Order 693, FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation**" (emphasis added). The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct inspections in which clearances are evaluated.				
Danny McDaniel	Cleco Power LLC	1	Negative	Cleco disagrees with the SDT revising the definition for Right-of-Way (ROW). Right-of-Way is a term that has had a consistent meaning throughout history. If NERC tries to redefine the term, it will only add confusion because most entities will not reference the NERC glossary for a term which is widely used in the industry. In lieu of "Active Transmission Line ROW", please use another term such as Transmission Corridor. No assumptions would be made when reading in the Standard the the Entity is to maintain vegetation located within the Transmission Corridor. Since the term is not commonly used, the NERC glossary would be referenced. Also, Cleco disagrees that an encroachment into the MCVD that does not cause an outage should be considered non-compliant as stated in R1 and R2. The encroachment should only be reportable similar to misoperations as is in the PRC-004 standard.
Response: Thank you for your comments. The existing ROW definition in the glossary was created by and for the FAC-003-1 and was moved there when that standard was adopted. The definition includes a series of options that give the Transmission Owner latitude in establishing ROW width. It does not require selecting a single method for its system. The term "blowout standard" is not capitalized and is not a defined				

Voter	Entity	Segment	Vote	Comment
term. This phrase in the definition allows a Transmission Owner to use its internal engineering standards or the general engineering standards that were in effect when the line was constructed to determine the ROW width. The SDT has limited the definition of Right-of-Way to a corridor of land with a defined width to operate a transmission line. This does not include danger tree rights. The definition of the MVCD is now added to this Standard. While use of the pre-2007 records is a compliance issue and is not in the purview of the SDT, it is the intent of the language in the definition that you could use this information. Regarding your second comment, R3 does not suggest the MVCD be used as a distance to manage vegetation. The MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD Other related requirements of this "Defense in Depth" Standard serve to address any number of scenarios which may arise or hinder the TO's ability to always strictly adhere to the management approach(s) established within R3. Thus the other requirements of this Standard provide the latitude for appropriate actions to remedy the condition without penalty. Further, trees which have encroached inside the MVCD are evidence of a deficiency in vegetation maintenance.				
Christopher L de Graffenried	Consolidated Edison Co. of New York	1	Affirmative	Reply to Question 5 on Comment Form: The added language for the annual work plan percentage complete calculation is shown in R7 not M7 as stated in the question. In the Guideline and Technical Basis Section for Requirement R6, there is a sample calculation shown for the amount of lines the TO failed to inspect. An example should also be included for Requirement R7 since there is some confusion regarding how modifications to the work plan affect the calculation. In the Lower VSL column for R7, it states that the TO failed to complete up to 5% of its annual vegetation work plan (including modifications if any). If a TO operates 100 lines and submits a justified modification that affects 10 miles of

Voter	Entity	Segment	Vote	Comment
				lines, the total number of units in the final amended plan is 90 miles. When you read the VSL, it is somewhat confusing since the information in parenthesis says that the calculation 'includes' the modifications. Should it state 'excludes modifications if any' or the VSLs can simply be re-written to state that ..The TO failed to complete up to x% of the final amended plan.' Also, the VSLs in R6 and R7 should be consistent with each other: R6 says '...TO failed to inspect 5% or less.....' and R7 says '...TO failed to complete up to 5%....' They both should use the same verbiage in each VSL whether it is 'x% or less' or 'up to and including x%.'
Response: The SDT thanks you for your comments. The percentage should be based on the plan as modified. The SDT has changed the language in the standard to reflect this more clearly, and has modified the VSLs to be consistent as you have suggested.				
Robert Martinko	FirstEnergy Energy Delivery	1	Affirmative	FirstEnergy supports standard FAC-003-2 and would appreciate consideration of our comments submitted through the formal comment period.
Response: The SDT thanks you for your comments. Please see our consideration of your comments within the responses to the formal comments.				
Luther E. Fair	Gainesville Regional Utilities	1	Negative	1. It would seem that the impetus for FAC003 is to eliminate vegetation related outages within the rights-of-way as defined and subject to the exclusions as stated in footnote 2. Thus the requirement is to manage the ROW to prevent vegetation related sustained outages with the measure being no outages. With grow-ins and fall-ins from within the defined ROW being controllable factors.

Voter	Entity	Segment	Vote	Comment
				2. Including encroachments leaves the door open for fines to be imposed with no actual outage(s) having occurred. This may be like being found guilty of a crime that has not yet taken place. 3. Combine vegetation related sustained outages by “grow-ins” and “blowing together of lines and vegetation located inside the ROW” as one item as they are both consequences of the growth of vegetation either vertically and horizontally. 4. Leave vegetation related sustained outages by “fall-in” as a standalone as this will be related to structural problems occurring from a variety of sources. 5. Combine R3 and R7 to R1 (development and implementation of a Transmission Vegetation Management Plan which shall include documented maintenance strategies or procedures or processes or specifications, delineation of an annual work plan and completion of same). Thus this would be the competency based requirements as a program without execution is meaningless. 6. R1 and R2 become R2 and R3.
Response: The SDT thanks you for your comments. In Order 693, FERC was very specific that “…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation**” (emphasis added). The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct				

Voter	Entity	Segment	Vote	Comment
inspections in which clearances are evaluated.				
Ted E Hobson	JEA	1	Negative	Need to align the "measures" with the standard requirement language and the performance-based philosophy.
Response: The SDT thanks you for your comments. We are not quite clear as to what misalignment you refer to between the standard language and the measures. The SDT went to great lengths to ensure continuity between the requirements and the measures. While this standard was a first attempt at a "Results Based" approach, the SDT did have limitation in deciding what could be excluded from the standard. This standard has a mixture of the three types of requirements that comprise a results based approach: 1) Performance Based 2) Risk Based and 3) Competency Based. Having only performance-based requirements would not have resulted in a comprehensive, proactive standard.				
Michael Gammon	Kansas City Power & Light Co.	1	Negative	The Standard lacks clarity regarding the facilities that are subject to Requirement 7. It is important that a Standard be clear and not introduce ambiguity or confusion. There are several references throughout the Standard to "for all applicable lines" and it should be made clear the work plan is specific to "all applicable lines".
Response: The SDT thanks you for your comments. The team has made the appropriate modifications where necessary.				
Stan T. Rzad	Keys Energy Services	1	Negative	Concern is that entities may not be able prove compliance with the standard. R1 and R2 say that: "Each Transmission Owner shall manage vegetation to prevent encroachments ...". If the requirements were interpreted such that "manage" is the operative word, then, we are OK because we can provide evidence of managing a program, such as a vegetation management plan and evidence of executing that plan (which does not align with the Measures). However, that 1) would cause the standard to not be performance based, and 2) it would be duplicative of the

Voter	Entity	Segment	Vote	Comment
				other requirements of the standard. If the requirements were interpreted with "prevent encroachment" as the operative phrase (which would be an incorrect interpretation from the construct of the sentence) there is no way to provide sufficient evidence that encroachment was prevented during the audit-period. The suggested Measures are not sufficient evidence to prove compliance with that interpretation of the requirement. For instance, most encroachments do not result in outages; hence, lack of outages cannot prove that there were no encroachments, and real time observations are insufficient because it is a spot-check that does not cover the audit period. There are other weaknesses in the standard, such as R4 being un-measurable therefore unenforceable. However, in the guilty until proven innocent paradigm we live in, FMPA's primary concern is that industry could be put into a no-win situation of not being able to prove compliance with the standard if R1 and R2 are interpreted as "prevent encroachment", and if R1 and R2 are interpreted as "manage" then it is not a performance based standard as advertised. One of two approaches are suggested: Performance based focused on preventing vegetation related outages. For instance: "Each Transmission Owner shall prevent vegetation related outages (except as noted in Footnote 2) of any of its applicable line(s) ..." Evidence of outages is practical to gather and provide, evidence of encroachment is not. Modify the standard to be similar to the currently mandatory

Voter	Entity	Segment	Vote	Comment
				non-results based standard and focus on the word "manage". This would essentially mean eliminating R1 and R2 since the rest of the standard focuses on having a plan and managing to that plan.
Response: The SDT thanks you for your comments. In Order 693, FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation**" (emphasis added). The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct inspections in which clearances are evaluated.				
Walt Gill	Lake Worth Utilities	1	Negative	CLWU's concern is that entities may not be able prove compliance with the standard. R1 and R2 say that: "Each Transmission Owner shall manage vegetation to prevent encroachments ...". If the requirements were interpreted such that "manage" is the operative word, then, we are OK because we can provide evidence of managing a program, such as a vegetation management plan and evidence of executing that plan (which does not align with the Measures). However, that 1) would cause the standard to not be performance based, and 2) it would be duplicative of the other requirements of the standard. If the requirements were interpreted with "prevent encroachment" as the operative phrase (which would be an incorrect interpretation from the construct of the sentence) there is no way to provide sufficient evidence that encroachment was prevented during the audit-period. The suggested Measures are not sufficient evidence to prove compliance with that interpretation of the requirement. For instance, most encroachments do not result in outages; hence, lack of outages cannot prove that there were no

The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct inspections in which clearances are evaluated.				

Voter	Entity	Segment	Vote	Comment
Saurabh Saksena	National Grid	1	Affirmative	The revised ROW definition emphasizes the ROW width needed to operate the transmission line(s). It is National Grid's interpretation that the width established when the line was constructed is the width to be maintained. This width is documented in engineering drawings, per-2007 vegetation records or blow-out standards. This definition does not imply that danger tree rights beyond the constructed and maintained width are incorporated in the definition; therefore fallins - from outside the ROW but within an area with danger tree rights would not be considered fallin-ins from within the ROW. National Grid would like the SDT to comment on this interpretation in its response to these comments.
Response: Your interpretation is consistent with the intent of the definition that the SDT provided. However the definition includes a series of options that give the Transmission Owner latitude in establishing ROW width. It does not require selecting a single method for its system. This phrase in the definition allows a TO to use its internal engineering standards or the general engineering standards that were in effect when the line was constructed to determine the ROW width. The SDT has limited the definition of Right-of-Way to a corridor of land with a defined width to operate a transmission line. This does not include danger tree rights.				
Michael T. Quinn	Oncor Electric Delivery	1	Affirmative	In footnote 2 (pg. 8) and 4 (page 10), the wording "arboricultural activities or horticultural or agricultural activities" should be deleted and replaced with "or removal of, installation of, or digging around vegetation."
Response: The SDT thanks you for your comments. The footnotes have been changed.				
John C. Collins	Platte River Power Authority	1	Negative	Vegetation Inspection: Is the intent of "... and those vegetation conditions under the TO's control" to clarify that an entity must have ownership of the transmission line and right-of-way in addition to maintenance or operational responsibility (control), or something different? In situations

Voter	Entity	Segment	Vote	Comment
				where a TO owns one circuit on a double circuit, but the other circuit, facilities and ROW belong to another TO who has maintenance, and vegetation management responsibility, who would be responsible for violations? If the definition was modified to allow both maintenance and vegetation inspections to be performed concurrently, the intent might be clearer if it read: “This may be combined with other line inspections”, or “This may be combined with a maintenance inspection” opposed to a general line inspection. R1 and R2: Does R1 correlate to facilities in 4.2.2. and 4.2.3. (overhead transmission lines operated below 200 kV) and R2 correlate to facilities in 4.2.1. (overhead transmission lines operated at 200kV or higher)? It isn’t clear why the two requirements are split. Could it be one requirement which reads “...identified as a facility in Section 4.2”? R4: Our current imminent threat procedure requires a call to the Manager who confirms the existence of a vegetation condition that is likely to cause a Fault at any moment prior to notifying the control center. We assume notification, without any intentional time delay, would take place after managerial confirmation but feel like the enforcement authorities could interpret this differently based on how it is written in R4. If the intent of the requirement is how we interpret it, the requirement might be clearer if it read: After a Transmission Owner has confirmed a vegetation condition likely to cause a Fault at any moment, they shall notify the control center holding switching authority for the associated applicable transmission line, without any

Voter	Entity	Segment	Vote	Comment
				intentional delay.
Response: The SDT thanks you for your comment. With regard to responsibility for a violation, the TO is the accountable party even if it has an agreement with another TO to inspect and manage vegetation. With regard to your suggestion in changing the definition of Vegetation Inspection, the SDT does not believe the proposed changes are necessary for the definition to be clear. With regard to R1 and R2, they applicability applies to 4.2.1 thru 4.2.3. The distinction between the requirement is R1 applies to all lines designated as having an Interconnection Reliability Operating Limit (IROL) in the planning horizon by the Planning Coordinator; or lines designated as Major Western Electricity Coordinating Council (WECC) transfer path(s). With regard to your imminent threat procedure, the standard is not prescriptive to define a TO's imminent threat procedure. So, if your procedure includes managerial confirmation, then this would not be considered intentional delay.				
Sammy Roberts	Progress Energy Carolinas	1	Affirmative	There needs to be a change in the footnote 2 and footnote 4 to remove the exemption for "arboricultural activities or horticultural or agricultural activities" and replace it with the term "or installation of."
Response: The SDT thanks you for your comments. The footnotes have been changed.				
Laurie Williams	Public Service Company of New Mexico	1	Negative	PNM is voting negative but offers the following comments to improve the standard. 1. The last sentence of the Background on page 7 states: Thus, this Standard's emphasis is on vegetation grow-ins. However, R1 says that we shall manage encroachments as follows: R1. Each Transmission Owner shall manage vegetation to prevent encroachment that could result in a Sustained Outage encroachments of the types shown

Voter	Entity	Segment	Vote	Comment
				below, into the Minimum Vegetation Clearance Distance (MVCD) of....... 2. An encroachment due to a fall-in from inside the active transmission line Right-of-Way (ROW) that caused a vegetation-related Sustained Outage, This seems contradictory. 2. Fac-003-2 makes reference to FAC-014 and a “Planning Coordinator” in section 4.2.2 of Applicability: pg 5 see below: 4.2.2. Overhead transmission lines operated below 200kV having been identified as included in the definition of an Interconnection Reliability Operating Limit (IROL) under NERC Standard FAC-014 by the Planning Coordinator. In addition, on pg 8, R1 of FAC-003-2 makes reference to the “planning coordinator” However, FAC-014 makes no reference, or at least it is inconsistent, to a “Planning Coordinator” See below: Taken from FAC-014 4. Applicability 4.1. Reliability Coordinator 4.2. Planning Authority 4.3. Transmission Planner 4.4. Transmission Operator The terminology and definitions seem to be inconsistent.

Voter	Entity	Segment	Vote	Comment
				3. R1 and R2 are the same requirements with different applicabilities. R1 applies to lines that are connected to WECC, IROL, etc. R2 applies to all other applicable lines that are NOT an element of WECC or IROL. My Question is: If the line is not part of WECC or IROL or any other connection then, how is it applicable to the Standard? 4. R7 says the TO shall complete a %100 of annual plan but allows for modifications that include: Change in expected growth rate/ environmental factors Major storms Circumstances that are beyond the control of a Transmission Owner5 Rescheduling work between growing seasons Crew or contractor availability/ Mutual assistance agreements Identified unanticipated high priority work Weather conditions/Accessibility Permitting delays Land ownership changes/Change in land use by the landowner Funding adjustments (increase or decrease) Emerging technologies [VRF - Medium] [Time Horizon - Operations Planning] The requirement says we shall complete a %100 of the annual plan however, some of the modifications have historically taken over a year to mitigate. SHALL should be

Voter	Entity	Segment	Vote	Comment
				replaced with SHOULD with acceptable modifications and without compromising integrity of system.
Response: The SDT thanks you for your comments. Item 1: It is intended that the Standard will cover any situation within the ROW that causes an encroachment into the MVCD including fall-ins, grow-ins or blowing-together. The arrangement of the Violation Severity Levels for R1. and R2. emphasize that a grow-in results in the greatest risk to a power system, and also is the most egregious and severe failure to meet the intent of these requirements. Item 2: The term Planning Authority (PA) included in FAC-014 was replaced by NERC in the functional model Version 5 with Planning Coordinator. Where references to PA are included in legacy Standards, Planning Coordinator is now used as follows Planning Coordinator (Planning Authority). Obviously, proposed new Standards or versions must use the currently accepted terms. Item 3: R1 and R2 are dealing with the differentiation between lines that fall into IROL/WECC Transfer Path definition and those lines that do not. Keep in mind that this standard refers to all transmission lines over 200-kV. Item 4: The SDT believes replacing the word "shall" with the word "should" in Requirement 7 changes the requirement to a recommendation.				
Pawel Krupa	Seattle City Light	1	Affirmative	The revisions to the proposed FAC-003-2 Standards produced a better version through greater clarity, appropriate pragmatism, and technical foundation; A few good points that highlight this follow: 1. Definition of Terms Used in Standard: The revised definition of Right-of-Way (ROW) establishes the width of the corridor from a technical basis with the following statement "The width of the corridor is established by engineering or construction standards..." 2. Introduction, Applicability, Section 4.2 Facilities: Section 4.2.4 which pertains to substations clarifies that this standard does not apply to applicable transmission lines, inside the substation, just to "any portion of the span of the

Voter	Entity	Segment	Vote	Comment
				transmission line that is crossing the substation fence". 3. Requirements and Measures: Requirement 1 underscores sensible purpose by replacing the wording of "preventing outages from vegetation" to "manage vegetation to prevent encroachments..." 4. Guideline and Technical Basis Section: Requirement 7 contains a great practicle reference explanation as it pertains to the annual work plan. Requirement 7 explains: ..." the vegetation management approach should use the full extent of the Transmission Owner's easement, fee simple and other legal rights allowed. A comprehensive approach that exercises the full extent of legal rights on the ROW is superior to incremental management in the long term because it reduces the overall potential for encroachment, and it ensures that future planned work and future planned inspection cycles are sufficient".
Response: The SDT thanks you for your comments.				
William G. Hutchison	Southern Illinois Power Coop.	1	Negative	I beleive that the reliability region should have the right to exclude lines below 200KV. Not all lines above 100KV negative impact the BES.
Response: The SDT thanks you for your comment. This issue is presently before FERC and NERC and is outside the scope of the SDT.				
Keith V Carman	Tri-State G & T Association, Inc.	1	Affirmative	There needs to be a change in the footnote 2 and footnote 4 to remove the exemption for "arboricultural activities or horticultural or agricultural activities" and replace it with the term " installation of".

Voter	Entity	Segment	Vote	Comment
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
Brandy A Dunn	Western Area Power Administration	1	Affirmative	There needs to be a change in the footnote 2 and footnote 4 to remove the exemption for "arboricultural activities or horticultural or agricultural activities" and replace it with the term " installation of"
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
Gregory L Pieper	Xcel Energy, Inc.	1	Affirmative	Xcel Energy still believes the requirement in R6 that mandates an annual inspection is an ineffective approach and may actually go against the Commission's determination in FERC Order No. 693. The drafting team's response to our last round of comments on this issue was that "...the SDT was directed by Order 693 to set a minimum inspection criteria". It is clear in Order 693 that the Commission is not satisfied with allowing entities to choose their own inspection cycles, as the standard currently allows. However, we fail to see where the Commission mandated a minimum inspection cycle to be uniformly applied continent-wide. We urge the drafting team to revisit paragraphs 719 through 721 of Order 693. According to paragraph 721, the Commission recognizes that unique intervals by region, "based on local factors", are reasonable and appropriate. By use of the plural term "cycles", FERC anticipates the resolution may include multiple inspection cycles. Furthermore, in paragraph 719, FERC acknowledges that a minimum inspection cycle may not be the only way to address their concern. In fact, mandating an annual inspection cycle may actually go against the Commission's guidance in paragraph 720. Here is an excerpt: "...the

Voter	Entity	Segment	Vote	Comment
				Commission is dissuaded from requiring the ERO to create a backstop inspection cycle at this time. Instead, the Commission agrees that an entity's vegetation management program should be tailored to anticipated growth in the region and take into account other environmental factors. The goal is to assure that transmission owners conduct inspections at reasonable intervals." As an alternative, we propose a mid-cycle inspection. A mid-cycle inspection is based on an interval that is justified with data and technical expertise. A mid-cycle inspection would still require entities to conduct inspections at a specified interval, while allowing for differences based upon "physical and geographic factors". Not only would this approach fully address the Commissions concerns, but it would take into account the interests of stakeholders, landowners and rate-payers. We recognize that a mid-cycle inspection interval is not as easy to audit as an annual requirement, but it is a far more practical and cost-effective approach that, when applied based on an entity's expertise with its own facilities, ensures reliability.
Response: The SDT thanks you for your comments. The SDT recognizes that a number of Transmission Owners in North America may prefer to set their own inspection intervals. The SDT can also see attractiveness for a mid-cycle inspection concept; however, this introduces new complexities in planning, documentation and auditing. Because there is substantial industry support for an annual inspection interval the SDT believes that the industry is best served with this approach.				
Mark B Thompson	Alberta Electric System Operator	2	Abstain	Due to slow vegetation growth rates in many parts of Alberta, not all transmission right-of-ways require annual inspection as required in R6. TOs should be able to include planned inspection cycles in their Transmission Vegetation Management Plan.

Voter	Entity	Segment	Vote	Comment
Response: The SDT thanks you for your comments. In FERC Order 693, para. 721, FERC stated, “The Commission continues to be concerned with leaving complete discretion to the transmission owners in determining inspection cycles, which limits the effectiveness of the Reliability Standard.” The SDT established an inspection cycle at least once per calendar year and with no more than 18 calendar months between inspections on the same ROW. There was a survey of the industry in a previous request for comments to this standard. The response to that survey is the basis for the use of the 1-year period. While there was a range of growth rates across the continent, the SDT had sufficient feedback to recommend the 1-year cycle. The inspection also would cover inspecting for fall-in threats. Please note that vegetation inspections can also be combined with other line inspections.				
Alden Briggs	New Brunswick System Operator	2	Affirmative	The term “encroachment” has to be defined, and the use of that term and the clearances required clarification. The Table listing the clearances also needed clarification.
Response: The SDT thanks you for your comment. The SDT endorses the standard dictionary definition of the term “encroachment” and as such it does not require a NERC-specific definition. The use of encroachment regarding the clearance table is explained in detail in the Technical Reference Document.”				
Richard J. Mandes	Alabama Power Company	3	Affirmative	There needs to be a change in the footnote 2 and footnote 4 to remove the exemption for “arboricultural activities or horticultural or agricultural activities” and replace it with the term “ installation of”.
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
Steven Norris	APS	3	Negative	The objective, as written, is about outages that can lead to cascading and not about reliability. Recommended change to Standard Objective: To maintain a reliable electric transmission system, implement a defense-in-depth strategy to manage vegetation located on transmission rights of way (ROW) and minimize encroachments from vegetation located adjacent to the ROW.

Voter	Entity	Segment	Vote	Comment
Response: The SDT thanks you for your comment. With respect to the Purpose as written in the proposed standard, the language clearly states “To improve the reliability of the electric Transmission system…”. The SDT made it a point to keep the Purpose as concise as possible without getting into issues that are covered further in the body of the standard.				
Rebecca Berdahl	Bonneville Power Administration	3	Affirmative	In R1 and R2 and their associated VSLs, the SDT added the phrase “in order of increasing severity” and added the sentence, “The types of encroachments are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a TO’s vegetation maintenance program.” to the Rationale boxes for R1/R2. Do you agree? If answer is no, please explain. BPA prefers the stratified levels of violation severity presented in the table for R1 and R2. Foot note # 2 on page 8 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. Foot note # 4 on page 12 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. In response to comments received that requirement R3 is unclear with respect to intent, the SDT added “maintenance strategies.” Do you agree this clarifies the intent? If answer is no, please offer alternative language. The TO procedures / policies and specifications shall demonstrate the TO’s ability to manage the system at all rated conditions to maintain reliability. BPA believes that the intent is clear, but the fundamental approach of using the MVCD (table 2) to manage a vegetation program is still

Voter	Entity	Segment	Vote	Comment
				problematic. These values are flashover distances and are way too close. This is acknowledged in a footnote to table 2 but no identification of allowable buffers/distances between energized phase conductors at rated temperatures and vegetation is discussed (this is left up the transmission owners). Clarity is needed on this topic. Setting a finite distance limit based on recognized standards, good science and risk avoidance should be done for the industry. BPA has previously made this comment during the drafting of the standard. It was not addressed then, nor has it been addressed now.
Response: The SDT thanks you for your comments. Footnotes #2 and #4 have been changed to reflect your suggestion to clarify arboricultural or horticultural or agricultural activities. With respect to comments about the MVCD, R3 does not suggest the MVCD be used as a distance to manage vegetation. The MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD In a performance based standard, requirements are focused on "what" needs to be accomplished to achieve desired results and avoids prescriptive requirements of "how" to achieve that result. TO's are in the best position to determine the appropriate management approach suited for their system, rather than a "one size fits all" or "fill in the blank" requirement that could suppress best practices for vegetation management.				
Matt Culverhouse	City of Bartow, Florida	3	Negative	The suggested Measures are not sufficient evidence to prove compliance with that interpretation of the requirement. For instance, most encroachments do not result in outages; hence, lack of outages cannot prove that there were no encroachments, and real time observations

Voter	Entity	Segment	Vote	Comment
				are insufficient because it is a spot-check that does not cover the audit period. There are other weaknesses in the standard, such as R4 being un-measurable therefore unenforceable. However, in the guilty until proven innocent paradigm we live in, FMPA's primary concern is that industry could be put into a no-win situation of not being able to prove compliance with the standard if R1 and R2 are interpreted as "prevent encroachment", and if R1 and R2 are interpreted as "manage" then it is not a performance based standard as advertised.
Response: The SDT thanks you for your comments. In Order 693, FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation**" (emphasis added). The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct inspections in which clearances are evaluated. Also please reference footnote 3.				
Bryan Y Harper	Cleco Utility Group	3	Negative	Cleco disagrees with the SDT revising the definition for Right-of-Way (ROW). Right-of-Way is a term that has had a consistent meaning throughout history. If NERC tries to redefine the term, it will only add confusion because most entities will not reference the NERC glossary for a term which is widely used in the industry. In lieu of "Active Transmission Line ROW", please use another term such as Transmission Corridor. No assumptions would be made when reading in the Standard the the Entity is to maintain vegetation located within the Transmission Corridor. Since the term is not commonly used, the NERC glossary would be referenced. Also, Cleco disagrees that an encroachment into the MCVD

Voter	Entity	Segment	Vote	Comment
				that does not cause an outage should be considered non-compliant as stated in R1 and R2. The encroachment should only be reportable similar to misoperations as is in the PRC-004 standard.
Response: Thanks for your comments. The existing ROW definition in the glossary was created by and for the FAC-003-1 and was moved there when that standard was adopted. The definition includes a series of options that give the Transmission Owner latitude in establishing ROW width. It does not require selecting a single method for its system. The term blowout standard is not capitalized and is not a defined term. This phrase in the definition allows a Transmission Owner to use its internal engineering standards or the general engineering standards that were in effect when the line was constructed to determine the ROW width. The SDT has limited the definition of Right-of-Way to a corridor of land with a defined width to operate a transmission line. This does not include danger tree rights. The definition of the MVCD is now added to this Standard. While use of the pre-2007 records is a compliance issue and is not in the purview of the SDT, it is the intent of the language in the definition that you could use this information. Regarding your second comment, the MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD. Other related requirements of this "Defense in Depth" Standard serve to address any number of scenarios which may arise or hinder the TO's ability to always strictly adhere to the management approach(s) established within R3. Thus the other requirements of this Standard provide the latitude for appropriate actions to remedy the condition without penalty. Further, trees which have encroached inside the MVCD are evidence of a deficiency in vegetation maintenance.				
Peter T Yost	Consolidated Edison Co. of New York	3	Affirmative	Reply to Question 5 on Comment Form: The added language for the annual work plan percentage complete calculation is shown in R7 not M7 as stated in the question. In the Guideline and Technical Basis Section for Requirement R6, there is a sample calculation shown for the amount of lines the TO failed to inspect. An example should

Voter	Entity	Segment	Vote	Comment
				also be included for Requirement R7 since there is some confusion regarding how modifications to the work plan affect the calculation. In the Lower VSL column for R7, it states that the TO failed to complete up to 5% of its annual vegetation work plan (including modifications if any). If a TO operates 100 lines and submits a justified modification that affects 10 miles of lines, the total number of units in the final amended plan is 90 miles. When you read the VSL, it is somewhat confusing since the information in parenthesis says that the calculation 'includes' the modifications. Should it state 'excludes modifications if any' or the VSLs can simply be re-written to state that ..The TO failed to complete up to x% of the final amended plan.' Also, the VSLs in R6 and R7 should be consistent with each other: R6 says '...TO failed to inspect 5% or less.....' and R7 says '...TO failed to complete up to 5%....' They both should use the same verbiage in each VSL whether it is 'x% or less' or 'up to and including x%.'
Response: The SDT thanks you for your comments. Your correction is accurate. The percentage should be based on the plan as modified. The SDT has changed the language in the standard to reflect this more clearly. The VSLs have been modified to be consistent as suggested.				
David A. Lapinski	Consumers Energy	3	Negative	Comments on FAC-003-2 February 25, 2011 Consumers Energy submits the following comments on FAC-003-2: In general we are please with FAC-003-2 and the many clarifications that the STD has made in this version of the standard. However, we do have one major disagreement with the STD and cannot support this standard as drafted.

Voter	Entity	Segment	Vote	Comment
				We disagree with the use of the Minimum Vegetation Clearance Distance (MVCD) developed by the drafting team for Requirements R1 and R2. These distances are not the design distances used for designing and constructing transmission facilities as stated in the document for minimum distances between conductors and grounded objects. The proposed Table 2 provides a distance of 3.12 feet as the acceptable distance for an alternate current 345kV line at sea level. This distance is considerably less than the distance used for line design to separate the grounded tower structure from the energized conductor. If the distance in Table 2 is acceptable to prevent energized portions of a transmission line from grounding to a tree why then is this distance not the design criteria used for tower design to prevent flashover from conductor to tower? The STD needs to explain why a ground tree should have a different standard that a grounded steel tower or wood pole structure. The STD erroneously viewed the possibility of transient over voltage as only occurring during re-energizing and not from natural events such as a lightning strike that can occur and does occur to energized operating lines. Secondly, the proposed distances in Table 2 are considerably less than the distances specified in OSHA requirements for air gap clearance required by tree workers to safely remove trees or limbs from conductors energized at the voltages specified. A transmission owner/operator could let a tree grow to within 3.5 feet of a 345 kV line and not be in violation of this proposed standard. To remove the tree, the

Voter	Entity	Segment	Vote	Comment
				line would have to be de-energized, tagged, tested de-energized, and grounded. Working clearance would have to be established by the operating entity and then the tree crew could remove the tree. The net result is the loss of the capacity of the line because an outage was forced on the line in order to remove the tree that did not trigger a violation of FAC-003-2. This situation, in our opinion, is a violation of the intent of the standard, which is to ensure the continued operation of the line. Therefore, the minimum distance any tree should be able to approach a conductor is more than the minimum requirement for air gap distance between the tree and conductor as required by OSHA worker standards. The STD did not like referring to another standard to provide the distance requirements for R1 and R2. This can be alleviated by putting in a table with the IEEE 516 distances but not reference it as the IEEE 516 standard. The distances provided in the current draft do not adequately provide or ensure the continued safe operation of the transmission facilities in the United States and the reasoning for the distances provided is unfounded and not based on current design practices.

Response: The SDT thanks you for your comments. You are correct that these distances do not represent complete design specifications for towers, nor define and describe safe worker approach distances. These practices are correctly specified in the other standards you referenced. The SDT feels the standard is clear in that regard. The footnote associated with the Table 2 distances clearly states that these are only distances to prevent flashover under appropriate conditions. The SDT would also like to point out that the transient overvoltage factors used to derive these distances are the maximums normally seen with a transmission line in steady state service. Thus, a tower design would have to account for the larger overvoltage factors that are possible while taking lines out of service.

As has been stated before, these distances were derived using a known set of line design equations and only represent distances that will prevent spark-over from the transmission line to a grounded object. These are not distances to be managed to – they have been established as a beginning of a series of “building blocks” for a program to ensure reliability of a

Voter	Entity	Segment	Vote	Comment
Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner' consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD. These distances are smaller than safety standard distances that have many other factors involved in the determination, such as inadvertent human movement and larger safety factors. In regard to the over-voltages caused by lightning, even the maximum overvoltage factors contained in the IEEE-516 tables do not account for these.				
Russell A Noble	Cowlitz County PUD	3	Negative	Referring back to Cowlitz' negative vote made on the 7/9-19/2010 ballot, Cowlitz tried to convey the problem that the statement in R4 "without intentional time delay" will require subjective judgment on the part of the auditor. In other words, maintaining equal auditing standard throughout the interconnection will be impossible with this verbiage in a requirement. Cowlitz agrees with the SDT that establishing an equitable time frame is very difficult (it may be impossible!); however leaving it to the judgment of the auditor to determine whether an intentional delay was made is most disagreeable. Cowlitz respectfully points out that the SDT did not adequately address the subjective nature the auditor is forced into with this requirement. If establishing "[t]he time required by the to report an issue is subject to many variables..." and "[f]or this reason it is difficult to establish a time period which would fairly apply to all TO's," how does leaving this to the auditor to decide going to make it any better?
Response: The SDT believes that it was not prudent to suggest a quantitative time element for notification in R4. The technical reference offers examples of acceptable unintentional delays for your review. The SDT notes that this language is already embodied in at least one other FERC-approved, in-force Standard.				

Voter	Entity	Segment	Vote	Comment
Kevin Querry	FirstEnergy Solutions	3	Affirmative	FirstEnergy supports standard FAC-003-2 and would appreciate consideration of our comments submitted through the formal comment period.
Response: The SDT thanks you for your comments. Please see our consideration of your comments within the responses to the formal comments.				
Lee Schuster	Florida Power Corporation	3	Affirmative	There needs to be a change in the footnote 2 and footnote 4 to remove the exemption for “arboricultural activities or horticultural or agricultural activities” and replace it with the term “installation of."
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
Anthony L Wilson	Georgia Power Company	3	Affirmative	There needs to be a change in the footnote 2 and footnote 4 to remove the exemption for “arboricultural activities or horticultural or agricultural activities” and replace it with the term “ installation of”.
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
Charles Locke	Kansas City Power & Light Co.	3	Negative	The Standard lacks clarity regarding the facilities that are subject to Requirement 7. It is important that a Standard be clear and not introduce ambiguity or confusion. There are several references throughout the Standard to "for all applicable lines" and it should be made clear the work plan is specific to "all applicable lines".
Response: The SDT thanks you for your comments. The team has made the appropriate modifications where necessary.				
Mace Hunter	Lakeland Electric	3	Affirmative	R1. Each Transmission Owner shall manage vegetation to prevent encroachments of the types shown below, ------------

Voter	Entity	Segment	Vote	Comment
				---- and all Rated Electrical Operating Conditions.2 1. An encroachment into the MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage, that is not corrected within 5 working days of discovery, Make the same change to R2 Type 1 encroachment and reflect the changes in Table 1. Rational: This condition would enable a entity to discover an encroachment and clear it without having to self report a possible violation as long as the conditions was corrected within 5 working days. The change should encourage extra inspections for problem areas more often than annually as required in R6. There should be no negative consequences for diligent inspection of lines as long as the problem is clear with a defined time such as 5 or 10 working days.
Response: The SDT thanks you for your comment. As a general rule, a revised standard should not be less stringent than the existing standard it replaces. In the existing standard, a violation occurs when the encroachment occurs. A 'find and fix' of five days would be viewed as a lowering of the level of required performance established by the current standard.				
Bruce Merrill	Lincoln Electric System	3	Affirmative	While supportive of the drafting team's efforts, LES believes a change is warranted in Footnote 2 and Footnote 4 to remove the exemption for "arboricultural activities or horticultural or agricultural activities" and replace with the term "installation of". As currently drafted, the wording could potentially be construed to mean that the TO would or could be constrained or refused permission to prune and remove any and all vegetation in the ROW in accordance with the full legal rights of the ROW agreement(s).
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
Don Horsley	Mississippi Power	3	Affirmative	There needs to be a change in the footnote 2 and footnote 4 to remove the exemption for "arboricultural activities or

Voter	Entity	Segment	Vote	Comment
				horticultural or agricultural activities" and replace it with the term " installation of".
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
Terry L Baker	Platte River Power Authority	3	Negative	FAC-003-2 Comments Vegetation Inspection: Is the intent of "... and those vegetation conditions under the TO's control" to clarify that an entity must have ownership of the transmission line and right-of-way in addition to maintenance or operational responsibility (control), or something different? In situations where a TO owns one circuit on a double circuit, but the other circuit, facilities and ROW belong to another TO who has maintenance, and vegetation management responsibility, who would be responsible for violations? If the definition was modified to allow both maintenance and vegetation inspections to be performed concurrently, the intent might be clearer if it read: "This may be combined with other line inspections", or "This may be combined with a maintenance inspection" opposed to a general line inspection. R1 and R2: Does R1 correlate to facilities in 4.2.2. and 4.2.3. (overhead transmission lines operated below 200 kV) and R2 correlate to facilities in 4.2.1. (overhead transmission lines operated at 200kV or higher)? It isn't clear why the two requirements are split. Could it be one requirement which reads "...identified as a facility in Section 4.2"? R4: Our current imminent threat procedure requires a call

Voter	Entity	Segment	Vote	Comment
				to the Manager who confirms the existence of a vegetation condition that is likely to cause a Fault at any moment prior to notifying the control center. We assume notification, without any intentional time delay, would take place after managerial confirmation but feel like the enforcement authorities could interpret this differently based on how it is written in R4. If the intent of the requirement is how we interpret it, the requirement might be clearer if it read: After a Transmission Owner has confirmed a vegetation condition likely to cause a Fault at any moment, they shall notify the control center holding switching authority for the associated applicable transmission line, without any intentional delay.
Response: The SDT thanks you for your comment. With regard to responsibility for a violation, the TO is the accountable party even if it has an agreement with another TO to inspect and manage vegetation. With regard to your suggestion in changing the definition of Vegetation Inspection, the SDT does not believe the proposed changes are necessary for the definition to be clear. With regard to R1 and R2, they applicability applies to 4.2.1 thru 4.2.3. The distinction between the requirement is R1 applies to all lines designated as having an Interconnection Reliability Operating Limit (IROL) in the planning horizon by the Planning Coordinator; or lines designated as Major Western Electricity Coordinating Council (WECC) transfer path(s). With regard to your imminent threat procedure, the standard is not prescriptive to define a TO's imminent threat procedure. So, if your procedure includes managerial confirmation, then this would not be considered intentional delay.				
Dana Wheelock	Seattle City Light	3	Affirmative	The revisions to the proposed FAC-003-2 Standards produced a better version through greater clarity, appropriate pragmatism, and technical foundation; A few good points that highlight this follow: 1. Definition of Terms Used in Standard: The revised definition of Right-of-Way (ROW) establishes the width of the corridor from a technical basis with the following

Voter	Entity	Segment	Vote	Comment
				statement "The width of the corridor is established by engineering or construction standards..." 2. Introduction, Applicability, Section 4.2 Facilities: Section 4.2.4 which pertains to substations clarifies that this standard does not apply to applicable transmission lines, inside the substation, just to "any portion of the span of the transmission line that is crossing the substation fence". 3. Requirements and Measures: Requirement 1 underscores sensible purpose by replacing the wording of "preventing outages from vegetation" to "manage vegetation to prevent encroachments..." 4. Guideline and Technical Basis Section: Requirement 7 contains a great practicle reference explanation as it pertains to the annual work plan. Requirement 7 explains: ..." the vegetation management approach should use the full extent of the Transmission Owner's easement, fee simple and other legal rights allowed. A comprehensive approach that exercises the full extent of legal rights on the ROW is superior to incremental management in the long term because it reduces the overall potential for encroachment, and it ensures that future planned work and future planned inspection cycles are sufficient".
Response: The SDT thanks you for your comments.				
Michael Ibold	Xcel Energy, Inc.	3	Affirmative	Xcel Energy still believes the requirement in R6 that mandates an annual inspection is an ineffective approach and may actually go against the Commission’s

Voter	Entity	Segment	Vote	Comment
				determination in FERC Order No. 693. The drafting team's response to our last round of comments on this issue was that "...the SDT was directed by Order 693 to set a minimum inspection criteria". It is clear in Order 693 that the Commission is not satisfied with allowing entities to choose their own inspection cycles, as the standard currently allows. However, we fail to see where the Commission mandated a minimum inspection cycle to be uniformly applied continent-wide. We urge the drafting team to revisit paragraphs 719 through 721 of Order 693. According to paragraph 721, the Commission recognizes that unique intervals by region, "based on local factors", are reasonable and appropriate. By use of the plural term "cycles", FERC anticipates the resolution may include multiple inspection cycles. Furthermore, in paragraph 719, FERC acknowledges that a minimum inspection cycle may not be the only way to address their concern. In fact, mandating an annual inspection cycle may actually go against the Commission's guidance in paragraph 720. Here is an excerpt: "...the Commission is dissuaded from requiring the ERO to create a backstop inspection cycle at this time. Instead, the Commission agrees that an entity's vegetation management program should be tailored to anticipated growth in the region and take into account other environmental factors. The goal is to assure that transmission owners conduct inspections at reasonable intervals." As an alternative, we propose a mid-cycle inspection. A mid-cycle inspection is based on an interval that is justified with data and technical expertise. A mid-cycle inspection would still require entities to conduct inspections at a specified interval, while allowing for differences based upon "physical

Voter	Entity	Segment	Vote	Comment
				and geographic factors". Not only would this approach fully address the Commissions concerns, but it would take into account the interests of stakeholders, landowners and rate-payers. We recognize that a mid-cycle inspection interval is not as easy to audit as an annual requirement, but it is a far more practical and cost-effective approach that, when applied based on an entity's expertise with its own facilities, ensures reliability.
Response: The SDT thanks you for your comments. The SDT recognizes that a number of Transmission Owners in North America may prefer to set their own inspection intervals. The SDT can also see attractiveness for a mid-cycle inspection concept; however, this introduces new complexities in planning, documentation and auditing. Because there is substantial industry support for an annual inspection interval the SDT believes that the industry is best served with this approach.				
Rick Syring	Cowlitz County PUD	4	Negative	Referring back to Cowlitz' negative vote made on the 7/9-19/2010 ballot, Cowlitz tried to convey the problem that the statement in R4 "without intentional time delay" will require subjective judgment on the part of the auditor. In other words, maintaining equal auditing standard throughout the interconnection will be impossible with this verbiage in a requirement. Cowlitz agrees with the SDT that establishing an equitable time frame is very difficult (it may be impossible!); however leaving it to the judgment of the auditor to determine whether an intentional delay was made is most disagreeable. Cowlitz respectfully points out that the SDT did not adequately address the subjective nature the auditor is forced into with this requirement. If "[t]he time required by the entity to report an issue is subject to many variables..." and "[f]or this reason it is difficult to establish a time period which would fairly apply to all TO's," how does leaving this to the auditor to decide going to make it any better? You will be forcing the audited entity to "prove the negative."

Voter	Entity	Segment	Vote	Comment
Response: The SDT believes that it was not prudent to suggest a quantitative time element for notification in R4. The technical reference offers examples of acceptable unintentional delays for your review. The SDT notes that this language is already embodied in at least one other FERC-approved, in-force Standard.				
Frank Gaffney	Florida Municipal Power Agency	4	Negative	R1 and R2 requirement reads: "Each Transmission Owner shall manage to prevent encroachment ....". The results of manage would be invoices of tree trimming actually performed, documentation of a vegetation management program that would be managed to, etc. However, the Measures proposed are all actual outages which are neither evidence of management nor evidence of encroachment since there can be encroachment without an outage, and in fact, many if not most encroachments do not result in outages. Hence, the Measures are inconsistent with the requirements. Further, there is ambiguity of the action required in requirements R1 and R2 - e.g., do entities need evidence that they: 1) "manage", or 2) "prevent encroachment"; or 3) as implied by the Measures, prevent vegetation related outages?. In other words, what needs to be proven through evidence? Certainly the third, prevent vegetation related outages, is not in the Requirement; yet, that us what is proposed for the Measures, highlighting the inconsistency between Requirements and Measures. But, how would the ambiguity between "manage" and "prevent encroachment" be resolved? One auditor could interpret that the requirement is to "manage" and accept a vegetation management program and plan and proof that the plan was executed as appropriate evidence. Another auditor could interpret that "prevent" is the key word and look for evidence proving that there was never a vegetation

Voter	Entity	Segment	Vote	Comment
				encroachment. How would evidence be produced to provide the auditor that vegetation never encroached? Would video cameras and other surveillance measures need to operate 24 hours a day? Would we cause an entity to survey the lines periodically? One can easily see that "prevent encroachment" is inappropriate here since it is infeasible to create evidence of compliance. FMPA suggests one of two approaches: Eliminate the word manage, but do not focus on encroachment and instead focus on outages. For instance: "Each Transmission Owner shall prevent vegetation related outages (except as noted in Footnote 2) of any of its applicable line(s) ..." Evidence of outages is practical to gather and provide, evidence of encroachment is not. Focus on the word "manage", similar to the existing FAC-003 standard, and move R3 to a new R1 to develop a management plan, and then the existing R1 and R2 become R2 an R3 and require execution of that plan in the words of R7, which would in turn enables elimination of R7.
Response: The SDT thanks you for your comments. In Order 693, FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation**" (emphasis added). The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct inspections in which clearances are evaluated.				
Thomas W. Richards	Fort Pierce Utilities	4	Negative	R1 and R2 requirement reads: "Each Transmission Owner shall manage to prevent encroachment ....". The results of

Voter	Entity	Segment	Vote	Comment
	Authority			manage would be invoices of tree trimming actually performed, documentation of a vegetation management program that would be managed to, etc. However, the Measures proposed are all actual outages which are neither evidence of management nor evidence of encroachment since there can be encroachment without an outage, and in fact, many if not most encroachments do not result in outages. Hence, the Measures are inconsistent with the requirements. Further, there is ambiguity of the action required in requirements R1 and R2 - e.g., do entities need evidence that they: 1) "manage", or 2) "prevent encroachment"; or 3) as implied by the Measures, prevent vegetation related outages?. 				with the full legal rights of the ROW agreement(s).”
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
Douglas Hohlbaugh	Ohio Edison Company	4	Affirmative	FirstEnergy supports standard FAC-003-2 and would appreciate consideration of our comments submitted through the formal comment period.
Response: The SDT thanks you for your comments. Please see our consideration of your comments within the responses to the formal comments.				
Hao Li	Seattle City Light	4	Affirmative	The revisions to the proposed FAC-003-2 Standards produced a better version through greater clarity, appropriate pragmatism, and technical foundation; A few good points that highlight this follow: 1. Definition of Terms Used in Standard: The revised definition of Right-of-Way (ROW) establishes the width of the corridor from a technical basis with the following statement "The width of the corridor is established by engineering or construction standards..." 2. Introduction, Applicability, Section 4.2 Facilities: Section 4.2.4 which pertains to substations clarifies that this standard does not apply to applicable transmission lines, inside the substation, just to "any portion of the span of the transmission line that is crossing the substation fence". 3. Requirements and Measures: Requirement 1 underscores sensible purpose by replacing the wording of "preventing outages from vegetation" to "manage vegetation to prevent encroachments..."

Voter	Entity	Segment	Vote	Comment
				4. Guideline and Technical Basis Section: Requirement 7 contains a great practicle reference explanation as it pertains to the annual work plan. Requirement 7 explains: ..." the vegetation management approach should use the full extent of the Transmission Owner's easement, fee simple and other legal rights allowed. A comprehensive approach that exercises the full extent of legal rights on the ROW is superior to incremental management in the long term because it reduces the overall potential for encroachment, and it ensures that future planned work and future planned inspection cycles are sufficient".
Response: The SDT thanks you for your comments.				
Brock Ondayko	AEP Service Corp.	5	Affirmative	American Electric Power believes that the phrase "arboricultural activities or horticultural or agricultural activities" was mistakenly introduced into Footnotes 2 and 4, and should be deleted from both footnotes. If the phrase remains in the Standard, it may empower orchard growers, landowners and others to plant trees on the right of way and challenge Transmission Owners' rights to perform maintenance on the presumption that the standard will exempt the TO from violating the outage or encroachment requirements. For increased clarity, AEP offers the following change to the second paragraph of M1, as well as the second paragraph of M2. The original text “If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the

Voter	Entity	Segment	Vote	Comment
				equivalent of a Real-time observation" should be replaced with "If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation growing into or blowing together with the conductor within the ROW, this shall be considered the equivalent of a Real-time observation. A brief encroachment caused by falling vegetation passing through the MVCD is not considered an encroachment in this requirement".
Response: Thanks you for your comments. The SDT made suggested changes. Regarding the issue of fall-ins, the SDT is sympathetic to your concern. In fact, the SDT had originally crafted language similar to that which you suggested. However, due to concerns expressed by regulators and others, the exemption for encroachment violations due to falling vegetation from inside the right of way was removed.				
Francis J. Halpin	Bonneville Power Administration	5	Affirmative	In R1 and R2 and their associated VSLs, the SDT added the phrase "in order of increasing severity" and added the sentence, "The types of encroachments are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a TO's vegetation maintenance program." to the Rationale boxes for R1/R2. Do you agree? If answer is no, please explain. BPA prefers the stratified levels of violation severity presented in the table for R1 and R2. Foot note # 2 on page 8 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. Foot note # 4 on page 12 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities.

Voter	Entity	Segment	Vote	Comment
				In response to comments received that requirement R3 is unclear with respect to intent, the SDT added "maintenance strategies." Do you agree this clarifies the intent? If answer is no, please offer alternative language. The TO procedures / policies and specifications shall demonstrate the TO's ability to manage the system at all rated conditions to maintain reliability. BPA believes that the intent is clear, but the fundamental approach of using the MVCD (table 2) to manage a vegetation program is still problematic. These values are flashover distances and are way too close. This is acknowledged in a footnote to table 2 but no identification of allowable buffers/distances between energized phase conductors at rated temperatures and vegetation is discussed (this is left up the transmission owners). Clarity is needed on this topic. Setting a finite distance limit based on recognized standards, good science and risk avoidance should be done for the industry. BPA has previously made this comment during the drafting of the standard. It was not addressed then, nor has it been addressed now.
Response: The SDT thanks you for your comments. The footnotes were changed to conform with your suggestions. With respect to comments about the MVCD, R3 does not suggest the MVCD be used as a distance to manage vegetation. The MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD distances.				

Voter	Entity	Segment	Vote	Comment
In a performance based standard, requirements are focused on “what” needs to be accomplished to achieve desired results and avoids prescriptive requirements of “how” to achieve that result. TO’s are in the best position to determine the appropriate management approach suited for their system rather than a “one size fits all” or “fill in the blanks” requirements that could suppress best practices for vegetation management.				
Wilket (Jack) Ng	Consolidated Edison Co. of New York	5	Affirmative	Reply to Question 5 on Comment Form: The added language for the annual work plan percentage complete calculation is shown in R7 not M7 as stated in the question. In the Guideline and Technical Basis Section for Requirement R6, there is a sample calculation shown for the amount of lines the TO failed to inspect. An example should also be included for Requirement R7 since there is some confusion regarding how modifications to the work plan affect the calculation. In the Lower VSL column for R7, it states that the TO failed to complete up to 5% of its annual vegetation work plan (including modifications if any). If a TO operates 100 lines and submits a justified modification that affects 10 miles of lines, the total number of units in the final amended plan is 90 miles. When you read the VSL, it is somewhat confusing since the information in parenthesis says that the calculation 'includes' the modifications. Should it state 'excludes modifications if any' or the VSLs can simply be re-written to state that ..The TO failed to complete up to x% of the final amended plan.' Also, the VSLs in R6 and R7 should be consistent with each other: R6 says '...TO failed to inspect 5% or less.....' and R7 says '...TO failed to complete up to 5%....' They both should use the same verbiage in each VSL whether it is 'x% or less' or 'up to and including x%.'

Voter	Entity	Segment	Vote	Comment
Response: The SDT thanks you for your comments. The percentage should be based on the plan as modified. The SDT has changed the language in the standard to reflect this more clearly, and has modified the VSLs to be consistent as you have suggested.				
James B Lewis	Consumers Energy	5	Negative	Consumers Energy submits the following comments on FAC-003-2: In general we are please with FAC-003-2 and the many clarifications that the STD has made in this version of the standard. However, we do have one major disagreement with the STD and cannot support this standard as drafted. We disagree with the use of the Minimum Vegetation Clearance Distance (MVCD) developed by the drafting team for Requirements R1 and R2. These distances are not the design distances used for designing and constructing transmission facilities as stated in the document for minimum distances between conductors and grounded objects. The proposed Table 2 provides a distance of 3.12 feet as the acceptable distance for an alternate current 345kV line at sea level. This distance is considerably less than the distance used for line design to separate the grounded tower structure from the energized conductor. If the distance in Table 2 is acceptable to prevent energized portions of a transmission line from grounding to a tree why then is this distance not the design criteria used for tower design to prevent flashover from conductor to tower? The STD needs to explain why a ground tree should have a different standard that a grounded steel tower or wood pole structure. The STD erroneously viewed the possibility of transient over

Voter	Entity	Segment	Vote	Comment
				voltage as only occurring during re-energizing and not from natural events such as a lightning strike that can occur and does occur to energized operating lines. Secondly, the proposed distances in Table 2 are considerably less than the distances specified in OSHA requirements for air gap clearance required by tree workers to safely remove trees or limbs from conductors energized at the voltages specified. A transmission owner/operator could let a tree grow to within 3.5 feet of a 345 kV line and not be in violation of this proposed standard. To remove the tree, the line would have to be de-energized, tagged, tested de-energized, and grounded. Working clearance would have to be established by the operating entity and then the tree crew could remove the tree. The net result is the loss of the capacity of the line because an outage was forced on the line in order to remove the tree that did not trigger a violation of FAC-003-2. This situation, in our opinion, is a violation of the intent of the standard, which is to ensure the continued operation of the line. Therefore, the minimum distance any tree should be able to approach a conductor is more than the minimum requirement for air gap distance between the tree and conductor as required by OSHA worker standards. The STD did not like referring to another standard to provide the distance requirements for R1 and R2. This can be alleviated by putting in a table with the IEEE 516 distances but not reference it as the IEEE 516 standard. The distances provided in the current draft do not adequately provide or ensure the continued safe operation of the transmission facilities in the United States and the reasoning for the distances provided is unfounded and not based on current design practices.

Voter	Entity	Segment	Vote	Comment
Response: The SDT thanks you for your comments. You are correct that these distances do not represent complete design specifications for towers, nor define and describe safe worker approach distances. These practices are correctly specified in the other standards you referenced. The SDT feels the standard is clear in that regard. The footnote associated with the Table 2 distances clearly states that these are only distances to prevent flashover under appropriate conditions. The SDT would also like to point out that the transient overvoltage factors used to derive these distances are the maximums normally seen with a transmission line in steady state service. Thus, a tower design would have to account for the larger overvoltage factors that are possible while taking lines out of service. As has been stated before, these distances were derived using a known set of line design equations and only represent distances that will prevent spark-over from the transmission line to a grounded object. These are not distances to be managed to – they have been established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD. These distances are smaller than safety standard distances that have many other factors involved in the determination, such as inadvertent human movement and larger safety factors. In regard to the over-voltages caused by lightning, even the maximum overvoltage factors contained in the IEEE-516 tables do not account for these.				
Bob Essex	Cowlitz County PUD	5	Negative	Referring back to Cowlitz' negative vote made on the 7/9-19/2010 ballot, Cowlitz tried to convey the problem that the statement in R4 "without intentional time delay" will require subjective judgment on the part of the auditor. In other words, maintaining equal auditing standard throughout the interconnection will be impossible with this verbiage in a requirement. Cowlitz agrees with the SDT that establishing an equitable time frame is very difficult (it may be impossible!); however leaving it to the judgment of the auditor to determine whether an intentional delay was made is most disagreeable. Cowlitz respectfully points out that the SDT did not adequately address the subjective nature the auditor is forced into with this requirement. If

Voter	Entity	Segment	Vote	Comment
				establishing "[t]he time required by the to report an issue is subject to many variables..." and "[f]or this reason it is difficult to establish a time period which would fairly apply to all TO's," how does leaving this to the auditor to decide going to make it any better?
Response: The SDT believes that it was not prudent to suggest a quantitative time element for notification in R4. The technical reference offers examples of acceptable unintentional delays for your review. The SDT notes that this language is already embodied in at least one other FERC-approved, in-force Standard.				
Kenneth Dresner	FirstEnergy Solutions	5	Affirmative	FirstEnergy supports standard FAC-003-2 and would appreciate consideration of our comments submitted through the formal comment period.
Response: The SDT thanks you for your comments. Please see our consideration of your comments within the responses to the formal comments.				
David Schumann	Florida Municipal Power Agency	5	Negative	R1 and R2 requirement reads: "Each Transmission Owner shall manage to prevent encroachment ....". The results of manage would be invoices of tree trimming actually performed, documentation of a vegetation management program that would be managed to, etc. However, the Measures proposed are all actual outages which are neither evidence of management nor evidence of encroachment since there can be encroachment without an outage, and in fact, many if not most encroachments do not result in outages. Hence, the Measures are inconsistent with the requirements. Further, there is ambiguity of the action required in requirements R1 and R2 - e.g., do entities need evidence that they: 1) "manage", or 2) "prevent encroachment"; or 3) as implied by the Measures, prevent vegetation related outages?. In other words, what needs to be proven through evidence? Certainly the third, prevent vegetation related

Voter	Entity	Segment	Vote	Comment
				outages, is not in the Requirement; yet, that us what is proposed for the Measures, highlighting the inconsistency between Requirements and Measures. But, how would the ambiguity between "manage" and "prevent encroachment" be resolved? One auditor could interpret that the requirement is to "manage" and accept a vegetation management program and plan and proof that the plan was executed as appropriate evidence. Another auditor could interpret that "prevent" is the key word and look for evidence proving that there was never a vegetation encroachment. How would evidence be produced to provide the auditor that vegetation never encroached? Would video cameras and other surveillance measures need to operate 24 hours a day? Would we cause an entity to survey the lines periodically? One can easily see that "prevent encroachment" is inappropriate here since it is infeasible to create evidence of compliance. FMPA suggests one of two approaches: Eliminate the word manage, but do not focus on encroachment and instead focus on outages. For instance: "Each Transmission Owner shall prevent vegetation related outages (except as noted in Footnote 2) of any of its applicable line(s) ..." Evidence of outages is practical to gather and provide, evidence of encroachment is not. Focus on the word "manage", similar to the existing FAC-003 standard, and move R3 to a new R1 to develop a management plan, and then the existing R1 and R2 become R2 an R3 and require execution of that plan in the words of R7, which would in turn enables elimination of R7.

Response: The SDT thanks you for your comments. In Order 693, FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation**" (emphasis added). The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines

Voter	Entity	Segment	Vote	Comment
how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct inspections in which clearances are evaluated.				
Richard J. Padilla	Pacific Gas and Electric Company	5	Affirmative	There needs to be a change in the footnotes 2 and 4 to remove the exemption for “arboricultural activities or horticultural or agricultural activities” and replace it with the term “ installation of"
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
Wayne Lewis	Progress Energy Carolinas	5	Affirmative	There needs to be a change in the footnote 2 and footnote 4 to remove the exemption for “arboricultural activities or horticultural or agricultural activities” and replace it with the term “installation of.
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
Liam Noailles	Xcel Energy, Inc.	5	Affirmative	Xcel Energy still believes the requirement in R6 that mandates an annual inspection is an ineffective approach and may actually go against the Commission’s determination in FERC Order No. 693. The drafting team’s response to our last round of comments on this issue was that “...the SDT was directed by Order 693 to set a minimum inspection criteria”. It is clear in Order 693 that the Commission is not satisfied with allowing entities to choose their own inspection cycles, as the standard currently allows. However, we fail to see where the Commission mandated a minimum inspection cycle to be uniformly applied continent-wide. We urge the drafting team to revisit paragraphs 719 through 721 of Order 693. According to paragraph 721, the Commission recognizes that unique intervals by region, “based on local factors”, are reasonable and appropriate. By use of the plural term “cycles”, FERC anticipates the resolution may include multiple inspection

Voter	Entity	Segment	Vote	Comment
				cycles. Furthermore, in paragraph 719, FERC acknowledges that a minimum inspection cycle may not be the only way to address their concern. In fact, mandating an annual inspection cycle may actually go against the Commission's guidance in paragraph 720. Here is an excerpt: "...the Commission is dissuaded from requiring the ERO to create a backstop inspection cycle at this time. Instead, the Commission agrees that an entity's vegetation management program should be tailored to anticipated growth in the region and take into account other environmental factors. The goal is to assure that transmission owners conduct inspections at reasonable intervals." As an alternative, we propose a mid-cycle inspection. A mid-cycle inspection is based on an interval that is justified with data and technical expertise. A mid-cycle inspection would still require entities to conduct inspections at a specified interval, while allowing for differences based upon "physical and geographic factors". Not only would this approach fully address the Commissions concerns, but it would take into account the interests of stakeholders, landowners and rate-payers. We recognize that a mid-cycle inspection interval is not as easy to audit as an annual requirement, but it is a far more practical and cost-effective approach that, when applied based on an entity's expertise with its own facilities, ensures reliability.
Response: The SDT thanks you for your comments. The SDT recognizes that a number of Transmission Owners in North America may prefer to set their own inspection intervals. The SDT can also see attractiveness for a mid-cycle inspection concept; however, this introduces new complexities in planning, documentation and auditing. Because there is substantial industry support for an annual inspection interval , the SDT believes that the industry is best served with this approach.				

Voter	Entity	Segment	Vote	Comment
Edward P. Cox	AEP Marketing	6	Affirmative	American Electric Power believes that the phrase "arboricultural activities or horticultural or agricultural activities" was mistakenly introduced into Footnotes 2 and 4, and should be deleted from both footnotes. If the phrase remains in the Standard, it may empower orchard growers, landowners and others to plant trees on the right of way and challenge Transmission Owners' rights to perform maintenance on the presumption that the standard will exempt the TO from violating the outage or encroachment requirements. For increased clarity, AEP offers the following change to the second paragraph of M1, as well as the second paragraph of M2. The original text "If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation" should be replaced with "If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation growing into or blowing together with the conductor within the ROW, this shall be considered the equivalent of a Real-time observation. A brief encroachment caused by falling vegetation passing through the MVCD is not considered an encroachment in this requirement".
Response: Thanks you for your comments. The SDT made the suggested changes to the footnotes. Regarding the issue of fall-ins, the SDT is sympathetic to your concern. In fact, the SDT had originally crafted language similar to that which you suggested. However, due to concerns expressed by regulators and others, the exemption for encroachment violations due to falling vegetation from inside the right of way was removed.				

Voter	Entity	Segment	Vote	Comment
Brenda S. Anderson	Bonneville Power Administration	6	Affirmative	BPA Comments with Yes Vote: In R1 and R2 and their associated VSLs, the SDT added the phrase “in order of increasing severity” and added the sentence, “The types of encroachments are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a TO’s vegetation maintenance program.” to the Rationale boxes for R1/R2. Do you agree? If answer is no, please explain. BPA prefers the stratified levels of violation severity presented in the table for R1 and R2. Foot note # 2 on page 8 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. Foot note # 4 on page 12 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. In response to comments received that requirement R3 is unclear with respect to intent, the SDT added “maintenance strategies.” Do you agree this clarifies the intent? If answer is no, please offer alternative language. The TO procedures / policies and specifications shall demonstrate the TO’s ability to manage the system at all rated conditions to maintain reliability. BPA believes that the intent is clear, but the fundamental approach of using the MVCD (table 2) to manage a vegetation program is still problematic. These values are

Voter	Entity	Segment	Vote	Comment
				flashover distances and are way too close. This is acknowledged in a footnote to table 2 but no identification of allowable buffers/distances between energized phase conductors at rated temperatures and vegetation is discussed (this is left up the transmission owners). Clarity is needed on this topic. Setting a finite distance limit based on recognized standards, good science and risk avoidance should be done for the industry. BPA has previously made this comment during the drafting of the standard. It was not addressed then, nor has it been addressed now.
Response: The SDT thanks you for your comments. The footnotes were changed to conform with your suggestions. With respect to comments about the MVCD, R3 does not suggest the MVCD be used as a distance to manage vegetation. The MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD distances. In a performance based standard, requirements are focused on "what" needs to be accomplished to achieve desired results and avoids prescriptive requirements of "how" to achieve that result. TO's are in the best position to determine the appropriate management approach suited for their system rather than a "one size fits all" or "fill in the blanks" requirements that could suppress best practices for vegetation management.				
Matthew D Cripps	Cleco Power LLC	6	Negative	Cleco disagrees with the SDT revising the definition for Right-of-Way (ROW). Right-of-Way is a term that has had a consistent meaning throughout history. If NERC tries to redefine the term, it will only add confusion because most entities will not reference the NERC glossary for a term which is widely used in the industry. In lieu of "Active Transmission Line ROW", please use another term such as Transmission Corridor. No assumptions would be made when reading in the Standard the the Entity is to maintain

Voter	Entity	Segment	Vote	Comment
				vegetation located within the Transmission Corridor. Since the term is not commonly used, the NERC glossary would be referenced. Also, Cleco disagrees that an encroachment into the MCVD that does not cause an outage should be considered non-compliant as stated in R1 and R2. The encroachment should only be reportable similar to misoperations as is in the PRC-004 standard.
Response: Thanks for your comments. The existing ROW definition in the glossary was created by and for the FAC-003-1 and was moved there when that standard was adopted. The definition includes a series of options that give the Transmission Owner latitude in establishing ROW width. It does not require selecting a single method for its system. The term blowout standard is not capitalized and is not a defined term. This phrase in the definition allows a Transmission Owner to use its internal engineering standards or the general engineering standards that were in effect when the line was constructed to determine the ROW width. The SDT has limited the definition of Right-of-Way to a corridor of land with a defined width to operate a transmission line. This does not include danger tree rights. The definition of the MVCD is now added to this Standard. While use of the pre-2007 records is a compliance issue and is not in the purview of the SDT, it is the intent of the language in the definition that you could use this information. Regarding your second comment (begins with Also,): the MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD. Other related requirements of this "Defense in Depth" Standard serve to address any number of scenarios which may arise or hinder the TO's ability to always strictly adhere to the management approach(s) established within R3. Thus the other requirements of this Standard provide the latitude for appropriate actions to remedy the condition without penalty. Further, trees which have encroached inside the MVCD are evidence of a deficiency in vegetation maintenance.				
Nickesha P Carrol	Consolidated Edison Co. of	6	Affirmative	Reply to Question 5 on Comment Form: The added language for the annual work plan percentage complete calculation is

Voter	Entity	Segment	Vote	Comment
	New York			shown in R7 not M7 as stated in the question. In the Guideline and Technical Basis Section for Requirement R6, there is a sample calculation shown for the amount of lines the TO failed to inspect. An example should also be included for Requirement R7 since there is some confusion regarding how modifications to the work plan affect the calculation. In the Lower VSL column for R7, it states that the TO failed to complete up to 5% of its annual vegetation work plan (including modifications if any). If a TO operates 100 lines and submits a justified modification that affects 10 miles of lines, the total number of units in the final amended plan is 90 miles. When you read the VSL, it is somewhat confusing since the information in parenthesis says that the calculation 'includes' the modifications. Should it state 'excludes modifications if any' or the VSLs can simply be re-written to state that ..The TO failed to complete up to x% of the final amended plan.'
Response: The SDT thanks you for your comments. The percentage should be based on the plan as modified. The SDT has changed the language in the standard to reflect this more clearly.				
Mark S Travaglianti	FirstEnergy Solutions	6	Affirmative	FirstEnergy supports standard FAC-003-2 and would appreciate consideration of our comments submitted through the formal comment period.
Response: The SDT thanks you for your comments. Please see our consideration of your comments within the responses to the formal comments.				
Thomas E Washburn	Florida Municipal Power Pool	6	Negative	The concern is that entities may not be able prove compliance with the standard. R1 and R2 say that: "Each Transmission Owner shall manage vegetation to prevent encroachments ...". If the requirements were interpreted such that "manage" is the operative word, then, we are OK because we can provide evidence of managing a program,

Voter	Entity	Segment	Vote	Comment
				such as a vegetation management plan and evidence of executing that plan (which does not align with the Measures). However, that 1) would cause the standard to not be performance based, and 2) it would be duplicative of the other requirements of the standard. If the requirements were interpreted with "prevent encroachment" as the operative phrase (which would be an incorrect interpretation from the construct of the sentence) there is no way to provide sufficient evidence that encroachment was prevented during the audit-period. The suggested Measures are not sufficient evidence to prove compliance with that interpretation of the requirement. For instance, most encroachments do not result in outages; hence, lack of outages cannot prove that there were no encroachments, and real time observations are insufficient because it is a spot-check that does not cover the audit period. There are other weaknesses in the standard, such as R4 being un-measurable therefore unenforceable. However, in the guilty until proven innocent paradigm we live in, FMPA's primary concern is that industry could be put into a no-win situation of not being able to prove compliance with the standard if R1 and R2 are interpreted as "prevent encroachment", and if R1 and R2 are interpreted as "manage" then it is not a performance based standard as advertised. Performance based focused on preventing vegetation related outages. For instance: "Each Transmission Owner

Voter	Entity	Segment	Vote	Comment
				shall prevent vegetation related outages (except as noted in Footnote 2) of any of its applicable line(s) ..." Evidence of outages is practical to gather and provide, evidence of encroachment is not. Modify the standard to be similar to the currently mandatory non-results based standard and focus on the word "manage". This would essentially mean eliminating R1 and R2 since the rest of the standard focuses on having a plan and managing to that plan..
Response: The SDT thanks you for your comments. In Order 693, FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation**" (emphasis added). The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct inspections in which clearances are evaluated.				
Silvia P. Mitchell	Florida Power & Light Co.	6	Affirmative	1. The SDT proposes a revised NERC Glossary definition for Right-of-Way (ROW). This revised definition will be used in lieu of the Active Transmission Line ROW. Do you agree? If answer is no, please explain. Yes 2. In R1 and R2 and their associated VSLs, the SDT added the phrase "in order of increasing severity" and added the sentence "The types of encroachments are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a TO's vegetation maintenance program." to the Rationale boxes for R1/R2. Do you agree? If answer is no, please explain. Yes Although NextEra Energy Inc. (NextEra), including Florida Power & Light Company, agrees with the changes referenced for R1

Voter	Entity	Segment	Vote	Comment
				and R2, NextEra is concerned that the exemptions identified in footnote 2 for "...arboricultural activities or horticultural or agricultural activities...," and similar language in footnote 4, are too broad. For example, this language appears to include an exemption for a landowner, who, during arboricultural activities or horticultural or agricultural activities, causes a vegetation contact with a transmission line (e.g., cutting or lifting a tree into a transmission line). This places the Transmission Owner in the difficult position of a landowner arguing it is exempt from a controllable risk. Thus, the "...arboricultural activities or horticultural or agricultural activities..." references should be removed from footnote 2, and the similar language in footnote 4 3. In response to comments received regarding the term "investigation" in M1/M2, the SDT substituted "confirmation...by the Transmission Owner.." in its place, among other minor edits to these measures. Do you agree? If answer is no, please explain. Yes 4. In response to comments received that requirement R3 is unclear with respect to intent, the SDT added "maintenance strategies". Do you agree this clarifies the intent? If answer is no, please offer alternative language. Yes 5. The SDT added clarifying language in M7 to explain how the annual work plan percentage complete calculation is to be performed. Is this adequate? If no, please provide improved examples. Yes

Voter	Entity	Segment	Vote	Comment
Response: The SDT thanks you for your comments. The team has made the appropriate modifications to the footnotes as you suggested.				
Thomas Saitta	Kansas City Power & Light Co.	6	Negative	The Standard lacks clarity regarding the facilities that are subject to Requirement 7. It is important that a Standard be clear and not introduce ambiguity or confusion. There are several references throughout the Standard to "for all applicable lines" and it should be made clear the work plan is specific to "all applicable lines".
Response: The SDT thanks you for your comments. The phrase, "applicable lines" was added to R7 in support of your suggestion.				
Eric Ruskamp	Lincoln Electric System	6	Affirmative	While supportive of the drafting team's efforts, LES believes a change is warranted in Footnote 2 and Footnote 4 to remove the exemption for "arboricultural activities or horticultural or agricultural activities" and replace with the term "installation of". As currently drafted, the wording could potentially be construed to mean that the TO would or could be constrained or refused permission to prune and remove any and all vegetation in the ROW in accordance with the full legal rights of the ROW agreement(s).
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
John T Sturgeon	Progress Energy	6	Affirmative	There needs to be a change in the footnote 2 and footnote 4 to remove the exemption for "arboricultural activities or horticultural or agricultural activities" and replace it with the term "installation of.
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
David F. Lemmons	Xcel Energy, Inc.	6	Affirmative	Xcel Energy still believes the requirement in R6 that mandates an annual inspection is an ineffective approach and may actually go against the Commission's

Voter	Entity	Segment	Vote	Comment
				determination in FERC Order No. 693. The drafting team's response to our last round of comments on this issue was that "...the SDT was directed by Order 693 to set a minimum inspection criteria". It is clear in Order 693 that the Commission is not satisfied with allowing entities to choose their own inspection cycles, as the standard currently allows. However, we fail to see where the Commission mandated a minimum inspection cycle to be uniformly applied continent-wide. We urge the drafting team to revisit paragraphs 719 through 721 of Order 693. According to paragraph 721, the Commission recognizes that unique intervals by region, "based on local factors", are reasonable and appropriate. By use of the plural term "cycles", FERC anticipates the resolution may include multiple inspection cycles. Furthermore, in paragraph 719, FERC acknowledges that a minimum inspection cycle may not be the only way to address their concern. In fact, mandating an annual inspection cycle may actually go against the Commission's guidance in paragraph 720. Here is an excerpt: "...the Commission is dissuaded from requiring the ERO to create a backstop inspection cycle at this time. Instead, the Commission agrees that an entity's vegetation management program should be tailored to anticipated growth in the region and take into account other environmental factors. The goal is to assure that transmission owners conduct inspections at reasonable intervals." As an alternative, we propose a mid-cycle inspection. A mid-cycle inspection is based on an interval that is justified with data and technical expertise. A mid-cycle inspection would still require entities to conduct inspections at a specified interval, while allowing for differences based upon "physical

Voter	Entity	Segment	Vote	Comment
				and geographic factors". Not only would this approach fully address the Commissions concerns, but it would take into account the interests of stakeholders, landowners and rate-payers. We recognize that a mid-cycle inspection interval is not as easy to audit as an annual requirement, but it is a far more practical and cost-effective approach that, when applied based on an entity's expertise with its own facilities, ensures reliability.
Response The SDT thanks you for your comments. The SDT recognizes that a number of Transmission Owners in North America may prefer to set their own inspection intervals. The SDT can also see attractiveness for a mid-cycle inspection concept; however, this introduces new complexities in planning, documentation and auditing. Because there is substantial industry support for an annual inspection interval and due to the vastly simpler auditing associated with an annual interval, the SDT believes that the industry is best served with this approach.				
Jacquie Smith	ReliabilityFirst Corporation	10	Negative	ReliabilityFirst votes "No" on the proposed FAC-003-2 because ReliabilityFirst believes that the currently effective FAC-003-1, despite any weaknesses it may have, better ensures the reliability of the bulk electric system. First, under the proposed FAC-003-2, Requirements 1 and 2, the minimum clearances are reduced. Second, under the proposed structure of FAC-003-2, Requirements 1 and 2, violations would only occur where an encroachment of the Minimum Vegetation Clearance Distance ("MVCD") is observed in real time or after vegetation contact, i.e., after actual harm has occurred. Consequently, the proposed structure appears to convert a preventative maintenance standard into a standard that is essentially only violated after it is too late. The current structure from Version 1 of the standard (i.e., the Clearance

Voter	Entity	Segment	Vote	Comment
				1 and 2 requirements) better ensures reliability because they seek to ensure that registered entities discover problematic vegetation conditions prior to encroachments leading to flashover or vegetation contacts. For example, the current Clearance 1 is the "clearance distances to be achieved at the time of transmission vegetation management work." And the current Clearance 2 is the "specific radial clearances to be maintained under all rated electrical operating conditions." See FAC-003-1, R1.2.1 and R1.2.2 (emphasis added). Third, the draft standard appears to inappropriately and unnecessarily reduce the risk factor assigned to some failures to manage vegetation. It draws a distinction between those transmission lines that are elements of IROLs or Major Western Electricity Coordinating Council ("WECC") transfer paths and those that are not. This distinction is apparently based on the assumption that vegetation management violations on transmission lines that are not elements of IROLS or Major WECC transfer paths are less important. ReliabilityFirst disagrees with this assumption. Simply put, both are serious issues and the distinction is inappropriate and unnecessary. The Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations, highlights the importance of all vegetation management work by identifying inadequate vegetation management as one of the causes of the 2003 Blackout. See Blackout Report, at p. 20. Finally, ReliabilityFirst disagrees with the proposed Violation Risk Factors ("VRFs") and Violation Severity Levels ("VSLs")

Voter	Entity	Segment	Vote	Comment
				because they are premised on the same inappropriate and unnecessary distinction that vegetation management violations on transmission lines that are not elements of IROLS or Major WECC transfer paths are less important. For the foregoing reasons, ReliabilityFirst votes “No” on the proposed FAC-003-2.

Response: As with a Transmission Owner's determination of its Clearance 1 distances under version 1 of the Standard, Requirement 3 of the revised Standard begins with the MVCD distances (just as Clearance 1 began with IEEE-516 distances) and then requires additional consideration for conductor movement, vegetation growth variables, and the utility's maintenance approach. These are essentially the same considerations required by version 1 of the existing Standard when developing Clearance 1 distances. Therefore, nothing has been lost in the revised Standard.

The MVCD was established as a beginning of a series of “building blocks” for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions.

R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner’s overall vegetation management approach. The net result of this “building block” approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD distances.

The defense-in-depth strategy for reliability standards development recognizes that each requirement in a NERC reliability standard has a role in preventing system failures, and that these roles are complementary and reinforcing. Reliability standards should not be viewed as a body of unrelated requirements, but rather should be viewed as part of a portfolio of requirements designed to achieve an overall defense-in-depth strategy and comport with the quality objectives of a reliability standard. The draft, when taken in whole, does present a "preventative” maintenance standard.

The Standard has been designed utilizing a "Defense in Depth" strategy which provides for multiple layers of defense against a MVCD encroachment or an outage. These other layers of defense are identified in requirements R3 through R7. R3 through R7 are the same preventative maintenance requirements as contained in Version 1 of the Standards. Additionally, Measure 3 for R3 now tests the reasonableness and practicality of a TO’s vegetation management approach long before field work is implemented; other requirements such as R7 require preventative maintenance work to be completed before encroachments occur.

The SDT asserts that different VRF’s for IROL and non-IROL lines strengthens the reliability of the standard. Vegetation

Voter	Entity	Segment	Vote	Comment
managers that do not know which lines have IROLs or are designated as WECC Transfer Paths may be inappropriately limiting resources allocated to vegetation management for a line with an IROL or a line designated as a WECC Transfer Path. A vegetation manager must ensure that the lines with IROLs and lines designated as WECC transfer paths are absolutely clear. By correctly identifying the risk associated with lines with IROLs line and/or lines designated as WECC Transfer Paths, the standard helps to assure that appropriate resources are applied.				

NORTH AMERICAN ELECTRIC
RELIABILITY CORPORATION

Non-binding Poll of VRFs and VSLs for FAC-003-2 (February 18-28, 2011) Consideration of Comments Report

Project 2007-07 Vegetation Management — September 30, 2011

Summary Consideration:

Some entities expressed concern regarding the use of the MVCD. The SDT explained that the MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions, and that R3 requires that a Transmission Owner to consider the MVCD distances, as well as variables of conductor movement and the variables associated with vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD.

Other entities questioned if the intent of the standard is to "manage vegetation" or to "prevent outages. The STD responded that In Order 693, FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation**" (emphasis added).

If you feel that the drafting team overlooked your comments, please let us know immediately. Our goal is to give every comment serious consideration in this process. If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Herb Schrayshuen, at 404-446-2563 or via email at herb.schrayshuen@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedure: http://www.nerc.com/files/RSDP_V6_1_12Mar07.pdf.

Voter	Entity	Segment	Vote	Comment
Gregory S Miller	Baltimore Gas & Electric Company	1	Affirmative	VRFs and VSLs seem reasonable.
Response: The SDT thanks you for your comments.				
Joseph S. Stonecipher	Beaches Energy Services	1	Negative	(See comments for 2007-07.)
Response: The SDT responded in the Successive Ballot Consideration of Comments document.				
Donald S. Watkins	Bonneville Power Administration	1	Affirmative	In R1 and R2 and their associated VSLs, the SDT added the phrase "in order of increasing severity" and added the sentence, "The types of encroachments are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a TO's vegetation maintenance program." to the Rationale boxes for R1/R2. Do you agree? If answer is no, please explain. BPA prefers the stratified levels of violation severity presented in the table for R1 and R2. Foot note # 2 on page 8 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. Foot note # 4 on page 12 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. In response to comments received that requirement R3 is unclear with respect to intent, the SDT added "maintenance strategies." Do you agree this clarifies the intent? If answer is no, please offer alternative language.

Voter	Entity	Segment	Vote	Comment
				The TO procedures / policies and specifications shall demonstrate the TO's ability to manage the system at all rated conditions to maintain reliability. BPA believes that the intent is clear, but the fundamental approach of using the MVCD (table 2) to manage a vegetation program is still problematic. These values are flashover distances and are way too close. This is acknowledged in a footnote to table 2 but no identification of allowable buffers/distances between energized phase conductors at rated temperatures and vegetation is discussed (this is left up the transmission owners). Clarity is needed on this topic. Setting a finite distance limit based on recognized standards, good science and risk avoidance should be done for the industry. BPA has previously made this comment during the drafting of the standard. It was not addressed then, nor has it been addressed now.
Response: The SDT thanks you for your comments. The footnotes were changed to conform with your suggestions. With respect to comments about the MVCD, R3 does not suggest the MVCD be used as a distance to manage vegetation. The MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this "building block" approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD. In a performance based standard, requirements are focused on "what" needs to be accomplished to achieve desired results and avoids prescriptive requirements of "how" to achieve that result. TO's are in the best position to determine the appropriate management approach suited for their system, rather than a "one size fits all" or "fill in the blank" requirement that could suppress best practices for vegetation management.				
Randall McCamish	City of Vero Beach	1	Negative	Vero Beach's concern is that entities may not be able prove compliance with the standard. R1 and R2 say that: "Each

Voter	Entity	Segment	Vote	Comment
				Transmission Owner shall manage vegetation to prevent encroachments ...". If the requirements were interpreted such that "manage" is the operative word, then, we are OK because we can provide evidence of managing a program, such as a vegetation management plan and evidence of executing that plan (which does not align with the Measures). However, that 1) would cause the standard to not be performance based, and 2) it would be duplicative of the other requirements of the standard. If the requirements were interpreted with "prevent encroachment" as the operative phrase (which would be an incorrect interpretation from the construct of the sentence) there is no way to provide sufficient evidence that encroachment was prevented during the audit-period. The suggested Measures are not sufficient evidence to prove compliance with that interpretation of the requirement. For instance, most encroachments do not result in outages; hence, lack of outages cannot prove that there were no encroachments, and real time observations are insufficient because it is a spot-check that does not cover the audit period. There are other weaknesses in the standard, such as R4 being un-measurable therefore unenforceable. However, in the guilty until proven innocent paradigm we live in, FMPA's primary concern is that industry could be put into a no-win situation of not being able to prove compliance with the standard if R1 and R2 are interpreted as "prevent encroachment", and if R1 and R2 are interpreted as "manage" then it is not a performance based standard as advertised. Vero Beach suggests one of two approaches: 1. Performance based focused on preventing vegetation

Voter	Entity	Segment	Vote	Comment
				related outages. For instance: "Each Transmission Owner shall prevent vegetation related outages (except as noted in Footnote 2) of any of its applicable line(s) ..." Evidence of outages is practical to gather and provide, evidence of encroachment is not. 2. Modify the standard to be similar to the currently mandatory non-results based standard and focus on the word "manage". This would essentially mean eliminating R1 and R2 since the rest of the standard focuses on having a plan and managing to that plan..
Response: The SDT thanks you for your comments. In Order 693, FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation**" (emphasis added). The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct inspections in which clearances are evaluated.				
Christopher L de Graffenried	Consolidated Edison Co. of New York	1	Affirmative	The VSLs in R6 and R7 should be consistent with each other: R6 says '...TO failed to inspect 5% or less.....' and R7 says '...TO failed to complete up to 5%....' They both should use the same verbiage in each VSL whether it is 'x% or less' or 'up to and including x%.'
Response: The SDT thanks you for your comments. The SDT has changed the verbiage in the VSLs in R6 and R7 such that it addresses you suggestion.				
Michael Gammon	Kansas City Power & Light Co.	1	Negative	The VSL for Requirement 7 should be clear and specifically state this specifically addresses only "all applicable lines".
Response: The SDT thanks you for your comments. The team has added the phrase, "applicable lines" as proposed to all the VSLs for R7.				
Stan T.	Keys Energy	1	Negative	Concern is that entities may not be able prove compliance with the standard. R1 and R2 say that: "Each Transmission

Marvin E VanBebber	Oklahoma Gas and Electric Co.	1	Negative	R3 VSL leaves a lot open to interpetation in the analysis area. This is one where the auditor could be heavy handed if he desired.
Response: The SDT thanks you for your comments. The Requirement 3 VSL does in fact give TO significant latitude with respect to maintaining appropriate clearances. As noted in the Rationale, "The documentation provides a basis for evaluating the competency of the Transmission Owner's vegetation program. There may be many acceptable approaches to maintain clearances." In a performance based standard, requirements (and associated VSLs) are focused on "what" needs to be accomplished to achieve desired results and avoids prescriptive requirements of "how" to achieve that result. TO's are in the best position to determine the appropriate management approach suited for their system rather than a "one-size-fits-all" requirement that could suppress best practices for vegetation management. With this in mind, if the TO is audited, and it has a well crafted vegetation management program and has properly documented procedures and results, it should be in a good position.				
Keith V Carman	Tri-State G & T Association, Inc.	1	Affirmative	There needs to be a change in the footnote 2 and footnote 4 to remove the exemption for "arboricultural activities or horticultural or agricultural activities" and replace it with the term " installation of".
Response: The SDT thanks you for your comments. The footnotes have been changed as proposed.				
Mark B Thompson	Alberta Electric System Operator	2	Abstain	VRFs and VSLs are set by Provincial authorities in Alberta.

David A. Lapinski	Consumers Energy	3	Negative	Comments on FAC-003-2 February 25, 2011 Consumers Energy submits the following comments on FAC-003-2: In general we are please with FAC-003-2 and the many clarifications that the STD has made in this version of the standard. However, we do have one major disagreement with the STD and cannot support this standard as drafted.

Voter	Entity	Segment	Vote	Comment
				We disagree with the use of the Minimum Vegetation Clearance Distance (MVCD) developed by the drafting team for Requirements R1 and R2. These distances are not the design distances used for designing and constructing transmission facilities as stated in the document for minimum distances between conductors and grounded objects. The proposed Table 2 provides a distance of 3.12 feet as the acceptable distance for an alternate current 345kV line at sea level. This distance is considerably less than the distance used for line design to separate the grounded tower structure from the energized conductor. If the distance in Table 2 is acceptable to prevent energized portions of a transmission line from grounding to a tree why then is this distance not the design criteria used for tower design to prevent flashover from conductor to tower? The STD needs to explain why a ground tree should have a different standard that a grounded steel tower or wood pole structure. The STD erroneously viewed the possibility of transient over voltage as only occurring during re-energizing and not from natural events such as a lightning strike that can occur and does occur to energized operating lines. Secondly, the proposed distances in Table 2 are considerably less than the distances specified in OSHA requirements for air gap clearance required by tree workers to safely remove trees or limbs from conductors energized at the voltages specified. A transmission owner/operator could let a tree grow to within 3.5 feet of a 345 kV line and not be in violation of this proposed standard. To remove the tree, the line would have to be de-energized, tagged, tested de-energized, and grounded. Working clearance would have to be established by the operating entity and then the tree crew could remove the

Voter	Entity	Segment	Vote	Comment
				tree. The net result is the loss of the capacity of the line because an outage was forced on the line in order to remove the tree that did not trigger a violation of FAC-003-2. This situation, in our opinion, is a violation of the intent of the standard, which is to ensure the continued operation of the line. Therefore, the minimum distance any tree should be able to approach a conductor is more than the minimum requirement for air gap distance between the tree and conductor as required by OSHA worker standards. The STD did not like referring to another standard to provide the distance requirements for R1 and R2. This can be alleviated by putting in a table with the IEEE 516 distances but not reference it as the IEEE 516 standard. The distances provided in the current draft do not adequately provide or ensure the continued safe operation of the transmission facilities in the United States and the reasoning for the distances provided is unfounded and not based on current design practices.
Response: The SDT thanks you for your comments. You are correct that these distances do not represent complete design specifications for towers, nor define and describe safe worker approach distances. These practices are correctly specified in the other standards you referenced. The SDT feels the standard is clear in that regard. The footnote associated with the Table 2 distances clearly states that these are only distances to prevent flashover under appropriate conditions. The SDT would also like to point out that the transient overvoltage factors used to derive these distances are the maximums normally seen with a transmission line in steady state service. Thus, a tower design would have to account for the larger overvoltage factors that are possible while taking lines out of service. As has been stated before, these distances were derived using a known set of line design equations and only represent distances that will prevent spark-over from the transmission line to a grounded object. These are not distances to be managed to – they have been established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner' consider the MVCD distances, as well as variables of conductor movement and vegetation growth, when designing the Transmission Owner's overall vegetation management approach. The net result of this				

Voter	Entity	Segment	Vote	Comment
“building block” approach is that when entities implement R7, their efforts will result in vegetation management at clearance distances greater than the MVCD. These distances are smaller than safety standard distances that have many other factors involved in the determination, such as inadvertent human movement and larger safety factors. In regard to the over-voltages caused by lightning, even the maximum overvoltage factors contained in the IEEE-516 tables do not account for these.				
Russell A Noble	Cowlitz County PUD	3	Negative	Referring back to Cowlitz’ negative vote made on the 7/9-19/2010 ballot, Cowlitz tried to convey the problem that the statement in R4 “without intentional time delay” will require subjective judgment on the part of the auditor. In other words, maintaining equal auditing standard throughout the interconnection will be impossible with this verbiage in a requirement. Cowlitz agrees with the SDT that establishing an equitable time frame is very difficult (it may be impossible!); however leaving it to the judgment of the auditor to determine whether an intentional delay was made is most disagreeable. Cowlitz respectfully points out that the SDT did not adequately address the subjective nature the auditor is forced into with this requirement. If establishing “[t]he time required by the to report an issue is subject to many variables...” and “[f]or this reason it is difficult to establish a time period which would fairly apply to all TO’s,” how does leaving this to the auditor to decide going to make it any better?
Response: The SDT thanks you for your comments. The SDT believes that it was not prudent to suggest a quantitative time element for notification in R4. The technical reference offers examples of acceptable unintentional delays for your review. The SDT notes that this language is already embodied in at least one other FERC-approved, in-force Standard.				
Charles Locke	Kansas City Power & Light Co.	3	Negative	The VSL for Requirement 7 should be clear and specifically state this specifically addresses only "all applicable lines".

Voter	Entity	Segment	Vote	Comment
Response: The SDT thanks you for your comments. The team has added the phrase, "applicable lines" as proposed to all the VSLs for R7.				
Mace Hunter	Lakeland Electric	3	Affirmative	R1. Each Transmission Owner shall manage vegetation to prevent encroachments of the types shown below, ---------------- and all Rated Electrical Operating Conditions.2 1. An encroachment into the MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage, that is not corrected within 5 working days of discovery, Make the same change to R2 Type 1 encroachment and reflect the changes in Table 1. Rational: This condition would enable a entity to discover an encroachment and clear it without having to self report a possible violation as long as the conditions was corrected within 5 working days. The change should encourage extra inspections for problem areas more often than annually as required in R6. There should be no negative consequences for diligent inspection of lines as long as the problem is clear with a defined time such as 5 or 10 working days.
Response: The SDT thanks you for your comment. As a general rule, a revised standards should not be less stringent than the existing standard it replaces. In the existing standard, a violation occurs when the encroachment occurs. A 'find and fix' of five days would be viewed as a lowering the level of performance required by the current standard.				
Rick Syring	Cowlitz County PUD	4	Negative	Referring back to Cowlitz' negative vote made on the 7/9-19/2010 ballot, Cowlitz tried to convey the problem that the statement in R4 "without intentional time delay" will require subjective judgment on the part of the auditor. In other words, maintaining equal auditing standard throughout the interconnection will be impossible with this verbiage in a requirement. Cowlitz agrees with the SDT that establishing an equitable time frame is very difficult (it may be impossible!); however leaving it to the judgment of the

If “[t]he time required by the entity to report an issue is subject to many variables...” and “[f]or this reason it is difficult to establish a time period which would fairly apply to all TO’s,” how does leaving this to the auditor to decide going to make it any better? You will be forcing the audited entity to "prove the negative."
Response: The SDT thanks you for your comments. The SDT believes that it was not prudent to suggest a quantitative time element for notification in R4. The technical reference offers examples of acceptable unintentional delays for your review. The SDT notes that this language is already embodied in at least one other FERC-approved, in-force Standard.				
Frank Gaffney	Florida Municipal Power Agency	4	Negative	R1 and R2 requirement reads: "Each Transmission Owner shall manage to prevent encroachment ....". The results of manage would be invoices of tree trimming actually performed, documentation of a vegetation management program that would be managed to, etc. However, the Measures proposed are all actual outages which are neither evidence of management nor evidence of encroachment since there can be encroachment without an outage, and in fact, many if not most encroachments do not result in outages. Hence, the Measures are inconsistent with the requirements. Further, there is ambiguity of the action required in requirements R1 and R2 - e.g., do entities need evidence that they: 1) "manage", or 2) "prevent encroachment"; or 3) as implied by the Measures, prevent vegetation related outages?. In other words, what needs to be proven through evidence? Certainly the third, prevent vegetation related outages, is not in the Requirement; yet, that us what is proposed for the Measures, highlighting the

Voter	Entity	Segment	Vote	Comment
				inconsistency between Requirements and Measures. But, how would the ambiguity between "manage" and "prevent encroachment" be resolved? One auditor could interpret that the requirement is to "manage" and accept a vegetation management program and plan and proof that the plan was executed as appropriate evidence. Another auditor could interpret that "prevent" is the key word and look for evidence proving that there was never a vegetation encroachment. How would evidence be produced to provide the auditor that vegetation never encroached? Would video cameras and other surveillance measures need to operate 24 hours a day? Would we cause an entity to survey the lines periodically? One can easily see that "prevent encroachment" is inappropriate here since it is infeasible to create evidence of compliance. FMPA suggests one of two approaches: Eliminate the word manage, but do not focus on encroachment and instead focus on outages. For instance: "Each Transmission Owner shall prevent vegetation related outages (except as noted in Footnote 2) of any of its applicable line(s) ..." Evidence of outages is practical to gather and provide, evidence of encroachment is not. Focus on the word "manage", similar to the existing FAC-003 standard, and move R3 to a new R1 to develop a management plan, and then the existing R1 and R2 become R2 an R3 and require execution of that plan in the words of R7, which would in turn enables elimination of R7.
Response: The SDT thanks you for your comments. In Order 693 FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation"** (emphasis added). The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct				

Voter	Entity	Segment	Vote	Comment
inspections in which clearances are evaluated.				
Douglas Hohlbaugh	Ohio Edison Company	4	Affirmative	For the Requirement R1 and R2 VSLs, we suggest that the proposed Moderate (fall-ins) and High (blowing together) VSL be interchanged. We believe that fall-ins are more severe encroachments than blowing together and the categories listed in the compliance section support this point. Category 1 (grow-ins) is most severe, followed by Category 2 & 3 (fall-ins) and Category 4 (blowing together. If the team elects to not make the suggested VSL changes then a change in the category listing within the compliance section is warranted. Either way they should be consistent.
Response: The SDT believes that there is consensus that "blowing-together" events are more indicative of a program failure than are "fall-in" events. Further, the risk to the transmission system from blowing-together events is greater than for fall-ins; partly because blowing-together events are more likely to repeat themselves, whereas fall-ins generally end on the spot. The SDT agrees with you that the ordering of the categories seems to convey a different message; however, re-sequencing the categories in order of severity would have led to a clash with the existing categories in Version 1 and thus would have provoked widespread confusion.				
Francis J. Halpin	Bonneville Power Administration	5	Affirmative	In R1 and R2 and their associated VSLs, the SDT added the phrase "in order of increasing severity" and added the sentence, "The types of encroachments are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a TO's vegetation maintenance program." to the Rationale boxes for R1/R2. Do you agree? If answer is no, please explain. BPA prefers the stratified levels of violation severity presented in the table for R1 and R2. Foot note # 2 on page 8 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities.

Voter	Entity	Segment	Vote	Comment
				Foot note # 4 on page 12 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. In response to comments received that requirement R3 is unclear with respect to intent, the SDT added "maintenance strategies." Do you agree this clarifies the intent? If answer is no, please offer alternative language. The TO procedures / policies and specifications shall demonstrate the TO's ability to manage the system at all rated conditions to maintain reliability. BPA believes that the intent is clear, but the fundamental approach of using the MVCD (table 2) to manage a vegetation program is still problematic. These values are flashover distances and are way too close. This is acknowledged in a footnote to table 2 but no identification of allowable buffers/distances between energized phase conductors at rated temperatures and vegetation is discussed (this is left up the transmission owners). Clarity is needed on this topic. Setting a finite distance limit based on recognized standards, good science and risk avoidance should be done for the industry. BPA has previously made this comment during the drafting of the standard. It was not addressed then, nor has it been addressed now.
Response: The SDT thanks you for your comments. The footnotes were changed to conform with your suggestions. With respect to comments about the MVCD, R3 does not suggest the MVCD be used as a distance to manage vegetation. The MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability of a Transmission line within its rating and all rated electrical operating conditions. R3 requires that a Transmission Owner consider the MVCD distances, as well as variables of conductor movement and

In a performance based standard, requirements are focused on “what” needs to be accomplished to achieve desired results and avoids prescriptive requirements of “how” to achieve that result. TO’s are in the best position to determine the appropriate management approach suited for their system rather than a “one size fits all” requirement that could suppress best practices for vegetation management.				
Nickesha P Carrol	Consolidated Edison Co. of New York	6	Affirmative	The VSLs in R6 and R7 should be consistent with each other: R6 says '...TO failed to inspect 5% or less.....' and R7 says '...TO failed to complete up to 5%....' They both should use the same verbiage in each VSL whether it is 'x% or less' or 'up to and including x%.'
Response: The SDT thanks you for your comments. The SDT has changed the verbiage in the VSLs in R6 and R7 such that it addresses you suggestion.				
Mark S Travaglianti	FirstEnergy Solutions	6	Affirmative	FirstEnergy supports standard FAC-003-2 and would appreciate consideration of our comments submitted through the formal comment period.
Response: The SDT thanks you for your comments and has reviewed and responded to your comments made during the formal comment period.				
Thomas E Washburn	Florida Municipal Power Pool	6	Negative	The concern is that entities may not be able prove compliance with the standard. R1 and R2 say that: "Each Transmission Owner shall manage vegetation to prevent encroachments ...". If the requirements were interpreted such that "manage" is the operative word, then, we are OK because we can provide evidence of managing a program, such as a vegetation management plan and evidence of

Voter	Entity	Segment	Vote	Comment
				executing that plan (which does not align with the Measures). However, that 1) would cause the standard to not be performance based, and 2) it would be duplicative of the other requirements of the standard. If the requirements were interpreted with "prevent encroachment" as the operative phrase (which would be an incorrect interpretation from the construct of the sentence) there is no way to provide sufficient evidence that encroachment was prevented during the audit-period. The suggested Measures are not sufficient evidence to prove compliance with that interpretation of the requirement. For instance, most encroachments do not result in outages; hence, lack of outages cannot prove that there were no encroachments, and real time observations are insufficient because it is a spot-check that does not cover the audit period. There are other weaknesses in the standard, such as R4 being un-measurable therefore unenforceable. However, in the guilty until proven innocent paradigm we live in, FMPA's primary concern is that industry could be put into a no-win situation of not being able to prove compliance with the standard if R1 and R2 are interpreted as "prevent encroachment", and if R1 and R2 are interpreted as "manage" then it is not a performance based standard as advertised. Performance based focused on preventing vegetation related outages. For instance: "Each Transmission Owner shall prevent vegetation related outages (except as noted in Footnote 2) of any of its applicable line(s) ..." Evidence of outages is practical to gather and provide, evidence of encroachment is not. Modify the standard to be similar to the currently mandatory non-results based standard and focus on the word "manage". This would essentially mean eliminating R1

Voter	Entity	Segment	Vote	Comment
				and R2 since the rest of the standard focuses on having a plan and managing to that plan..
Response: The SDT thanks you for your comments. In Order 693 FERC was very specific that "…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation**" (emphasis added). The drafting team followed that concept and used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. Item 1 in the requirements defines how an encroachment without an outage would be documented. Each Transmission Owner is also required to conduct inspections in which clearances are evaluated.				
Thomas Saitta	Kansas City Power & Light Co.	6	Negative	The VSL for Requirement 7 should be clear and specifically state this specifically addresses only "all applicable lines".
Response: The SDT thanks you for your comments. The team has added the phrase, "applicable lines" as proposed to all the VSLs for R7.				
James Eckelkamp	Progress Energy	6	Affirmative	There needs to be a change in the footnote 2 and footnote 4 to remove the exemption for "arboricultural activities or horticultural or agricultural activities" and replace it with the term "installation of."
Response: The SDT thanks you for your comments. The changes to the footnotes have been made as proposed.				
Guy V. Zito	Northeast Power Coordinating Council, Inc.	10	Affirmative	The use of the term "encroachment", and the lack of clarity in defining clearances is an issue that should be addressed by the Drafting Team.
Response: The SDT thanks you for your comments. With regard to the use of "encroachment" and the clarity in defining clearances as it relates to the VRFs and VSLs, the SDT has taken what was a "gray" area in Version 1 and added more clarity with regard to compliance. In Version 1, it is not actually clear whether experiencing an encroachment or experiencing outage is a violation of the standard. The SDT recognized this concern and has addressed this via the proposed VSLs for R1 and R2. These proposed VSLs are designed such to correlate to the severity level of failure of the Transmission Owner's vegetation management program.				

Voter	Entity	Segment	Vote	Comment
If you refer to the VSLs for R1 and R2, only the "Lower" VSLs apply to an encroachment, and that has been defined as "an encroachment into the MVCD observed in Real-time, absent a Sustained Outage." The "MVCD" clearance distance is clearly defined in Table 2 of the Standard. After the Lower VSL level for these requirements, the Moderate to Severe VSLs are correlated more directly to the severity of failure of the Transmission Owner's vegetation management program associated with a Sustained Outage. The SDT makes this recommendation of VSLs based on this being an improvement for compliance clarity over version 1 of the standard.				
Anthony E Jablonski	ReliabilityFirst Corporation	10	Negative	ReliabilityFirst votes negative and has the following comments regarding the VRFs and VSLs: 1. VRF for R1 and R2 a. The Final Report on the August 14th, 2003 Blackout in the United States and Canada: Causes and Recommendations Blackout Report, highlights the importance of all vegetation management work by identifying inadequate vegetation management as one of the causes of the 2003 Blackout. Based on the Blackout Report there should be no distinction between encroachments of applicable line(s) identified as an element of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path(s) and encroachments of applicable line(s) not identified as an element of an Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path(s). Therefore, ReliabilityFirst recommends that VRFs should be the same for R1 and R2. 2. VSL for R3 a. Since this requirement has sub-parts associated with it, the associated sub-part number should be referenced in the VSL itself.

Voter	Entity	Segment	Vote	Comment
				3. VSL for R4 a. The words in the VLS do not match the language in the requirement. The words “vegetation threat” is not mentioned in Requirement R4. Based on the FERC Guideline #3 “Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement” 4. VSL for R6 a. The following qualifier should be added to the end of each of the four VSLs, “...at least once per calendar year and with no more than 18 months between inspections on the same ROW” to be consistent with the corresponding requirement and in accordance with the FERC Guideline #3. 5. VSL for R7 a. There is no associated VSL dealing with the second part of the requirement which references that “... the Modifications to the work plan... must be documented.” Where does an entity fall if they have complete 100% of its annual vegetation work plan, but failed to document any modifications to the work plan? This aspect of the requirement should be addressed in the corresponding VSLs.

Response: The SDT thanks you for your comments.

1) In Order 693 FERC was very specific that “…FAC-003-1 is designed to minimize transmission outages from vegetation located on or near transmission rights-of-way **by maintaining safe clearances between transmission lines and vegetation**” (emphasis added). Following that concept, the SDT used R1 and R2 to move the clearance from a documentation requirement to a performance requirement. .

R1 and R2 are dealing with the differentiation between lines that fall into an IROL or WECC Transfer Path definition and those lines that do not. The SDT asserts that different VRF’s for IROL and non-IROL lines strengthens the reliability of the standard. Vegetation managers that do not know which lines are IROL or WECC Transfer Paths may be inappropriately limiting resources allocated to vegetation management for an IROL line or a WECC Transfer Path. A vegetation manager must ensure that the

Voter	Entity	Segment	Vote	Comment
IROL lines and WECC transfer paths are absolutely clear. By correctly identifying the risk associated with an IROL line and/or a WECC Transfer Path, the standard helps to assure that appropriate resources are applied. 2) The sub-parts referred to are part of the RBS building block approach to document how a TO prevents encroachment of vegetation into the MVCD. The sub parts are not separate elements but make up the processes, strategies, procedures or specifications to prevent encroachment in to the MVCD. 3) The SDT believes the correlation between R4 and the VSL is appropriate. 4) The SDT believes the correlation between R6 and the VSL is appropriate. 5) The wording in the VSL for R7 has been modified to address modifications to the annual work plan.				

Consideration of Comments on Draft 5 of FAC-003-2

Project 2007-07 Vegetation Management — September 30, 2011

Background
The Transmission Vegetation Management Drafting Team thanks all commenters who submitted comments on the 5th Draft of FAC-003-2 Transmission Vegetation Management standards. These standards were posted for a 30-day public comment period from January 27, 2011 through February 28, 2011. The stakeholders were asked to provide feedback on the standards through a special Electronic Comment Form. There were 41 sets of comments, including comments from more than 106 different people from approximately 63 companies representing 9 of the 10 Industry Segments as shown in the table on the following pages.

Summary of Changes
In order to be consistent with the latest version of NERC's Results Based Standards template, the heading "Objective" was replaced with "Purpose," and the numbering, headings, and sections were reformatted as necessary.

One repeated concern was whether or not "danger trees" rights outside the Right-of-Way (ROW) should be an extension of the ROW. The SDT has limited the definition of Right-of-Way to a corridor of land with a defined width to operate a transmission line, which does not include danger tree rights.

Another repeated concern was reference to the term "blowout standard" and commenters were asking for more clarification and/or a specific definition of that term. To this line of comments the SDT responded, "the definition includes a series of options that give the Transmission Owner latitude in establishing ROW width. It does not require selecting a single method for its system. The term blowout standard is not capitalized and is not a defined term, and is intended to represent whatever conductor "blow out" (as opposed to vegetation "blow in") design criteria were used when the line was constructed. This phrase in the definition allows a Transmission Owner to use its internal engineering standards or the general engineering standards that were in effect when the line was constructed to determine the ROW width."

A request was made to include the definition of MVCD within the definition section of the standard. The SDT agreed with the commenter's request and used the appropriate portion of the existing language in the rationale text box associated with R1 for the MVCD definition. The SDT understands that this term will be added to the NERC glossary coincident with this standard becoming effective. This is not a substantive change to the standard, it is merely procedural.

The SDT made minor changes to the footnotes in response to several requests.

There was some concern expressed regarding the relationships between the VSLs and language in the requirements. The SDT revised the language in the Rationale box to explain the program performance relationships between types of encroachments, faults and outages, and various types of failed maintenance, and how the various types of failed maintenance have historically been associated with known vegetation related events.

One commenter requested that “of applicable lines” be added to the requirements and VSL verbiage to clearly denote applicability within the requirements and VSL verbiage. The SDT made those changes as requested to the requirements, measures and VSLs.

Two commenters requested an example be added to the Guidelines and Technical Basis similar to the examples in R6 to clarify that the % calculations should be based on the Annual Plan as modified; the SDT added the example as requested.

1. **The SDT proposes a revised NERC Glossary definition for Right-of-Way (ROW). This revised definition will be used in lieu of the Active Transmission Line ROW. Do you agree? If answer is no, please explain.**

Summary Consideration: There are 40 comments; 29 of those comments were in agreement with the definition, and 11 were in disagreement.

One repeated concern in the disagreements was whether or not "danger trees" rights outside the Right-of-Way (ROW) should be an extension of the ROW. The SDT responded "The SDT has limited the definition of Right-of-Way to a corridor of land with a defined width to operate a transmission line. This does not include danger tree rights."

Another repeated concern in the disagreements was reference to the term "blowout standard" and commenters were asking for more clarification and/or a definition of that term. To this line of comment the SDT responded "The definition includes a series of options that gives the Transmission Owner latitude in establishing ROW width. It does not require selecting a single method for its system. The term blowout standard is not capitalized and is not a defined term, and is intended to represent whatever conductor "blow out" (as opposed to vegetation "blow in") design criteria were used when the line was constructed. This phrase in the definition allows a Transmission Owner to use its internal engineering standards or the general engineering standards that were in effect when the line was constructed to determine the ROW width."

A request was made to include the definition of MVCD within the definition section of the standard. The SDT agreed with the commenter's request and used the appropriate portion of the existing language in the rationale text box associated with R1 for the MVCD definition. The SDT understands that this term will be added to the NERC glossary coincident with this standard becoming effective. This is not a substantive change to the standard, it is merely procedural.

A request was made to remove the existing and future definition of ROW from the glossary. The SDT understands that this is not consistent with the NERC intent for each repeated acronym used in multiple requirements to be available in the glossary for ready reference.

A request was made to change the definition of ROW to include special permissions given by some property owners. To this the SDT responded "The SDT has limited the definition of Right-of-Way to a corridor of land with a defined width to operate a transmission line. The SDT does not propose to change the definition because of the numerous and varied special property owner permissions that may exist, and which are not always legally binding."

A concern within one disagreement was related to possible misuse of the "pre-2007 vegetation maintenance records." The SDT explained that this term was placed in the definition as a method to cover situations where the other alternatives are not viable. The SDT will address this issue in the Technical Reference Document.

Organization	Yes or No	Question 1 Comment
SERC Vegetation Management sub-committee	No	We agree with the proposed definition as a replacement for active transmission ROW, however, in a review of NERC standards, the term ROW is not used except in FAC-003. It is therefore recommended that the term be removed from the NERC glossary. r
Response: The SDT thanks you for your comments. The SDT considered your request but cannot implement it because it is not consistent with the NERC Standards Development Process for defining the use of a term solely within a standard itself. All defined terms must be included in the glossary.		
Hydro One Networks	No	The revised definition of ROW is unclear in regards to the application of standards and/or historic records as a means of determining ROW width; is it necessary for a TO to select one method to apply in all cases, or can each span be treated in the manner deemed most appropriate by the TO? Additionally "blowout Standard" has not been defined in the document or in the technical paper, and therefore it is not clear exactly how this method would be applied, and subsequently defended under scrutiny.
Response: The SDT thanks you for your comments. The definition includes a series of options that give the Transmission Owner latitude in establishing ROW width. It does not require selecting a single method for its system. The term blowout standard is not capitalized and is not a defined term, and is intended to represent whatever conductor "blow out" (as opposed to vegetation "blow in") design criteria were used when the line was constructed. This phrase in the definition allows a Transmission Owner to use its internal engineering standards or the general engineering standards that were in effect when the line was constructed to determine the ROW width.		
Northeast Power Coordinating Council	No	There was no definition of ROW listed in FAC-003-1. The revised definition of ROW in FAC-003-2 is unclear regarding the application of standards and/or historic records as a means of determining

Organization	Yes or No	Question 1 Comment
		ROW width. Is it necessary for a TO to select one method to apply in all cases, or can each span be treated in the manner deemed most appropriate by the TO? “Blowout standard” has not been defined in the document, technical paper, or NERC Glossary and it is not clear what this method is, and exactly how it would be applied. It could not be defended under scrutiny. It is still unclear whether Danger Tree rights are included in this definition.In the NERC Glossary of Terms, Right-of-Way (ROW) is defined as “A corridor of land on which electric lines may be located. The Transmission Owner may own the land in fee, own an easement, or have certain franchise, prescription, or license rights to construct and maintain lines.” Propose keeping this definition.Is encroachment into the MVCD, or (MVCD plus additional distance as defined by the TO)? MVCD, as specified within the body of FAC-003-2 "is a calculated minimum distance stated in feet (meters) to prevent flashover between conductors and vegetation, for various altitudes and operating voltages." MVCD should be “formally” defined in this document, and the NERC Glossary. Can a list/database be established in 2011 that lists the widths for the pre-2007 vegetation management records?
Response: The SDT thanks you for your comments. The existing ROW definition in the glossary was created by and for the FAC-003-1 and was moved there when that standard was adopted. The definition includes a series of options that give the Transmission Owner latitude in establishing ROW width. It does not require selecting a single method for its system. The term blowout standard is not capitalized and is not a defined term, and is intended to represent whatever conductor “blow out” (as opposed to vegetation “blow in”) design criteria were used when the line was constructed. This phrase in the definition allows a Transmission Owner to use its internal engineering standards or the general engineering standards that were in effect when the line was constructed to determine the ROW width. The SDT has limited the definition of Right-of-Way to a corridor of land with a defined width to operate a transmission line. This does not include danger tree rights. The definition of the MVCD is now added to this Standard. While use of the pre-2007 records is a compliance issue and is not in the purview of the SDT, it is the intent of the language in the definition that you could use this information.		
Platte River Power Authority Substation Maintenance Group	No	We agree that the ROW width in no case exceeds the TO’s legal rights but may be less. We do not agree that the revised NERC Glossary definition for Right-of-Way addresses paragraph 734 of FERC Order 693 “that rights-of-way be defined to encompass the required clearance areas instead of the

Organization	Yes or No	Question 1 Comment
		corresponding legal rights, and that the standards should not require clearing the entire right-of-way when the required clearance for an existing line does not take up the entire right-of-way”. The engineering or construction standards for establishing the width of the corridor outlined in the definition are in most cases not useful. We will continue to rely on our easements and legal rights with this definition. We believe the Active Transmission Line ROW definition in the previous version more clearly addressed paragraph 734 of FERC Order 693.
Response: The SDT thanks you for your comments. The standard covers lines that have been built over many years where records could be lost. The ROW definition provides three alternatives to determine the width of the corridor to be maintained.		
NERC Staff	No	NERC supports a revised definition and prefers the definition in Draft 5 over the Active Transmission Line ROW definition used in Draft 4. NERC believes the use of the term “pre-2007 vegetation maintenance records” in the proposed definition is ambiguous and will likely be interpreted differently throughout the industry. Therefore, NERC supports this change subject to removing the aforementioned term.
Response: The SDT thanks you for your comments. The phrase “…pre-2007 vegetation maintenance records…” was placed in the definition as a method to cover situations where the other alternatives are not viable. The SDT has addressed this issue in detail in the Technical Reference Document.		
FirstEnergy	No	Although for the most part we agree with the changes to the definition of ROW, we suggest the following changes. 1. The last sentence of the definition states "The ROW width in no case exceeds the Transmission Owner's legal rights but may be less based on the aforementioned criteria." We do not agree with the phrase "in no case exceeds the Transmission Owner's legal rights" because there could be instances where special permission has been granted by landowners to the TO. We suggest revising this statement to "The ROW width may be less than the Transmission Owner’s granted rights based on the aforementioned criteria."

Organization	Yes or No	Question 1 Comment
		2. Regarding the phrase "blowout standard" used in the definition, we are assuming this is in reference to the company specific calculations for sag and sway on not on any one specific industry standard. We suggest clarification such as "Transmission Owner's specific blowout or sag and sway analysis in effect when the line was built".
Response: The SDT thanks you for your comments. The SDT has limited the definition of Right-of-Way to a corridor of land with a defined width to operate a transmission line. The SDT does not propose to change the definition because of the numerous and varied special property owner permissions that may exist, and which are not always legally binding. The term blowout standard is not capitalized and is not a defined term, and is intended to represent whatever conductor “blow out” (as opposed to vegetation “blow in”) design criteria were used when the line was constructed. This phrase in the definition allows a Transmission Owner to use its internal engineering standards or the general engineering standards that were in effect when the line was constructed to determine the ROW width.		
Central Maine Power Company - IberdrolaUSA	No	The definition does not define transmission owner responsibility for areas covered by “danger tree” rights. This area is outside the maintained width but for economic and social reasons the transmission owner can not remove all danger trees. Utilities have procedures in place to remove the hazard trees but it is not practical to remove all danger trees that have the potential to violate the MVCD should they fail. This area of the definition requires clarification.
Response: The SDT thanks you for your comments. The SDT has limited the definition of Right-of-Way to a corridor of land with a defined width to operate a transmission line. This does not include danger tree rights.		
TVA	No	I suggest that "arboricultural activities or horticultural or agricultural activities be removed and changed to installation, removal or digging of vegetation.
Response: The SDT thanks you for your comments. The changes have been made in the footnotes.		
Niagara Mohawk Power Corporation (dba National	No	It is still unclear whether Danger Tree rights are included in this definition. Additional question: Can we establish a list/database in 2011 stating the widths for the pre-2007 vegetation

Organization	Yes or No	Question 1 Comment
Grid)		management records? There is no definition of ROW listed in FAC-003-1, however in the NERC Glossary of Terms, Right-of-Way (ROW) is defined as "A corridor of land on which electric lines may be located. The Transmission Owner may own the land in fee, own an easement, or have certain franchise, prescription, or license rights to construct and maintain lines." We propose keeping this definition.
Response: The SDT thanks you for your comments. The SDT has limited the definition of Right-of-Way to a corridor of land with a defined width to operate a transmission line. This does not include danger tree rights. While use of the pre-2007 records is a compliance issue and is not in the purview of the SDT, it is the intent of the language in the definition that you could use this information.		
CenterPoint Energy	No	CenterPoint Energy agrees with the removal of "Active Transmission Line ROW" as a defined term. The change in the NERC Glossary definition for Right-of-Way (ROW) alone, however, does not address all of the remaining interpretation issues within the Standard that still exist. The following issues still require resolution: 1. The "force majeure" was moved from the Applicability section to a footnote, and is no longer an encompassing exception for each Requirement. Therefore, the "force majeure" footnote needs to be applied not only to R1, R2, R6, and R7 but also R4 and R5. For R4, notification to the control center would likely be restricted during a natural disaster. For R5, correction action by the control center may not be possible during a natural disaster. 2. The exception for applicability beyond the "Rating and all Rated Electrical Operating Conditions" should be included not only in R1, R2, and R3, but also R5 and R7. For R5 and R7, the encroachment into the MVCD should consider whether the line is operating within its design limits. 3. The use of the term "Fault" in M1 and M2 should be revised to "Sustained Outage". A "Fault" can be associated with a Momentary Outage or a Sustained Outage. The scope of R1 and R2 is specific to Sustained Outages only. The Periodic Data Submittal is specific to Sustained Outages only as well. If a later confirmation of a "Fault" by the Transmission Owner indicates that a vegetation encroachment into the MVCD was due to a fall-in from inside the ROW, yet caused only

Organization	Yes or No	Question 1 Comment
		a Momentary Outage, the Transmission Owner would be in violation of R1 because M1 considers it to be the equivalent of a Real-time observation. The current scope of the Standard is not intended to include Momentary Outages. If it was, the Periodic Data Submittal would capture this type of outage, which it does not. 4. In the Introduction Section 5 - Background, fall-ins are characterized as “statistically intermittent” and “these types of events are highly unlikely to cause large-scale grid failures”. CenterPoint Energy agrees and therefore recommends that fall-ins be excluded from the Requirements R1, R2, and Periodic Data Submittal of outages. This would negate the need for determining the limits of the ROW, thus simplifying the Standard to a great margin while not sacrificing the emphasis of the Standard. The Draft 5 Background Information states the criteria for developing a results-based reliability standard such that “each requirement should identify a clear and measurable expected outcome.” When the determination of the limits of the ROW goes beyond the interpretation of the legal limits of the ROW, it adds a level of complexity that may be unclear and not deterministically measurable. 5. For R6, CenterPoint Energy believes the detailed rationale and studies used for the determination of the required one year inspection cycle should be included in the Guidelines and Technical Basis. The explanation provided in the Rationale that it is “based upon average growth rates across North America and on common utility practice” are unfounded and arbitrary without a specific reference to a North American study. 6. R7 contains the phrase, “provided they do not put the transmission system at risk of a vegetation encroachment”. CenterPoint Energy recommends this phrase be replaced with the more specific terminology used in the Rationale for R7 and R3: “provided they do not allow encroachment of vegetation into the MVCD.” 7. CenterPoint Energy believes the Periodic Data Submittal should be clarified as to the specific conditions under which Sustained Outages are reported. There is a reference to footnote 2 regarding the exclusion for the “force majeure”; however, the exclusion for lines operating outside their design limits as mentioned in R1, R2, and R3 is missing. CenterPoint Energy believes the

Organization	Yes or No	Question 1 Comment
		wording should be changed to include all applicable exclusions for added clarity and recommends the following wording: "The Transmission Owner will submit a quarterly report to its Regional Entity, or Regional Entity's designee, identifying all Sustained Outages of applicable transmission lines operating within their Facility Rating and all Rated Electrical Operating Conditions as determined by the Transmission Owner to have been caused by vegetation, except as excluded in footnote 2, which includes as a minimum, the following:" 8. The Guidelines and Technical Basis and the Technical Reference with the Gallet Equation should be combined into one document as a supplement to the Standard to avoid duplication in wording and misinterpretation of context. 9. The Guideline and Technical Basis under Requirement R6 refers to the "percentage of the required ROW inspections completed" and should be revised to match the wording of R6 and the VSL for R6 as the "percentage of applicable transmission line inspections completed." 10. CenterPoint Energy agrees that the Rationale test boxes should be deleted from the Standard and applicable explanatory text be included within the Guidelines and Technical Basis. 11. The Guidelines and Technical Basis should contain specific examples for determining if a fall-in is considered inside or outside the ROW. 12. CenterPoint Energy recommends modifying the Technical Reference section regarding "Selecting a Maintenance Approach" to delete the sentences beginning with, "If constraints cannot be overcome and if design clearances are sufficient..." and continuing through to, "identified early for rectification." This example may lead the public to inappropriately ask the utilities for exceptions to allow vegetation beneath the transmission lines, and it also does not address the dynamics of future modifications to the transmission lines (e.g. higher operating temperatures or new conductors) that may necessitate reduced clearances to ground, thus requiring removal of now mature vegetation. The example should not be included in a Standard intended to reduce vegetation risks to the transmission system. It is also in conflict with later statements in the Technical Reference regarding Set Objectives which emphasize maintaining access and clear lines of

Organization	Yes or No	Question 1 Comment
		sight. 13. In general, CenterPoint Energy strongly believes the proposed FAC-003-2 has gone far beyond what was contemplated by the Commission in FERC Order 693. The Commission's determination dealt with the following areas: (1) applicability; (2) inspection cycles; and (3) minimum clearances on National Forest Service lands. For instance, in Paragraph 729, the Commission states, “As proposed in the NOPR, the Commission approves Reliability Standard FAC-003-1 with no proposed modification on the issue of clearances. The Commission reaffirms its interpretation that FAC-003-1 requires sufficient clearances to prevent outages due to vegetation management practices under all applicable conditions....” Rewriting the minimum clearances introduces a new set of confusing definitions, and further burdens the Transmission Owners with new documentation requirements while providing little, if any, benefit when compared to the Clearance 2 concept in the existing Standard.A preferred approach would be to incorporate the following few items into the existing Standard FAC-003-1: (1) the RC versus the RRO; (2) the designation of a specific inspection frequency; (3) the Gallet equation; and (4) the applicability to National Forest Service lands.
Response: The SDT thanks you for your comments: For clarity the SDT separated various items in your comments and repeated them below with the numbered responses: CenterPoint Energy agrees with the removal of “Active Transmission Line ROW” as a defined term. The change in the NERC Glossary definition for Right-of-Way (ROW) alone, however, does not address all of the remaining interpretation issues within the Standard that still exist. The following issues still require resolution: 1. The “force majeure” was moved from the Applicability section to a footnote, and is no longer an encompassing exception for each Requirement. Therefore, the “force majeure” footnote needs to be applied not only to R1, R2, R6, and R7 but also R4 and R5. For R4, notification to the control center would likely be restricted during a natural disaster. For R5, correction action by the control center may not be possible during a natural disaster. **Response:** Thank you for your comment. The SDT considers the term “without intentional delay” to be adequate coverage for force majeure issues in R4. R5 requires that if you cannot perform work regardless of the reason you must come up with a plan to ensure that you prevent		

Organization	Yes or No	Question 1 Comment

encroachments, therefore a force majeure exemption is not applicable.

2. The exception for applicability beyond the “Rating and all Rated Electrical Operating Conditions” should be included not only in R1, R2, and R3, but also R5 and R7. For R5 and R7, the encroachment into the MVCD should consider whether the line is operating within its design limits.

Response: The SDT thanks you for your comments. The SDT made the suggested changes to remove references to arboricultural, horticultural or agricultural activities from the footnote 2, but did not adopt the suggestion for the new footnote 6 which replaces the footnote 4 to which you refer” because that footnote 4 is concerned with completing the annual work plan, The SDT does not envision that actions by property owners such as installation, or removal or digging of vegetation as a valid impediment to completion of the annual work plan. However this term is relevant in R1 and R2 and as such is within foot note 2 because such actions do occur from time to time without the transmission Owner’s knowledge and do then result in conditions that could lead to encroachments and outages before the Transmission Owner has the opportunity to rectify the condition.

3. The use of the term “Fault” in M1 and M2 should be revised to “Sustained Outage”. A “Fault” can be associated with a Momentary Outage or a Sustained Outage. The scope of R1 and R2 is specific to Sustained Outages only. The Periodic Data Submittal is specific to Sustained Outages only as well. If a later confirmation of a “Fault” by the Transmission Owner indicates that a vegetation encroachment into the MVCD was due to a fall-in from inside the ROW, yet caused only a Momentary Outage, the Transmission Owner would be in violation of R1 because M1 considers it to be the equivalent of a Real-time observation. The current scope of the Standard is not intended to include Momentary Outages. If it was, the Periodic Data Submittal would capture this type of outage, which it does not.

Response: Thank you for your comment. The reporting of Sustained Outages is simply to fulfill routine data submission. The SDT does not intend to create a system that requires a root cause analysis of all Faults which are not Sustained Outages. The SDT did intend for those Faults as referenced in M1 and M2 to be considered the equivalent of an encroachment observed in real time. The SDT also notes that the term Fault is an existing defined term and momentary interruption is not.

4. In the Introduction Section 5 - Background, fall-ins are characterized as “statistically intermittent” and “these types of events are highly unlikely to cause large-scale grid failures”. CenterPoint Energy agrees and therefore recommends that fall-ins be excluded from the Requirements R1, R2, and Periodic Data Submittal of outages. This would negate the need for determining the limits of the ROW, thus simplifying the Standard to a great margin while not sacrificing the emphasis of the Standard. The Draft 5 Background Information states the criteria for developing a results-based reliability standard such that “each requirement should identify a clear and measurable expected outcome.” When the determination of the limits

Organization	Yes or No	Question 1 Comment
of the ROW goes beyond the interpretation of the legal limits of the ROW, it adds a level of complexity that may be unclear and not deterministically measurable. **Response:** Thank you for your comment. Fall-ins from inside the ROW are indicators of a poor performing vegetation management program. The definition of Right-of-Way identifies methods to define the width of the corridor establishing whether vegetation was located within the ROW and subject to the Transmission Owner's legal rights. 5. For R6, CenterPoint Energy believes the detailed rationale and studies used for the determination of the required one year inspection cycle should be included in the Guidelines and Technical Basis. The explanation provided in the Rationale that it is "based upon average growth rates across North America and on common utility practice" are unfounded and arbitrary without a specific reference to a North American study. **Response:** Thank you for your comment. The SDT established an inspection cycle at least once per calendar year and with no more than 18 months between inspections on the same ROW. This cycle was based on industry comments submitted to Draft 1 of this standard ending on 11-25-2008 6. R7 contains the phrase, "provided they do not put the transmission system at risk of a vegetation encroachment". CenterPoint Energy recommends this phrase be replaced with the more specific terminology used in the Rationale for R7 and R3: "provided they do not allow encroachment of vegetation into the MVCD." **Response:** Thank you for your comment. The SDT agrees and has made the requested change to the draft standard. 7. CenterPoint Energy believes the Periodic Data Submittal should be clarified as to the specific conditions under which Sustained Outages are reported. There is a reference to footnote 2 regarding the exclusion for the "force majeure"; however, the exclusion for lines operating outside their design limits as mentioned in R1, R2, and R3 is missing. CenterPoint Energy believes the wording should be changed to include all applicable exclusions for added clarity and recommends the following wording: "The Transmission Owner will submit a quarterly report to its Regional Entity, or Regional Entity's designee, identifying all Sustained Outages of applicable transmission lines operating within their Facility Rating and all Rated Electrical Operating Conditions as determined by the Transmission Owner to have been caused by vegetation, except as excluded in footnote 2, which includes as a minimum, the following:" **Response:** Thank you for your comment. The SDT added your recommended language on "within its Rating and all Rated Electrical Operating		

Organization	Yes or No	Question 1 Comment

Conditions”.

8. The Guidelines and Technical Basis and the Technical Reference with the Gallet Equation should be combined into one document as a supplement to the Standard to avoid duplication in wording and misinterpretation of context.

Response: Thank you for your comment. The Guideline and Technical section is part of the NERC Results Based Standard format. The Technical Reference is a supplemental document that explains the VMSDT thought process in developing the requirements and applies to this version of the standard.

9. The Guideline and Technical Basis under Requirement R6 refers to the “percentage of the required ROW inspections completed” and should be revised to match the wording of R6 and the VSL for R6 as the “percentage of applicable transmission line inspections completed.”

Response: Thank you for your comment. VSL’s for R6 has been changed to align with the NERC Standard Development guidelines to “a Transmission Owner failed to inspect”.

10. CenterPoint Energy agrees that the Rationale test boxes should be deleted from the Standard and applicable explanatory text be included within the Guidelines and Technical Basis.

Response: Thank you for your comment.

11. The Guidelines and Technical Basis should contain specific examples for determining if a fall-in is considered inside or outside the ROW.

Response: Thank you for your comment. The SDT established the definition of a ROW and a fall-in resulting from vegetation would be determined through investigation of the sustained outage.

12. CenterPoint Energy recommends modifying the Technical Reference section regarding “Selecting a Maintenance Approach” to delete the sentences beginning with, “If constraints cannot be overcome and if design clearances are sufficient...” and continuing through to, “identified early for rectification.” This example may lead the public to inappropriately ask the utilities for exceptions to allow vegetation beneath the transmission lines, and it also does not address the dynamics of future modifications to the transmission lines (e.g. higher operating temperatures or new conductors) that may necessitate reduced clearances to ground, thus requiring removal of now mature vegetation. The example should not be

Organization	Yes or No	Question 1 Comment
included in a Standard intended to reduce vegetation risks to the transmission system. It is also in conflict with later statements in the Technical Reference regarding Set Objectives which emphasize maintaining access and clear lines of sight. **Response:** Thank you for your comment. This verbiage is part of an example describing a combination of strategies which may be utilized by a Transmission Owner. 13. In general, CenterPoint Energy strongly believes the proposed FAC-003-2 has gone far beyond what was contemplated by the Commission in FERC Order 693. The Commission's determination dealt with the following areas: (1) applicability; (2) inspection cycles; and (3) minimum clearances on National Forest Service lands. For instance, in Paragraph 729, the Commission states, "As proposed in the NOPR, the Commission approves Reliability Standard FAC-003-1 with no proposed modification on the issue of clearances. The Commission reaffirms its interpretation that FAC-003-1 requires sufficient clearances to prevent outages due to vegetation management practices under all applicable conditions...." Rewriting the minimum clearances introduces a new set of confusing definitions, and further burdens the Transmission Owners with new documentation requirements while providing little, if any, benefit when compared to the Clearance 2 concept in the existing Standard.A preferred approach would be to incorporate the following few items into the existing Standard FAC-003-1: (1) the RC versus the RRO; (2) the designation of a specific inspection frequency; (3) the Gallet equation; and (4) the applicability to National Forest Service lands. **Response:** Thank you for your comment. The SDT believes the FAC 003-2 is an improvement over Version 1 and followed the SAR establishing that the SDT should revise the standard.		
Duke Energy	Yes	
South Carolina Electric and Gas	Yes	
Oncor Electric Delivery Company LLC	Yes	
Ameren	Yes	

Organization	Yes or No	Question 1 Comment
Individual		My Comments do not relate to the question asked, however, I saw no other place to add my comment. I would like to thank NERC for allowing the public to participate in the process of improving the reliability standard FAC-003-1. I became interested in Vegetation Management requirements for Transmission Lines, after Con Edison clear cut the ROW behind my home. I appreciate the importance of safe and reliable electrical service, and recognize how an effective TVMP contributes to this goal. In this whole process, what has dispirited me the most, is the inaccurate information being conveyed about why the clear cutting was necessary and, the causes of the August 14th, 2003 blackout. The narrative goes something like..”a tree falling onto transmission lines caused the black out of 2003.” I find it harmful because it misdirects the focus from the grid’s short fallings, and impedes upgrading the system to improve reliability. I found this same philosophy in the initial pages of CN Utility’s document, UTILITY VEGETATION MANAGEMENT FINAL REPORT MARCH 2004. It suggests that had the trees been adequately maintained, the blackout would have most “likely” not happened. Now I am aware of the qualification of the word “likely,” but the document is heavily weighted on the contribution of tree contact to the blackout. We know that de-regulation and the physical nature of A.C. current had more to do with the causes of the blackout, than tree contact. The timeline shows a range of cascading system failures that created the catastrophic event. The trouble began at 1:58 p.m. when First Energy generating plant in Eastlake, Ohio, shuts down. At 3:06 p.m. a First Energy 345-kV transmission line fails. As a result, at 3:17 p.m voltage dips temporarily on the Ohio portion of the grid. Controllers take no action, but power shifted onto another power line, overloading it and, causing it to sag into a tree and go offline at 3:32 p.m. Mid West ISO and First Energy controllers fail to inform system controllers in nearby states. At 3:41 and 3:46 p.m., two breakers connecting First EnergyÊ¼s grid with American Electric Power are tripped. 4:05 p.m., a sustained power surge on some Ohio lines signals more trouble building. At 4:09:02 p.m., voltage sags deeply, as Ohio draws 2 GW of power from Michigan. 4:10:34 p.m., many transmission lines trip out, beginning in

Organization	Yes or No	Question 1 Comment
		Michigan and then in Ohio, blocking the eastward ï¬‚ow of power. Generators go down, creating a huge power deficit, in seconds, power surges out of the East, tripping East coast generators, and the rest is history. The U.S.-Canada Power System Outage Task Force: Final Report on Implementation of Recommendations, September 2006, states that “Inadequate reactive supply was a factor in most of the events.” and “the assumed contribution of dynamic reactive output of system generators was greater than the generators actually produced, resulting in more significant voltage problems.” The backup generators were not adequate to handle the amperage load or voltage needed. A lack of coordination of System Protection Programs(relays tripping), inadequate communication between Utilities/TOs, and lack of "training of operating personnel in dealing with severe system disturbances" are all the causes for the blackout. With respect to vegetation management, the findings from The U.S.-Canada Power System Outage Task Force: Final Report on Implementation of Recommendations, September 2006, clearly did not intend for transmission owners to develop a one-size-fits-all standard. The Energy Policy Act of 2005, initiated NERC to draft and adopt the standard FAC-003-1. When I read through the standard, it all seems very reasonable. I can understand the stiff penalties for noncompliance because it seems, like an easy fix, compared to the necessary, major changes in infrastructure. The principles further outlined in ANSI A300 VII, and “Best Practices” IVM, seem very reasonable too. There is mention of the environment, property owners, even proper pruning techniques. The wire zone clearance of 10 feet and, allowing low growing compatible vegetation in the boarder zone, seems to retain more vegetation, than remove. However, in practice, the TOs are simply clear cutting the ROW, with no regard for the enviroment, the trees that they are cutting, or the abutting properties. It took Con Edison 2 1/2 half days to clear 450 tress form behind our home. We are now forced to see and hear 93,000 cars a day from the Sprain Parkway. Following the clearing, our real estate broker dropped the asking price by 30%. The house remains empty and unsold. Apparently, no one is interested in spending 32,000K a year in property taxes to look at transmission towers/lines and live on a highway. This has been

Organization	Yes or No	Question 1 Comment
		devastating to our family, and thousands of others in Westchester County. They removed a buffer of trees that were 150 feet away from wires and towers, on a downward slope. These trees would have never made contact with conductors. Con Edison's defense is that they did it because it was in their right to. Moreover, they use the NERC fine structure to defend their behavior.I went through the Notice of Penalties that NERC has issued from 6/2/08-2/01/11. Out of 646 Notice of Penalties, 1700 violations were sited, 36 out of 1700 penalties were issued for violations to the FAC- 003-1 standard. Some NOPs had multiple violations-18 R1 violations were cited and 29 penalties were issued for R2 violations. Out of the 29 R2 penalties, 20 involved tree contact. Some outages were caused by sagging wires, some were caused by arcing electricity looking for a ground fault, but none were caused by a tree falling onto the transmissions wires. The numbers should put into perspective how immaterial the problem of tree contact really is. Think about it... 20 out of 1700 involved tree contact, and none of then resulted in a sustained outage. That means 1680 violations were issued due to other system failures. To use these penalties as an excuse is a complete over exaggeration. What is missing from the standard and the fine structure, are penalties for over cutting and violations to other stipulations, such as proper communication, training, and aftercare of the affected areas. The problems that have arisen from current TVMP activities being executed nationally on our ROWs, is not a public perception problem. Rather, TOs are not complying with standards that are meant protect the environment and they are not respecting the property rights of the neighboring homeowners. I appreciate the opportunity to share my views, and would take any opportunity to further participate in protecting the rights of property owners, and the environment, while working to secure safe and reliable electrical service. Most respectfully, Amy M Kupferberg - Utility Whisperer

Response: The SDT thanks you for your comments. You raise a host of issues regarding the operations of electric transmission systems as well as recounting the blackout of 2003. We agree there seems to be wide public opinion of what actually was the cause of the blackout. Relative to your recommendations for our team, we note that appropriate NERC standards contain requirements regarding training and communications among

Organization	Yes or No	Question 1 Comment
other things. For example, requirement R4 of this standard contains language which requires communication when certain vegetation conditions are discovered. As you know training and communications were just two of the many issues addressed in the blackout report. In response to your comment "What is missing from the standard and the fine structure, are penalties for over cutting and violations to other stipulations, such as proper communication, training, and aftercare of the affected areas," this Standard is meant to define what needs to be accomplished to achieve reliability; it is up to the Transmission Owner to perform the vegetation maintenance in a manner to accomplish that goal consistent with applicable environmental concerns and local regulations.		
Consolidated Edison Company of New York, Inc. - Transmission Line Maintenance	Yes	
USACE	Yes	
CECD	Yes	
Entergy Services, Inc	Yes	The revised Glossary definition of ROW helps to clarify the intent of what is expected and/or considered ROW stipulations. This is a beneficial addition/clarification.
Response: The SDT thanks you for your comments.		
Orange and Rockland Utilities, Inc.	Yes	
National Grid	No	The revised ROW definition emphasizes the ROW width needed to operate the transmission line(s). It is National Grid's interpretation that the width established when the line was constructed is the width to be maintained. This width is documented in engineering drawings, per-2007 vegetation records or blow-out standards. This definition does not imply that danger tree rights beyond the constructed and maintained width are incorporated in the definition; therefore fallins - from

Organization	Yes or No	Question 1 Comment
		outside the ROW but within within an area with danger tree rights would not be considered fallin-ins from within the ROW. National Grid would like the SDT to comment on this interpretation in its response to these comments.
Response: The SDT thanks you for your comments. Your interpretation is consistent with the intent of the definition that the SDT provided. However the definition includes a series of options that give the Transmission Owner latitude in establishing ROW width. It does not require selecting a single method for its system. This phrase in the definition allows a TO to use its internal engineering standards or the general engineering standards that were in effect when the line was constructed to determine the ROW width. The SDT has limited the definition of Right-of-Way to a corridor of land with a defined width to operate a transmission line. This does not include danger tree rights.		
Western Electricity Coordinating Council	Yes	
Georgia Transmission Corp.	Yes	
Northern Indiana Public Service Company	Yes	

2. **In R1 and R2 and their associated VSLs, the SDT added the phrase "in order of increasing severity" and added the sentence "The types of encroachments are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a TO's vegetation maintenance program." to the Rationale boxes for R1/R2. Do you agree? If answer is no, please explain.**

Summary Consideration: 32 of the 38 responses agreed with the changes. The SDT made changes to the footnotes in response to 4 requests. Three of the "yes" response comments included positive references to the improved clarity, alignment with results based standards, reinstatement of Category 3 outages and the importance of investigations which will be necessary to categorize violations across the various VSLs.

The disagreements included concerns over the relationships between the VSLs and language in requirements. The SDT revised the language in the Rationale box to explain the program performance relationships between types of encroachments, faults and outages, and various types of failed maintenance, and how the various types of failed maintenance have historically been associated with known vegetation related events.

In response to a request to exchange the order of severity levels of the failure to maintain vegetation to prevent encroachments from blowing together versus fall-ins, the SDT explained that the blowing together is considered a higher severity level of failed maintenance since the sway of the conductor is in most cases more determinable and less variable than the more complex geometry associated and numerous variables associated with fall-ins.

In response to a comment that there was no need for R1 and R2, the SDT explained that removal of R1 and R2 could be viewed as lessening the reliability of the standard.

One comment recommended that the standard include language to allow any encroachment found and removed, absent a Fault or Sustained Outage, to not be considered a violation. The SDT noted that the MVCD is a component that must be considered in the "building block" approach inherent in the standard, and as such, any encroachment inside the MVCD indicates a significant failure in overall vegetation program approach.

One comment requested a return to the Clearance 1 in the existing standard to support work that is resisted by property owners and other parties that do not want vegetation to be adequately maintained. The SDT referenced the problem associated with a fill-in-the-blank requirement, and explained how this standard does not preclude a utility from removing or pruning vegetation well beyond the MVCD, but primarily focuses on determining when a violation occurs. The SDT asserts that vegetation maintenance must address the many variables that exist such as growth rates, vegetation maintenance cycles, conductor sag and sway, etc. that could result in an encroachment of the MVCD which would be a direct violation of the standard. The vegetation program must factor in delays and/or mitigation measures associated with stakeholder concerns, but must clearly communicate the need for maintenance to ensure strict compliance with this zero-tolerance standard.

Organization	Yes or No	Question 2 Comment

Northeast Power Coordinating Council	Yes	
Platte River Power Authority Substation Maintenance Group	Yes	
Bonneville Power Administration	Yes	BPA prefers the stratified levels of violation severity presented in the table for R1 and R2.Foot note #2 on page 8 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. What specifically does this phrase refer to?Foot note #4 on page 12 needs to be clarified with respect to arboricultural activities or horticultural or agricultural activities. What specifically does this phrase refer to?

Response: The SDT thanks you for your comments.

The SDT has changed footnote 2 to read as follows:

This requirement does not apply to circumstances that are beyond the control of a Transmission Owner subject to this reliability standard,

Organization	Yes or No	Question 2 Comment
including natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods; human or animal activity such as logging, animal severing tree, vehicle contact with tree, or installation, removal, or digging of vegetation. Nothing in this footnote should be construed to limit the Transmission Owner's right to exercise its full legal rights on the ROW. The SDT has changed footnote 4 (now footnote 6 in the revised standard) to read as follows: Circumstances that are beyond the control of a Transmission Owner include but are not limited to natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, ice storms, floods, or major storms as defined either by the TO or an applicable regulatory body.		
NERC Staff	No	The sentence was added to the rationale but the phrase "in order of increasing severity" is not in the requirement or their associated VSLs. NERC staff does not support the language in the rationale box which differentiates the VSL based on skill level of maintenance personnel rather than the impact to reliability of the encroachment. The VSL should be based on whether or not the owner managed the vegetation to prevent encroachment and therefore be binary. See additional comments submitted separately regarding combining R1 and R2.
Response: The SDT thanks you for your comments. VSLs should not be assigned based on the impact to reliability, as is proposed by the commenter. NERC's VSL Guidelines state the following regarding VSLs: "This is not the same as saying that the requirement is really important and any noncompliance would have an adverse reliability impact – **the impact to reliability should be addressed through the VRF, not the VSL."** However, the SDT has made changes to reword the rationale in R1 and R2 to further explain how program performance must successfully account for the relationships between types of encroachments, faults and outages, various types of failed maintenance, and how the various types of failed maintenance have historically been associated with known vegetation related events.		
Pepco Holdings Inc and Affiliates	Yes	
FirstEnergy	No	For the Requirement R1 and R2 VSLs, we suggest that the proposed Moderate (fall-ins) and High (blowing together) VSL be interchanged. We believe that fall-ins are more severe encroachments than blowing together and the categories listed in the compliance section support this point.

Organization	Yes or No	Question 2 Comment
		Category 1 (grow-ins) is most severe, followed by Category 2 & 3 (fall-ins) and Category 4 (blowing together).
Response: The SDT thanks you for your comments. The choice of the VSL for the fall-ins versus the blowing together was made by the SDT using logic in the language in the rationale text box for R1: "The types of failure to manage vegetation are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a TO's vegetation maintenance program, since the encroachments listed require different and increasing levels of skills and knowledge and thus constitute a logical progression of how well, or poorly, a TO manages vegetation relative to this Requirement."		
Dominion Electric Market Policy	Yes	
Southern Company Transmission	Yes	
Arizona Public Service Company	No	This is a reliability standard and the TO should know what its clearance needs are at all rated conditions, especially considering today's technology. If the TO manages to this standard there is no need for R1 and R2.
Response: The SDT thanks you for your comments. Elimination of R1 and R2 would be considered as a lessening of the standard.		
Salt River Project	Yes	
Tampa Electric Company	Yes	Adds clarity to the VSL from an audit perspective, this is an improved description to the Standard.
Response: The SDT thanks you for your comments.		
NextEra Energy	Yes	Although NextEra Energy Inc. (NextEra), including Florida Power & Light Company, agrees with the changes referenced for R1 and R2, NextEra is concerned that the exemptions identified in footnote

Organization	Yes or No	Question 2 Comment
		2 for "...arboricultural activities or horticultural or agricultural activities...," and similar language in footnote 4, are too broad. For example, this language appears to include an exemption for a landowner, who, during arboricultural activities or horticultural or agricultural activities, causes a vegetation contact with a transmission line (e.g., cutting or lifting a tree into a transmission line). This places the Transmission Owner in the difficult position of a landowner arguing it is exempt from a controllable risk. Thus, the "...arboricultural activities or horticultural or agricultural activities..." references should be removed from footnote 2, and the similar language in footnote 4
Response: The SDT thanks you for your comments. The SDT made the suggested changes.		
SDG&E	Yes	
ASSET MANAGEMENET	Yes	
Hydro-Quebec TransEnergie (NCR07112)	Yes	
Kansas City Power & Light	No	These proposed Requirements, Measures and Violation Severity Levels as written do not give credit to the Transmission Owners for effectively monitoring their systems and taking appropriate actions in regard to vegetation clearing. Why does it make sense to punish and penalize a Transmission Owner for discovering an encroachment when they take the appropriate actions to remedy the condition before any facility outage occurs that results in compromising the reliability of the Bulk Electric System? These Requirements, Measures and VSL's should recognize the good practices of effective response to a vegetation condition and penalize ineffective response. Recommend the SDT consider including appropriate language to recognize effective remedial actions by Transmission Owners and by doing so, recognize effective efforts instead of punishing them. In addition, proving encroachments have not occurred will pose audit challenges in determining that encroachments have not occurred for the Auditors as well as Registered Entities. If no encroachments occur, then there is nothing to report or record. This is a weak platform to stand

Organization	Yes or No	Question 2 Comment
		compliance on. Facility interruption events caused by vegetation contacts is definitively measurable and recordable. Recommend the SDT reconsider the concept of compliance with FAC-003 on the basis of sustained outages and remove the references regarding encroachments only. Recommend the SDT remove the LOWER VSL language from Requirements R1 and R2 and revise the Requirements and Measures to reflect the same.
Response: The SDT thanks you for your comments. The MVCD was established as a beginning of a series of "building blocks" for a good program. R3 requires that a TO add to MVCD distances with further considerations for the variables of conductor movement and the variables associated with vegetation growth when designing the TO's overall vegetation management approach(s). The net result of this "building block" approach is the management of vegetation at clearance distances much greater than the MVCD distances. Other related requirements of this "Defense in Depth" Standard serve to address any number of scenarios which may arise or hinder the TO's ability to always strictly adhere to the management approach(s) established within R3. Thus the other requirements of this Standard provide the latitude for "appropriate actions to remedy the condition" without penalty. Further, it is obvious that trees which have encroached inside of the MVCD are clear evidence of a failed vegetation management program.		
Manitoba Hydro	Yes	
Central Maine Power Company - IberdrolaUSA	Yes	
BC Hydro	Yes	
American Transmission Company, LLC	Yes	
American Electric Power	No	American Electric Power believes that the phrase "arboricultural activities or horticultural or agricultural activities" was mistakenly introduced into Footnotes 2 and 4, and should be deleted from both footnotes. If the phrase remains in the Standard, it may empower orchard growers, landowners and others to plant trees on the right of way and challenge Transmission Owners'

Organization	Yes or No	Question 2 Comment
		rights to perform maintenance on the presumption that the standard will exempt the TO from violating the outage or encroachment requirements.
Response: The SDT thanks you for your comments. The SDT made the suggested changes.		
Baltimore Gas and Electric Co.	Yes	
TVA	Yes	
Niagara Mohawk Power Corporation (dba National Grid)	Yes	
CenterPoint Energy	Yes	
Duke Energy	Yes	We agree with the drafting team's approach, and also agree with reinstating reporting of Category 3 (Fall-ins from outside the ROW) in the Additional Compliance Information section. The SDT responded to comments submitted with the last ballot that:"Zero tolerance for vegetation caused outages is a stated goal of FERC and NERC as it relates to this standard. This policy is part of FAC-003-1 and in concept did not change with the proposed version. The SDT recognizes this concern and has developed gradation taking into account line criticality in VRF's and type of outage not contained in the current version FAC-003-1. Finally, it is also important to note that each and every incident or potential violation is investigated and addressed based on the specific circumstances surrounding the particular event. These investigations should necessarily take into consideration and recognize the utility's individual efforts in responding to an encroachment situation." In addition, we believe that clarifying changes need to be made to footnotes 2 and 4. Clarify footnote 2 by removing the phrase "arboricultural activities or horticultural or agricultural activities" and replacing it with the phrase "installation of". Similarly, clarify footnote 4 by removing the phrase "arboricultural, horticultural or agricultural activities", and replacing it with the phrase "or human

Organization	Yes or No	Question 2 Comment
		activities such as installation, or removal or digging of vegetation.”
Response: The SDT thanks you for your comments. The SDT made the suggested changes to remove references to arboricultural, horticultural or agricultural activities from the footnote 2, but did not adopt the suggestion for the new footnote 6 which replaces the footnote 4 to which you refer” because that footnote 4 is concerned with completing the annual work plan, The SDT does not envision that actions by property owners such as installation, or removal or digging of vegetation as a valid impediment to completion of the annual work plan. However this term is relevant in R1 and R2 and as such is within foot note 2 because such actions do occur from time to time without the transmission Owner’s knowledge and do then result in conditions that could lead to encroachments and outages before the Transmission Owner has the opportunity to rectify the condition.		
South Carolina Electric and Gas	Yes	
Oncor Electric Delivery Company LLC	Yes	
Ameren	Yes	This is more in alignment with a results-based reliability standard.

Georgia Transmission Corp.	Yes	
Northern Indiana Public Service Company	No	While there are some enhancements to the organization and content of the standard such as the addition of the Guidelines and Technical Basis section, clarification of what constitutes evidence of compliance, and tailoring of VSL severity levels for the requirements based on the risk each poses to the likelihood of contributing to a cascade, too many elements present in FAC-003-1 and which are vital to preventing vegetation caused outages and maximizing system reliability, have been eliminated from FAC-003-2. Specifically, the elimination of concrete, declared and audited clearance standards between vegetation and conductors (the existing Clearance 1 and Clearance 2 (R1.2)) Requirements) in the revised standard is a major defect that will decrease system reliability. It has been indispensable for NIPSCO when communicating with stake holders (governments, interest groups, land owners, the public, etc.) to point to these clearance standards to give credibility and support to the kind of tree removal and trimming that is necessary to achieve the stated objective of zero preventable tree caused outages. Without these declared clearance standards in the NERC standard, utility vegetation managers will constantly be challenged by stake holders to show them that such work is required rather than an elective choice on the utility's part. One of the key lessons learned from the 2003 blackout and First Energy's overgrown ROW tree

Organization	Yes or No	Question 2 Comment
		problem was that individual land owners, local governments, and interest groups will exert pressure on the utility to only do the minimum amount of vegetation management. Without external and enforceable Vegetation Clearance Standards and by returning to a pre-2003 regime where the extent of vegetation clearing is left to the individual discretion and pressures at each utility, there is no doubt that tree clearance conditions will deteriorate over time and put system reliability at greater risk of vegetation contact.
Response: The SDT thanks you for your comments. At the request of FERC in Order 693, the SDT was asked to eliminate the fill-in-the-blank clearance requirements that are currently in FAC-003-1. A proven Engineering calculation was utilized to determine when a transmission line could spark over to vegetation without direct contact. Based on this calculation, each utility must determine what clearance levels need to be maintained as part of their TVMP. The current version does not preclude a utility from removing or pruning vegetation well beyond the MVCD, it just establishes a line in the sand that determines when a violation occurs. Individual TOs must establish a program that addresses the many variables that exist such as growth rates, vegetation management cycles, conductor sag and sway, etc. that could result in an encroachment of the MVCD which would be a direct violation of the standard. Establishing a specific clearance value to be attained during vegetation management activities is too prescriptive and is in direct conflict with the Results-Based Standard initiative that the SDT is currently implementing. Each TO must factor in delays and/or mitigation measures associated with stakeholder concerns but must clearly communicate the challenges with maintaining strict compliance with this zero-tolerance standard.		

3. **In response to comments received regarding the term “investigation” in M1/M2, the SDT substituted “confirmation…by the Transmission Owner..” in its place, among other minor edits to these measures. Do you agree? If answer is no, please explain.**

Summary Consideration: 34 of the 40 comments agreed with the change. One of the affirmative comments noted the need to make a minor change in the Guidelines and Technical Basis to assure conformance with the standard language; that change was made.

One commenter questioned what would compel an entity to document and report outages. The SDT feels that this issue is addressed by the NERC Sanctions guidelines.

It was noted that the last two paragraphs in M1 and M2 were not really measures and should be addressed in the requirements. The requirements now include this language in footnote 3.

Two commenters wished to include language to exempt brief encroachments into the MVCD due to falling trees. The SDT chose not to make that change due to concerns raised by regulatory observers.

One commenter felt that a violation should occur for any calculated potential for an MVCD encroachment. The SDT noted that the MVCD is a beginning of a series of “building blocks” for a program to ensure reliability within the line’s rating and all rated electrical operating conditions. R3 requires that a TO add to MVCD distances with further considerations for the variables of conductor movement and the variables associated with vegetation growth when designing the TO’s overall vegetation management approach(s). Additionally there is a “Defense in Depth” in this Standard to address any number of scenarios which may arise or hinder the TO’s ability to always strictly adhere to the management approach(s) established within R3. Thus the other requirements of this Standard provide the latitude for appropriate actions to remedy the condition without penalty.

One comment replied that there was no value to the measure due to the lack of reference to a violation for any calculated potential MVCD encroachment. The SDT pointed again to requirement R3 which requires this to be addressed in the maintenance strategies in R3.

One commenter suggested to delete the reference to measures in the evidence retention section; the SDT chose to retain the existing language.

Organization	Yes or No	Question 3 Comment

Organization	Yes or No	Question 3 Comment
SERC Vegetation Management sub-committee	Yes	
Hydro One Networks	Yes	
Northeast Power Coordinating Council	Yes	
Platte River Power Authority Substation Maintenance Group	Yes	
Bonneville Power Administration	Yes	
NERC Staff	No	Concur with restating as mentioned above. Other issues remain regarding data reports indicating no sustained outages or real-time observations. These measures appear to indicate that if the outages or real-time observations are not documented then an encroachment didn't occur. What will compel an entity to document these occurrences? In addition, the last two paragraphs of the Measure are not really measures. They would be better served as part of the Requirement.
Response: The SDT thanks you for your comments. The issue of how does one prove that an event did not occur is problematic. A TO must document the inspections it completes. If an inspection does not note an encroachment then none was observed. The NERC Sanction Guidelines provide adequate sanctions for the dishonest. The SDT agrees that the last two paragraphs are not measures and would belong in the requirement. The SDT has moved them to the requirement as footnotes.		
Pepco Holdings Inc and Affiliates	Yes	

Organization	Yes or No	Question 3 Comment
FirstEnergy	Yes	
Dominion Electric Market Policy	Yes	
Southern Company Transmission	No	We would recommend the middle paragraph of M1 and M2 be revised as follows: "If a later confirmation of a Fault by the TO shows that vegetation encroachment within the MVCD has occurred from vegetation growing into or blowing into the conductor within the ROW, this shall be considered the equivalent of a Real-time observation. Brief encroachments caused by a falling tree going through the MVCD is not considered an encroachment."
Response: The SDT thanks you for your comments. The SDT is sympathetic to your concern. In fact, the SDT had originally crafted language similar to that which you suggested. However, due to concerns expressed by regulators and others, the exemption for encroachment violations due to falling vegetation from inside the right of way was removed.		
Arizona Public Service Company	No	The TO should be managing for reliability. The system is not static, like vegetation it moves and changes over time and that fluctuation should be taken into account to maintain reliability at all rated conditions.
Response: The SDT thanks you for your comments. The SDT agrees with your statement, and in that vein, the MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability within its rating and all rated electrical operating conditions. R3 requires that a TO add to MVCD distances with further considerations for the variables of conductor movement and the variables associated with vegetation growth when designing the TO's overall vegetation management approach(s). The net result of this "building block" approach is the management of vegetation at clearance distances much greater than the MVCD distances. Other related requirements of this "Defense in Depth" Standard serve to address any number of scenarios which may arise or hinder the TO's ability to always strictly adhere to the management approach(s) established within R3. Thus, the other requirements of this Standard provide the latitude for appropriate actions to remedy the condition without penalty. Further, trees which have encroached inside the MVCD are evidence of a deficiency in vegetation maintenance.

American Transmission Company, LLC	Yes	
American Electric Power	No	For increased clarity, AEP offers the following change to the second paragraph of M1, as well as the

Organization	Yes or No	Question 3 Comment
		second paragraph of M2. The original text “If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation” should be replaced with ““If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation growing into or blowing together with the conductor within the ROW, this shall be considered the equivalent of a Real-time observation. A brief encroachment caused by falling vegetation passing through the MVCD is not considered an encroachment in this requirement”.
Response: The SDT thanks you for your comments. The SDT is sympathetic to your concern. In fact, the SDT had originally crafted language similar to that which you suggested. However, due to concerns expressed by regulators and others, the exemption for encroachment violations due to falling vegetation from inside the right of way was removed.		
Baltimore Gas and Electric Co.	No	M1 & M2 bullet: “Real-time observation of any MVCD encroachments.” implies that real-time observation of vegetation encroachment ensures reliable operation the Bulk Electric System. The reliability standard objective states;”To improve the reliability of the electric Transmission system by preventing those vegetation related outages that could lead to Cascading.”However, real time observation of current operating conditions provides no assurance that vegetation will not lead to outages since it doesn’t take into consideration the full conductor range of motion including maximum sag. BGE recommends removing the language. If an inspector finds vegetation encroaching into the MVCD during a visual inspection he / she should immediately initiate an Immediate Threat Notification. Therefore, this measure has no value.
Response: The SDT thanks you for your comments. The SDT agrees with your statement and in that vein, the MVCD was established as a beginning of a series of “building blocks” for a program to ensure reliability within its rating and all rated electrical operating conditions. R3 requires that a TO add to MVCD distances with further considerations for the variables of conductor movement and the variables associated with vegetation growth when designing the TO’s overall vegetation management approach(s). The net result of this “building block” approach is the management of vegetation at clearance distances much greater than the MVCD distances. Other related requirements of this “Defense in Depth” Standard serve to address any number of scenarios which may arise or hinder the TO’s ability to always strictly adhere to the management approach(s)

4. **In response to comments received that requirement R3 is unclear with respect to intent, the SDT added "maintenance strategies". Do you agree this clarifies the intent? If answer is no, please offer alternative language.**

Summary Consideration: 36 responses were in agreement, 2 disagreed with no comments and 2 disagreements included comments.

A concern was raised with regard to using the MVCD as a distance "to manage a vegetation program" and asked the SDT to provide a buffer distance. The SDT explained that the MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability within its rating and all rated electrical operating conditions. R3 requires that a TO add to MVCD distances with further considerations for the variables of conductor movement and the variables associated with vegetation growth when designing the TO's overall vegetation management approach(s). The net result of this "building block" approach is the management of vegetation at clearance distances much greater than the MVCD distances. Other related requirements of this "Defense in Depth" Standard serve to address any number of scenarios which may arise or hinder the TO's ability to always strictly adhere to the management approach(s) established within R3. Thus the other requirements of this Standard provide the latitude for appropriate actions to remedy the condition without penalty. Further, trees which have encroached inside the MVCD are evidence of a deficiency in vegetation maintenance. A performance based standard is not prescriptive in nature but gives guidance to a TO on "what" to accomplish rather than "how" to accomplish it.

Another agreeable response requested R5 and R7 to include a relationship between the document that is developed for maintenance strategies and the annual work plan. The SDT explained that the references to the work plan in R5 and R7 are sufficient. The SDT considers maintenance strategies and work plans to be separate functions. Avoiding the reference to the work plans in R3 minimizes confusing the two functions.

One disagreement stated that the term "maintenance strategies" was not helpful and recommends the following: "Each Transmission Owner shall have a documented vegetation management plan that includes maintenance strategies, procedures, processes, and specifications it uses to prevent the encroachment of vegetation into the MVCD of its applicable lines that include(s) the following:" The SDT notes that Requirement 3 is a results-based competency requirement and that having a TVMP as required in version 1 is simply a matter of having documentation, but there was no stipulation or concern for the quality of the TVMP as called for by version 1. In R3 of the revised Standard, the aspect of quality is introduced. The Transmission Owner must show that it has maintenance strategies in place that will logically keep vegetation from encroaching into the MVCD.

Another disagreement stated that the TVMP shall demonstrate the TO's ability to manage the system at all rated conditions to maintain reliability. The SDT agrees that this is the purpose of R3 and referenced the language in the rationale text for R3 clarifies - "... documentation provides a basis for evaluating the competency of the Transmission Owner's vegetation program. There may be many acceptable approaches to maintain clearances. Any approach must demonstrate that the Transmission Owner avoids vegetation-to-wire conflicts under all Ratings and all Rated Electrical Operating Conditions. See Figure 1 for an illustration of possible conductor locations." A TVMP is one example of an approach to which this refers.

Northeast Power Coordinating Council	Yes	
Platte River Power Authority Substation Maintenance Group	Yes	
Bonneville Power Administration	Yes	The TO procedures / policies and specifications shall demonstrate the TO's ability to manage the system at all rated conditions to maintain reliability.BPA believes that the intent is clear, but the fundamental approach of using the MVCD (table 2) to manage a vegetation program is still problematic. These values are flashover distances and are way too close. This is acknowledged in a footnote to table 2 but no identification of allowable buffers/distances between energized phase conductors at rated temperatures and vegetation is discussed (this is left up the transmission owners). Clarity is needed on this topic. Setting a finite distance limit based on recognized standards, good science and risk avoidance should be done for the industry. BPA previously made this comment during the drafting of the standard. It was not addressed then, nor has it been

Organization	Yes or No	Question 4 Comment
		addressed now.
Response: The SDT thanks you for your comments. The SDT agrees with your statement, and in that vein, the MVCD was established as a beginning of a series of "building blocks" for a program to ensure reliability within its rating and all rated electrical operating conditions. R3 requires that a TO add to MVCD distances with further considerations for the variables of conductor movement and the variables associated with vegetation growth when designing the TO's overall vegetation management approach(s). The net result of this "building block" approach is the management of vegetation at clearance distances much greater than the MVCD distances. Other related requirements of this "Defense in Depth" Standard serve to address any number of scenarios which may arise or hinder the TO's ability to always strictly adhere to the management approach(s) established within R3. Thus the other requirements of this Standard provide the latitude for appropriate actions to remedy the condition without penalty. Further, trees which have encroached inside the MVCD are evidence of a deficiency in vegetation maintenance. A performance based standard is not prescriptive in nature but gives guidance to a TO on "what" to accomplish rather than "how" to accomplish it.		
NERC Staff	No	Adding the term "maintenance strategies" is not helpful in the requirement. NERC staff recommends the following: "Each Transmission Owner shall have a documented vegetation management plan that includes maintenance strategies, procedures, processes, and specifications it uses to prevent the encroachment of vegetation into the MVCD of its applicable lines that include(s) the following:"
Response: The SDT thanks you for your comments. Requirement R3 is a results-based competency requirement. Having a TVMP as required in version 1 is simply a matter of having documentation. 5. **The SDT added clarifying language in M7 to explain how the annual work plan percentage complete calculation is to be performed. Is this adequate? If no, please provide improved examples.**

Summary Consideration: There were 31 agreements and 8 disagreements. Seven comments noted that the question should have referenced R7 not M7. The SDT acknowledged that observation and agreed that the reference should have been R7. The SDT added the term "of applicable lines" to M7 and to the VSL's for R4, R5 and R6. The SDT also made minor changes to VSLs for R7 to conform to verbiage in R6.

One commenter agreed with R7 changes and noted "there is no requirement....that a plan is....developed." The SDT sees no reason to add such a requirement for documentation, since a fundamental precept of results-based standards is that having a requirement to complete any particularly activity also presupposes that the elements required to complete the activity are included in the requirement, even if unstated.

One affirmative comment requested that exceptions for crew performance and availability be noted explicitly: the SDT noted that while the requested condition could be listed, the list is not meant to be exhaustive, and that any modification to the work plan can be made provided it does not allow encroachment into the MVCD. The same commenter wished to include language related to derating the line to indicate that the purpose of such action would be to "ensure continued...reliability." The SDT saw problems associated with proving that a reliability contribution by a derating was in fact accomplished and chose to retain the existing language. The same commenter wished to remove Category 3 outage reporting, but the SDT sees great value in the investigation of each vegetation related outage and feels that this reporting is justified to ensure that all outages are sufficiently investigated. The same commenter requested removing the reference to "defense-in-depth" in the Background section; the SDT chose to leave this reference as is. Lastly that same commenter suggested that "promptly" could be substituted for "without intentional time delay" in R4, the SDT saw no difference in the two terms and chose to keep the existing verbiage.

A commenter suggested in lieu of the annual inspection requirement that a time interval based on growth rates be used instead. The SDT chose to retain the existing annual interval based on industry's consensus support for the one year interval in a previous posting of the Standard.

A commenter requested that "of applicable lines" be added to the requirements and VSL verbiage to clearly denote applicability within the requirements and VSL verbiage. The SDT made those changes as requested to the requirements, measures and VSLs. That same commenter requested that Category 3 outages be reported by type A & B similar to other categories. The SDT saw no value to this change since Category 3 serves its purpose without that distinction being made. The same commenter requested changes to the ROW definition; the SDT chose to retain the existing language since it has been vetted with significant industry consensus.

Another comment suggested adding reference to financial reports in the examples for reasons for modifications to the annual plan, the SDT feels that such a reference to financial conditions was inappropriate. The same commenter noted the need for clarity in the structure of the VSLs ; the SDT made those changes. The same commenter requested clarity on use of Table 2 when an entity has a voltage category not in the table - the team added language to clarify that where the TO has transmission lines operated at nominal levels not listed in Table 2, the TO should use the clearance distances based on the maximum system voltage (i.e. for a nominal system voltage of 287 kV the appropriate distances would be for a maximum system voltage of 362 kV). Two commenters requested an example be added to the Guidelines and Technical Basis section for R7, similar to the examples in R6, to clarify that the % calculations should be based on the Annual Plan as modified; the SDT added the example as requested.

Another commenter questioned the 48-hour reporting in the 12/17/2008 NERC Public Notice - NERC Compliance Process #2008-001. The SDT discussed the issue with NERC staff and did not receive any direction that it would be necessary to add this as a Requirement within the Standard

Additional comments were offered by NERC staff as a separate attachment to comments submitted with the comment form, and those responses are covered following this question.

Organization	Yes or No	Question 5 Comment
SERC Vegetation Management sub-committee	Yes	
Hydro One Networks	Yes	
Northeast Power Coordinating Council	No	There is no percentage language in M7. Is it R7 that is being referred to?
Response: The SDT thanks you for your comment. The SDT meant to refer to R7.		

Organization	Yes or No	Question 5 Comment
Platte River Power Authority Substation Maintenance Group	Yes	
Bonneville Power Administration	Yes	
NERC Staff	Yes	Actually, R7 contains the clarifying language. It should be noted that although R7 indicates the TO shall complete 100% of the VM work plan, there is no requirement in this draft that a plan is actually developed.
Response: The SDT thanks you for your comments. The SDT meant to refer to R7, not to M7. As to the seeming lack of an actual requirement for a work plan, the SDT asserts that a fundamental precept of results-based standards is that having a requirement to complete any particularly activity also presupposes that the elements required to complete the activity are included in the requirement, even if unstated.		
Pepco Holdings Inc and Affiliates	Yes	
FirstEnergy	Yes	Although we generally agree with Requirements R7 and its measure M7, we suggest adding clarifying wording to bullet 4 which states "Crew or contractor availability/ Mutual assistance agreements". In addition to availability, contractor performance may be another issue that requires modification to the work plan. We suggest adding another bullet that reads "Crew or contractor performance". The rationale behind this addition is to address poor safety, productivity and/or quality issues with a crew or contractor assigned to perform vegetation management.FirstEnergy provides the following additional comments and suggestions not related to the specific questions asked in this posting: 1. Requirement R5 - We appreciate this requirement which recognizes that the TO may face situations in which it is constrained from performing its vegetation management and are permitted

Organization	Yes or No	Question 5 Comment
		to seek alternative methods. However, there may be instances where the TO has exhausted all course of action to perform vegetation and must utilize other means to prevent vegetation encroachment into the MVCD. Therefore, in these instances, "continued vegetation management" as stated in the requirement is not possible, but other methods such as line deratings and deenergizing of lines may have to be used. We ask that the phrase "to ensure continued vegetation management to prevent encroachments" be changed to read “to ensure continued reliability of the BES”. 2. Compliance Section - Category 3 - We suggest removing this category from the standard. Since fall-ins from outside the ROW are not considered a violation of this standard per Requirements R1 and R2, the entity should not have to report these fall-ins. 3. Objectives - We do not believe that is necessary for the Objectives statement to include the "defense-in-depth" concept which is actually an overarching goal of results-based standards in general and not specific to FAC-003-2. We suggest removing this phrase. 4. Background Section 5 - Similar to our comment above regarding defense-in-depth in the objectives statement, this is an overarching goal of results based standard and not specific to FAC-003-2. Therefore, we suggest removing the explanation of defense-in-depth from the background section. 5. Vegetation Inspection Definition - We suggest replacing the word "hazard" with "risk". 6. Requirement R4 - We do not agree with the phrase "without any intentional time delay" and suggest it be removed. This phrase is not measurable. Also, other drafting teams have attempted to incorporate this statement but industry comments have persuaded them to remove it; for example, the Reliability Coordination drafting team (Project 2006-06) initially proposed the same phrase but later removed it in their development of the COM/IRO standards. At the very least standards development should be consistent throughout the NERC standards drafting teams. We suggest the following as wording for Requirement R7: "Each Transmission Owner shall ensure the control center holding switching authority for the applicable transmission line is promptly notified

Organization	Yes or No	Question 5 Comment
		when the Transmission Owner has confirmed the existence of a vegetation condition that can potentially cause a Fault."

Response: The SDT thanks you for your comments. The SDT considered your request to add to the acceptable reasons for modifications the bullet, "Crew or contractor performance," and observes that since R7 states "Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made (provided they do not allow encroachment of vegetation into the MVCD)..." the bullet could be added, but the SDT did not intend the list of examples to be exhaustive and decided not to add the new bullet.

In reference to the comment 1) that the phrase "to ensure continued vegetation management to prevent encroachments" be changed to read "to ensure continued reliability of the BES," the SDT agrees that the corrective actions of de-ratings and de-energization as you suggest must be considered when vegetation cannot be maintained to prevent encroachment into the MVCD, and those examples are explicitly listed in M5. If a de-rating is used, it must be sufficient to prevent the encroachment into the MVCD. The de-rating or de-energization of the line removes the threat of an energized line and adjacent vegetation having less separation that the MVCD (i.e. less Fault probability), but the realized reliability value of those actions will depend on the events that occur while the condition persists. For these reasons the SDT retains the R5 language without changes.

In reference to the comment 2) "Compliance Section - Category 3 -...suggest removing this category from the standard," an investigation of the location of the tree with respect to the edge of the ROW for fall-ins must be made to determine whether the event represents a self-report of a violation or not. A record of those findings when the tree is found to be outside the ROW is valuable for both the Compliance Monitoring and Enforcement and the TO, should any questions later arise; therefore the SDT chose to retain the Category 3 reporting.

Regarding your comment 3) "Objectives - We do not believe that is necessary for the Objectives statement to include the "defense-in-depth" concept which is actually an overarching goal of results-based standards in general and not specific to FAC-003-2. We suggest removing this phrase." The SDT notes that the Purpose language is a general statement, and could be expanded or contracted without impacting the requirements. However, since the current language has undergone extensive debate, comment and revision the SDT sees no compelling reason to request industry to review another change at this time.

Regarding your comment 4) "Background Section 5 -.... suggest removing the explanation of defense-in-depth from the background section" The SDT notes again that the background section language is a general statement and could be expanded or contracted without impacting the requirements. However, since the defense-in-depth drove many of the changes in the standard the SDT thinks this section is relevant and should be retained.

Organization	Yes or No	Question 5 Comment
Regarding your comment 5) “suggest ...for Requirement R7(actually R4): "Each Transmission Owner shall ensure the control center holding switching authority for the applicable transmission line is promptly notified when the Transmission Owner has confirmed the existence of a vegetation condition that can potentially cause a Fault." The SDT has searched for but not found a time limit more suitable than “without intentional time delay.” An extensive list of event scenarios between the time that a condition is observed and the time it is reported can be studied. In the final analysis the intent is for the notification to be made to allow time for the control center to take steps to maintain reliability if possible before conditions deteriorate further. “Without intentional time delay” is as sufficient and as measurable as “promptly”.		
Dominion Electric Market Policy	No	The red-line revision does not indicated changes to M7; therefore, Dominion is unable to evaluate the clarifying language identified in this question. If the SDT meant to reference R7, we agree that the clarification is adequate.
Response: The SDT thanks you for your comments. The SDT means to reference R7.		
Southern Company Transmission	Yes	
Arizona Public Service Company	Yes	
Salt River Project	Yes	
Tampa Electric Company	Yes	This allows flexibility for the T.O. to determine the type of “unit” used in calculating the percentage complete.
Response: The SDT thanks you for your comments.		
NextEra Energy	Yes	
SDG&E	Yes	

Organization	Yes or No	Question 5 Comment
ASSET MANAGEMENET	Yes	
Hydro-Quebec TransEnergie (NCR07112)	No	The minimum frequency of Vegetation Inspection should be based upon an average growth rates of smaller regions than all North America. Example, above the latitude of about 50 degrees North, the vegetation growth rates is limited. We think that Vegetation Inspection frequency should be relaxed to 3 years for those areas in Canada. As indicator of the minimum frequency requested in R6, we suggest to use a global vegetation index like the Normalized Difference Vegetation Index (NDVI). The NDVI has been in use for many years to measure the vigor of vegetation growth among other things. http://earthobservatory.nasa.gov/Features/MeasuringVegetation/
Response: The SDT thanks you for your comments. In FERC Order 693, para. 721, FERC stated, “The Commission continues to be concerned with leaving complete discretion to the transmission owners in determining inspection cycles, which limits the effectiveness of the Reliability Standard.” The SDT established an inspection cycle at least once per calendar year and with no more than 18 months between inspections on the same ROW. There was a survey of the industry in a previous request for comments to this standard. The response to that survey is the basis for the use of the 1-year period. While there was a range of growth rates across the continent, the SDT had sufficient feedback to recommend the 1-year cycle. The inspection also would cover inspecting for fall-in threats. Please note that vegetation inspections can also be combined with other line inspections.		
Kansas City Power & Light	No	1) R7 states “Each Transmission Owner shall complete 100% of its annual vegetation work plan...”. We suggest to be consistent with all other sections of the rule that it should read, “Each Transmission Owner shall complete 100% of its annual vegetation work plan for all applicable lines...”. Otherwise, leaves room for interpretation to include all lines including those not defined as applicable. Also require these same revisions to row R7 of the table “Time Horizons, Violation Risk Factors, and Violation Severity Levels”. 2) In the “Additional Compliance Information” section Categories 1, 2, and 4 are each defined to have an A & B component to recognize the severity level difference for “applicable transmission lines” identified versus not identified “as an element of an IROL or Major WECC Transfer Path”. However, Category 3 does not separate these two scenarios however it appears that the same

Organization	Yes or No	Question 5 Comment
		distinction should apply. Additional comments:Vegetation Inspection Definition Recommend the SDT consider removing the conditional language, “that are likely to pose a hazard to the line(s) prior to the next”. Vegetation inspections are not dependent on a predisposed condition of vegetation. Suggest the SDT remove that phrase and consider the following definition:The systematic examination of vegetation conditions on a maintained transmission line Right-of-Way under the Transmission Owner’s control under a planned maintenance or inspection which may be combined with a general line inspection.
Response: The SDT thanks you for your comments. 1) The team has made the appropriate modifications, adding the reference to ‘applicable lines’ where necessary. 2) Since the Category 3 outages do not have any violations associated with their occurrences, the SDT did not see the value in reporting by type A or type B lines. 3) The SDT chooses to keep the current language because it addresses the core need to find conditions that will need correcting before the next planned maintenance or next planned inspection is performed.		
Manitoba Hydro	Yes	
Central Maine Power Company - IberdrolaUSA	Yes	
BC Hydro	Yes	You could also include other documentation such as monthly financial and program variance reports. Additional Comments Table 1: R6 definitions could be clearer. Suggested clarification: VSL Lower - Greater than 95% of annual inspections complete but less than 100% complete. VSL Moderate - Greater than 90 % of annual inspections complete but less than 95% complete VSL High - Greater than 85% of annual inspections complete but less than 90% complete VSL Severe - Less than 85% of annual inspections completed

Organization	Yes or No	Question 5 Comment
		Table 1 R7 definitions could be clearer. Suggested clarification: VSL Lower - Greater than 95% of annual work plan complete but less than 100% complete. VSL Moderate - Greater than 90 % of annual work plan complete but less than 95% complete VSL High - Greater than 85% of annual work plan complete but less than 90% complete VSL Severe - Less than 85% of annual work plan completed Table 2: This table includes a number of common nominal system voltages vs MVCD distances by altitude. However, some utilities have other non-standard voltages, in our case 287 kV, which forms a significant part of their system. It may be worthwhile for the standard to state what a utility should follow when a standard voltage class is not present - i.e. go to the next higher voltage MVCD if a particular voltage isn't in the table, or direct the utility to do its own Gallett Equation calcuations for their unique voltage class. Otherwise, different utilities may create a non-standard solution that wouldn't address the risk.
Response: The SDT thanks you for your comments. The SDT did not intend for the list of examples to be exhaustive. To the extent that financial or variance reports include evidence of the work units completed they may be useful as supportive evidence. inappropriate. The SDT used the NERC VSL Guidelines to develop the VSLs; therefore the SDT feels that the VSL's for R7 are adequate as listed. The proposed VSLs would leave some 'gaps' – for example the proposed VSLs aren't clear on what VSLs is assigned when an entity has completed exactly 95% of its inspections. Table 2 in the Standard lists both the nominal system voltages and the corresponding maximum system voltages. The clearance distances listed for each nominal system voltage were calculated using the maximum system voltage values. Therefore, where the TO has transmission lines operated at nominal levels not listed in Table 2, the TO should use the clearance distances based on the maximum system voltage (i.e. for a nominal system voltage of 287 kV the appropriate distances would be for a maximum system voltage of 362 kV). The SDT has added language to the guidelines and technical basis section to clarify this point.		
American Transmission	Yes	

Organization	Yes or No	Question 5 Comment
Company, LLC		
American Electric Power	Yes	
Baltimore Gas and Electric Co.	Yes	
TVA	No	I suggest that footnote 4 be changed by removing the reference to arbicultural, horticultural or agricultural activities.
Response: The SDT thanks you for your comments. The recommended changes have been made to footnote 4.		
Niagara Mohawk Power Corporation (dba National Grid)	No	There is currently no percentage language in M7. If they are referring to R7, then YES it is adequate.
Response: The SDT thanks you for your comments. The question should have referred to R7.		
CenterPoint Energy	No	CenterPoint Energy could not find any reference to an example percentage complete calculation for the annual work plan in the Standard for M7, in the Guideline and Technical Basis for M7, nor in the Technical Reference for M7. There was such an example for M6 which was helpful. CenterPoint Energy recommends such an example be included for M7.
Response: The SDT thanks you for your comments. The percentage complete should be based on the annual plan as modified. The SDT has changed the language in the standard to reflect more clearly that the percentage complete should be based on the plan as modified, and the following example has been added to the Guideline and Technical Basis: For example, when a Transmission Owner identifies 1,000 miles of 230 kV transmission lines to be completed in the TO's annual plan, the Transmission Owner will be responsible completing those identified miles. If a TO makes a modification to the annual plan that does not put the transmission system at risk of an encroachment the annual plan may be modified. If 100 miles of the annual plan is deferred until next year the calculation to determine what percentage the TO completed for the current year would be: 1000 – 100 (deferred miles) = 900 modified annual		

Organization	Yes or No	Question 5 Comment
plan, or 900 / 900 = 100% completed annual miles. If a TO only completed 875 of the total 1000 miles with no acceptable documentation for modification of the annual plan the calculation for failure to complete the annual plan would be: 1000 – 875 = 125 miles failed to complete then, 125 miles (not completed) / 1000 total annual plan miles = 12% failed to complete.		
Duke Energy	Yes	
South Carolina Electric and Gas	Yes	
Oncor Electric Delivery Company LLC	Yes	
Ameren	Yes	This is directed toward R7 rather than M7.
Response: The SDT thanks you for your comments.		
Individual		
Consolidated Edison Company of New York, Inc. - Transmission Line Maintenance	Yes	The added language for the annual work plan percentage complete calculation is shown in R7 not M7 as stated in the question. In the Guideline and Technical Basis Section for Requirement R6, there is a sample calculation shown for the amount of lines the TO failed to inspect. An example should also be included for Requirement R7 since there is some confusion regarding how modifications to the work plan affect the calculation. In the Lower VSL column for R7, it states that the TO failed to complete up to 5% of its annual vegetation work plan (including modifications if any). If a TO operates 100 lines and submits a justified modification that affects 10 miles of lines, the total number of units in the final amended plan is 90 miles. When you read the VSL, it is somewhat confusing since the information in parenthesis says that the calculation 'includes' the modifications. Should it state 'excludes modifications if any' or the VSLs can simply be re-written to state that ..The TO failed to complete up to x% of the final amended plan.' Also, the VSLs in R6 and

Organization	Yes or No	Question 5 Comment
		R7 should be consistent with each other: R6 says '...TO failed to inspect 5% or less.....' and R7 says '...TO failed to complete up to 5%....' They both should use the same verbiage in each VSL whether it is 'x% or less' or 'up to and including x%.'
Response: The SDT thanks you for your comments. The percentage should be based on the plan as modified. The SDT has changed the language in the standard to reflect this more clearly.		
USACE	Yes	
CECD	Yes	
Entergy Services, Inc	Yes	The actual clarifying language seems to have been added to R7 instead of M7 (as stated above). The clarifying language provides benefit as added to R7, and should remain in R7.Additionally, we feel that, in an effort to promote consistency with the other 6 Requirements, the term "on applicable Transmission lines" should be added at the end of the first sentence of R7, as it is listed in all other R's. The first sentence of R7 currently reads: "Each Transmission Owner shall complete 100% of its annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD". We feel the first sentence should read "Each Transmission Owner shall complete 100% of its annual vegetation work plan to ensure no vegetation encroachments occur within the MVCD on applicable transmission lines".
Response: The SDT thanks you for your comments. The first sentence does now contain the term “applicable lines”.		
Orange and Rockland Utilities, Inc.	Yes	
National Grid	No	There is currently no percentage language in M7. If they are referring to R7, then YES it is adequate.

Organization	Yes or No	Question 5 Comment
Response: The SDT thanks you for your comments. The SDT was referring to R7.		
Western Electricity Coordinating Council	Yes	We support the clarifying languae in M7However, since there is no generic "Any other Comments" section associated with this on-line comment form, we raise a question here. On December 24, 2008, NERC issued an e-mail to all Transmission Owners in which it referenced its December 17, 2008 Public Notice - NERC Compliance Process #2008-001, Vegetation-related Transmission Outage Reporting. The notice stated that: "Due to the potential severity of transmission outages caused by vegetation associated with Standard FAC-003-1, NERC is encouraging each Transmission Owner to self-report all Category 1 and Category 2 transmission outages related to vegetation to the Regional Entity within 48 hours utilizing the 48-hour vegetation reporting notice form provided by your appropriate Regional Entity."We do not see any reference to a 48-hour reporting notice in lthis version of the standard. Is this still a requirement? The only reference to reporting is in the Additional Compliance Information section and references quarterly reporting only.
Response: The SDT thanks you for your comments. The SDT is aware of the 48 hour, voluntary self-report request from NERC for outages where vegetation may be involved. The SDT also agrees with the general philosophy proposed by WECC that all requirements associated with a Standard are best served in the Standard. Also, the SDT did examine the general concept of an "investigation" type requirement. However, the SDT did not pursue this because it did not satisfy the basic rule for requirements as embedded in the Standards Process Manual, "What functional entity shall do what under what conditions to achieve what reliability objective." After the fact investigation and reporting, while important to the Compliance and Enforcement (CMEP) aspect of mandatory and enforceable Standards, does not achieve a reliability objective such that the failure to comply with the Requirement would jeopardize reliability. The SDT also notes that any useful (other than CMEP) information related to an outage that is subsequently reported under the NERC voluntary request would generally be available for industry use through TADS. Finally, the SDT did discuss the issue with NERC staff and did not receive direction that it was necessary, or desirable, to include one or more elements of the voluntary request in this Standard.		
Georgia Transmission Corp.	Yes	
Northern Indiana Public	Yes	

Organization	Yes or No	Question 5 Comment
Service Company		

Additional Comments from NERC:

In addition to the comments NERC submitted to the five questions on the official comment form, NERC staff has numerous other comments to make with regard to this Draft 5. Before that, NERC staff first wants to acknowledge the significant effort and talent that the industry brought to attempt to improve upon Reliability Standard FAC-003-1 – Vegetation Management. This Draft 5 of FAC-003-2 – Vegetation Management entailed significant industry work towards understanding the issue, compromising on proposals and attempting to reach consensus utilizing the NERC Standards Development Process. While NERC staff believes this draft represents some improvements to the existing standard, it does not believe the draft in its totality represents an improvement to the existing standard. FERC Order 693 approved the existing Vegetation Management Standard and it provided a number of directives for NERC with regard to further developing the Standard in order to improve it. Such directives and NERC comments regarding how the directives were addressed included:

- FERC Directive - Develop compliance audit procedures, using relevant industry experts, which would identify appropriate inspection cycles based on local factors. The Commission is dissuaded from requiring the ERO to create a backstop inspection cycle at this time.

  NERC Comment – Compliance audit procedures are outside the scope of the SDT and this Draft 5. Although not required by the Commission, the SDT added an annual inspection cycle to the Standard, with a maximum of 18 months between inspections. NERC believes this requirement represents an improvement to the existing Standard and does not believe it is overly burdensome on utilities.

Response: The SDT thanks you for your comments.

- FERC Directive - Remove the general limitation on lines 200kV and above to include lines that have an impact on reliability.
  - Do not reduce facilities included
  - Develop an acceptable definition for the applicability of this Reliability Standard that covers facilities that impact reliability while not unreasonably increasing the burden on transmission owners.
  - Evaluate the suggestions proposed by LPPC, APPA and Avista that regional entities should determine which facilities this standard applies to

  NERC Comment – NERC believes Draft 5 partially addresses this issue by increasing applicable facilities to IROL lines under 200kV. NERC staff is also concerned about

- The possibility that this very addition could limit a regional entity's desire to include additional lines.
- The exclusion of facilities inside the fenced area of switching stations, stations and substations. These excluded areas still pose a vegetation related outage risk and the rationale for excluding them is not compelling enough.
- The separation of IROL (any voltage level) and non-IROL (200 kV and above) Transmission Lines into separate requirements with different VRFs. NERC believes all Transmission Lines subject to this standard should be under the same requirement and associated VRFs. IROL lines are relatively few and do not warrant their own requirement. By having lower VRFs for non-IROL lines, this version of the standard is weaker than the existing standard. These two requirements should be a single requirement with high VRFs

Response: The SDT thanks you for your comments. In the guidelines provided by NERC to the drafting team, the SDT is dissuaded from writing 'fill in the blank' requirements. In version one, the team directed the RO to designate which critical lines below 200kV should fall under the standard without defining what critical meant. This is a 'fill-in-the- blank.' There is no assurance that this applicability would be applied consistency across North America. The SDT followed FERCs suggestion to take into account "…the suggestions by Progress Energy, SERC and MISO to limit applicability to lower voltage lines associated with IROL…" The team went further by including WECC transfer paths. The SDT asserts that the inclusion of both IROL lines and WECC Transfer paths addresses the comments by LPPC, APPA and Avista along with Progress Energy, SERC and MISO. The NERC Staff needs to consider that the comments all contend that each inclusion of a below 200kV line is an added burden to the rate payers. Not to give some direction to the Planning Coordinator would allow a planner to include ALL transmission lines, which would be an unreasonable burden to the rate payer. We added this language for clarity at the request of stakeholder concerns.

Neither the standard nor its original SAR were intended to cover fenced or discrete locations such as substations, which entail entirely different issues compared to linear corridors. Often substations are owned by either DPs or GOs, therefore, the TO may not have rights inside the fenced facility. The requirements in this standard would not be sufficient to include stations and switch yards. Should there be a compelling need for a vegetation standard for fenced facilities, a new SAR should be introduced.

The SDT asserts that different VRF's for IROL and non-IROL lines strengthens the reliability of the standard. Vegetation managers that do not know which lines are IROL or WECC Transfer Paths may be inappropriately limiting resources allocated to vegetation management for an IROL line or a WECC Transfer Path. A vegetation manager must ensure that the IROL lines and WECC transfer paths are absolutely clear. By correctly identifying the risk associated with an IROL line and/or a WECC Transfer Path, the standard helps to assure that appropriate resources are applied.

VRF guidelines require an analysis of impact to BES. We did that by considering the relative risk levels to the interconnected transmission system of an interruption of a non-IROL/non-Transfer Path line versus the interruption of IROL/Transfer Path lines. The fact that the PENALTY might be higher or lower DOES NOT AFFECT the strength or weakness of the Standard, since even the Medium Risk Factor value in the Base Penalty Matrix in the sanctions guidelines is $350,000 per violation per day. In both R1 and R2 of Version 2 there is zero-tolerance for encroachments, and Version 2 increases the scope to include observed encroachments without Faults, and confirmed vegetation Faults without Sustained Outages which were not clearly included in Version 1. The 1) distinction by separation of VRFs and 2) inclusion of clear language to inspect for, investigate, correct, and report to all known reliability threats will strengthen the standard.

- FERC Directive - Develop a Reliability Standard that defines the minimum clearance needed as an improvement to IEEE 516 which FERC does not believe is appropriately used for purposes of reliability and/or safety.

  NERC Comment – Draft 5 makes a change from IEEE 516 and utilizes Gallet equations for industry clearances. While NERC believes these equations are technically accurate, NERC is concerned about the usefulness of the clearances determined under this methodology as put forth in this draft. NERC is not aware of any utility which would maintain clearances as specified in this draft as it has no built in safety factor. NERC is further concerned that utilities could be mandated by courts of law to reduce existing maintained clearances to values much closer to those determined by the methodology in this draft.

Response: The SDT thanks you for your comments. As with a Transmission Owner's determination of its Clearance 1 distances under version 1 of the Standard, Requirement 3 of the revised Standard begins with the MVCD distances (just as Clearance 1 began with IEEE-516 distances) and then requires additional consideration for conductor movement, vegetation growth variables, and the utility's maintenance approach. These are essentially the same considerations required by version 1 of the existing Standard when developing Clearance 1 distances. Therefore, nothing has been "lost" in the revised Standard. In fact, the proposed Standard is better from an auditing perspective because the overall logic and rationale used by the TO in complying with the new Requirement 3 is now subject to an overall test of adequacy, competency and reasonableness. Also, informal polls conducted by the SDT show that many Transmission Owners are unsuccessful in utilizing Clearance 1 as a tool, because it is easily challenged by landowners as being an arbitrary fill-in-the-blank value set by the Transmission Owner. Further, if the Transmission Owner would cut only to Clearance 1 instead of to the full extent of its legal rights, courts could rule against the Transmission Owner for failing to exercise its full legal rights. Thus, in the revised Standard, the Transmission Owner has neither gained nor lost any tool or advantage in dealing with landowners, but the SDT asserts that the bar has been raised with regard to the adequacy of the Transmission Owner's overall vegetation management program.

- FERC Directive - Define rights-of-way to encompass the required clearance areas instead of the corresponding legal rights, and the standards should not require clearing the entire right-of-way when the required clearance for an existing line does not take up the entire right-of-way.

  NERC Comment – NERC staff believes this directive was met and is addressed in question 1 of the comment form.

Response: The SDT thanks you for your comments.

- FERC Directive – NERC should address the proposed modifications through its Reliability Standards development process.

  NERC Comment – NERC staff believes this directive was met in preparing this draft standard.

Response: The SDT thanks you for your comments.

- FERC Directive - Collect outage data for transmission outages, analyze it, and use the results of this analysis and information in the development of the Reliability Standard.

  NERC Comment – NERC staff believes more work needs to be done in this area. NERC staff believes the drafting team should consider modifying the Periodic Data Submittal to include if outages occur on Federal land.

Response: The SDT thanks you for your comments. After discussion with NERC staff, NERC has agreed to address this issue outside the work of the SDT. The SDT recommends that NERC staff consider adding a field to the TADS data to capture vegetation outages on applicable lines on federal lands.

Other Draft 5 Issues

- Removal of a formal transmission vegetation management program, of Clearance 1 and of a documented vegetation management plan.

NERC Comment – NERC does not support the removal of these items. NERC does not believe these changes represent an improvement to the standard and does not believe this existing requirement is overly burdensome to utilities. NERC does not understand why industry would not be willing to be held accountable to their vegetation management plans. NERC is concerned that the removal of these items could make it difficult for utilities to obtain permissions needed to maintain clearances between inspection cycles which are prudent for reliability and safety due to intervener or landowners exercising their rights and then pointing to this new standard as a the basis for smaller clearances. . Requirement 3 in this draft needs to include a documented plan and to clearly identify the specifics to be included in the plan and provide clarity of expectations. The SDT may not support such specifics as not being consistent with results-based standards development but NERC staff believes otherwise.

Response: The SDT thanks you for your comments. The existing series of items in Requirement R3 along with R3.2 are collectively with the balance of the standard equivalent to the term TVMP. These combined items in R3 are the defense in depth approach that require the TO to maintain vegetation so that it does not enter into the MVCD before the next planned vegetation work, thus accomplishing the equivalent of a C1 without a fill-in-the-blank issue.

- Objectives**:** A qualifier in the standard Objective that it should apply to preventing the risk of vegetation related outages *that could lead to cascading outages.*

  NERC Comment – This qualifier limits the purpose of the standard, which should be to prevent vegetation related outages, not cascading outages. The more outages there are, the less the overall system reliability. An outage does not necessarily have to lead to a cascading outage to be significant and represent a reasonable risk to the BES. References to cascading outages should be removed.

Response: The SDT thanks you for your comments. The SDT has thoughtfully considered every aspect of this version of the Standard to ensure that the pieces are consistent, aligned, and support each other. The SDT added the phrase "with Cascading" not to limit the Standard, but rather to recognize that the 200 kV bright-line for applicability (which is not in question) is founded on the very notion that the 200 kV serves as a proxy for "The Big Three": Cascading, Separation, and Instability. The SDT considered adding all of these conditions to the Purpose statement. However, given the focus of this Standard is on vegetation, and vegetation was deemed to be related to Cascading (i.e. 2003 Blackout report), rather than the other two undesirable system conditions, it seemed more logical and consistent to include the likely outcome of an unmanaged vegetation condition on a Transmission Owner's system. If NERC Staff has evidence that other two are likely related to vegetation, it has not yet been provided to the SDT.

Unlike other types of outages on lines (such as those caused by failed insulators, broken cross-arms, rotten poles and lightning flashover), vegetation outages uniquely affect lines when they are heavily loaded and thus susceptible to a cascading event.

- Background**:** This section excludes vegetations fall-ins and blow-ins from outside the ROW on the basis that they are not preventable.

  NERC Comment – Many fall-ins and blow-ins from outside the ROW are preventable. Trees outside the ROW must be managed adequately to prevent outages on the BES. The work to remove and/or prune trees outside the ROW may be more difficult and costly than such work inside the ROW, but that is not sufficient reason to exclude this work. In addition, utilities wishing to perform such work might be prevented from doing so by regulatory bodies based upon the lack of a specific requirement in this standard.

Response: The SDT thanks you for your comments and has reworded the Background by removing the term non-preventable.

- Requirement 1 & 2: These requirements discuss preventing encroachments into the MVCD of an applicable line that is operating within its Rating.

  NERC Comments –NERC staff would like confirmation that "Rating" is intended to include all published ratings issued by the facility owner, such as Normal, Emergency, etc.

Response: The SDT thanks you for your response. The glossary term “Rating” is adequate to address the issues you raise.

- Requirement 4: R4 states that “Each Transmission Owner, without any intentional time delay, shall notify…”

  NERC Comments: The previous version of the standard included a time limit of 15 minutes once communications became available. This should be reinstated.

Response: The SDT thanks you for your response. The SDT is not aware any posting with a 15 minute rule included.

- Requirement 7: R7 sets the requirement for each Transmission Owner to complete 100 percent of its annual vegetation work plan.

  NERC Comments – NERC is concerned that the draft doesn’t have a requirement for a Transmission Owner to have a documented annual plan making Requirement 7 unenforceable. In addition, Requirement 7 has a number of other qualifiers that would seem to allow manipulation of the annual plan to ensure compliance.

Response: The SDT thanks you for your comments. The SDT asserts that a fundamental precept of results-based standards is that having a requirement to complete any particularly activity also presupposes that the elements required to complete the activity are included in the requirement, even if unstated.

- Draft 5 document quality

  NERC Comments – this draft has some typographical errors which need to be fixed. For example, on page 28, reference to use of Table 5 versus Table 7 based on knowledge of maximum transient over-voltage factor is reversed. These edits could probably be handled through a recirculation ballet.

Response: The SDT thanks you for your comments. We agree with the typo you found and we have changed the language in the draft standard.

- Previously raised NERC issues

  NERC Comments – NERC staff posted several comments on the Draft 4 version of this standard in July 2010. NERC believes most of the concerns it raised in those comments are not addressed in Draft 5 and continue to be a concern for NERC.

Response: The SDT thanks you for your comments; however there are not enough specifics for the SDT to respond.

- General compliance and audit issues

  NERC Comments –

  - The whole "sustained outage" concept in R1 (for fall ins and blow ins) is unworkable from an enforcement perspective.
  - The difference between a violation and a non-violation in Draft 5 is whether the registered entity was fortunate with regard to an encroachment. This part should be rewritten to say that any tree contact is a violation. VRFs and VSLs could then be used to address whether the violation was minor or serious.
  - There could be a lot of litigation over whether "circumstances" were really "beyond the control" of the TO. NERC had previously objected to the implementation of a force majeure clause in the standard. If an entity failed to carry out its annual plan, that should be treated as a violation, and any excuses for failing to do so or for changing the plan mid-year all go to whether the penalty should be $0 or substantial.
  - For the evidence retention period, the entity really should retain evidence of compliance until the next compliance audit. Since some TOs may be on a 6 year audit schedule, the 3 year retention period is not sufficient.

Response: The SDT thanks you for your comments.

- The SDT does not understand your comment. The violations under the existing standards are largely due to sustained outages.
- Version 2 has a violation for every known and confirmed encroachment. The Penalty for those encroachments that do no cause Faults is up to $30,000 per violation per day
- The SDT thanks you for your comments. The SDT believes this language is appropriate for this standard due to the many factors related to vegetation that are truly outside the TO's control. Unlike the vast majority of other NERC standards, implementation of FAC-003 is not under

the absolute control of the utilities. These influences range from landowner and agency obstacles to weather events, and as such the SDT believes the force majeure provisions should be applicable. The recognition of this provision is also supported by 90% of the industry. An attempt at similar language is contained in version 1 but it is ambiguous and lacks clarity. This language adds clarity and reduces the opportunity for misapplication. Further, TO's must have supporting evidence for claims that situations are "beyond their control".

- The SDT thanks you for your comments, and will use the NERC approved retention times.

End of Report

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed

1. SC approved SAR for initial posting (January 11, 2007).
2. SAR posted for comment (January 15–February 14, 2007).
3. SAR posted for comment (April 10–May 9, 2007).
4. SC authorized moving the SAR forward to standard development (June 27, 2007).
5. First draft of proposed standard posted (October 27, 2008-November 25, 2008)).
6. Second draft of revised standard posted (September 10, 20-October 24, 2009).
7. Third draft of revised standard posted (March 1, 2010-March 31, 2010).
8. Fourth draft of revised standard posted (June 17, 2010-July 17, 2010).
9. Fifth draft of revised standard posted (February 18, 2011-February 28, 2011)
10. Sixth draft of revised standard posted (September xx - 2011)

Proposed Action Plan and Description of Current Draft

This is the fourth posting of the proposed revisions to the standard in accordance with Results-Based Criteria and the sixth draft overall.

Future Development Plan

Anticipated Actions	Anticipated Date
Recirculation ballot of standards.	September 2011
Receive BOT approval	November 2011

Effective Dates

This standard becomes effective on the first calendar day of the first calendar quarter one year after the date of the order approving the standard from applicable regulatory authorities where such explicit approval is required. Where no regulatory approval is required, the standard becomes effective on the first calendar day of the first calendar quarter one year after Board of Trustees adoption.

Effective dates for individual lines when they undergo specific transition cases:

1. A line operated below 200kV, designated by the Planning Coordinator as an element of an Interconnection Reliability Operating Limit (IROL) or designated by the Western Electricity Coordinating Council (WECC) as an element of a Major WECC Transfer Path, becomes subject to this standard the latter of: 1) 12 months after the date the Planning Coordinator or WECC initially designates the line as being an element of an IROL or an element of a Major WECC Transfer Path, or 2) January 1 of the planning year when the line is forecast to become an element of an IROL or an element of a Major WECC Transfer Path.

2. A line operated below 200 kV currently subject to this standard as a designated element of an IROL or a Major WECC Transfer Path which has a specified date for the removal of such designation will no longer be subject to this standard effective on that specified date.

3. A line operated at 200 kV or above, currently subject to this standard which is a designated element of an IROL or a Major WECC Transfer Path and which has a specified date for the removal of such designation will be subject to Requirement R2 and no longer be subject to Requirement R1 effective on that specified date.

4. An existing transmission line operated at 200kV or higher which is newly acquired by an asset owner and which was not previously subject to this standard becomes subject to this standard 12 months after the acquisition date.

5. An existing transmission line operated below 200kV which is newly acquired by an asset owner and which was not previously subject to this standard becomes subject to this standard 12 months after the acquisition date of the line if at the time of acquisition the line is designated by the Planning Coordinator as an element of an IROL or by WECC as an element of a Major WECC Transfer Path.

Version History

Version	Date	Action	Change Tracking
1	TBA	1. Added "Standard Development Roadmap." 2. Changed "60" to "Sixty" in section A, 5.2. 3. Added "Proposed Effective Date: April 7, 2006" to footer. 4. Added "Draft 3: November 17, 2005" to footer.	01/20/06
1	April 4, 2007	Regulatory Approval — Effective Date	New
2			

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary.

Right-of-Way (ROW)

The corridor of land under a transmission line(s) needed to operate the line(s). The width of the corridor is established by engineering or construction standards as documented in either construction documents, pre-2007 vegetation maintenance records, or by the blowout standard in effect when the line was built. The ROW width in no case exceeds the Transmission Owner's legal rights but may be less based on the aforementioned criteria.

The current glossary definition of this NERC term is modified to address the issues set forth in Paragraph 734 of FERC Order 693.

Vegetation Inspection

The systematic examination of vegetation conditions on a Right-of-Way and those vegetation conditions under the Transmission Owner's control that are likely to pose a hazard to the line(s) prior to the next planned maintenance or inspection. This may be combined with a general line inspection.

The current glossary definition of this NERC term is modified to allow both maintenance inspections and vegetation inspections to be performed concurrently.

Current definition of Vegetation Inspection: The systematic examination of a transmission corridor to document vegetation conditions.

Minimum Vegetation Clearance Distance (MVCD)

The calculated minimum distance stated in feet (meters) to prevent flash-over between conductors and vegetation, for various altitudes and operating voltages.

When this standard has received ballot approval, the text boxes will be moved to the Guideline and Technical Basis Section.

A. Introduction

1. **Title:** Transmission Vegetation Management

2. **Number:** FAC-003-2

3. **Purpose:** To maintain a reliable electric transmission system by using a defense-in-depth strategy to manage vegetation located on transmission rights of way (ROW) and minimize encroachments from vegetation located adjacent to the ROW, thus preventing the risk of those vegetation-related outages that could lead to Cascading.

4. **Applicability**

4.1. Functional Entities:

4.1.1 Transmission Owners

4.2. Facilities: Defined below (referred to as "applicable lines"), including but not limited to those that cross lands owned by federal[1], state, provincial, public, private, or tribal entities:

4.2.1. Each overhead transmission line operated at 200kV or higher.

4.2.2. Each overhead transmission line operated below 200kV identified as an element of an IROL under NERC Standard FAC-014 by the Planning Coordinator.

4.2.3. Each overhead transmission line operated below 200 kV identified as an element of a Major WECC Transfer Path in the Bulk Electric System by WECC.

4.2.4. Each overhead transmission line identified above (4.2.1 through 4.2.3) located outside the fenced area of the switchyard, station or substation and any portion of the span of the transmission line that is crossing the substation fence.

Rationale: The areas excluded in 4.2.4 were excluded based on comments from industry for reasons summarized as follows: 1) There is a very low risk from vegetation in this area. Based on an informal survey, no TOs reported such an event. 2) Substations, switchyards, and stations have many inspection and maintenance activities that are necessary for reliability. Those existing process manage the threat. As such, the formal steps in this standard are not well suited for this environment. 3) NERC has a project in place to address at a later date the applicability of this standard to Generation Owners. 4) Specifically addressing the areas where the standard does and does not apply makes the standard clearer.

[1] EPAct 2005 section 1211c: *"Access approvals by Federal agencies."*

Enforcement:
The Requirements within a Reliability Standard govern and will be enforced. The Requirements within a Reliability Standard define what an entity must do to be compliant and binds an entity to certain obligations of performance under Section 215 of the Federal Power Act. Compliance will in all cases be measured by determining whether a party met or failed to meet the Reliability Standard Requirement given the specific facts and circumstances of its use, ownership or operation of the bulk power system.

Measures provide guidance on assessing non-compliance with the Requirements. Measures are the evidence that could be presented to demonstrate compliance with a Reliability Standard Requirement and are not intended to contain the quantitative metrics for determining satisfactory performance nor to limit how an entity may demonstrate compliance if valid alternatives to demonstrating compliance are available in a specific case. A Reliability Standard may be enforced in the absence of specified Measures.

Entities must comply with the “Compliance” section in its entirety, including the Administrative Procedure that sets forth, among other things, reporting requirements.

The “Guideline and Technical Basis” section, the Background section and text boxes with “Examples” and “Rationale” are provided for informational purposes. They are designed to convey guidance from NERC’s various activities. The “Guideline and Technical Basis” section and text boxes with “Examples” and “Rationale” are not intended to establish new Requirements under NERC’s Reliability Standards or to modify the Requirements in any existing NERC Reliability Standard. Implementation of the “Guideline and Technical Basis” section, the Background section and text boxes with “Examples” and “Rationale” is not a substitute for compliance with Requirements in NERC’s Reliability Standards.”

5. **Background:**

This standard uses three types of requirements to provide layers of protection to prevent vegetation related outages that could lead to Cascading:

a) Performance-based — defines a particular reliability objective or outcome to be achieved. In its simplest form, a results-based requirement has four components: *who, under what conditions (if any), shall perform what action, to achieve what particular bulk power system <u>performance result or outcome</u>*?

b) Risk-based — preventive requirements to reduce the risks of failure to acceptable tolerance levels. A risk-based reliability requirement should be framed as: *who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome <u>that reduces a stated risk</u> to the reliability of the bulk power system*?

c) Competency-based — defines a minimum set of capabilities an entity needs to have to demonstrate it is able to perform its designated reliability functions. A competency-based reliability requirement should be framed as: *who, under what*

> *conditions (if any), shall have what capability, to achieve what particular result or outcome to perform an action to achieve a result or outcome or to reduce a risk to the reliability of the bulk power system*?

The defense-in-depth strategy for reliability standards development recognizes that each requirement in a NERC reliability standard has a role in preventing system failures, and that these roles are complementary and reinforcing. Reliability standards should not be viewed as a body of unrelated requirements, but rather should be viewed as part of a portfolio of requirements designed to achieve an overall defense-in-depth strategy and comport with the quality objectives of a reliability standard.

This standard uses a defense-in-depth approach to improve the reliability of the electric Transmission system by:

- Requiring that vegetation be managed to prevent vegetation encroachment inside the flash-over clearance (R1 and R2);
- Requiring documentation of the maintenance strategies, procedures, processes and specifications used to manage vegetation to prevent potential flash-over conditions including consideration of 1) conductor dynamics and 2) the interrelationships between vegetation growth rates, control methods and the inspection frequency (R3);
- Requiring timely notification to the appropriate control center of vegetation conditions that could cause a flash-over at any moment (R4);
- Requiring corrective actions to ensure that flash-over distances will not be violated due to work constrains such as legal injunctions (R5);
- Requiring inspections of vegetation conditions to be performed annually (R6); and
- Requiring that the annual work needed to prevent flash-over is completed (R7).

For this standard, the requirements have been developed as follows:

- Performance-based: Requirements 1 and 2
- Competency-based: Requirement 3
- Risk-based: Requirements 4, 5, 6 and 7

R3 serves as the first line of defense by ensuring that entities understand the problem they are trying to manage and have fully developed strategies and plans to manage the problem. R1, R2, and R7 serve as the second line of defense by requiring that entities carry out their plans and manage vegetation. R6, which requires inspections, may be either a part of the first line of defense (as input into the strategies and plans) or as a third line of defense (as a check of the first and second lines of defense). R4 serves as the final line of defense, as it addresses cases in which all the other lines of defense have failed.

Major outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations. Adherence to the standard requirements for applicable lines on any kind of land or easement, whether they are Federal Lands, state or provincial lands, public or private lands, franchises, easements or lands owned in fee, will reduce and manage this risk. For the purpose of the standard the term "public lands" includes municipal lands, village lands, city lands, and a host of other governmental entities.

This standard addresses vegetation management along applicable overhead lines and does not apply to underground lines, submarine lines or to line sections inside an electric station boundary.

This standard focuses on transmission lines to prevent those vegetation related outages that could lead to Cascading. It is not intended to prevent customer outages due to tree contact with lower voltage distribution system lines. For example, localized customer service might be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. However, this standard is not written to address such isolated situations which have little impact on the overall electric transmission system.

Since vegetation growth is constant and always present, unmanaged vegetation poses an increased outage risk, especially when numerous transmission lines are operating at or near their Rating. This can present a significant risk of consecutive line failures when lines are experiencing large sags thereby leading to Cascading. Once the first line fails the shift of the current to the other lines and/or the increasing system loads will lead to the second and subsequent line failures as contact to the vegetation under those lines occurs. Conversely, most other outage causes (such as trees falling into lines, lightning, animals, motor vehicles, etc.) are not an interrelated function of the shift of currents or the increasing system loading. These events are not any more likely to occur during heavy system loads than any other time. There is no cause-effect relationship which creates the probability of simultaneous occurrence of other such events. Therefore these types of events are highly unlikely to cause large-scale grid failures. Thus, this standard places the highest priority on the management of vegetation to prevent vegetation grow-ins.

B. Requirements and Measures

R1. Each Transmission Owner shall manage vegetation to prevent encroachments into the MVCD of its applicable line(s) which are either an element of an IROL, or an element of a Major WECC Transfer Path; operating within its Rating and all Rated Electrical Operating Conditions of the types shown below[2] [*Violation Risk Factor: High*] [*Time Horizon: Real-time*]:

1. An encroachment into the MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage[3],
2. An encroachment due to a fall-in from inside the ROW that caused a vegetation-related Sustained Outage[4],
3. An encroachment due to the blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained Outage[4],
4. An encroachment due to vegetation growth into the MVCD that caused a vegetation-related Sustained Outage[4].

Rationale for R1 and R2:
Lines with the highest significance to reliability are covered in R1; all other lines are covered in R2.

Rationale for the types of failure to manage vegetation which are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a Transmission Owner's vegetation maintenance program:

1. This management failure is found by routine inspection or Fault event investigation, and is normally symptomatic of unusual conditions in an otherwise sound program.

2. This management failure occurs when the height and location of a side tree within the ROW is not adequately addressed by the program.

3. This management failure occurs when side growth is not adequately addressed and may be indicative of an unsound program.

4. This management failure is usually indicative of a program that is not addressing the most fundamental dynamic of vegetation management, (i.e. a grow-in under the line). If this type of failure is pervasive on multiple lines, it provides a mechanism for a Cascade.

---

[2] This requirement does not apply to circumstances that are beyond the control of a Transmission Owner subject to this reliability standard, including natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods; human or animal activity such as logging, animal severing tree, vehicle contact with tree, or installation, removal, or digging of vegetation. Nothing in this footnote should be construed to limit the Transmission Owner's right to exercise its full legal rights on the ROW.

[3] If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation.

[4] Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period.

M1. Each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R1. Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-time observations of any MVCD encroachments. (R1)

R2. Each Transmission Owner shall manage vegetation to prevent encroachments into the MVCD of its applicable line(s) which are not either an element of an IROL, or an element of a Major WECC Transfer Path; operating within its Rating and all Rated Electrical Operating Conditions of the types shown below[2] [*Violation Risk Factor: Medium*] [*Time Horizon: Real-time*]:

1. An encroachment into the MVCD, observed in Real-time as shown in FAC-003-Table 2, absent a Sustained Outage[3],
2. An encroachment due to a fall-in from inside the ROW that caused a vegetation-related Sustained Outage[4],
3. An encroachment due to blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained Outage[4],
4. An encroachment due to vegetation growth into the MVCD that caused a vegetation-related Sustained Outage[4]

M2. Each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R2. Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-time observations of any MVCD encroachments. (R2)

R3. Each Transmission Owner shall have documented maintenance strategies or procedures or processes or specifications it uses to prevent the encroachment of vegetation into the MVCD of its applicable lines that accounts for the following:

3.1 Movement of applicable line conductors under their Rating and all Rated Electrical Operating Conditions;

3.2 Inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency.

[*Violation Risk Factor: Lower*] [*Time Horizon: Long Term Planning*]:

Rationale

The documentation provides a basis for evaluating the competency of the Transmission Owner's vegetation program. There may be many acceptable approaches to maintain clearances. Any approach must demonstrate that the Transmission Owner avoids vegetation-to-wire conflicts under all Ratings and all Rated Electrical Operating Conditions. See Figure 1 for an illustration of possible conductor locations.

M3. The maintenance strategies or procedures or processes or specifications provided demonstrate that the Transmission Owner can prevent encroachment into the MVCD considering the factors identified in the requirement. (R3)

R4. Each Transmission Owner, without any intentional time delay, shall notify the control center holding switching authority for the associated applicable line when the Transmission Owner has confirmed the existence of a vegetation condition that is likely to cause a Fault at any moment [*Violation Risk Factor: Medium*] [*Time Horizon: Real-time*].

Rationale

This is to ensure expeditious communication between the Transmission Owner and the control center when a critical situation is confirmed.

M4. Each Transmission Owner that has a confirmed vegetation condition likely to cause a Fault at any moment will have evidence that it notified the control center holding switching authority for the associated transmission line without any intentional time delay. Examples of evidence may include control center logs, voice recordings, switching orders, clearance orders and subsequent work orders. (R4)

R5. When a Transmission Owner is constrained from performing vegetation work on an applicable line operating within its Rating and all Rated Electrical Operating Conditions, and the constraint may lead to a vegetation encroachment into the MVCD prior to the implementation of the next annual work plan, then the Transmission Owner shall take corrective action to ensure continued vegetation management to prevent encroachments [*Violation Risk Factor: Medium*] [*Time Horizon: Operations Planning*].

Rationale

Legal actions and other events may occur which result in constraints that prevent the Transmission Owner from performing planned vegetation maintenance work.

In cases where the transmission line is put at potential risk due to constraints, the intent is for the Transmission Owner to put interim measures in place, rather than do nothing.

The corrective action process is not intended to address situations where a planned work methodology cannot be performed but an alternate work methodology can be used.

M5. Each Transmission Owner has evidence of the corrective action taken for each constraint where an applicable transmission line was put at potential risk. Examples of acceptable forms of evidence may include initially-planned work orders, documentation of constraints from landowners, court orders, inspection records of increased monitoring, documentation of the de-rating of lines, revised work orders, invoices, or evidence that the line was de-energized. (R5)

R6. Each Transmission Owner shall perform a Vegetation Inspection of 100% of its applicable transmission lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.) at least once per calendar year and with no more than 18 calendar months between inspections on the same ROW[5] [*Violation Risk Factor: Medium*] [*Time Horizon: Operations Planning*].

Rationale

Inspections are used by Transmission Owners to assess the condition of the entire ROW. The information from the assessment can be used to determine risk, determine future work and evaluate recently-completed work. This requirement sets a minimum Vegetation Inspection frequency of once per calendar year but with no more than 18 months between inspections on the same ROW. Based upon average growth rates across North America and on common utility practice, this minimum frequency is reasonable. Transmission Owners should consider local and environmental factors that could warrant more frequent inspections.

[5] When the Transmission Owner is prevented from performing a Vegetation Inspection within the timeframe in R6 due to a natural disaster, the TO is granted a time extension that is equivalent to the duration of the time the TO was prevented from performing the Vegetation Inspection.

M6. Each Transmission Owner has evidence that it conducted Vegetation Inspections of the transmission line ROW for all applicable lines at least once per calendar year but with no more than 18 calendar months between inspections on the same ROW. Examples of acceptable forms of evidence may include completed and dated work orders, dated invoices, or dated inspection records. (R6)

R7. Each Transmission Owner shall complete 100% of its annual vegetation work plan of applicable lines to ensure no vegetation encroachments occur within the MVCD. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made (provided they do not allow encroachment of vegetation into the MVCD) and must be documented. The percent completed calculation is based on the number of units actually completed divided by the number of units in the final amended plan (measured in units of choice - circuit, pole line, line miles or kilometers, etc.) Examples of reasons for modification to annual plan may include [*Violation Risk Factor: Medium*] [*Time Horizon: Operations Planning*]:

Rationale

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. It allows modifications to the planned work for changing conditions, taking into consideration anticipated growth of vegetation and all other environmental factors, provided that those modifications do not put the transmission system at risk of a vegetation encroachment.

- Change in expected growth rate/ environmental factors
- Circumstances that are beyond the control of a Transmission Owner[6]
- Rescheduling work between growing seasons
- Crew or contractor availability/ Mutual assistance agreements
- Identified unanticipated high priority work
- Weather conditions/Accessibility
- Permitting delays
- Land ownership changes/Change in land use by the landowner
- Emerging technologies

M7. Each Transmission Owner has evidence that it completed its annual vegetation work plan for its applicable lines. Examples of acceptable forms of evidence may include a copy of the completed annual work plan (as finally modified), dated work orders, dated invoices, or dated inspection records. (R7)

[6] Circumstances that are beyond the control of a Transmission Owner include but are not limited to natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, ice storms, floods, or major storms as defined either by the TO or an applicable regulatory body.

C. Compliance

1. Compliance Monitoring Process

1.1 Compliance Enforcement Authority

1.2 Regional Entity Evidence Retention

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Transmission Owner retains data or evidence to show compliance with Requirements R1, R2, R3, R5, R6 and R7, Measures M1, M2, M3, M5, M6 and M7 for three calendar years unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

The Transmission Owner retains data or evidence to show compliance with Requirement R4, Measure M4 for most recent 12 months of operator logs or most recent 3 months of voice recordings or transcripts of voice recordings, unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

If a Transmission Owner is found non-compliant, it shall keep information related to the non-compliance until found compliant or for the time period specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3 Compliance Monitoring and Enforcement Processes:

Compliance Audit

Self-Certification

Spot Checking

Periodic Data Submittal

1.4 Additional Compliance Information

Periodic Data Submittal: The Transmission Owner will submit a quarterly report to its Regional Entity, or the Regional Entity's designee, identifying all Sustained Outages of applicable lines operated within their Rating and all Rated Electrical Operating Conditions as determined by the Transmission Owner to have been caused by vegetation, except as excluded in footnote 2, and including as a minimum the following:

- The name of the circuit(s), the date, time and duration of the outage; the voltage of the circuit; a description of the cause of the outage; the category associated with the Sustained Outage; other pertinent comments; and any countermeasures taken by the Transmission Owner.

A Sustained Outage is to be categorized as one of the following:

- Category 1A — Grow-ins: Sustained Outages caused by vegetation growing into applicable lines, that are identified as an element of an IROL or Major WECC Transfer Path, by vegetation inside and/or outside of the ROW;
- Category 1B — Grow-ins: Sustained Outages caused by vegetation growing into applicable lines, but are not identified as an element of an IROL or Major WECC Transfer Path, by vegetation inside and/or outside of the ROW;
- Category 2A — Fall-ins: Sustained Outages caused by vegetation falling into applicable lines that are identified as an element of an IROL or Major WECC Transfer Path, from within the ROW;
- Category 2B — Fall-ins: Sustained Outages caused by vegetation falling into applicable lines, but are not identified as an element of an IROL or Major WECC Transfer Path, from within the ROW;
- Category 3 — Fall-ins: Sustained Outages caused by vegetation falling into applicable lines from outside the ROW;
- Category 4A — Blowing together: Sustained Outages caused by vegetation and applicable lines that are identified as an element of an IROL or Major WECC Transfer Path, blowing together from within the ROW.
- Category 4B — Blowing together: Sustained Outages caused by vegetation and applicable lines, but are not identified as an element of an IROL or Major WECC Transfer Path, blowing together from within the ROW.

The Regional Entity will report the outage information provided by Transmission Owners, as per the above, quarterly to NERC, as well as any actions taken by the Regional Entity as a result of any of the reported Sustained Outages.

Table of Compliance Elements

R#	Time Horizon	VRF	Violation Severity Level			
			Lower	Moderate	High	Severe
R1	Real-time	High	The Transmission Owner failed to manage vegetation in a manner such that the Transmission Owner had an encroachment into the MVCD observed in Real-time, absent a Sustained Outage.	The Transmission Owner failed to manage vegetation in a manner such that the Transmission Owner had an encroachment into the MVCD due to a fall-in from inside the ROW that caused a vegetation-related Sustained Outage.	The Transmission Owner failed to manage vegetation in a manner such that the Transmission Owner had an encroachment into the MVCD due to blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained Outage.	The Transmission Owner failed to manage vegetation in a manner such that the Transmission Owner had an encroachment into the MVCD due to a grow-in that caused a vegetation-related Sustained Outage.
R2	Real-time	Medium	The Transmission Owner failed to manage vegetation in a manner such that the Transmission Owner had an encroachment into the MVCD observed in Real-time, absent a Sustained Outage.	The Transmission Owner failed to manage vegetation in a manner such that the Transmission Owner had an encroachment into the MVCD due to a fall-in from inside the ROW that caused a vegetation-related Sustained Outage.	The Transmission Owner failed to manage vegetation in a manner such that the Transmission Owner had an encroachment into the MVCD due to blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained Outage.	The Transmission Owner failed to manage vegetation in a manner such that the Transmission Owner had an encroachment into the MVCD due to a grow-in that caused a vegetation-related Sustained Outage.
R3	Long-Term Planning	Lower		The Transmission Owner has maintenance strategies or documented procedures or processes or specifications but has not accounted for the inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency, for the Transmission Owner's	The Transmission Owner has maintenance strategies or documented procedures or processes or specifications but has not accounted for the movement of transmission line conductors under their Rating and all Rated Electrical Operating Conditions, for the Transmission Owner's	The Transmission Owner does not have any maintenance strategies or documented procedures or processes or specifications used to prevent the encroachment of vegetation into the MVCD, for the Transmission Owner's applicable lines.

				applicable lines. (Requirement R3, Part 3.2)	applicable lines. Requirement R3, Part 3.1)	
R4	Real-time	Medium			The Transmission Owner experienced a confirmed vegetation threat and notified the control center holding switching authority for that applicable line, but there was intentional delay in that notification.	The Transmission Owner experienced a confirmed vegetation threat and did not notify the control center holding switching authority for that applicable line.
R5	Operations Planning	Medium				The Transmission Owner did not take corrective action when it was constrained from performing planned vegetation work where an applicable line was put at potential risk.
R6	Operations Planning	Medium	The Transmission Owner failed to inspect 5% or less of its applicable lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.)	The Transmission Owner failed to inspect more than 5% up to and including 10% of its applicable lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.).	The Transmission Owner failed to inspect more than 10% up to and including 15% of its applicable lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.).	The Transmission Owner failed to inspect more than 15% of its applicable lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.).
R7	Operations Planning	Medium	The Transmission Owner failed to complete 5% or less of its annual vegetation work plan for its applicable lines (as finally modified).	The Transmission Owner failed to complete more than 5% and up to and including 10% of its annual vegetation work plan for its applicable lines (as finally modified).	The Transmission Owner failed to complete more than 10% and up to and including 15% of its annual vegetation work plan for its applicable lines (as finally modified).	The Transmission Owner failed to complete more than 15% of its annual vegetation work plan for its applicable lines (as finally modified).

Guideline and Technical Basis (attached).

Guideline and Technical Basis

Effective dates:

The first two sentences of the Effective Dates section is standard language used in most NERC standards to cover the general effective date and is sufficient to cover the vast majority of situations. Five special cases are needed to cover effective dates for individual lines which undergo transitions after the general effective date. These special cases cover the effective dates for those lines which are initially becoming subject to the standard, those lines which are changing their applicability within the standard, and those lines which are changing in a manner that removes their applicability to the standard.

Case 1 is needed because the Planning Coordinators may designate lines below 200 kV to become elements of an IROL or Major WECC Transfer Path in a future Planning Year (PY). For example, studies by the Planning Coordinator in 2011 may identify a line to have that designation beginning in PY 2021, ten years after the planning study is performed. It is not intended for the Standard to be immediately applicable to, or in effect for, that line until that future PY begins. The effective date provision for such lines ensures that the line will become subject to the standard on January 1 of the PY specified with an allowance of at least 12 months for the Transmission Owner to make the necessary preparations to achieve compliance on that line. The table below has some explanatory examples of the application.

Date that Planning Study is completed	PY the line will become an IROL element	Date 1	Date 2	Effective Date The latter of Date 1 or Date 2
05/15/2011	2012	05/15/2012	01/01/2012	05/15/2012
05/15/2011	2013	05/15/2012	01/01/2013	01/01/2013
05/15/2011	2014	05/15/2012	01/01/2014	01/01/2014
05/15/2011	2021	05/15/2012	01/01/2021	01/01/2021

Case 2 is needed because a line operating below 200kV designated as an element of an IROL or Major WECC Transfer Path may be removed from that designation due to system improvements, changes in generation, changes in loads or changes in studies and analysis of the network.

Case 3 is needed because a line operating at 200 kV or above that once was designated as an element of an IROL or Major WECC Transfer Path may be removed from that designation due to system improvements, changes in generation, changes in loads or changes in studies and analysis of the network. Such changes result in the need to apply R1 to that line until that date is reached and then to apply R2 to that line thereafter.

Case 4 is needed because an existing line that is to be operated at 200 kV or above can be acquired by a Transmission Owner from a third party such as a Distribution Provider or other end-user who was using the line solely for local distribution purposes, but the Transmission Owner, upon acquisition, is incorporating the line into the interconnected electrical energy transmission network which will thereafter make the line subject to the standard.

Case 5 is needed because an existing line that is operated below 200 kV can be acquired by a Transmission Owner from a third party such as a Distribution Provider or other end-user who was using the line solely for local distribution purposes, but the Transmission owner, upon acquisition, is incorporating the line into the interconnected electrical energy transmission network. In this special case the line upon acquisition was designated as an element of an Interconnection Reliability Operating Limit (IROL) or an element of a Major WECC Transfer Path.

Defined Terms:

Explanation for revising the definition of ROW:
The current NERC glossary definition of Right of Way has been modified to address the matter set forth in Paragraph 734 of FERC Order 693. The Order pointed out that Transmission Owners may in some cases own more property or rights than are needed to reliably operate transmission lines. This modified definition represents a slight but significant departure from the strict legal definition of “right of way” in that this definition is based on engineering and construction considerations that establish the width of a corridor from a technical basis. The pre-2007 maintenance records are included in the revised definition to allow the use of such vegetation widths if there were no engineering or construction standards that referenced the width of right of way to be maintained for vegetation on a particular line but the evidence exists in maintenance records for a width that was in fact maintained prior to this standard becoming mandatory. Such widths may be the only information available for lines that had limited or no vegetation easement rights and were typically maintained primarily to ensure public safety. This standard does not require additional easement rights to be purchased to satisfy a minimum right of way width that did not exist prior to this standard becoming mandatory.

Explanation for revising the definition of Vegetation Inspections:
The current glossary definition of this NERC term is being modified to allow both maintenance inspections and vegetation inspections to be performed concurrently. This allows potential efficiencies, especially for those lines with minimal vegetation and/or slow vegetation growth rates.

Explanation of the definition of the MVCD:
The MVCD is a calculated minimum distance that is derived from the Gallet Equations. This is a method of calculating a flash over distance that has been used in the design of high voltage transmission lines. Keeping vegetation away from high voltage conductors by this distance will prevent voltage flash-over to the vegetation. See the explanatory text below for Requirement R3 and associated Figure 1. Table 2 below provides MVCD values for various voltages and altitudes. Details of the equations and an example calculation are provided in Appendix 1 of the Technical Reference Document.

Requirements R1 and R2:
R1 and R2 are performance-based requirements. The reliability objective or outcome to be achieved is the management of vegetation such that there are no vegetation encroachments within a minimum distance of transmission lines. Content-wise, R1 and R2 are the same requirements; however, they apply to different Facilities. Both R1 and R2 require each Transmission Owner to manage vegetation to prevent encroachment within the MVCD of transmission lines. R1 is applicable to lines that are identified as an element of an IROL or Major WECC Transfer Path. R2 is applicable to all other lines that are <u>not</u> elements of IROLs, and <u>not</u> elements of Major WECC Transfer Paths.

The separation of applicability (between R1 and R2) recognizes that inadequate vegetation management for an applicable line that is an element of an IROL or a Major WECC Transfer Path is a greater risk to the interconnected electric transmission system than applicable lines that are not elements of IROLs or Major WECC Transfer Paths. Applicable lines that are not elements of IROLs or Major WECC Transfer Paths do require effective vegetation management, but these lines are comparatively less operationally significant. As a reflection of this difference in risk impact, the Violation Risk Factors (VRFs) are assigned as High for R1 and Medium for R2.

Requirements R1 and R2 state that if inadequate vegetation management allows vegetation to encroach within the MVCD distance as shown in Table 2, it is a violation of the standard. Table 2 distances are the minimum clearances that will prevent spark-over based on the Gallet equations as described more fully in the Technical Reference document.

These requirements assume that transmission lines and their conductors are operating within their Rating. If a line conductor is intentionally or inadvertently operated beyond its Rating and Rated Electrical Operating Condition (potentially in violation of other standards), the occurrence of a clearance encroachment may occur solely due to that condition. For example, emergency actions taken by a Transmission Operator or Reliability Coordinator to protect an Interconnection may cause excessive sagging and an outage.

Another example would be ice loading beyond the line's Rating and Rated Electrical Operating Condition. Such vegetation-related encroachments and outages are not violations of this standard.

Evidence of failures to adequately manage vegetation include real-time observation of a vegetation encroachment into the MVCD (absent a Sustained Outage), or a vegetation-related encroachment resulting in a Sustained Outage due to a fall-in from inside the ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to the blowing together of the lines and vegetation located inside the ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to a grow-in. Faults which do not cause a Sustained outage and which are confirmed to have been caused by vegetation encroachment within the MVCD are considered the equivalent of a Real-time observation for violation severity levels.

With this approach, the VSLs for R1 and R2 are structured such that they directly correlate to the severity of a failure of a Transmission Owner to manage vegetation and to the corresponding performance level of the Transmission Owner's vegetation program's ability to meet the objective of "preventing the risk of those vegetation related outages that could lead to Cascading." Thus violation severity increases with a Transmission Owner's inability to meet this goal and its potential of leading to a Cascading event. The additional benefits of such a combination are that it simplifies the standard and clearly defines performance for compliance. A performance-based requirement of this nature will promote high quality, cost effective vegetation management programs that will deliver the overall end result of improved reliability to the system.

Multiple Sustained Outages on an individual line can be caused by the same vegetation. For example initial investigations and corrective actions may not identify and remove the actual outage cause then another outage occurs after the line is re-energized and previous high conductor temperatures return. Such events are considered to be a single vegetation-related Sustained Outage under the standard where the Sustained Outages occur within a 24 hour period.

The MVCD is a calculated minimum distance stated in feet (or meters) to prevent spark-over, for various altitudes and operating voltages that is used in the design of Transmission Facilities. Keeping vegetation from entering this space will prevent transmission outages.

If the Transmission Owner has applicable lines operated at nominal voltage levels not listed in Table 2, then the TO should use the next largest clearance distance based on the next highest nominal voltage in the table to determine an acceptable distance.

Requirement R3: R3 is a competency based requirement concerned with the maintenance strategies, procedures, processes, or specifications, a Transmission Owner uses for vegetation management.

An adequate transmission vegetation management program formally establishes the approach the Transmission Owner uses to plan and perform vegetation work to prevent transmission Sustained Outages and minimize risk to the transmission system. The approach provides the basis for evaluating the intent, allocation of appropriate resources, and the competency of the Transmission Owner in managing vegetation. There are many acceptable approaches to manage vegetation and avoid Sustained Outages. However, the Transmission Owner must be able to show the documentation of its approach and how it conducts work to maintain clearances.

An example of one approach commonly used by industry is ANSI Standard A300, part 7. However, regardless of the approach a utility uses to manage vegetation, any approach a Transmission Owner chooses to use will generally contain the following elements:

1. *the maintenance strategy used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that MVCD clearances are never violated.*
2. *the work methods that the Transmission Owner uses to control vegetation*
3. *a stated Vegetation Inspection frequency*
4. *an annual work plan*

The conductor's position in space at any point in time is continuously changing in reaction to a number of different loading variables. Changes in vertical and horizontal conductor positioning are the result of thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation. Physical loading applied to the conductor affects sag and sway by combining physical factors such as ice and wind loading. The movement of the transmission line conductor and the MVCD is illustrated in Figure 1 below. In the Technical Reference document more figures and explanations of conductor dynamics are provided.

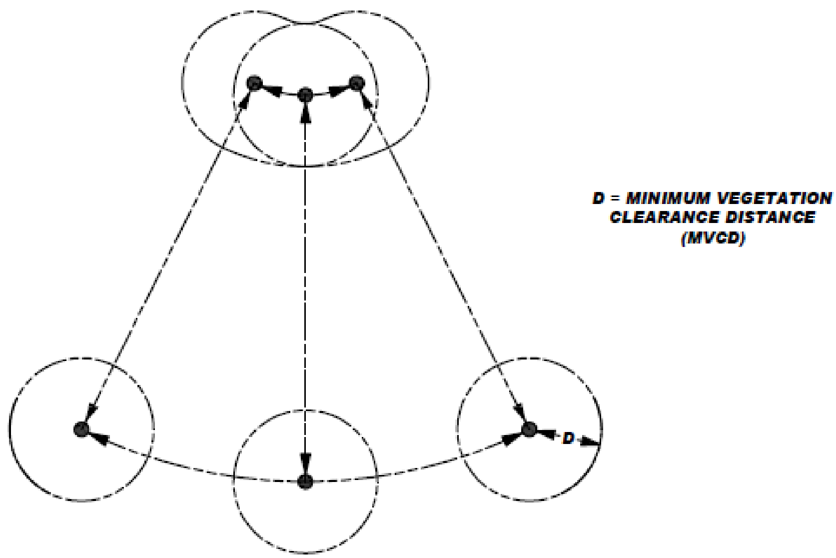

Figure 1

A cross-section view of a single conductor at a given point along the span is shown with six possible conductor positions due to movement resulting from thermal and mechanical loading.

Requirement R4:
R4 is a risk-based requirement. It focuses on preventative actions to be taken by the Transmission Owner for the mitigation of Fault risk when a vegetation threat is confirmed. R4 involves the notification of potentially threatening vegetation conditions, without any intentional delay, to the control center holding switching authority for that specific transmission line. Examples of acceptable unintentional delays may include communication system problems (for example, cellular service or two-way radio disabled), crews located in remote field locations with no communication access, delays due to severe weather, etc.

Confirmation is key that a threat actually exists due to vegetation. This confirmation could be in the form of a Transmission Owner's employee who personally identifies such a threat in the field. Confirmation could also be made by sending out an employee to evaluate a situation reported by a landowner.

Vegetation-related conditions that warrant a response include vegetation that is near or encroaching into the MVCD (a grow-in issue) or vegetation that could fall into the transmission conductor (a fall-in issue). A knowledgeable verification of the risk would include an assessment of the possible sag or movement of the conductor while operating between no-load conditions and its rating.

The Transmission Owner has the responsibility to ensure the proper communication between field personnel and the control center to allow the control center to take the appropriate action until or as the vegetation threat is relieved. Appropriate actions may include a temporary reduction in the line loading, switching the line out of service, or other preparatory actions in recognition of the increased risk of outage on that circuit. The notification of the threat should be communicated in terms of minutes or hours as opposed to a longer time frame for corrective action plans (see R5).

All potential grow-in or fall-in vegetation-related conditions will not necessarily cause a Fault at any moment. For example, some Transmission Owners may have a danger tree identification program that identifies trees for removal with the potential to fall near the line. These trees would not require notification to the control center unless they pose an immediate fall-in threat.

Requirement R5:
R5 is a risk-based requirement. It focuses upon preventative actions to be taken by the Transmission Owner for the mitigation of Sustained Outage risk when temporarily constrained from performing vegetation maintenance. The intent of this requirement is to deal with situations that prevent the Transmission Owner from performing planned vegetation management work and, as a result, have the potential to put the transmission line at risk. Constraints to performing vegetation maintenance work as planned could result from legal injunctions filed by property owners, the discovery of easement stipulations which limit the Transmission Owner's rights, or other circumstances.

This requirement is not intended to address situations where the transmission line is not at potential risk and the work event can be rescheduled or re-planned using an alternate work methodology. For example, a land owner may prevent the planned use of chemicals on non-threatening, low growth vegetation but agree to the use of mechanical clearing. In this case the Transmission Owner is not under any immediate time constraint for achieving the management objective, can easily reschedule work using an alternate approach, and therefore does not need to take interim corrective action.

However, in situations where transmission line reliability is potentially at risk due to a constraint, the Transmission Owner is required to take an interim corrective action to mitigate the potential risk to the transmission line. A wide range of actions can be taken to address various situations. General considerations include:

- Identifying locations where the Transmission Owner is constrained from performing planned vegetation maintenance work which potentially leaves the transmission line at risk.

- Developing the specific action to mitigate any potential risk associated with not performing the vegetation maintenance work as planned.
- Documenting and tracking the specific action taken for the location.
- In developing the specific action to mitigate the potential risk to the transmission line the Transmission Owner could consider location specific measures such as modifying the inspection and/or maintenance intervals. Where a legal constraint would not allow any vegetation work, the interim corrective action could include limiting the loading on the transmission line.
- The Transmission Owner should document and track the specific corrective action taken at each location. This location may be indicated as one span, one tree or a combination of spans on one property where the constraint is considered to be temporary.

Requirement R6:
R6 is a risk-based requirement. This requirement sets a minimum time period for completing Vegetation Inspections. The provision that Vegetation Inspections can be performed in conjunction with general line inspections facilitates a Transmission Owner's ability to meet this requirement. However, the Transmission Owner may determine that more frequent vegetation specific inspections are needed to maintain reliability levels, based on factors such as anticipated growth rates of the local vegetation, length of the local growing season, limited ROW width, and local rainfall. Therefore it is expected that some transmission lines may be designated with a higher frequency of inspections.

The VSLs for Requirement R6 have levels ranked by the failure to inspect a percentage of the applicable lines to be inspected. To calculate the appropriate VSL the Transmission Owner may choose units such as: circuit, pole line, line miles or kilometers, etc.

For example, when a Transmission Owner operates 2,000 miles of applicable transmission lines this Transmission Owner will be responsible for inspecting all the 2,000 miles of lines at least once during the calendar year. If one of the included lines was 100 miles long, and if it was not inspected during the year, then the amount failed to inspect would be 100/2000 = 0.05 or 5%. The "Low VSL" for R6 would apply in this example.

Requirement R7:
R7 is a risk-based requirement. The Transmission Owner is required to complete its an annual work plan for vegetation management to accomplish the purpose of this standard. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made and documented provided they do not put the transmission system at risk. The annual work plan requirement is not intended to necessarily require a “span-by-span”, or even a “line-by-line” detailed description of all work to be performed. It is only intended to require that the Transmission Owner provide evidence of annual planning and execution of a vegetation management maintenance approach which successfully prevents encroachment of vegetation into the MVCD.

For example, when a Transmission Owner identifies 1,000 miles of applicable transmission lines to be completed in the Transmission Owner’s annual plan, the Transmission Owner will be responsible completing those identified miles. If a Transmission Owner makes a modification to the annual plan that does not put the transmission system at risk of an encroachment the annual plan may be modified. If 100 miles of the annual plan is deferred until next year the calculation to determine what percentage was completed for the current year would be: 1000 – 100 (deferred miles) = 900 modified annual plan, or 900 / 900 = 100% completed annual miles. If a Transmission Owner only completed 875 of the total 1000 miles with no acceptable documentation for modification of the annual plan the calculation for failure to complete the annual plan would be: 1000 – 875 = 125 miles failed to complete then, 125 miles (not completed) / 1000 total annual plan miles = 12.5% failed to complete.

The ability to modify the work plan allows the Transmission Owner to change priorities or treatment methodologies during the year as conditions or situations dictate. For example recent line inspections may identify unanticipated high priority work, weather conditions (drought) could make herbicide application ineffective during the plan year, or a major storm could require redirecting local resources away from planned maintenance. This situation may also include complying with mutual assistance agreements by moving resources off the Transmission Owner’s system to work on another system. Any of these examples could result in acceptable deferrals or additions to the annual work plan provided that they do not put the transmission system at risk of a vegetation encroachment.

In general, the vegetation management maintenance approach should use the full extent of the Transmission Owner’s easement, fee simple and other legal rights allowed. A comprehensive approach that exercises the full extent of legal rights on the ROW is superior to incremental management because in the long term it reduces the overall potential for encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient.

When developing the annual work plan the Transmission Owner should allow time for procedural requirements to obtain permits to work on federal, state, provincial, public, tribal lands. In some cases the lead time for obtaining permits may necessitate preparing work plans more than a year prior to work start dates. Transmission Owners may also need to consider those special landowner requirements as documented in easement instruments.

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. Therefore, deferrals or relevant changes to the annual plan shall be documented. Depending on the planning and documentation format used by the Transmission Owner, evidence of successful annual work plan execution could consist of signed-off work orders, signed contracts, printouts from work management systems, spreadsheets of planned versus completed work, timesheets, work inspection reports, or paid invoices. Other evidence may include photographs, and walk-through reports.

FAC-003 — TABLE 2 — Minimum Vegetation Clearance Distances (MVCD)[7]

* Such lines are applicable to this standard only if PC has determined such per FAC-014 (refer to the Applicability Section above)

[7] The distances in this Table are the minimums required to prevent Flash-over; however prudent vegetation maintenance practices dictate that substantially greater distances will be achieved at time of vegetation maintenance.

[8] Where applicable lines are operated at nominal voltages other than those listed, The Transmission Owner should use the maximum system voltage to determine the appropriate clearance for that line.

TABLE 2 (CONT) — Minimum Vegetation Clearance Distances (MVCD)[7]

For **Alternating Current** Voltages (meters)

Notes:

The SDT determined that the use of IEEE 516-2003 in version 1 of FAC-003 was a misapplication. The SDT consulted specialists who advised that the Gallet Equation would be a technically justified method. The explanation of why the Gallet approach is more appropriate is explained in the paragraphs below.

The drafting team sought a method of establishing minimum clearance distances that uses realistic weather conditions and realistic maximum transient over-voltages factors for in-service transmission lines.

The SDT considered several factors when looking at changes to the minimum vegetation to conductor distances in FAC-003-1:

- avoid the problem associated with referring to tables in another standard (IEEE-516-2003)
- transmission lines operate in non-laboratory environments (wet conditions)
- transient over-voltage factors are lower for in-service transmission lines than for inadvertently re-energized transmission lines with trapped charges.

FAC-003-1 uses the minimum air insulation distance (MAID) without tools formula provided in IEEE 516-2003 to determine the minimum distance between a transmission line conductor and vegetation. The equations and methods provided in IEEE 516 were developed by an IEEE Task Force in 1968 from test data provided by thirteen independent laboratories. The distances provided in IEEE 516 Tables 5 and 7 are based on the withstand voltage of a dry rod-rod air gap, or in other words, dry laboratory conditions. Consequently, the validity of using these distances in an outside environment application has been questioned.

FAC-003-01 allowed Transmission Owners to use either Table 5 or Table 7 to establish the minimum clearance distances. Table 7 could be used if the Transmission Owner knew the maximum transient over-voltage factor for its system. Otherwise, Table 5 would have to be used. Table 5 represented minimum air insulation distances under the worst possible case for transient over-voltage factors. These worst case transient over-voltage factors were as follows: 3.5 for voltages up to 362 kV phase to phase; 3.0 for 500 - 550 kV phase to phase; and 2.5 for 765 to 800 kV phase to phase. These worst case over-voltage factors were also a cause for concern in this particular application of the distances.

In general, the worst case transient over-voltages occur on a transmission line that is inadvertently re-energized immediately after the line is de-energized and a trapped charge is still present. The intent of FAC-003 is to keep a transmission line that is *in service* from becoming de-energized (i.e. tripped out) due to spark-over from the line conductor to nearby vegetation. Thus, the worst case transient overvoltage assumptions are not appropriate for this application. Rather, the appropriate over voltage values are those that occur only while the line is energized.

Typical values of transient over-voltages of in-service lines, as such, are not readily available in the literature because they are negligible compared with the maximums. A conservative value for the maximum transient over-voltage that can occur anywhere along the length of an in-service ac line is approximately 2.0 per unit. This value is a conservative estimate of the transient over-voltage that is created at the point of application (e.g. a substation) by switching a capacitor bank without pre-insertion devices (e.g. closing resistors). At voltage levels where capacitor banks are not very common (e.g. Maximum System Voltage of 362 kV), the maximum transient over-voltage of an in-service ac line are created by fault initiation on adjacent ac lines and shunt reactor bank switching. These transient voltages are usually 1.5 per unit or less.

Even though these transient over-voltages will not be experienced at locations remote from the bus at which they are created, in order to be conservative, it is assumed that all nearby ac lines are subjected to this same level of over-voltage. Thus, a maximum transient over-voltage factor of 2.0 per unit for transmission lines operated at 302 kV and below is considered to be a realistic maximum in this application. Likewise, for ac transmission lines operated at Maximum System Voltages of 362 kV and above a transient over-voltage factor of 1.4 per unit is considered a realistic maximum.

The Gallet Equations are an accepted method for insulation coordination in tower design. These equations are used for computing the required strike distances for proper transmission line insulation coordination. They were developed for both wet and dry applications and can be used with any value of transient over-voltage factor. The Gallet Equation also can take into account various air gap geometries. This approach was used to design the first 500 kV and 765 kV lines in North America.

If one compares the MAID using the IEEE 516-2003 Table 7 (table D.5 for English values) with the critical spark-over distances computed using the Gallet wet equations, for each of the nominal voltage classes and identical transient over-voltage factors, the Gallet equations yield a more conservative (larger) minimum distance value.

Distances calculated from either the IEEE 516 (dry) formulas or the Gallet “wet” formulas are not vastly different when the same transient overvoltage factors are used; the “wet” equations will consistently produce slightly larger distances than the IEEE 516 equations when the same transient overvoltage is used. While the IEEE 516 equations were only developed for dry conditions the Gallet equations have provisions to calculate spark-over distances for both wet and dry conditions.

While EPRI is currently trying to establish empirical data for spark-over distances to live vegetation, there are no spark-over formulas currently derived expressly for vegetation to conductor minimum distances. Therefore the SDT chose a proven method that has been used in other EHV applications. The Gallet equations relevance to wet conditions and the selection of a Transient Overvoltage Factor that is consistent with the absence of trapped charges on an in-service transmission line make this methodology a better choice.
The following table is an example of the comparison of distances derived from IEEE 516 and the Gallet equations.

Comparison of spark-over distances computed using Gallet wet equations vs. IEEE 516-2003 MAID distances

(AC) Nom System Voltage (kV)	(AC) Max System Voltage (kV)	Transient Over-voltage Factor (T)	Clearance (ft.) Gallet (wet) @ Alt. 3000 feet	Table 7 (Table D.5 for feet) IEEE 516-2003 MAID (ft) @ Alt. 3000 feet

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard becomes effective.

Development Steps Completed

1. SC approved SAR for initial posting (January 11, 2007).
2. SAR posted for comment (January 15–February 14, 2007).
3. SAR posted for comment (April 10–May 9, 2007).
4. SC authorized moving the SAR forward to standard development (June 27, 2007).
5. First draft of proposed standard posted (October 27, 2008-November 25, 2008)).
6. Second draft of revised standard posted (September 10, 20-October 24, 2009).
7. Third draft of revised standard posted (March 1, 2010-March 31, 2010).
8. ~~Forth~~Fourth draft of revised standard posted (June 17, 2010-July 17, 2010).
9. Fifth draft of revised standard posted (February 18, 2011-February 28, 2011)
10. Sixth draft of revised standard posted (September xx - 2011)

Proposed Action Plan and Description of Current Draft

This is the ~~third~~fourth posting of the proposed revisions to the standard in accordance with Results-Based Criteria and the ~~fifth~~sixth draft overall.

Future Development Plan

Anticipated Actions	Anticipated Date
Recirculation ballot of standards.	~~January~~September 2011
Receive BOT approval	~~February~~November 2011

Effective Dates

~~First~~This standard becomes effective on the first calendar day of the first calendar quarter one year after the date of the order approving the standard from applicable regulatory authorities where such explicit approval is required. Where no regulatory approval is required, the standard becomes effective on the first calendar day of the first calendar quarter one year after Board of Trustees adoption.

~~Exceptions:~~Effective dates for individual lines when they undergo specific transition cases:

1. A line operated below 200kV, designated by the Planning Coordinator as an element of an Interconnection Reliability Operating Limit (IROL) or designated by the Western Electricity Coordinating Council (WECC) as an element of a Major WECC ~~transfer path~~Transfer Path, becomes subject to this standard the latter of: 1) 12 months after the date the Planning Coordinator or WECC initially designates the line as being ~~subject~~an element of an IROL or an element of a Major WECC Transfer Path, or 2) January 1 of the planning year when the line is forecast to ~~this standard.~~become an element of an IROL or an element of a Major WECC Transfer Path.

2. A line operated below 200 kV currently subject to this standard as a designated element of an IROL or a Major WECC Transfer Path which has a specified date for the removal of such designation will no longer be subject to this standard effective on that specified date.

3. A line operated at 200 kV or above, currently subject to this standard which is a designated element of an IROL or a Major WECC Transfer Path and which has a specified date for the removal of such designation will be subject to Requirement R2 and no longer be subject to Requirement R1 effective on that specified date.

4. An existing transmission line operated at 200kV or higher ~~that~~which is newly acquired by an asset owner and which was not previously subject to this standard~~,~~ becomes subject to this standard 12 months after the acquisition date~~ of the line.~~.

5. An existing transmission line operated below 200kV which is newly acquired by an asset owner and which was not previously subject to this standard becomes subject to this standard 12 months after the acquisition date of the line if at the time of acquisition the line is designated by the Planning Coordinator as an element of an IROL or by WECC as an element of a Major WECC Transfer Path.

Version History

Version	Date	Action	Change Tracking
1	TBA	1. Added “Standard Development Roadmap.” 2. Changed “60” to “Sixty” in section A, 5.2. 3. Added “Proposed Effective Date: April 7, 2006” to footer. 4. Added “Draft 3: November 17, 2005” to footer.	01/20/06
1	April 4, 2007	Regulatory Approval — Effective Date	New
2			

Definitions of Terms Used in Standard

This section includes all newly defined or revised terms used in the proposed standard. Terms already defined in the Reliability Standards Glossary of Terms are not repeated here. New or revised definitions listed below become approved when the proposed standard is approved. When the standard becomes effective, these defined terms will be removed from the individual standard and added to the Glossary. ~~*When this standard has received ballot approval, the text boxes will be moved to the Guideline and Technical Basis Section.*~~

Right-of-Way (ROW)

The corridor of land under a transmission line(s) needed to operate the line(s). The width of the corridor is established by engineering or construction standards as documented in either construction documents, pre-2007 vegetation maintenance records, or by the blowout standard in effect when the line was built. The ROW width in no case exceeds the Transmission Owner's legal rights but may be less based on the aforementioned criteria.

The current glossary definition of this NERC term is modified to address the issues set forth in Paragraph 734 of FERC Order 693.

Vegetation Inspection

The systematic examination of vegetation conditions on a Right-of-Way and those vegetation conditions under the Transmission Owner's control that are likely to pose a hazard to the line(s) prior to the next planned maintenance or inspection. This may be combined with a general line inspection.

~~The current glossary definition of this NERC term is modified to allow both maintenance inspections and vegetation inspections to be performed concurrently.~~

~~Current definition of Vegetation Inspection: The systematic examination of a transmission corridor to document vegetation conditions.~~

Minimum Vegetation Clearance Distance (MVCD)

The calculated minimum distance stated in feet (meters) to prevent flash-over between conductors and vegetation, for various altitudes and operating voltages.

When this standard has received ballot approval, the text boxes will be moved to the Guideline and Technical Basis Section.

A. Introduction

1. Title: Transmission Vegetation Management

2. Number: FAC-003-2

3. ~~Objectives~~Purpose: To maintain a reliable electric transmission system by using a defense-in-depth strategy to manage vegetation located on transmission rights of way (ROW) and minimize encroachments from vegetation located adjacent to the ROW, thus preventing the risk of those vegetation-related outages that could lead to Cascading.

4. Applicability

4.1. Functional Entities:

4.1.1 Transmission Owners

4.2. Facilities: Defined below (referred to as “applicable lines”), including but not limited to those that cross lands owned by federal[1], state, provincial, public, private, or tribal entities:

4.2.1. ~~Overhead~~Each overhead transmission ~~lines~~line operated at 200kV or higher.

4.2.2. ~~Overhead~~Each overhead transmission ~~lines~~line operated below 200kV ~~having been~~ identified as ~~included in the definition~~an element of an ~~Interconnection Reliability Operating Limit (~~IROL~~)~~ under NERC Standard FAC-014 by the Planning Coordinator.

4.2.3. ~~Overhead~~Each overhead transmission ~~lines~~line operated below 200 kV ~~having been~~ identified as ~~included in the definition~~an element of ~~one of the~~a Major WECC Transfer ~~*Paths*~~Path in the Bulk Electric System by WECC.

4.2.4. ~~This standard applies to~~Each overhead transmission ~~lines~~line

Rationale: The areas excluded in 4.2.4 were excluded based on comments from industry for reasons summarized as follows: 1) There is a very low risk from vegetation in this area. Based on an informal survey, no TOs reported such an event. 2) Substations, switchyards, and stations have many inspection and maintenance activities that are necessary for reliability. Those existing process manage the threat. As such, the formal steps in this standard are not well suited for this environment. 3) NERC has a

~~**Rationale**~~

~~The areas excluded in 4.2.4 were excluded based on comments from industry for reasons summarized as follows: 1) There is a very low risk from vegetation in this area. Based on an informal survey, no TOs reported such an event. 2) Substations, switchyards, and stations have many inspection and maintenance activities that are necessary for reliability. Those existing process manage the threat. As such, the formal steps in this standard are not well suited for this environment. 3) The standard was written for Transmission Owners. Rolling the excluded areas into this standard will bring GO and DP into the standard, even though NERC has an initiative in place to address this bigger registry issue. 4) Specifically addressing the areas where the standard applies or doesn’t makes the standard stronger as it relates to clarity.~~

[1] EPAct 2005 section 1211c: “*Access approvals by Federal agencies*~~”.~~.”

identified above (4.2.1 through 4.2.3) located outside the fenced area of the switchyard, station or substation and any portion of the span of the transmission line that is crossing the substation fence.

Enforcement: ~~*The reliability obligations of the applicable entities and facilities are contained within the technical requirements of this standard. [Straw proposal]*~~

~~**5. Background:**~~

~~This NERC Vegetation Management Standard ("Standard") uses a defense-in-depth approach to improve the reliability of the electric Transmission System by preventing those vegetation related outages that could lead to Cascading. This Standard is not intended to address non-preventable outages such as those due to vegetation fall-ins or blow-ins from outside the Right-of-Way, vandalism, human activities and acts of nature. Operating experience indicates that trees that have grown out of specification have contributed to Cascading, especially under heavy electrical loading conditions.~~

~~With a defense-in-depth strategy, this Standard utilizes~~The Requirements within a Reliability Standard govern and will be enforced. The Requirements within a Reliability Standard define what an entity must do to be compliant and binds an entity to certain obligations of performance under Section 215 of the Federal Power Act. Compliance will in all cases be measured by determining whether a party met or failed to meet the Reliability Standard Requirement given the specific facts and circumstances of its use, ownership or operation of the bulk power system.

Measures provide guidance on assessing non-compliance with the Requirements. Measures are the evidence that could be presented to demonstrate compliance with a Reliability Standard Requirement and are not intended to contain the quantitative metrics for determining satisfactory performance nor to limit how an entity may demonstrate compliance if valid alternatives to demonstrating compliance are available in a specific case. A Reliability Standard may be enforced in the absence of specified Measures.

Entities must comply with the "Compliance" section in its entirety, including the Administrative Procedure that sets forth, among other things, reporting requirements.

The "Guideline and Technical Basis" section, the Background section and text boxes with "Examples" and "Rationale" are provided for informational purposes. They are designed to convey guidance from NERC's various activities. The "Guideline and Technical Basis" section and text boxes with "Examples" and "Rationale" are not intended to establish new Requirements under NERC's Reliability Standards or to modify the Requirements in any existing NERC Reliability Standard. Implementation of the "Guideline and Technical Basis" section, the Background section and text boxes with "Examples" and "Rationale" is not a substitute for compliance with Requirements in NERC's Reliability Standards."

5. Background:

This standard uses three types of requirements to provide layers of protection to prevent vegetation related outages that could lead to Cascading:

a) Performance-based —— defines a particular reliability objective or outcome to be achieved. In its simplest form, a results-based requirement has four components: *who, under what conditions (if any), shall perform what action, to achieve what particular bulk power system performance result or outcome*?

b) Risk-based —— preventive requirements to reduce the risks of failure to acceptable tolerance levels. A risk-based reliability requirement should be framed as: *who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome that reduces a stated risk to the reliability of the bulk power system*?

c) Competency-based —— defines a minimum ~~capability~~set of capabilities an entity needs to have to demonstrate it is able to perform its designated reliability functions. A competency-based reliability requirement should be framed as: *who, under what conditions (if any), shall have what capability, to achieve what particular result or outcome to perform an action to achieve a result or outcome or to reduce a risk to the reliability of the bulk power system*?

The defense-in-depth strategy for reliability standards development recognizes that each requirement in a NERC reliability standard has a role in preventing system failures, and that these roles are complementary and reinforcing. Reliability standards should not be viewed as a body of unrelated requirements, but rather should be viewed as part of a portfolio of requirements designed to achieve an overall defense-in-depth strategy and comport with the quality objectives of a reliability standard. ~~For this Standard, the requirements have been developed as follows:~~

~~•~~ This standard uses a defense-in-depth approach to improve the reliability of the electric Transmission system by:

- Requiring that vegetation be managed to prevent vegetation encroachment inside the flash-over clearance (R1 and R2);
- Requiring documentation of the maintenance strategies, procedures, processes and specifications used to manage vegetation to prevent potential flash-over conditions including consideration of 1) conductor dynamics and 2) the interrelationships between vegetation growth rates, control methods and the inspection frequency (R3);
- Requiring timely notification to the appropriate control center of vegetation conditions that could cause a flash-over at any moment (R4);
- Requiring corrective actions to ensure that flash-over distances will not be violated due to work constrains such as legal injunctions (R5);
- Requiring inspections of vegetation conditions to be performed annually (R6); and
- Requiring that the annual work needed to prevent flash-over is completed (R7).

For this standard, the requirements have been developed as follows:

- Performance-based: Requirements 1 and 2
- ~~•~~ Competency-based: Requirement 3
- ~~•~~ Risk-based: Requirements 4, 5, 6 and 7

~~Thus the various requirements associated with a successful vegetation program could be viewed as using R1, R2 and R3 as first levels of defense; while R4 could be a subsequent or final level of defense. R6 depending on the particular vegetation approach may be either an initial defense barrier or a final defense barrier.~~ R3 serves as the first line of defense by ensuring that entities understand the problem they are trying to manage and have fully developed strategies and plans to manage the problem. R1, R2, and R7 serve as the second line of defense by requiring that entities carry out their plans and manage vegetation. R6, which requires inspections, may be either a part of the first line of defense (as input into the strategies and plans) or as a third line of defense (as a check of the first and second lines of defense). R4 serves as the final line of defense, as it addresses cases in which all the other lines of defense have failed.

Major outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations. Adherence to the ~~Standard~~standard requirements for applicable lines on any kind of land or easement, whether they are Federal Lands, state or provincial lands, public or private lands, franchises, easements or lands owned in fee, will reduce and manage this risk. For the purpose of the ~~Standard~~standard the term "public lands" includes municipal lands, village lands, city lands, and a host of other governmental entities.

This ~~Standard~~standard addresses vegetation management along applicable overhead lines and does not apply to underground lines, submarine lines or to line sections inside an electric station boundary.

This ~~Standard~~standard focuses on transmission lines to prevent those vegetation related outages that could lead to Cascading. It is not intended to prevent customer outages due to tree contact with lower voltage distribution system lines. For example, localized customer service might be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. However, this ~~Standard~~standard is not written to address such isolated situations which have little impact on the overall electric transmission system.

Since vegetation growth is constant and always present, unmanaged vegetation poses an increased outage risk, especially when numerous transmission lines are operating at or near their Rating. This can present a significant risk of ~~multiple~~consecutive line failures ~~and~~when lines are experiencing large sags thereby leading to Cascading. Once the first line fails the shift of the current to the other lines and/or the increasing system loads will lead to the second and subsequent line failures as contact to the vegetation under those lines occurs. Conversely, most other outage causes (such as trees falling into lines, lightning, animals, motor vehicles, etc.) ~~are statistically intermittent.~~ are not an interrelated function of the shift of currents or the increasing system loading. These events are not any more likely to occur during heavy system loads than any other time. There is no cause-effect relationship which creates the probability of simultaneous occurrence of other such events. Therefore these types of events are highly unlikely to cause large-scale grid failures. Thus, this ~~Standard's emphasis is~~standard places the highest priority on the management of vegetation to prevent vegetation grow-ins.

B. Requirements and Measures

R1. Each Transmission Owner shall manage vegetation to prevent encroachments ~~of the types shown below,~~ into the ~~Minimum Vegetation Clearance Distance (~~MVCD~~) of any~~ of its applicable line(s) ~~identified as~~which are either an element of an ~~Interconnection Reliability Operating Limit (~~IROL~~) in the planning horizon by the Planning Coordinator;~~, or an element of a Major ~~Western Electricity Coordinating Council (~~WECC~~) transfer path(s);~~ Transfer Path; operating within its Rating and all Rated Electrical Operating Conditions~~.~~ ~~[2]~~ of the types shown below[3] [*Violation Risk Factor: High*] [*Time Horizon: Real-time*]:

1. An encroachment into the MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage[4],
2. An encroachment due to a fall-in from inside the ~~Right-of-Way (~~ROW~~)~~ that caused a vegetation-related Sustained Outage[5],
3. An encroachment due to the blowing together of applicable

Rationale for R1 and R2:

~~**Rationale**~~

~~The MVCD is a calculated minimum distance stated in feet (meters) to prevent flash-over between conductors and vegetation, for various altitudes and operating voltages. The distances in Table 2 were derived using a proven transmission design method. The types of failure to manage vegetation are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a TO's vegetation maintenance program since the encroachments listed require different and increasing levels of skills and knowledge and thus constitute a logical progression of how well, or poorly, a TO manages vegetation relative to this Requirement.~~

3. This management failure occurs when side growth is not adequately addressed and may be indicative of an unsound program.

4. This management failure is usually indicative of a program that is not addressing the most fundamental dynamic of vegetation management, (i.e. a grow-in under the line). If this type of failure is pervasive on multiple lines, it provides a mechanism for a Cascade.

~~[2] This requirement does not apply to circumstances that are b[...] this reliability standard, including natural disasters such as ea[...] shear, fresh gale, major storms as defined either by the Trans[...] storms, and floods; human or animal activity such as logging, [...] arboricultural activities or horticultural or agricultural activities, or removal or digging of vegetation. Nothing in this footnote should be construed to limit the Transmission Owner's right to exercise its full legal rights on the ROW.~~

[3] This requirement does not apply to circumstances that are beyond the control of a Transmission Owner subject to this reliability standard, including natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods; human or animal activity such as logging, animal severing tree, vehicle contact with tree, or installation, removal, or digging of vegetation. Nothing in this footnote should be construed to limit the Transmission Owner's right to exercise its full legal rights on the ROW.

[4] If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation.

[5] Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period.

lines and vegetation located inside the ROW that caused a vegetation-related Sustained ~~Outage~~Outage[4],

4. An encroachment due to ~~a grow-in~~vegetation growth into the MVCD that caused a vegetation-related Sustained ~~Outage.~~ Outage[4].

~~[VRF – High] [Time Horizon – Real-time]~~

M1. Each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R1. Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-time observations of any MVCD encroachments. (R1)

~~If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation.~~

~~Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period. (R1)~~

R2. Each Transmission Owner shall manage vegetation to prevent encroachments ~~of the types shown below,~~ into the MVCD of ~~any of~~ its applicable line(s) ~~that is~~which are not either an element of an IROL~~;~~, or an element of a Major WECC ~~transfer path~~Transfer Path; operating within its Rating and all Rated Electrical Operating Conditions~~.~~[2] of the types shown below[2] [*Violation Risk Factor: Medium*] [*Time Horizon: Real-time*]:

1. An encroachment into the MVCD as shown in FAC-003-Table 2 ~~as shown in FAC-003-Table 2~~, observed in Real-time, absent a Sustained ~~Outage~~Outage[3],
2. An encroachment due to a fall-in from inside the ROW that caused a vegetation-related Sustained ~~Outage~~Outage[4],
3. An encroachment due to blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained ~~Outage~~Outage[4],
4. An encroachment due to ~~a grow-in~~vegetation growth into the MVCD that caused a vegetation-related Sustained ~~Outage.~~Outage[4]

~~**Rationale**~~

~~The MVCD is a calculated minimum distance stated in feet (meters) to prevent flash-over between conductors and vegetation, for various altitudes and operating voltages. The distances in Table 2 were derived using a proven transmission design method. The types of failure to manage vegetation are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a TO's vegetation maintenance program since the encroachments listed require different and increasing levels of skills and knowledge and thus constitute a logical progression of how well, or poorly, a TO manages vegetation relative to this Requirement.~~

~~*[VRF – Medium] [Time Horizon – Real-time]*~~

M2. Each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R2. Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-time observations of any MVCD encroachments. (R2)

~~If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation.~~

~~Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period. (R2)~~

R3. Each Transmission Owner shall have documented maintenance strategies or procedures or processes or specifications it uses to prevent the encroachment of vegetation into the MVCD of its applicable ~~transmission~~ lines that ~~include(s)~~accounts for the following:

3.1 ~~Accounts for the movement~~Movement of applicable ~~transmission~~ line conductors under their ~~Facility~~ Rating and all Rated Electrical Operating Conditions;

3.2 ~~Accounts for the inter~~Inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency.

~~*[VRF —*~~*[Violation Risk Factor:* *Lower*] [*Time Horizon*~~—~~*:* *Long Term Planning*~~]~~*]:*

Rationale

The documentation provides a basis for evaluating the competency of the Transmission Owner's vegetation program. There may be many acceptable approaches to maintain clearances. Any approach must demonstrate that the Transmission Owner avoids vegetation-to-wire conflicts under all Ratings and all Rated Electrical Operating Conditions. See Figure 1 for an illustration of possible conductor locations.

M3. The maintenance strategies or procedures or processes or specifications provided demonstrate that the Transmission Owner can prevent encroachment into the MVCD considering the factors identified in the requirement. (R3)

R4. Each Transmission Owner, without any intentional time delay, shall notify the control center holding switching authority for the associated applicable ~~transmission~~ line when the Transmission Owner has confirmed the existence of a vegetation condition that is likely to cause a Fault at any moment~~.~~ *[Violation Risk Factor: Medium*] [*Time Horizon: Real-time*].

Rationale

~~To~~This is to ensure expeditious communication between the Transmission Owner and the control center when a critical situation is confirmed.

~~*[VRF — Medium] [Time Horizon — Real-time]*~~

M4. Each Transmission Owner that has a confirmed vegetation condition likely to cause a Fault at any moment will have evidence that it notified the control center holding switching authority for the associated transmission line without any intentional time delay. Examples of evidence may include control center logs, voice recordings, switching orders, clearance orders and subsequent work orders. (R4)

R5. When a Transmission Owner is constrained from performing vegetation work on an applicable line operating within its Rating and all Rated Electrical Operating Conditions, and the constraint may lead to a vegetation encroachment into the MVCD ~~of its applicable transmission lines~~ prior to the implementation of the next annual work plan, then the Transmission Owner shall take corrective action to ensure continued vegetation management to prevent encroachments~~.~~ [*Violation Risk Factor: Medium*] [*Time Horizon: Operations Planning*].

Rationale

Legal actions and other events may occur which result in constraints that prevent the Transmission Owner from performing planned vegetation maintenance work.

In cases where the transmission line is put at potential risk due to constraints, the intent is for the Transmission Owner to put interim measures in place, rather than do nothing.

The corrective action process is not intended to address situations where a planned work methodology cannot be performed but an alternate work methodology can be used.

~~*[VRF – Medium] [Time Horizon – Operations Planning]*~~

M5. Each Transmission Owner has evidence of the corrective action taken for each constraint where an applicable transmission line was put at potential risk. Examples of acceptable forms of evidence may include initially-planned work orders, documentation of constraints from landowners, court orders, inspection records of increased monitoring, documentation of the de-rating of lines, revised work orders, invoices, ~~and~~or evidence that ~~a~~the line was de-energized. (R5)

R6. Each Transmission Owner shall perform a Vegetation Inspection of 100% of its applicable transmission lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.) at least once per calendar year and with no more than 18 calendar months between inspections on the same ROW~~.~~[~~6~~7] [*Violation Risk Factor:*

~~**Rationale**~~

~~Inspections are used by Transmission Owners to assess the condition of the entire ROW. The information from the assessment can be used to determine risk, determine future work and evaluate recently-completed work. This requirement sets a minimum Vegetation Inspection frequency of once per calendar year but with no more than 18 months between inspections on the same ROW. Based upon average growth rates across North America and on common utility practice, this minimum frequency is reasonable. Transmission Owners should consider local and environmental factors that could warrant more frequent inspections.~~

~~[6] When the Transmission Owner is prevented from performing a V~~
~~due to a natural disaster, the TO is granted a time extension that i~~
~~prevented from performing the Vegetation Inspection.~~

Medium] [*Time Horizon: Operations Planning*].

~~*[VRF – Medium] [Time Horizon – Operations Planning]*~~

M6. Each Transmission Owner has evidence that it conducted Vegetation Inspections of the transmission line ROW for all applicable ~~transmission~~ lines at least once per calendar year but with no more than 18 calendar months between inspections on the same ROW. Examples of acceptable forms of evidence may include completed and dated work orders, dated invoices, or dated inspection records. (R6)

R7. Each Transmission Owner shall complete 100% of its annual vegetation work plan of applicable lines to ensure no vegetation encroachments occur within the MVCD. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made (provided they do not ~~put the transmission system at risk~~allow encroachment of ~~a~~ vegetation ~~encroachment~~into the MVCD) and must be documented. The percent completed calculation is based on the number of units actually completed divided by the number of units in the final amended plan (measured in units of choice - circuit, pole line, line miles or kilometers, etc.) Examples of reasons for modification to annual plan may include~~:~~ [*Violation Risk Factor: Medium*] [*Time Horizon: Operations Planning*]:

- Change in expected growth rate/ environmental factors
- Circumstances that are beyond the control of a Transmission Owner[8]
- Rescheduling work between growing seasons
- Crew or contractor availability/ Mutual assistance agreements
- Identified unanticipated high priority work
- Weather conditions/Accessibility
- Permitting delays
- Land ownership changes/Change in land use by the landowner
- Emerging technologies

~~**Rationale**~~

~~This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. An annual vegetation work plan allows for work to be modified for changing conditions, taking into consideration anticipated growth of vegetation and all other environmental factors, provided that the changes do not violate the encroachment within the MVCD.~~

factors, provided that those modifications do not put the transmission system at risk of a vegetation encroachment.

[7] When the Transmission Owner is prevented from performing a Vegetation Inspection within the timeframe in R6 due to a natural disaster, the TO is granted a time extension that is equivalent to the duration of the time the TO was prevented from performing the Vegetation Inspection.

[8] Circumstances that are beyond the control of a Transmission Owner include but are not limited to natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, ice storms, floods, or major storms as defined either by the TO or an applicable regulatory body~~, ice storms, and floods; arboricultural, horticultural or agricultural activities~~.

~~*[VRF – Medium] [Time Horizon – Operations Planning]*~~

M7. Each Transmission Owner has evidence that it completed its annual vegetation work plan~~.~~ for its applicable lines. Examples of acceptable forms of evidence may include a copy of the completed annual work plan (~~including modifications if any~~as finally modified), dated work orders, dated invoices, or dated inspection records. (R7)

C. Compliance

1. Compliance Monitoring Process

1.1 Compliance Enforcement Authority

1.2 Regional Entity Evidence Retention

~~**Compliance Monitoring and Enforcement Processes:**~~

- ~~Compliance Audits~~
- ~~Self-Certifications~~
- ~~Spot Checking~~
- ~~Compliance Violation Investigations~~
- ~~Self-Reporting~~
- ~~Complaints~~
- ~~Periodic Data Submittals~~

~~**Evidence Retention**~~

The following evidence retention periods identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full time period since the last audit.

The Transmission Owner retains data or evidence to show compliance with Requirements R1, R2, R3, R5, R6 and R7, Measures M1, M2, M3, M5, M6 and M7 for three calendar years unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

The Transmission Owner retains data or evidence to show compliance with Requirement R4, Measure M4 for most recent 12 months of operator logs or most recent 3 months of voice recordings or transcripts of voice recordings, unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

If a Transmission Owner is found non-compliant, it shall keep information related to the non-compliance until found compliant or for the time period specified above, whichever is longer.

The Compliance Enforcement Authority shall keep the last audit records and all requested and submitted subsequent audit records.

1.3 Compliance Monitoring and Enforcement Processes:

Compliance Audit

Self-Certification

Spot Checking

Compliance Violation Investigation

Self-Reporting

Complaint

Periodic Data Submittal

~~1.3~~1.4 Additional Compliance Information

Periodic Data Submittal: The Transmission Owner will submit a quarterly report to its Regional Entity, or the Regional Entity's designee, identifying all Sustained Outages of applicable ~~transmission lines~~lines operated within their Rating and all Rated Electrical Operating Conditions as determined by the Transmission Owner to have been caused by vegetation, except as excluded in footnote 2, ~~which includes~~and including as a minimum~~,~~ the following:

- The name of the circuit(s), the date, time and duration of the outage; the voltage of the circuit; a description of the cause of the outage; the category associated with the Sustained Outage; other pertinent comments; and any countermeasures taken by the Transmission Owner.

A Sustained Outage is to be categorized as one of the following:

- Category 1A — Grow-ins: Sustained Outages caused by vegetation growing into applicable ~~transmission~~ lines, that are identified as an element of an IROL or Major WECC Transfer Path, by vegetation inside and/or outside of the ROW;
- Category 1B — Grow-ins: Sustained Outages caused by vegetation growing into applicable ~~transmission~~ lines, but are not identified as an element of an IROL or Major WECC Transfer Path, by vegetation inside and/or outside of the ROW;
- Category 2A — Fall-ins: Sustained Outages caused by vegetation falling into applicable ~~transmission~~ lines that are identified as an element of an IROL or Major WECC Transfer Path, from within the ROW;
- Category 2B — Fall-ins: Sustained Outages caused by vegetation falling into applicable ~~transmission~~ lines, but are not identified as an element of an IROL or Major WECC Transfer Path, from within the ROW;
- Category 3 — Fall-ins: Sustained Outages caused by vegetation falling into applicable ~~transmission~~ lines from outside the ROW;
- Category 4A — Blowing together: Sustained Outages caused by vegetation and applicable ~~transmission~~ lines that are identified as an element of an IROL or Major WECC Transfer Path, blowing together from within the ROW.

- Category 4B — Blowing together: Sustained Outages caused by vegetation and applicable ~~transmission~~ lines, but are not identified as an element of an IROL or Major WECC Transfer Path, blowing together from within the ROW.

The Regional Entity will report the outage information provided by Transmission Owners, as per the above, quarterly to NERC, as well as any actions taken by the Regional Entity as a result of any of the reported Sustained Outages.

~~Time Horizons, Violation Risk Factors, and Violation Severity Levels~~

~~Table 1~~

Table of Compliance Elements

R#	Time Horizon	VRF	Violation Severity Level			
			Lower	Moderate	High	Severe
R1	Real-time	High	~~The~~The Transmission Owner failed to manage vegetation in a manner such that the Transmission Owner had an encroachment into the MVCD observed in Real-time, absent a Sustained Outage.	~~The~~The Transmission Owner failed to manage vegetation in a manner such that the Transmission Owner had an encroachment into the MVCD due to a fall-in from inside the ROW that caused a vegetation-related Sustained Outage.	~~The~~The Transmission Owner failed to manage vegetation in a manner such that the Transmission Owner had an encroachment into the MVCD due to blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained Outage.	~~The~~The Transmission Owner failed to manage vegetation in a manner such that the Transmission Owner had an encroachment into the MVCD due to a grow-in that caused a vegetation-related Sustained Outage.
R2	Real-time	Medium	~~The~~The Transmission Owner failed to manage vegetation in a manner such that the Transmission Owner had an encroachment into the MVCD observed in Real-time, absent a Sustained Outage.	~~The~~The Transmission Owner failed to manage vegetation in a manner such that the Transmission Owner had an encroachment into the MVCD due to a fall-in from inside the ROW that caused a vegetation-related Sustained Outage.	~~The~~The Transmission Owner failed to manage vegetation in a manner such that the Transmission Owner had an encroachment into the MVCD due to blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained Outage.	~~The~~The Transmission Owner failed to manage vegetation in a manner such that the Transmission Owner had an encroachment into the MVCD due to a grow-in that caused a vegetation-related Sustained Outage.

F. Associated Documents

Guideline and Technical Basis (attached).

Guideline and Technical Basis

Effective dates:

The first two sentences of the Effective Dates section is standard language used in most NERC standards to cover the general effective date and is sufficient to cover the vast majority of situations. Five special cases are needed to cover effective dates for individual lines which undergo transitions after the general effective date. These special cases cover the effective dates for those lines which are initially becoming subject to the standard, those lines which are changing their applicability within the standard, and those lines which are changing in a manner that removes their applicability to the standard.

Case 1 is needed because the Planning Coordinators may designate lines below 200 kV to become elements of an IROL or Major WECC Transfer Path in a future Planning Year (PY). For example, studies by the Planning Coordinator in 2011 may identify a line to have that designation beginning in PY 2021, ten years after the planning study is performed. It is not intended for the Standard to be immediately applicable to, or in effect for, that line until that future PY begins. The effective date provision for such lines ensures that the line will become subject to the standard on January 1 of the PY specified with an allowance of at least 12 months for the Transmission Owner to make the necessary preparations to achieve compliance on that line. The table below has some explanatory examples of the application.

Date that Planning Study is completed	PY the line will become an IROL element	Date 1	Date 2	Effective Date The latter of Date 1 or Date 2
05/15/2011	2012	05/15/2012	01/01/2012	05/15/2012
05/15/2011	2013	05/15/2012	01/01/2013	01/01/2013
05/15/2011	2014	05/15/2012	01/01/2014	01/01/2014
05/15/2011	2021	05/15/2012	01/01/2021	01/01/2021

Case 2 is needed because a line operating below 200kV designated as an element of an IROL or Major WECC Transfer Path may be removed from that designation due to system improvements, changes in generation, changes in loads or changes in studies and analysis of the network.

Case 3 is needed because a line operating at 200 kV or above that once was designated as an element of an IROL or Major WECC Transfer Path may be removed from that designation due to system improvements, changes in generation, changes in loads or changes in studies and analysis of the network. Such changes result in the need to apply R1 to that line until that date is reached and then to apply R2 to that line thereafter.

Case 4 is needed because an existing line that is to be operated at 200 kV or above can be acquired by a Transmission Owner from a third party such as a Distribution Provider or other end-user who was using the line solely for local distribution purposes, but the Transmission Owner, upon acquisition, is incorporating the line into the interconnected electrical energy transmission network which will thereafter make the line subject to the standard.

Case 5 is needed because an existing line that is operated below 200 kV can be acquired by a Transmission Owner from a third party such as a Distribution Provider or other end-user who was using the line solely for local distribution purposes, but the Transmission owner, upon acquisition, is incorporating the line into the interconnected electrical energy transmission network. In this special case the line upon acquisition was designated as an element of an Interconnection Reliability Operating Limit (IROL) or an element of a Major WECC Transfer Path.

Defined Terms:

Explanation for revising the definition of ROW:

The current NERC glossary definition of Right of Way has been modified to address the matter set forth in Paragraph 734 of FERC Order 693. The Order pointed out that Transmission Owners may in some cases own more property or rights than are needed to reliably operate transmission lines. This modified definition represents a slight but significant departure from the strict legal definition of "right of way" in that this definition is based on engineering and construction considerations that establish the width of a corridor from a technical basis. The pre-2007 maintenance records are included in the revised definition to allow the use of such vegetation widths if there were no engineering or construction standards that referenced the width of right of way to be maintained for vegetation on a particular line but the evidence exists in maintenance records for a width that was in fact maintained prior to this standard becoming mandatory. Such widths may be the only information available for lines that had limited or no vegetation easement rights and were typically maintained primarily to ensure public safety. This standard does not require additional easement rights to be purchased to satisfy a minimum right of way width that did not exist prior to this standard becoming mandatory.

Explanation for revising the definition of Vegetation Inspections:

The current glossary definition of this NERC term is being modified to allow both maintenance inspections and vegetation inspections to be performed concurrently. This allows potential efficiencies, especially for those lines with minimal vegetation and/or slow vegetation growth rates.

Explanation of the definition of the MVCD:

The MVCD is a calculated minimum distance that is derived from the Gallet Equations. This is a method of calculating a flash over distance that has been used in the design of high voltage transmission lines. Keeping vegetation away from high voltage conductors by this distance will prevent voltage flash-over to the vegetation. See the explanatory text below for Requirement R3 and associated Figure 1. Table 2 below provides MVCD values for various voltages and altitudes. Details of the equations and an example calculation are provided in Appendix 1 of the Technical Reference Document.

Requirements R1 and R2:

R1 and R2 are performance-based requirements. The reliability objective or outcome to be achieved is the ~~prevention of~~management of vegetation such that there are no vegetation encroachments within a minimum distance of transmission lines. Content-wise, R1 and R2 are the same requirements; however, they apply to different Facilities. Both R1 and R2 require each Transmission Owner to manage vegetation to prevent encroachment within the ~~Minimum Vegetation Clearance Distance (“~~MVCD~~”)~~ of transmission lines. R1 is applicable to lines “that are identified as an element of an ~~Interconnection Reliability Operating Limit (IROL) or Major Western Electricity Coordinating Council (WECC) transfer path (operating within Rating and Rated Electrical Operating Conditions) to avoid a Sustained Outage”. R2 applies~~IROL or Major WECC Transfer Path. R2 is applicable to all other ~~applicable~~ lines that are not ~~an element~~elements of ~~an IROL or~~IROLs, and not elements of Major WECC Transfer ~~Path~~Paths.

The separation of applicability (between R1 and R2) recognizes that inadequate vegetation management for an ~~encroachment into the MVCD~~applicable line that is an element of an IROL or a Major WECC Transfer Path ~~transmission line~~ is a greater risk to the interconnected electric transmission system~~.~~ than applicable lines that are not elements of IROLs or Major WECC Transfer Paths. Applicable lines that are not ~~an element~~elements of ~~an IROL~~IROLs or Major WECC Transfer ~~Path are required to be clear of~~Paths do require effective vegetation management, but these lines are comparatively less operationally significant. As a reflection of this difference in risk impact, the Violation Risk Factors (VRFs) are assigned as High for R1 and Medium for R2.

~~These requirements (~~Requirements R1 and R2~~)~~ state that if inadequate vegetation ~~encroaches~~management allows vegetation to encroach within the ~~distances~~ MVCD distance as shown in Table ~~1 in Appendix 1 of this supplemental Transmission Vegetation Management Standard FAC-003~~ 2 ~~Technical Reference document~~, it is ~~in~~a violation of the standard. Table 2 ~~tabulates~~distances are the

~~distances necessary to~~minimum clearances that will prevent spark-over based on the Gallet equations as described more fully in ~~Appendix 1 below.~~ the Technical Reference document.

These requirements assume that transmission lines and their conductors are operating within their Rating. If a line conductor is intentionally or inadvertently operated beyond its Rating and Rated Electrical Operating Condition (potentially in violation of other standards), the occurrence of a clearance encroachment may occur~~.~~ solely due to that condition. For example, emergency actions taken by a Transmission Operator or Reliability Coordinator to protect an Interconnection may cause ~~the transmission line to sag more~~excessive sagging and ~~come closer to vegetation, potentially causing~~ an outage. Another example would be ice loading beyond the line's Rating and Rated Electrical Operating Condition. Such vegetation-related encroachments and outages are not ~~a violation~~violations of ~~these requirements~~this standard.

Evidence of ~~violation of Requirement R1 and R2~~failures to adequately manage vegetation include real-time observation of a vegetation encroachment into the MVCD (absent a Sustained Outage), or a vegetation-related encroachment resulting in a Sustained Outage due to a fall-in from inside the ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to the blowing together of ~~applicable~~the lines and vegetation located inside the ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to a grow-in. ~~If an investigation of~~ Faults which do not cause a ~~Fault by a Transmission Owner confirms that a~~Sustained outage and which are confirmed to have been caused by vegetation encroachment within the MVCD ~~occurred, then it shall be~~are considered the equivalent of a Real-time observation for violation severity levels.

With this approach, the VSLs ~~were defined~~for R1 and R2 are structured such that they directly correlate to the severity of a failure of a Transmission Owner to manage vegetation and to the corresponding performance level of the Transmission Owner's vegetation program's ability to meet the ~~goal~~objective of "preventing ~~a Sustained Outage~~the risk of those vegetation related outages that could lead to Cascading." Thus violation severity increases with a Transmission Owner's inability to meet this goal and its potential of leading to a Cascading event. The additional benefits of such a combination are that it simplifies the standard and clearly defines performance for compliance. A performance-based requirement of this nature will promote high quality, cost effective vegetation management programs that will deliver the overall end result of improved reliability to the system.

Multiple Sustained Outages on an individual line can be caused by the same vegetation. For example~~, a limb~~ initial investigations and corrective actions may ~~only partially break and intermittently contact a~~not identify and remove the actual outage cause then another outage occurs after the line is re-energized and previous high conductor~~.~~ temperatures return. Such events are considered to be a single vegetation-related Sustained Outage under the ~~Standard~~standard where the Sustained Outages occur within a 24 hour period.

The MVCD is a calculated minimum distance stated in feet (or meters) to prevent spark-over, for various altitudes and operating voltages that is used in the design of Transmission Facilities. Keeping vegetation from entering this space will prevent transmission outages.

If the Transmission Owner has applicable lines operated at nominal voltage levels not listed in Table 2, then the TO should use the next largest clearance distance based on the next highest nominal voltage in the table to determine an acceptable distance.

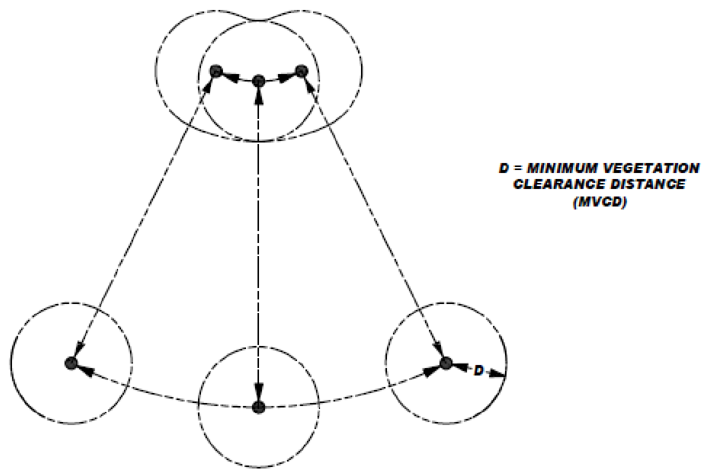
Requirement R3:
~~Requirement~~ R3 is a competency based requirement concerned with the maintenance strategies, procedures, processes, or specifications, a Transmission Owner uses for vegetation management.

An adequate transmission vegetation management program formally establishes the approach the Transmission Owner uses to plan and perform vegetation work to prevent transmission Sustained Outages and minimize risk to the ~~Transmission System.~~transmission system. The approach provides the basis for evaluating the intent, allocation of appropriate resources, and the competency of the Transmission Owner in managing vegetation. There are many acceptable approaches to manage vegetation and avoid Sustained Outages. However, the Transmission Owner must be able to ~~state what~~show the documentation of its approach ~~is~~ and how it conducts work to maintain clearances.

An example of one approach commonly used by industry is ANSI Standard A300, part 7. However, regardless of the approach a utility uses to manage vegetation, any approach a Transmission Owner chooses to use will generally contain the following elements:

1. *the maintenance strategy used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that MVCD clearances are never violated.*
2. *the work methods that the Transmission Owner uses to control vegetation*
3. *a stated Vegetation Inspection frequency*
4. *an annual work plan*

The conductor's position in space at any point in time is continuously changing ~~as a~~in reaction to a number of different loading variables. Changes in vertical and horizontal conductor positioning are the result of thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation. Physical loading applied to the conductor affects sag and sway by combining physical factors such as ice and wind loading. The movement of the transmission line conductor and the MVCD is illustrated in Figure 1 below. In the Technical Reference document more figures and explanations of conductor dynamics are provided.



D
D = MINIMUM VEGETATION
CLEARANCE DISTANCE
(MVCD)

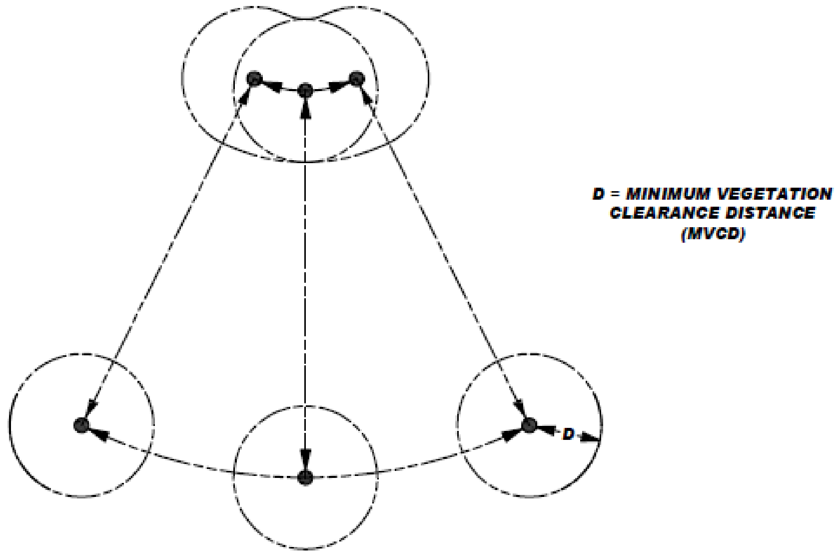


Figure 1

~~Cross~~
A cross-section view of a single conductor at a given point along the span ~~showing~~is shown with six possible conductor positions due to movement resulting from thermal and mechanical loading.

Requirement R4:
R4 is a risk-based requirement. It focuses on preventative actions to be taken by the Transmission Owner for the mitigation of Fault risk when a vegetation threat is confirmed. R4 involves the notification of potentially threatening vegetation conditions, without any intentional delay, to the control center holding switching authority for that specific transmission line. Examples of acceptable unintentional delays may include communication system problems (for example, cellular service or two-way radio disabled), crews located in remote field locations with no communication access, delays due to severe weather, etc.

Confirmation is key that a threat actually exists due to vegetation. This confirmation could be in the form of a Transmission Owner's employee who personally identifies such a threat in the field. Confirmation could also be made by sending out an employee to evaluate a situation reported by a landowner.

Vegetation-related conditions that warrant a response include vegetation that is near or encroaching into the MVCD (a grow-in issue) or vegetation that could fall into the transmission conductor (a fall-in issue). A knowledgeable verification of the risk would include an assessment of the possible sag or movement of the conductor while operating between no-load conditions and its rating.

The Transmission Owner has the responsibility to ensure the proper communication between field personnel and the control center to allow the control center to take the appropriate action until or as the vegetation threat is relieved. Appropriate actions may include a temporary reduction in the line loading, switching the line out of service, or ~~positioning the system~~other preparatory actions in recognition of the ~~increasing~~increased risk of outage on that circuit. The notification of the threat should be communicated in terms of minutes or hours as opposed to a longer time frame for corrective action plans (see R5).

All potential grow-in or fall-in vegetation-related conditions will not necessarily cause a Fault at any moment. For example, some Transmission Owners may have a danger tree identification program that identifies trees for removal with the potential to fall near the line. These trees would not require notification to the control center unless they pose an immediate fall-in threat.

Requirement R5:
R5 is a risk-based requirement. It focuses upon preventative actions to be taken by the Transmission Owner for the mitigation of Sustained Outage risk when temporarily constrained from performing vegetation maintenance. The intent of this requirement is to deal with situations that prevent the Transmission Owner from performing planned vegetation management work and, as a result, have the potential to put the transmission line at risk. Constraints to performing vegetation maintenance work as planned could result from legal injunctions filed by property owners, the discovery of easement stipulations which limit the Transmission Owner's rights, or other circumstances.

This requirement is not intended to address situations where the transmission line is not at potential risk and the work event can be rescheduled or re-planned using an alternate work methodology. For example, a land owner may prevent the planned use of chemicals on non-threatening, low growth vegetation but agree to the use of mechanical clearing. In this case the Transmission Owner is not under any immediate time constraint for achieving the management objective, can easily reschedule work using an alternate approach, and therefore does not need to take interim corrective action.

However, in situations where transmission line reliability is potentially at risk due to a constraint, the Transmission Owner is required to take an interim corrective action to mitigate the potential risk to the transmission line. A wide range of actions can be taken to address various situations. General considerations include:

- Identifying locations where the Transmission Owner is constrained from performing planned vegetation maintenance work which potentially leaves the transmission line at risk.

- Developing the specific action to mitigate any potential risk associated with not performing the vegetation maintenance work as planned.
- Documenting and tracking the specific action taken for ~~each~~the location.
- In developing the specific action to mitigate the potential risk to the transmission line the Transmission Owner could consider location specific measures such as modifying the inspection and/or maintenance intervals. Where a legal constraint would not allow any vegetation work, the interim corrective action could include limiting the loading on the transmission line.
- The Transmission Owner should document and track the specific corrective action taken at each location. This location may be indicated as one span, one tree or a combination of spans on one property where the constraint is considered to be temporary.

Requirement R6:
R6 is a risk-based requirement. This requirement sets a minimum time period for completing Vegetation Inspections~~ that fits general industry practice. In addition, the fact~~. The provision that Vegetation Inspections can be performed in conjunction with general line inspections~~ further~~ facilitates a Transmission Owner's ability to meet this requirement. However, the Transmission Owner may determine that more frequent vegetation specific inspections are needed to maintain reliability levels, ~~dependent upon such~~based on factors such as anticipated growth rates of the local vegetation, length of the local growing season~~ for the geographical area~~, limited ROW width, and local rainfall~~ amounts~~. Therefore it is expected that some transmission lines may be designated with a higher frequency of inspections.

The ~~VSL~~VSLs for Requirement R6 ~~has VSL categories~~have levels ranked by the failure to inspect a percentage of the ~~required ROW inspections completed.~~applicable lines to be inspected. To calculate the ~~percentage of inspection completion, ~~appropriate VSL the Transmission Owner may choose units such as: circuit, pole line, line miles or kilometers, ~~circuit miles or kilometers, pole line miles, ROW miles, ~~etc.

For example, when a Transmission Owner operates 2,000 miles of ~~230 kV~~applicable transmission lines this Transmission Owner will be responsible for inspecting all the 2,000 miles of ~~230 kV transmission ~~lines at least once during the calendar year. If one of the included lines was 100 miles long, and if it was not inspected during the year, then the amount failed to inspect would be 100/2000 = 0.05 or 5%. The "Low VSL" for R6 would apply in this example.

Requirement R7:

R7 is a risk-based requirement. The Transmission Owner is required to ~~implement~~complete its an annual work plan for vegetation management to accomplish the purpose of this standard. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made and documented provided they do not put the transmission system at risk. The annual work plan requirement is not intended to necessarily require a "span-by-span", or even a "line-by-line" detailed description of all work to be performed. It is only intended to require that the Transmission Owner provide evidence of annual planning and execution of a vegetation management maintenance approach which successfully prevents encroachment of vegetation into the MVCD.

For example, when a Transmission Owner identifies 1,000 miles of applicable transmission lines to be completed in the Transmission Owner's annual plan, the Transmission Owner will be responsible completing those identified miles. If a Transmission Owner makes a modification to the annual plan that does not put the transmission system at risk of an encroachment the annual plan may be modified. If 100 miles of the annual plan is deferred until next year the calculation to determine what percentage was completed for the current year would be: 1000 – 100 (deferred miles) = 900 modified annual plan, or 900 / 900 = 100% completed annual miles. If a Transmission Owner only completed 875 of the total 1000 miles with no acceptable documentation for modification of the annual plan the calculation for failure to complete the annual plan would be: 1000 – 875 = 125 miles failed to complete then, 125 miles (not completed) / 1000 total annual plan miles = 12.5% failed to complete.

The ability to modify the work plan allows the Transmission Owner to change priorities or treatment methodologies during the year as conditions or situations dictate. For example recent line inspections may identify unanticipated high priority work, weather conditions (drought) could make herbicide application ineffective during the plan year, or a major storm could require redirecting local resources away from planned maintenance. This situation may also include complying with mutual assistance agreements by moving resources off the Transmission Owner's system to work on another system. Any of these examples could result in acceptable deferrals or additions to the annual work plan~~. Modifications to the annual work plan must always ensure the reliability of the electric Transmission system.~~ provided that they do not put the transmission system at risk of a vegetation encroachment.

In general, the vegetation management maintenance approach should use the full extent of the Transmission Owner's easement, fee simple and other legal rights allowed. A comprehensive approach that exercises the full extent of legal rights on the ROW is superior to incremental management because in the long term~~ because~~ it reduces the overall potential for encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient.

When developing the annual work plan the Transmission Owner should allow time for procedural requirements to obtain permits to work on federal, state, provincial, public, tribal lands. In some cases the lead time for obtaining permits may necessitate preparing work plans more than a year prior to work start dates. Transmission Owners may also need to consider those special landowner requirements as documented in easement instruments.

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. Therefore, deferrals or relevant changes to the annual plan shall be documented. Depending on the planning and documentation format used by the Transmission Owner, evidence of successful annual work plan execution could consist of signed-off work orders, signed contracts, printouts from work management systems, spreadsheets of planned versus completed work, timesheets, work inspection reports, or paid invoices. Other evidence may include photographs, and walk-through reports.

Notes:

The SDT determined that the use of IEEE 516-2003 in version 1 of FAC-003 was a misapplication. The SDT consulted specialists who advised that the Gallet Equation would be a technically justified method. The explanation of why the Gallet approach is more appropriate is explained in the paragraphs below.

The drafting team sought a method of establishing minimum clearance distances that uses realistic weather conditions and realistic maximum transient over-voltages factors for in-service transmission lines.

The SDT considered several factors when looking at changes to the minimum vegetation to conductor distances in FAC-003-1:

- avoid the problem associated with referring to tables in another standard (IEEE-516-2003)
- transmission lines operate in non-laboratory environments (wet conditions)
- transient over-voltage factors are lower for in-service transmission lines than for inadvertently re-energized transmission lines with trapped charges.

FAC-003-1 uses the minimum air insulation distance (MAID) without tools formula provided in IEEE 516-2003 to determine the minimum distance between a transmission line conductor and vegetation. The equations and methods provided in IEEE 516 were developed by an IEEE Task Force in 1968 from test data provided by thirteen independent laboratories. The distances provided in IEEE 516 Tables 5 and 7 are based on the withstand voltage of a dry rod-rod air gap, or in other words, dry laboratory conditions. Consequently, the validity of using these distances in an outside environment application has been questioned.

FAC-003-01 allowed Transmission Owners to use either Table 5 or Table 7 to establish the minimum clearance distances. Table ~~5~~7 could be used if the Transmission Owner knew the maximum transient over-voltage factor for its system. Otherwise, Table ~~7~~5 would have to be used. Table ~~7~~5 represented minimum air insulation distances under the worst possible case for transient over-voltage factors. These worst case transient over-voltage factors were as follows: 3.5 for voltages up to 362 kV phase to phase; 3.0 for 500 - 550 kV phase to phase; and 2.5 for 765 to 800 kV phase to phase. These worst case over-voltage factors were also a cause for concern in this particular application of the distances.

In general, the worst case transient over-voltages occur on a transmission line that is inadvertently re-energized immediately after the line is de-energized and a trapped charge is still present. The intent of FAC-003 is to keep a transmission line that is *in service* from becoming de-energized (i.e. tripped out) due to spark-over from the line conductor to nearby vegetation. Thus, the worst case transient overvoltage assumptions are not appropriate for this application. Rather, the appropriate over voltage values are those that occur only while the line is energized.

Typical values of transient over-voltages of in-service lines, as such, are not readily available in the literature because they are negligible compared with the maximums. A conservative value for the maximum transient over-voltage that can occur anywhere along the length of an in-service ac line is approximately 2.0 per unit. This value is a conservative estimate of the transient over-voltage that is created at the point of application (e.g. a substation) by switching a capacitor bank without pre-insertion devices (e.g. closing resistors). At voltage levels where capacitor banks are not very common (e.g. Maximum System Voltage of 362 kV), the maximum transient over-voltage of an in-service ac line are created by fault initiation on adjacent ac lines and shunt reactor bank switching. These transient voltages are usually 1.5 per unit or less.

Even though these transient over-voltages will not be experienced at locations remote from the bus at which they are created, in order to be conservative, it is assumed that all nearby ac lines are subjected to this same level of over-voltage. Thus, a maximum transient over-voltage factor of 2.0 per unit for transmission lines operated at ~~242~~302 kV and below is considered to be a realistic maximum in this application. Likewise, for ac transmission lines operated at Maximum System Voltages of 362 kV and above a transient over-voltage factor of 1.4 per unit is considered a realistic maximum.

The Gallet Equations are an accepted method for insulation coordination in tower design. These equations are used for computing the required strike distances for proper transmission line insulation coordination. They were developed for both wet and dry applications and can be used with any value of transient over-voltage factor. The Gallet Equation also can take into account various air gap geometries. This approach was used to design the first 500 kV and 765 kV lines in North America~~ [1].~~.

If one compares the MAID using the IEEE 516-2003 Table 7 (table D.5 for English values) with the critical spark-over distances computed using the Gallet wet equations, for each of the nominal voltage classes and identical transient over-voltage factors, the Gallet equations yield a more conservative (larger) minimum distance value.

Distances calculated from either the IEEE 516 (dry) formulas or the Gallet “wet” formulas are not vastly different when the same transient overvoltage factors are used; the “wet” equations will consistently produce slightly larger distances than the IEEE 516 equations when the same transient overvoltage is used. While the IEEE 516 equations were only developed for dry conditions the Gallet equations have provisions to calculate spark-over distances for both wet and dry conditions.

While EPRI is currently trying to establish empirical data for spark-over distances to live vegetation, there are no spark-over formulas currently derived expressly for vegetation to conductor minimum distances. Therefore the SDT chose a proven method that has been used in other EHV applications. The Gallet equations relevance to wet conditions and the selection of a Transient Overvoltage Factor that is consistent with the absence of trapped charges on an in-service transmission line make this methodology a better choice.
The following table is an example of the comparison of distances derived from IEEE 516 and the Gallet equations ~~using various transient overvoltage values~~.

Comparison of spark-over distances computed using Gallet wet equations vs. IEEE 516-2003 MAID distances

Implementation Plan

FAC-003-2

Prerequisite Approvals

There are no other Reliability Standards or Standard Authorization Requests (SARs), in progress or approved, that must be implemented before this standard can be implemented.

FAC-003-2 – Vegetation Management

Revision to Sections of Approved Standards and Definitions

There are no proposed revisions to requirements in other already approved standards. There are two revised definitions in the proposed standard. FAC-003-1 will be retired when FAC-003-2 becomes effective.

Compliance with Standard

The standard applies to Transmission Owners.

Effective Date

The effective date is the date entities are expected to meet the performance identified in this standard. The effective date allows entities time to make revisions to their existing transmission vegetation management programs to comply with the new requirements.

This standard becomes effective on the first calendar day of the first calendar quarter one year after the date of the order approving the standard from applicable regulatory authorities where such explicit approval is required. Where no regulatory approval is required, the standard becomes effective on the first calendar day of the first calendar quarter one year after Board of Trustees adoption.

Effective dates for individual lines when they undergo specific transition cases:

1. A line operated below 200kV, designated by the Planning Coordinator as an element of an Interconnection Reliability Operating Limit (IROL) or designated by the Western Electricity Coordinating Council (WECC) as an element of a Major WECC transfer Path, becomes subject to this standard the latter of: 1) 12 months after the date the Planning Coordinator or WECC initially designates the line as being an element of an IROL or an element of a Major WECC transfer Path, or 2) January 1 of the planning year when the line is forecast to become an element of an IROL or an element of a Major WECC transfer Path.
2. A line operated below 200 kV currently subject to this standard as a designated element of an IROL or a Major WECC Transfer Path which has a specified date for the removal of such designation will no longer be subject to this standard effective on that specified date.

3. A line operated at 200 kV or above, currently subject to this standard which is a designated element of an IROL or a Major WECC Transfer Path and which has a specified date for the removal of such designation will be subject to Requirement R2 and no longer be subject to Requirement R1 effective on that specified date.
4. An existing transmission line operated at 200kV or higher which is newly acquired by an asset owner and which was not previously subject to this standard, becomes subject to this standard 12 months after the acquisition date.
5. An existing transmission line operated below 200kV which is newly acquired by an asset owner and which was not previously subject to this standard becomes subject to this standard 12 months after the acquisition date of the line if at the time of acquisition the line is designated by the Planning Coordinator as an element of an IROL or by WECC as an element of a Major WECC Transfer Path.

Implementation Plan

FAC-003-2

Prerequisite Approvals

There are no other Reliability Standards or Standard Authorization Requests (SARs), in progress or approved, that must be implemented before this standard can be implemented.

FAC-003-2 – Vegetation Management

Revision to Sections of Approved Standards and Definitions

There are no proposed revisions to requirements in other already approved standards. There are two revised definitions in the proposed standard. FAC-003-1 will be retired when FAC-003-2 becomes effective.

Compliance with Standard

The standard applies to Transmission Owners.

Effective Date

The effective date is the date entities are expected to meet the performance identified in this standard. The effective date allows entities time to make revisions to their existing transmission vegetation management programs to comply with the new requirements.

This standard becomes effective on the ~~F~~first calendar day of the first calendar quarter one year after the date of the order approving the standard from applicable regulatory authorities where such explicit approval is required. Where no regulatory approval is required, the standard becomes effective on the first calendar day of the first calendar quarter one year after Board of Trustees adoption.

Effective dates for individual lines when they undergo specific transition cases:
~~Exceptions:~~

1. A line operated below 200kV, designated by the Planning Coordinator as an element of an Interconnection Reliability Operating Limit (IROL) or designated by the Western Electricity Coordinating Council (WECC) as an element of a Major WECC transfer ~~path~~Path, becomes subject to this standard the latter of: 1) 12 months after the date the Planning Coordinator or WECC initially designates the line as being an element of an IROL or an element of a Major WECC transfer Path, or 2) January 1 of the planning year when the line is forecast to become an element of an IROL or an element of a Major WECC transfer Path~~subject to this standard~~.

2. A line operated below 200 kV currently subject to this standard as a designated element of an IROL or a Major WECC Transfer Path which has a specified date for the removal of such designation will no longer be subject to this standard effective on that specified date.

~~1.~~3. A line operated at 200 kV or above, currently subject to this standard which is a designated element of an IROL or a Major WECC Transfer Path and which has a specified date for the removal of such designation will be subject to Requirement R2 and no longer be subject to Requirement R1 effective on that specified date.

4. An existing transmission line operated at 200kV or higher ~~that~~which is newly acquired by an asset owner and which was not previously subject to this standard, becomes subject to this standard 12 months after the acquisition date~~of the line.~~

~~2.~~5. An existing transmission line operated below 200kV which is newly acquired by an asset owner and which was not previously subject to this standard becomes subject to this standard 12 months after the acquisition date of the line if at the time of acquisition the line is designated by the Planning Coordinator as an element of an IROL or by WECC as an element of a Major WECC Transfer Path.

Disclaimer

This supporting document is supplemental to the reliability standard FAC-003-2 — Transmission Vegetation Management and does not contain mandatory requirements subject to compliance review. Throughout this document, for ready reference, there are “copies” in italic font of the wording in the Standard. Any “copy” of any part of the Standard in this document should be cross checked to the Standard and if any difference exists, then the Standard’s exact wording should be considered the intended wording for this document.

Introduction

This document is intended to provide supplemental information and guidance for complying with the requirements of Reliability Standard FAC-003-2.

The purpose of the Standard is to improve the reliability of the electric transmission system by preventing those vegetation related outages that could lead to Cascading.

Compliance with the Standard is mandatory and enforceable.

Special Note: The Application of the Results-Based Approach to FAC-003-2

In its three-year assessment as the ERO, NERC acknowledged stakeholder comments and committed to:

i) addressing quality issues to ensure each reliability standard has a clear statement of purpose, and has outcome-focused requirements that are clear and measurable; and
ii) eliminating requirements that do not have an impact on bulk power system reliability.

In 2010, the Standards Committee approved a recommendation to use Project 2007-07 Vegetation Management as a first proof of concept for developing results-based standards.

This standard is not intended to address outages such as those due to vegetation fall-ins or blow-ins from outside the Right-of-Way, vandalism, human activities or acts of nature. Operating experience indicates that trees that have grown out of specification have contributed to Cascading, especially under heavy electrical loading conditions.

This standard utilizes three types of requirements to provide layers of protection to prevent vegetation related outages that could lead to Cascading:

a) Performance-based — defines a particular reliability objective or outcome to be achieved. In its simplest form, a results-based requirement has four components: *who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome*?
b) Risk-based — preventive requirements to reduce the risks of failure to acceptable tolerance levels. A risk-based reliability requirement should be framed as: who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome *<u>that reduces a stated risk to the reliability of the bulk power system</u>*?
c) Competency-based — defines a minimum set of capabilities an entity needs to have to demonstrate it is able to perform its designated reliability functions. A competency-based reliability requirement should be framed as: *who, under what conditions (if any), shall have what capability, to achieve what particular result or outcome to perform an action to achieve a result or outcome or to reduce a risk to the reliability <u>of the bulk power system</u>*?

The defense-in-depth strategy for reliability standards development recognizes that each requirement in a NERC reliability standard has a role in preventing system failures, and that these roles are complementary and reinforcing. Reliability standards should not be viewed as a body of unrelated requirements, but rather should be viewed as part of a portfolio of requirements designed to achieve an overall defense-in-depth strategy and comport with the quality objectives of a reliability standard.

This NERC Vegetation Management Standard (“standard”) uses a defense-in-depth approach to improve the reliability of the electric Transmission System by:

- Requiring that vegetation be managed to prevent vegetation encroachment inside the flash-over clearance (R1 and R2);
- Requiring documentation of the maintenance strategies, procedures, processes and specifications used to manage vegetation to prevent potential flash-over conditions including consideration of 1) conductor dynamics and 2) the interrelationships between vegetation growth rates, control methods and the inspection frequency (R3);
- Requiring timely notification to the appropriate control center of vegetation conditions that could cause a flash-over at any moment (R4);
- Requiring corrective actions to ensure that flash-over distances will not be violated due to work constrains such as legal injunctions (R5);
- Requiring inspections of vegetation conditions to be performed annually (R6); and
- Requiring that the annual work needed to prevent flash-over is completed (R7).

For this standard, the requirements have been developed as follows:

- Performance-based: Requirements 1 and 2
- Competency-based: Requirement 3
- Risk-based: Requirements 4, 5, 6 and 7

R3 serves as the first line of defense by ensuring that entities understand the problem they are trying to manage and have fully developed strategies and plans to manage the problem. R1, R2, and R7 serve as the second line of defense by requiring that entities carry out their plans and manage vegetation. R6, which requires inspections, may be either a part of the first line of defense (as input into the strategies and plans) or as a third line of defense (as a check of the first and second lines of defense). R4 serves as the final line of defense, as it addresses cases in which all the other lines of defense have failed.

Major outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations. Adherence to the standard requirements for applicable lines on any kind of land or easement, whether they are Federal Lands, state or provincial lands, public or private lands, franchises, easements or lands owned in fee, will reduce and manage this risk. For the purpose of the standard the term “public lands” includes municipal lands, village lands, city lands, and a host of other governmental entities.

The standard addresses vegetation management along applicable overhead lines and does not apply to underground lines, submarine lines or to line sections inside an electric station boundary.

The standard focuses on transmission lines to prevent those vegetation related outages that could lead to Cascading. It is not intended to prevent customer outages due to tree contact with lower voltage distribution system lines. For example, localized customer service might be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. However, this standard is not written to address such isolated situations which have little impact on the overall electric transmission system.
Since vegetation growth is constant and always present, unmanaged vegetation poses an increased outage risk, especially when numerous transmission lines are operating at or near their Rating. This can present a significant risk of consecutive line failures when lines are experiencing large sags thereby leading to Cascading. Once the first line fails the shift of the current to the other lines and/or the increasing system loads will lead to the second and subsequent line failures as contact to the vegetation under those lines occurs. Conversely, most other outage causes (such as trees falling into lines, lightning, animals, motor vehicles, etc.) are not an interrelated function of the shift of currents or the increasing system loading. These events are not any more likely to occur during heavy system loads than any other time. There is no cause-effect relationship which creates the probability of simultaneous occurrence of other such events. Therefore these types of events are highly unlikely to cause large-scale grid failures. Thus, this standard places the highest priority on the management of vegetation to prevent vegetation grow-ins.

The drafting team reviewed and edited version 1 of FAC-003-1 to remove prescriptive and administrative language in order to distill the technical requirements down to their essential reliability content. Explanatory text is offered within two special sections, <u>Background</u> and <u>Guideline and Technical Basis</u>, to aid in understanding the standard and its requirements. <u>Rationale</u> text boxes and other text boxes are also inserted throughout the standard to aid understanding the sections. The <u>Effective Dates</u> section covers five special cases for lines that undergo specific transitions as or after the standard has reached the general effective date.

Preface

The NERC Vegetation Management Standard Drafting Team (VM SDT) acknowledges those across the industry who contributed to the development of this Standard and companion Technical Reference document. This Technical Reference document is intended to provide supplemental explanatory background and guidance related to requirements contained in the Standard but does not in itself contain requirements subject to compliance review.

The Standard requires the Transmission Owner to have documentation of the maintenance strategies or procedures or processes or specifications it uses to be successful in managing vegetation. This allows the Transmission Owner to exercise substantial flexibility in designing its overall program to meet its specific needs provided that the Transmission Owner also meets the purpose of the Standard.

While there are many approaches to vegetation management, the VMSDT supports industry best practices contained in ANSI A300 (Part 7) – Integrated Vegetation Management (IVM) practices on Utility Rights-of-way, as well as the companion publication Best Management Practices – Integrated Vegetation Management, as an effective strategy to maintain compliance with this Standard. ANSI A300 (Part 7), approved by industry consensus in 2006, contains many elements needed for an effective vegetation management. Those elements are similar to the requirements in this Standard. One key element is the "wire zone – border zone" concept. Supported by over 50 years of continuous research, wire zone – border zone is a proven method to manage vegetation on transmission rights-of-ways and is an industry accepted best practice to help ensure electric system reliability.

The VM SDT believes that Transmission Owners who adopt and effectively implement IVM principles, particularly the "wire zone – border zone" concept, are far less likely to experience a vegetation caused outage than those who do not.

Effective Dates & Special States of Transition

The first sentence of the Effective Dates section is standard language used in most NERC standards to cover the general effective date and is sufficient to cover the vast majority of situations. Five special cases are needed to cover effective dates for individual lines which undergo transitions after the general effective date. These special cases cover the effective dates for those lines which are initially becoming subject to the standard, those lines which are changing their applicability within the standard, and those lines which are changing in a manner that removes their applicability to the standard. The text for each of these five cases is copied from the standard and is shown below in italic font. An explanation of the need for each special exception follows each copied text section.

1. *A line operated below 200kV, designated by the Planning Coordinator as an element of an Interconnection Reliability Operating Limit (IROL) or designated by the Western Electricity Coordinating Council (WECC) as an element of a Major WECC Transfer Path, becomes subject to this standard the latter of: 1) 12 months after the date the Planning Coordinator or WECC initially designates the line as being an element of an IROL or an element of a Major WECC Transfer Path, or 2) January 1 of the planning year when the line is forecast to become an element of an IROL or an element of a Major WECC Transfer Path.*

Case 1 is needed because the Planning Coordinators may designate lines below 200 kV to become elements of an IROL or Major WECC Transfer Path in a future Planning Year (PY). For example, studies by the Planning Coordinator in 2011 may identify a line to have that designation beginning in PY 2021, ten years after the planning study is performed. It is not intended for the Standard to be immediately applicable to, or in effective for, that line until that future PY begins. The effective date provision for such lines ensures that the line will become subject to the standard on the January 1 of the PY specified with an allowance of at least 12 months for the Transmission Owner to make the necessary preparations to achieve compliance on that line. The table below has some explanatory examples of the application.

Date that Planning Study is completed	PY the line will become an IROL element	Date 1	Date 2	Effective Date The latter of Date 1 or Date 2
05/15/2011	2012	05/15/2012	01/01/2012	05/15/2012
05/15/2011	2013	05/15/2012	01/01/2013	01/01/2013
05/15/2011	2014	05/15/2012	01/01/2014	01/01/2014
05/15/2011	2021	05/15/2012	01/01/2021	01/01/2021

2. *A line operated below 200 kV currently subject to this standard as a designated element of an IROL or a Major WECC Transfer Path which has a specified date for the removal of such designation will no longer be subject to this standard effective on that specified date.*

Case 2 is needed because a line operating below 200kV designated as an element of an IROL or Major WECC Transfer Path may be removed from that designation due to system improvements, changes in generation, changes in loads or changes in studies and analysis of the network.

3. *A line operated at 200 kV or above, currently subject to this standard which is a designated element of an IROL or a Major WECC Transfer Path and which has a specified date for the removal of such designation will be subject to Requirement R2 and no longer be subject to Requirement R1 effective on that specified date*

Case 3 is needed because a line operating at 200 kV or above that once was designated as an element of an IROL or Major WECC Transfer Path may be removed from that designation due to system improvements, changes in generation, changes in loads or changes in studies and analysis of the network. Such changes result in the need to apply R1 to that line until that date is reached and then to apply R2 to that line thereafter.

4. *An existing transmission line operated at 200kV or higher which is newly acquired by an asset owner and which was not previously subject to this standard becomes subject to this standard 12 months after the acquisition date.*

Case 4 is needed because an existing line that is to be operated at 200 kV or above can be acquired by a Transmission Owner from a third party such as a Distribution Provider or other end-user who was using the line solely for local distribution purposes, but the Transmission owner, upon acquisition, is incorporating the line into the interconnected electrical energy transmission network which will thereafter make the line subject to the standard.

5. *An existing transmission line operated below 200kV which is newly acquired by an asset owner and which was not previously subject to this standard becomes subject to this standard 12 months after the acquisition date of the line if at the time of acquisition the line is designated by the Planning Coordinator as an element of an IROL or by WECC as an element of a Major WECC Transfer Path.*

Case 5 is needed because an existing line that is operated below 200 kV can be acquired by a Transmission Owner from a third party such as a Distribution Provider or other end-user who was using the line solely for local distribution purposes, but the Transmission owner, upon acquisition, is incorporating the line into the interconnected electrical energy transmission network. In this special case the line upon acquisition was designated as an element of an Interconnection Reliability Operating Limit (IROL) or an element of a Major WECC transfer Path.

Definition of Terms

Right-of-Way (ROW)*

The corridor of land under a transmission line(s) needed to operate the line(s). The width of the corridor is established by engineering or construction standards as documented in either construction documents, pre-2007 vegetation maintenance records, or by the blowout standard in effect when the line was built. The ROW width in no case exceeds the Transmission Owner's legal rights but may be less based on the aforementioned criteria.

> The current glossary definition of this NERC term is modified to address the issues set forth in Paragraph 734 of FERC Order 693.

The current NERC glossary definition of Right of Way has been modified to address the matter set forth in Paragraph 734 of FERC Order 693. The Order pointed out that Transmission Owners may in some cases own more property or rights than are needed to reliably operate transmission lines. This modified definition represents a slight but significant departure from the strict legal definition of "right of way" in that this definition is based on engineering and construction considerations that establish the width of a corridor from a technical basis. The pre-2007 maintenance records are included to allow the use of such vegetation widths if there were no engineering or construction standards that referenced the width of right of way to be maintained for vegetation on a particular line but the evidence exists in maintenance records for a width that was in fact maintained prior to this standard becoming mandatory. Such widths may be the only information available for lines that had limited or no vegetation easement rights and were typically maintained primarily to ensure public safety. This standard does not require additional easement rights to be purchased to satisfy a minimum right of way width that did not exist prior to this standard becoming mandatory.

This definition does not imply that danger tree rights beyond the constructed and maintained width are incorporated in the definition; therefore fall-ins from outside the ROW but within an area with danger tree rights would not be considered fall-ins from within the ROW.

Vegetation Inspection*

The systematic examination of vegetation conditions on a Right-of-Way and those vegetation conditions under the Transmission Owner's control that are likely to pose a hazard to the line(s) prior to the next planned maintenance or inspection. This may be combined with a general line inspection.

The inspection includes the identification of any vegetation that may pose a threat to reliability

> The current glossary definition of this NERC term is modified to allow both maintenance inspections and vegetation inspections to be performed concurrently.
>
> Current definition of Vegetation Inspection: The systematic examination of a transmission corridor to document vegetation conditions.

prior to the next planned maintenance or inspection work, considering the current location of the conductor and other possible locations of the conductor due to sag and sway for rated conditions.

This definition allows both maintenance inspections and vegetation inspections to be performed concurrently.

* This is a modification to a defined term in the NERC glossary and will be incorporated into the NERC glossary of terms with final approval of this standard revision.

See the Guidelines and Technical Basis section on Requirement R6 contained within the Standard for more details on inspections.

Minimum Vegetation Clearance Distance (MVCD)

The calculated minimum distance stated in feet (meters) to prevent flash-over between conductors and vegetation, for various altitudes and operating voltages.

The MVCD is a calculated minimum distance that is derived from the Gallet Equations. This is a method has been in the design of high voltage transmission lines. Keeping vegetation away from high voltage conductors by this distance will prevent voltage flash-over to the vegetation. See the explanatory text below for Requirement R3 and associated Figures 1, 2 and 3. Details of the equations and an example calculation are provided in Appendix 1below of the Technical Reference document. Table 1in Appendix 1 below provides MVCD values for various voltages and altitudes.

Applicability of the Standard

4. Applicability

4.1. Functional Entities:
Transmission Owners

4.2. Facilities: *Defined below (referred to as "applicable lines"), including but not limited to those that cross lands owned by federal*[1]*, state, provincial, public, private, or tribal entities:*

_4.2.1_ *Each overhead transmission lines operated at 200kV or higher.*

_4.2.2_ *Each overhead transmission lines operated below 200kV identified as an element of an IROL under NERC Standard FAC-014 by the Planning Coordinator.*

_4.2.3_ *Each overhead transmission lines operated below 200 kV identified as an element of a Major WECC Transfer Paths in the Bulk Electric System by WECC.*

_4.2.4_ Each overhead transmission line identified above (4.2.1 through 4.2.3) located outside the fenced area of the switchyard, station or substation and any portion of the span *of the transmission line that is crossing the substation fence.*

4.3. Enforcement: *The reliability obligations of the applicable entities and facilities are contained within the technical requirements of this standard*

Rationale

The areas excluded in 4.2.4 were excluded based on comments from industry for reasons summarized as follows: 1) There is a very low risk from vegetation in this area. Based on an informal survey, no TOs reported such an event. 2) Substations, switchyards, and stations have many inspection and maintenance activities that are necessary for reliability. Those existing process manage the threat. As such, the formal steps in this standard are not well suited for this environment. 3) NERC has a project in place to address at a later date the applicability of this standard to Generation Owners. 4) Specifically addressing the areas where the standard does and does not apply makes the standard clearer.

In Order 693, FERC discussed the 200 kV bright-line test of applicability. While FERC did not change the 200 kV bright-line, the Commission remained concerned that there may be some transmission lines operating at lesser voltages that could have significant impact on the Bulk Electric System that should therefore be subject to this standard.

[1] EPAct 2005 section 1211c: *"Access approvals by Federal agencies"*.

NERC Standard FAC-014 has the stated purpose, "*To ensure that System Operating Limits (SOLs) used in the reliable planning and operation of the Bulk Electric System (BES) are determined based on an established methodology or methodologies.*" FAC-014 requires Reliability Coordinators, Planning Coordinators, and Transmission Planners to have a methodology to identify all lines that might comprise an IROL. Thus, these entities would identify sub-200 kV lines that qualify as part of an IROL and should be subject to FAC-003-2.

Although all three entities may prepare the list of elements, the list as provided by the Planning Coordinator function is the more appropriate choice for this Standard. The Time Horizon needed to plan vegetation management work does not lend itself to the operating horizon of a Reliability Coordinator. Additionally, the Planning Coordinator has a wider-area view than the Transmission Planner and could thus identify any elements of importance to a sub-set of its area that might be missed by a Transmission Planner.

Transmission Owners, who do not already get the list of circuits included in the definition of an IROL, can get them from the Planning Coordinator. Specifically R5 of FAC-014 specifies that "*The Reliability Coordinator, Planning Authority (Coordinator) and Transmission Planner shall each provide its SOLs and IROLs to those entities that have a reliability-related need for those limits and provide a written request that includes a schedule for delivery of those limits*"

Vegetation-related Sustained Outages that occur due to natural disasters are beyond the control of the Transmission Owner. These events are not classified as vegetation-related Sustained Outages and are therefore exempt from the Standard. Transmission lines are not designed to withstand the impacts of natural disasters such as flood, drought, earthquake, major storms, fire, hurricane, tornado, landslides, ice storms, etc. In the aftermath of catastrophic system damage from natural disasters the Transmission Owner's focus is on electric system restoration for public safety and critical support infrastructure.

Sustained Outages due to human or animal activity are beyond the control of the Transmission Owner. These outages are not classified as vegetation-related Sustained Outages and are therefore exempt from the Standard. Examples of these events may include new plantings by outside parties of tall vegetation under the transmission line planted since the last Vegetation Inspection, tree contacts with line initiated by vehicles, logging activities, etc.

The foregoing exemptions are addressed in a new footnote 2. Referred to collectively as force majeure events and activities, this footnote applies to requirements R1 and R2 in FAC-003-2.

The reliability objective of this NERC Vegetation Management Standard ("Standard") is to prevent vegetation-related outages which could lead to Cascading by effective vegetation maintenance while recognizing that certain outages such as those due to vandalism, human errors and acts of nature are not preventable. Operating experience clearly indicates that trees that have grown out of specification could contribute to a cascading grid failure, especially under heavy electrical loading conditions.

Serious outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations. To properly reduce and manage this risk, it is necessary to apply the Standard to applicable lines on any kind of land or easement, whether they are Federal Lands, state or provincial lands, public or private lands, franchises, easements or lands owned in fee. For the purposes of the Standard and this Technical Reference document, the term “public lands” includes municipal lands, village lands, city lands, and land owned by a host of other governmental entities.

The Standard addresses vegetation management along applicable overhead lines that serve to connect one electric station to another. However, it is not intended to be applied to lines sections inside the electric station fence or other boundary of an electric station, submarine or underground lines.

The Standard is intended to reduce the risk of Cascading involving vegetation. It is not intended to prevent customer outages from occurring due to tree contact with all transmission lines and voltages. For example, localized customer service might be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. However, this Standard is not written to address such isolated situations which have little impact on the overall Bulk Electric System.

Vegetation growth is constant and always present. Unmanaged vegetation below numerous transmission lines that are operating at or near their Rating is highly problematic. This situation has led to multiple subsequent line failures and Cascading. Conversely, most other outage causes (such as trees falling into lines, lightning, animals, motor vehicles, etc.) are statistically intermittent. These events are not any more likely to occur during heavy system loads than any other time. There is no cause-effect relationship which creates the probability of simultaneous occurrence of other such events. Therefore these types of events are highly unlikely to cause large-scale grid failures. Thus, this Standard’s emphasis is on vegetation grow-ins.

In preparing the original vegetation management standard in 2005, industry stakeholders set the threshold for applicability of the standard at 200kV. This was because an unexpected loss of lines operating at above 200kV has a higher probability of initiating a widespread blackout or cascading outages compared with lines operating at less than 200kV.

The original NERC Standard FAC-003-1 also allowed for application of the standard to “critical” circuits (critical from the perspective of initiating widespread blackouts or cascading outages) operating below 200kV. While the percentage of these circuits is relatively low, it remains a fact that there are sub-200kV circuits whose loss could contribute to a widespread outage. Given the very limited exposure and unlikelihood of a major event related to these lower-voltage lines, it would be an imprudent use of resources to apply the Standard to all sub-200kV lines. The drafting team, after evaluating several alternatives, selected the IROL and WECC Major Transfer Path criteria to determine applicable lines below 200 kV that are subject to this standard.

Requirements R1 and R2

R1. Each Transmission Owner shall manage vegetation to prevent encroachments into the Minimum Vegetation Clearance Distance (MVCD) of its applicable line(s) which are either an element of an IROL, or an element of a Major WECC Transfer Path; operating within its Rating and all Rated Electrical Operating Conditions of the types shown below[2]:

1. An encroachment into the MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage[3],
2. An encroachment due to a fall-in from inside the Right-of-Way (ROW) that caused a vegetation-related Sustained Outage[4],
3. An encroachment due to the blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained Outage[4],
4. An encroachment due to vegetation growth into the MVCD that caused a vegetation-related Sustained Outage[4].

R2. Each Transmission Owner shall manage vegetation to prevent encroachments into the MVCD of its applicable line(s) which are not either an element of an IROL, or an element of a Major WECC Transfer

Rationale for R1 and R2:

Lines with the highest significance to reliability are covered in R1; all other lines are covered in R2.

Rationale for the types of failure to manage vegetation which are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a Transmission Owner's vegetation maintenance program:

1. This management failure is found by routine inspection or Fault event investigation, and is normally symptomatic of unusual conditions in an otherwise sound program.

2. This management failure occurs when the height and location of a side tree within the ROW is not adequately addressed by the program.

3. This management failure occurs when side growth is not adequately addressed and may be indicative of an unsound program.

4. This management failure is usually indicative of a program that is not addressing the most fundamental dynamic of vegetation management, (i.e. a grow-in under the line). If this type of failure is pervasive on multiple lines, it provides a mechanism for a Cascade.

[2] This requirement does not apply to circumstances that are beyond the control of a Transmission Owner subject to this reliability standard, including natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods; human or animal activity such as logging, animal severing tree, vehicle contact with tree, or installation, removal, or digging of vegetation. Nothing in this footnote should be construed to limit the Transmission Owner's right to exercise its full legal rights on the ROW.

[3] If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation.

[4] Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period.

Path; operating within its Rating and all Rated Electrical Operating Conditions of the types shown below[2]:

1. An encroachment into the MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage[3],
2. An encroachment due to a fall-in from inside the ROW that caused a vegetation-related Sustained Outage[4],
3. An encroachment due to blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained Outage[4],
4. An encroachment due to vegetation growth into the MVCD that caused a vegetation-related Sustained Outage[4]

M1. Each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R1. Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-time observations of any MVCD encroachments. (R1)

M2. Each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R2. Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-time observations of any MVCD encroachments. (R2)

R1 and R2 are performance-based requirements. The reliability objective or outcome to be achieved is the prevention of vegetation encroachments within a minimum distance of transmission lines. Content-wise, R1 and R2 are the same requirements; however, they apply to different Facilities. Both R1 and R2 require each Transmission Owner to manage vegetation to prevent encroachment within the MVCD of transmission lines. R1 is applicable to lines that are identified as an element of an IROL or Major WECC transfer path. R2 is applicable to all other lines that are not an element of an IROL, and not an element of a Major WECC Transfer Path.

The separation of applicability (between R1 and R2) recognizes that inadequate vegetation management for an applicable line that is an element of an IROL or Major WECC Transfer Path is a greater risk to the interconnected electric transmission system than applicable lines that are not an element of an IROL or a Major WECC Transfer Path. Applicable lines that are not an element of an IROL or Major WECC Transfer Path do require effective vegetation management, but these lines are comparatively less operationally significant. As a reflection of this difference in risk impact, the Violation Risk Factors (VRFs) are assigned as High for R1 and Medium for R2.

R1 and R2 state that if vegetation encroaches within the distances in Table 1 in Appendix 1 of this supplemental Technical Reference document, it is in violation of the standard. Table 1below, which is the same as Table 2 in the standard, tabulates the distances necessary to prevent spark-over based on the Gallet equations as described more fully in Appendix 1 below.

These requirements assume that transmission lines and their conductors are operating within their Rating. If a line conductor is intentionally or inadvertently operated beyond its Rating and Rated Electrical Operating Condition (potentially in violation of other standards), the occurrence of a clearance encroachment may occur solely due to that condition. For example, emergency actions taken by a Transmission Operator or Reliability Coordinator to protect an Interconnection may cause excessive sagging and an outage. Another example would be ice loading beyond the line's Rating and Rated Electrical Operating Condition. Such vegetation-related encroachments and outages are not violations of this standard.

Evidence of failures to adequately manage vegetation include real-time observation of a vegetation encroachment into the MVCD (absent a Sustained Outage), or a vegetation-related encroachment resulting in a Sustained Outage due to a fall-in from inside the ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to the blowing together of the lines and vegetation located inside the ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to a grow-in. Faults which do not cause a Sustained outage and which are confirmed to have been caused by vegetation encroachment within the MVCD are considered the equivalent of a Real-time observation for violation severity levels.

With this approach, the VSLs for R1 and R2 are structured such that they directly correlate to the severity of a failure of a Transmission Owner to <u>manage</u> vegetation and to the corresponding performance level of the Transmission Owner's vegetation program's ability to meet the objective of "preventing the risk of those vegetation related outages that could lead to Cascading." Thus violation severity increases with a Transmission Owner's inability to meet this goal and its potential of leading to a Cascading event. The additional benefits of such a combination are that it simplifies the standard and clearly defines performance for compliance. A performance-based requirement of this nature will promote high quality, cost effective vegetation management programs that will deliver the overall end result of improved reliability to the system.

Multiple Sustained Outages on an individual line can be caused by the same vegetation. For example initial investigations and corrective actions may not identify and remove the actual outage cause then another outage occurs after the line is re-energized and previous high conductor temperatures return. Such events are considered to be a single vegetation-related Sustained Outage under the standard where the Sustained Outages occur within a 24 hour period.

The MVCD is a calculated minimum distance stated in feet (or meters) to prevent spark-over, for various altitudes and operating voltages that is used in the design of Transmission Facilities. Keeping vegetation from entering this space will prevent transmission outages.

If the TO has applicable lines operated at nominal voltage levels not listed in Table 2, then the TO should use the next largest clearance distance based on the next highest nominal voltage in the table to determine an acceptable distance.

Requirement R3

Rationale

The documentation provides a basis for evaluating the competency of the Transmission Owner's vegetation program. There may be many acceptable approaches to maintain clearances. Any approach must demonstrate that the Transmission Owner avoids vegetation-to-wire conflicts under all Rated Electrical Operating Conditions. See Figure 1 for an illustration of possible conductor locations.

R3. *Each Transmission Owner shall have documented maintenance strategies or procedures or processes or specifications it uses to prevent the encroachment of vegetation into the MVCD of its applicable transmission lines that accounts for the following:*

3.1 *Movement of applicable line conductors under their Facility Rating and all Rated Electrical Operating Conditions;*

3.2 *Inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency.*

M3. *The maintenance strategies or procedures or processes or specifications provided demonstrate that the Transmission Owner can prevent encroachment into the MVCD considering the factors identified in the requirement. (R3)*

Requirement R3 is a competency based requirement concerned with the maintenance strategies, procedures, processes, or specifications, a Transmission Owner uses for vegetation management.

An adequate transmission vegetation management program formally establishes the approach the Transmission Owner uses to plan and perform vegetation work to prevent transmission Sustained Outages and minimize risk to the transmission system. The approach provides the basis for evaluating the intent, allocation of appropriate resources and the competency of the Transmission Owner in managing vegetation. There are many acceptable approaches to manage vegetation and avoid Sustained Outages. However, the Transmission Owner must be able to show the documentation of its approach and how it conducts work to maintain clearances.

An example of one approach commonly used by industry is ANSI Standard A300, part 7.

However, regardless of the approach a utility uses to manage vegetation, any approach a Transmission Owner chooses to use will generally contain the following elements:

1. *the maintenance strategy used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that MVCD clearances are never violated.*
2. *the work methods that the Transmission Owner uses to control vegetation*
3. *a stated Vegetation Inspection frequency*

4. *an annual work plan*

The conductor's position in space at any point in time is continuously changing in reaction to a number of different loading variables. Changes in vertical and horizontal conductor positioning are the result of thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation. Physical loading applied to the conductor affects sag and sway by combining physical factors such as ice and wind loading. The movement of the transmission line conductor and the MVCD is illustrated in Figures 1, 2, and 3 below.

Conductor Dynamics

In order for a Transmission Owner to develop a specific maintenance approach, it is important to understand the dynamics of a line conductor's movements. This paper will first address the complexities inherent in observing and predicting conductor movement, particularly for field personnel. It will then present some examples of maintenance approaches which Transmission Owners may consider that take into account these complexities, and the practical approaches that can be utilized by field personnel.

Additionally, it is important the Transmission Owner consider all conductor locations, the MVCD, and vegetation growth between maintenance activities when developing a maintenance approach.

Understanding Conductor Position and Movement

The conductor's position in space at any point in time is continuously changing as a reaction to a number of different loading variables. Changes in vertical and horizontal conductor positioning are the result of thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation. Physical loading applied to the conductor affects sag and sway by combining physical factors such as ice and wind loading.

As a consequence of these loading variables, the conductor's position in space is dynamic and moving. When calculating the range of conductor positions, the Transmission Owner should use the same design criteria and assumptions that are used to establish Ratings and System Operating Limits (SOLs), as described in other standards. Typically, the greatest conductor movements occur at mid-span. As the conductor moves through various positions, a spark-over zone surrounding the conductor moves with it. The radius of the spark-over zone may be found by referring to Table 1 below. For illustrations of this zone and conductor movements, Figures 1, 2 and 3 below are provided. At the time of making a field observation, however, it is very difficult to precisely know where the conductor is in relation to its wide range of all possible positions. Therefore, Transmission Owners must adopt maintenance approaches that account for this dynamic situation.

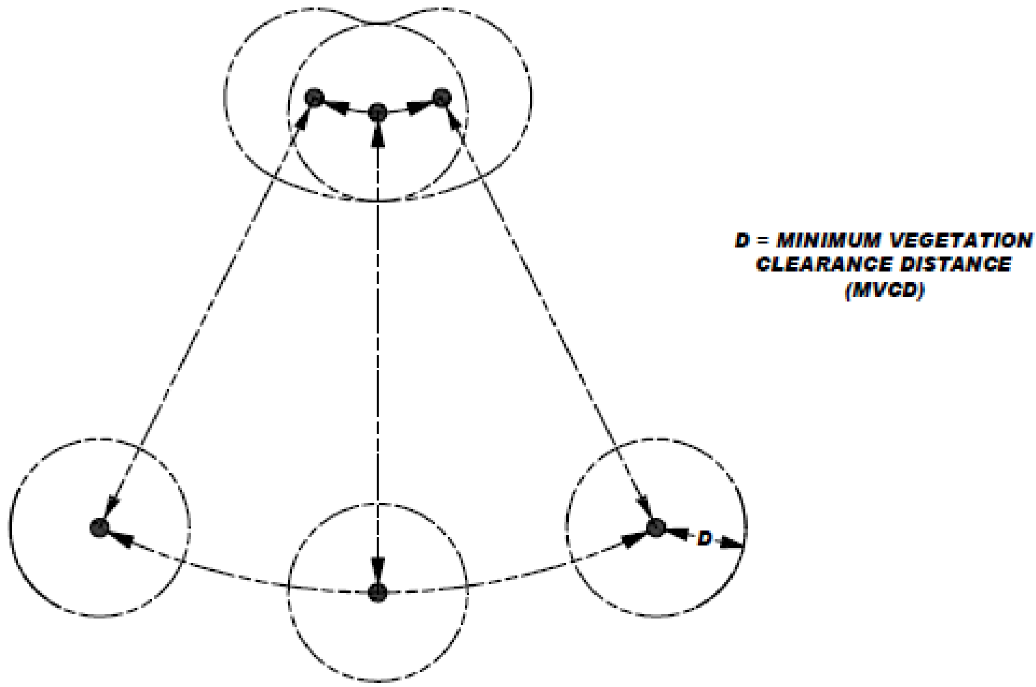

Figure 3

A cross-section view of a single conductor at a given point along the span is shown with six possible conductor positions due to movement resulting from thermal and mechanical loading.

Selecting a Maintenance Approach

In order to maintain adequate separation between vegetation and transmission line conductors, the Transmission Owner must craft a maintenance strategy that keeps vegetation well away from the spark-over zone mentioned above. In fact, it is generally necessary to incorporate a variety of maintenance strategies. For example, one Transmission Owner may utilize a combination of routine cycles, traditional IVM techniques and long-term planning. Another Transmission Owner may place a higher reliance on frequent inspections and follow-up remediation as opposed to a set cyclical approach. This variation of approaches is further warranted when factors, such as terrain, vegetation types, weather and climate, and any, environmental, legal or other land use constraints, must be considered in developing a Transmission Owner's specific approach to satisfying R3.

The following describes some strategies which may be utilized by a Transmission Owner. A Transmission Owner's basic maintenance approach in relatively flat terrain could be to remove all incompatible vegetation from the ROW if it has the right to do so and has no constraints. In mountainous terrain, however, this strategy could change to managing vegetation based on vegetation-to-conductor clearances, since it might not be necessary to remove vegetation in a valley that is far below the conductors at maximum sag.

If faced with easement constraints on a line design with sufficient ground clearance, the approach could be to allow vegetation such as fruit trees, but only up to a given height at maturity (for example 10 feet from the ground). If constraints cannot be overcome and if design clearances are sufficient, an exception to the Transmission Owner's 10-foot guideline might be made. If an approach is chosen to manage vegetation based primarily on clearance distances it could include an inspection regimen to regularly ensure that impending clearance problems are identified early for rectification.

ANSI A300 – Best Management Practices for Tree Care Operations

A description of ANSI A-300, part 7, is offered below to illustrate another maintenance approach that could be used in developing a comprehensive transmission vegetation management program.

Introduction

Integrated Vegetation Management (IVM) is a best management practice conveyed in the American National Standard for Tree Care Operations, Part 7 (ANSI 2006) and the International Society of Arboriculture *Best Management Practices: Integrated Vegetation Management* (Miller 2007). IVM is consistent with the requirements in FAC-003-02, and it provides practitioners with what industry experts consider to be appropriate techniques to apply to electric right-of-way projects in order to meet or exceed the Standard.

IVM is a system of managing plant communities whereby managers set objectives; identify compatible and incompatible vegetation; consider action thresholds; and evaluate, select and implement the most appropriate control method or methods to achieve set objectives. The choice of control method or methods should be based on the environmental impact and anticipated effectiveness; along with site characteristics, security, economics, current land use and other factors.

Planning and Implementation

Best management practices provide a systematic way of planning and implementing a vegetation management program. While designed primarily with transmission systems in mind, it is also applicable to distribution projects. As presented in ANSI A300 part 7 and the ISA best management practices, IVM consists of 6 elements:

1) Set Objectives
2) Evaluate the Site
3) Define Action Thresholds
4) Evaluate and Select Control Methods
5) Implement IVM
6) Monitor Treatment and Quality Assurance

The setting of objectives, defining action thresholds, and evaluating and selecting control methods all require decisions. The planning and implementation process is cyclical and continuous, because vegetation is dynamic and managers must have the flexibility to adjust their plans. Adjustments may be made at each stage as new information becomes available and circumstances evolve.

Set Objectives

Objectives should be clearly defined and documented. Examples of objectives can include promoting safety, preventing sustained outages caused by vegetation growing into electric facilities, maintaining regulatory compliance, protecting structures and security, restoring electric service during emergencies, maintaining access and clear lines of sight, protecting the environment, and facilitating cost effectiveness. Objectives should be based on site factors, such as workload and vegetation type, in addition to human, equipment and financial resources. They will vary from utility to utility and project to project, depending on line voltage and criticality, as well as topographical, environmental, fiscal and political considerations. However, where it is appropriate, the overriding focus should be on environmentally-sound, cost effective control of species that potentially conflict with the electric facility, while promoting compatible, early successional, sustainable plant communities.

Work Load Evaluations

Work-load evaluations are inventories of vegetation that could have a bearing on management objectives. Work load assessments can capture a variety of vegetation characteristics, such as location, height, species, size and condition, hazard status, density and clearance from conductors. Assessments should be conducted considering voltage, conductor sag from ambient temperatures and loading, and the potential influence of wind on line sway.

Evaluate and Select Control Methods

Control methods are the process through which managers achieve objectives. The most suitable control method best achieves management objectives at a particular site. Many cases call for a combination of methods. Managers have a variety of controls from which to choose, including manual, mechanical, herbicide and tree growth regulators, biological, and cultural options.

Manual Control Methods

Manual methods employ workers with hand-carried tools, including chainsaws, handsaws, pruning shears and other devices to control incompatible vegetation. The advantage of manual techniques is that they are selective and can be used where others may not be. On the other hand, manual techniques can be inefficient and expensive compared to other methods.

Mechanical Control Methods

Mechanical controls are done with machines. They are efficient and cost effective, particularly for clearing dense vegetation during initial establishment, or reclaiming neglected or overgrown right of way. On the other hand, mechanical control methods can be non-selective and disturb sensitive sites.

Tree Growth Regulator and Herbicide Control Methods

Tree growth regulators and herbicides can be effective for vegetation management. Tree growth regulators (TGRs) are designed to reduce growth rates by interfering with natural plant processes. TGRs can be helpful where removals are prohibited or impractical by reducing the growth rates of some fast-growing species.

Herbicides control plants by interfering with specific botanical biochemical pathways. Herbicide use can control individual plants that are prone to re-sprout or sucker after removal. When trees that re-sprout or sucker are removed without herbicide treatment, dense thickets develop, impeding access, swelling workloads, increasing costs, blocking lines-of-site, and deteriorating wildlife habitat. Treating suckering plants allows early successional, compatible species to dominate the right-of-way and out-compete incompatible species, ultimately reducing work.

Cultural Control Methods

Cultural methods modify habitat to discourage incompatible vegetation and establish and manage desirable, early successional plant communities. Cultural methods take advantage of seed banks of native, compatible species lying dormant on site. In the long run, cultural control is the most desirable method where it is applicable.

A cultural control known as cover-type conversion provides a competitive advantage to short-growing, early successional plants, allowing them to thrive and eventually out-compete unwanted tree species for sunlight, essential elements and water. The early successional plant community is relatively stable, tree-resistant and reduces the amount of work, including herbicide application, with each successive treatment.

Wire-Border Zone

The wire-border zone technique is a management philosophy that can be applied through cultural control. W.C. Bramble and W.R. Byrnes developed it in the mid-1980s out of research begun in 1952 on a transmission right-of-way in the Pennsylvania State Game Lands 33 Research and Demonstration project (Yahner and Hutnik (2004).

The wire zone is the section of a utility transmission right-of-way directly under the wires and extending outward about 10 feet on each side. The wire zone is managed to promote a low-growing plant community dominated by grasses, herbs and small shrubs (under 3 feet in height at maturity). The border zone is the remainder of the right-of-way. It is managed to establish small trees and tall shrubs (under 25 feet in height at maturity). When properly managed, diverse, tree-resistant plant communities develop in wire and border zones. The communities not only protect the electric facility and reduce long-term maintenance, but also enhance wildlife habitat, forest ecology and aesthetic values.

Although the wire-border zone is a best practice in many instances, it is not necessarily universally suitable. For example, standard wire-border zone prescriptions may be unnecessary where lines are high off the ground, such as across low valleys or canyons, so the technique can be modified without sacrificing reliability.

One way to accommodate variances in topography is to establish different regions based on wire height. For example, over canyon bottoms or other areas where conductors are 100 feet or more above the ground, only a few trees are likely to be tall enough to conflict with the lines. In those cases, trees that potentially interfere with the transmission lines can be removed selectively on a case-by-case basis.

In areas where the wire is lower, perhaps between 50-100 feet from the ground, a border zone community can be developed throughout the right-of-way. Note that in many cases, conductor attachment points are more than 50 feet off the ground, so a border zone community can be cultivated near structures. Where the line is less than 50 feet off the ground, managers could apply a full wire-border zone prescription.

An environmental advantage of this type of modification is stream protection. Streams often course through the valleys and canyons where lines are likely to be elevated. Leaving timber or border zone communities in canyon bottoms helps shelter this valuable habitat, enabling managers to achieve environmentally sensitive objectives.

Implement IVM

All laws and regulations governing IVM practices and specifications written by qualified vegetation managers must be followed. Integrated vegetation management control methods should be implemented on regular work schedules, which are based on established objectives and completed assessments. Work should progress systematically, using control measures determined to be best for varying conditions at specific locations along a right-of-way. Some considerations used in developing schedules include the importance and type of line, vegetation clearances, workloads, growth rate of predominant vegetation, geography, accessibility, and in some cases, time lapsed since the last scheduled work.

Clearances Following Work

Clearances following work should be sufficient to meet management objectives, including preventing trees from entering the Minimum Vegetation Clearance Distance, electric safety risks, service-reliability threats and cost.

Monitor Treatment and Quality Assurance

An effective program includes documented processes to evaluate results. Evaluations can involve quality assurance while work is underway and after it is completed. Monitoring for quality assurance should begin early to correct any possible miscommunication or misunderstanding on the part of crewmembers. Early and consistent observation and evaluation also provides an opportunity to modify the plan, if need be, in time for a successful outcome.

Utility vegetation management programs should have systems and procedures in place for documenting and verifying that vegetation management work was completed to specifications. Post-control reviews can be comprehensive or based on a statistically representative sample. This final review points back to the first step and the planning process begins again.

Summary of A-300 example

Integrated Vegetation Management offers among others, a systematic way of planning and implementing a vegetation management program as presented in ANSI A300 Part 7. This methodology enables a program to comply with the NERC *Transmission Vegetation Management Program* standard (FAC-003-2). Managers should select control options to best promote management objectives.

Vegetation Inspections

The standard in R6 establishes the frequency of vegetation inspections. These inspections can be used to “evaluate the site” as referred to in the second element of ANSI A300 Part 7. This necessary frequency may need to be less than the annually based on anticipated growth rates of the local vegetation, length of the growing season for the geographical area, limited ROW width, rainfall amounts, etc.

Annual Work Plan

Requirement R7 of the Standard addresses the execution of the annual work plan. A comprehensive approach that exercises the full extent of legal rights is superior to incremental management in the long term because it reduces overall encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient at all locations on the ROW. Removal is superior to pruning. Removal minimizes the possibility of conflicts between energized conductors and vegetation. When this is not possible, the approach should be to use vegetation maintenance methods to work towards or achieve the maximum use of the ROW.

Requirement R4

R4. *Each Transmission Owner, without any intentional time delay, shall notify the control center holding switching authority for the associated applicable transmission line when the Transmission Owner has confirmed the existence of a vegetation condition that is likely to cause a Fault at any moment.*

Rationale

This is to ensure expeditious communication between the Transmission Owner and the control center when a critical situation is confirmed.

M4. *Each Transmission Owner that has a confirmed vegetation condition likely to cause a Fault at any moment will have evidence that it notified the control center holding switching authority for the associated transmission line without any intentional time delay. Examples of evidence may include control center logs, voice recordings, switching orders, clearance orders and subsequent work orders. (R4)*

R4 is a risk-based requirement. It focuses on preventative actions to be taken by the Transmission Owner for the mitigation of Fault risk when a vegetation threat is confirmed. R4 involves the notification of potentially threatening vegetation conditions, without any intentional delay, to the control center holding switching authority for that specific transmission line. Examples of acceptable unintentional delays may include communication system problems (for example, cellular service or two-way radio disabled), crews located in remote field locations with no communication access, delays due to severe weather, etc.

Confirmation is key that a threat actually exists due to vegetation. This confirmation could be in the form of a Transmission Owner's employee who personally identifies such a threat in the field. Confirmation could also be made by sending out an employee to evaluate a situation reported by a landowner.

Vegetation-related conditions that warrant a response include vegetation that is near or encroaching into the MVCD (a grow-in issue) or vegetation that could fall into the transmission conductor (a fall-in issue). A knowledgeable verification of the risk would include an assessment of the possible sag or movement of the conductor while operating between no-load conditions and its rating.

The Transmission Owner has the responsibility to ensure the proper communication between field personnel and the control center to allow the control center to take the appropriate action until the vegetation threat is relieved. Appropriate actions may include a temporary reduction in the line loading, switching the line out of service, or positioning the system in recognition of the increasing risk of outage on that circuit. The notification of the threat should be communicated in terms of minutes or hours as opposed to a longer time frame for corrective action plans (see R5).

All potential grow-in or fall-in vegetation-related conditions will not necessarily cause a Fault at any moment. For example, some Transmission Owners may have a danger tree identification program that identifies trees for removal with the potential to fall near the line. These trees would not require notification to the control center unless they pose an immediate fall-in threat.

Requirement R5

R5. *When a Transmission Owner is constrained from performing vegetation work on an applicable line operating within their Rating and all Rated Electrical Operating Conditions, and the constraint may lead to a vegetation encroachment into the MVCD prior to the implementation of the next annual work plan, then the Transmission Owner shall take corrective action to ensure continued vegetation management to prevent encroachments.*

M5. *Each Transmission Owner has evidence of the corrective action taken for each constraint where an applicable transmission line was put at potential risk. Examples of acceptable forms of evidence may include initially-planned work orders, documentation of constraints from landowners, court orders, inspection records of increased monitoring, documentation of the de-rating of lines, revised work orders, invoices, or evidence that a line was de-energized. (R5)*

Rationale

Legal actions and other events may occur which result in constraints that prevent the Transmission Owner from performing planned vegetation maintenance work.

In cases where the transmission line is put at potential risk due to constraints, the intent is for the Transmission Owner to put interim measures in place, rather than do nothing.

The corrective action process is not intended to address situations where a planned work methodology cannot be performed but an alternate work methodology can be used.

R5 is a risk-based requirement. It focuses upon preventative actions to be taken by the Transmission Owner for the mitigation of Sustained Outage risk when temporarily constrained from performing vegetation maintenance. The intent of this requirement is to deal with situations that prevent the Transmission Owner from performing planned vegetation management work and, as a result, have the potential to put the transmission line at risk. Constraints to performing vegetation maintenance work as planned could result from legal injunctions filed by property owners, the discovery of easement stipulations which limit the Transmission Owner's rights, or other circumstances.

This requirement is not intended to address situations where the transmission line is not at potential risk and the work event can be rescheduled or re-planned using an alternate work methodology. For example, a land owner may prevent the planned use of chemicals on non-threatening, low growth vegetation but agree to the use of mechanical clearing. In this case the Transmission Owner is not under any immediate time constraint for achieving the management objective, can easily reschedule work using an alternate approach, and therefore does not need to take interim corrective action.

However, in situations where transmission line reliability is potentially at risk due to a constraint, the Transmission Owner is required to take an interim corrective action to mitigate the potential risk to the transmission line. A wide range of actions can be taken to address various situations. General considerations include:

- Identifying locations where the Transmission Owner is constrained from performing planned vegetation maintenance work which potentially leaves the transmission line at risk.
- Developing the specific action to mitigate any potential risk associated with not performing the vegetation maintenance work as planned.
- Documenting and tracking the specific action taken for each location.
- In developing the specific action to mitigate the potential risk to the transmission line the Transmission Owner could consider location specific measures such as modifying the inspection and/or maintenance intervals. Where a legal constraint would not allow any vegetation work, the interim corrective action could include limiting the loading on the transmission line.
- The Transmission Owner should document and track the specific corrective action taken at each location. This location may be indicated as one span, one tree or a combination of spans on one property where the constraint is considered to be temporary.

Requirement R6

R6. *Each Transmission Owner shall perform a Vegetation Inspection of 100% of its applicable lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.) at least once per calendar year and with no more than 18 months between inspections on the same ROW.*[5]

M6. *Each Transmission Owner has evidence that it conducted Vegetation Inspections of the transmission line ROW for all applicable lines at least once per calendar year but with no more than 18 months between inspections on the same ROW. Examples of acceptable forms of evidence may include completed and dated work orders, dated invoices, or dated inspection records. (R6)*

Rationale

Inspections are used by Transmission Owners to assess the condition of the entire ROW. The information from the assessment can be used to determine risk, determine future work and evaluate recently-completed work. This requirement sets a minimum Vegetation Inspection frequency of once per calendar year but with no more than 18 months between inspections on the same ROW. Based upon average growth rates across North America and on common utility practice, this minimum frequency is reasonable. Transmission Owners should consider local and environmental factors that could warrant more frequent inspections.

R6 is a risk-based requirement. This requirement sets a minimum time period for completing Vegetation Inspections that fits general industry practice. In addition, the fact that Vegetation Inspections can be performed in conjunction with general line inspections further facilitates a Transmission Owner's ability to meet this requirement. However, the Transmission Owner may determine that more frequent inspections are needed to maintain reliability levels, dependent upon such factors as anticipated growth rates of the local vegetation, length of the growing season for the geographical area, limited ROW width, and rainfall amounts. Therefore it is expected that some transmission lines may be designated with a higher frequency of inspections.

Footnote 5 is added to address the situation where a Transmission Owner through no fault of its own, would be unable to complete the vegetation inspection within the allotted time period. This would include the situation of mutual aid as well as disasters to the Transmission Owner's own system.

[5] When the Transmission Owner is prevented from performing a Vegetation Inspection within the timeframe in R6 due to a natural disaster, the TO is granted a time extension that is equivalent to the duration of the time the TO was prevented from performing the Vegetation Inspection.

The VSL for Requirement R6 has VSL categories ranked by the percentage of the required ROW inspections completed. To calculate the percentage of inspection completion, the Transmission Owner may choose units such as: line miles or kilometers, circuit miles or kilometers, pole line miles, ROW miles, etc.

For example, when a Transmission Owner operates 2,000 miles of applicable transmission lines this Transmission Owner will be responsible for inspecting all the 2,000 miles of lines at least once during the calendar year. If one of the included lines was 100 miles long, and if it was not inspected during the year, then the amount failed to inspect would be 100/2000 = 0.05 or 5%.

The “Low VSL” for R6 would apply in this example.

Requirement R7

R7. *Each Transmission Owner shall complete 100% of its annual vegetation work plan of applicable lines to ensure no vegetation encroachments occur within the MVCD. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made (provided they do not allow encroachment of vegetation into the MVCD) and must be documented. The percent completed calculation is based on the number of units actually completed divided by the number of units in the final amended plan (measured in units of choice - circuit, pole line, line miles or kilometers, etc.) Examples of reasons for modification to annual plan may include:*

Rationale

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. It allows modifications to the planned work for changing conditions, taking into consideration anticipated growth of vegetation and all other environmental factors, provided that those modifications do not put the transmission system at risk of a vegetation encroachment.

- Change in expected growth rate/ environmental factors
- Circumstances that are beyond the control of a Transmission Owner[6]
- Rescheduling work between growing seasons
- Crew or contractor availability/ Mutual assistance agreements
- Identified unanticipated high priority work
- Weather conditions/Accessibility
- Permitting delays
- Land ownership changes/Change in land use by the landowner
- Emerging technologies

M7. *Each Transmission Owner has evidence that it completed its annual vegetation work plan. Examples of acceptable forms of evidence may include a copy of the completed annual work plan (including modifications if any), dated work orders, dated invoices, or dated inspection records. (R7)*

R7 is a risk-based requirement. The Transmission Owner is required to implement its work plan for vegetation management to accomplish the purpose of this Standard. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made and documented provided they do not put the transmission system at risk. The annual

[6] Circumstances that are beyond the control of a Transmission Owner include but are not limited to natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, ice storms, floods, or major storms as defined either by the TO or an applicable regulatory body.

work plan requirement is not intended to necessarily require a "span-by-span", or even a "line-by-line" detailed description of all work to be performed. It is only intended to require that the Transmission Owner provide evidence of annual planning and execution of a vegetation management maintenance approach which successfully prevents encroachment of vegetation into the MVCD.

For example, when a Transmission Owner identifies 1,000 miles of applicable transmission lines to be completed in the TO's annual plan, the Transmission Owner will be responsible completing those identified miles. If a TO makes a modification to the annual plan that does not put the transmission system at risk of an encroachment the annual plan may be modified. If 100 miles of the annual plan is deferred until next year the calculation to determine what percentage was completed for the current year would be: 1000 – 100 (deferred miles) = 900 modified annual plan, or 900 / 900 = 100% completed annual miles. If a TO only completed 875 of the total 1000 miles with no acceptable documentation for modification of the annual plan the calculation for failure to complete the annual plan would be: 1000 – 875 = 125 miles failed to complete then, 125 miles (not completed) / 1000 total annual plan miles = 12.5% failed to complete.

The ability to modify the work plan allows the Transmission Owner to change priorities or treatment methodologies during the year as conditions or situations dictate. For example recent line inspections may identify unanticipated high priority work, weather conditions (drought) could make herbicide application ineffective during the plan year, or a major storm could require redirecting local resources away from planned maintenance or work may be deferred to a subsequent year because of slower-than-expected growth. This situation may also include complying with mutual assistance agreements by moving resources off the Transmission Owner's system to work on another system. Any of these examples could result in acceptable deferrals or additions to the annual work plan. Modifications to the annual work plan must always ensure the reliability of the electric Transmission system.

In general, the vegetation management maintenance approach should use the full extent of the Transmission Owner's legal rights on the ROW. A comprehensive approach that exercises the full extent of legal rights on the ROW is superior to incremental management in the long term because it reduces the overall potential for encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient.

When developing the annual work plan the Transmission Owner should allow time for procedural requirements to obtain permits to work on federal, state, provincial, public, tribal lands. In some cases the lead time for obtaining permits may necessitate preparing work plans more than a year prior to work start dates. Transmission Owners may also need to consider those special landowner requirements as documented in easement instruments.

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. Therefore, deferrals or relevant changes to the annual plan shall be documented. Depending on the planning and documentation format used by the Transmission Owner, evidence of successful annual work plan execution could consist of signed-off work orders, signed contracts, printouts from work management systems, spreadsheets of planned

versus completed work, timesheets, work inspection reports, or paid invoices. Other evidence may include photographs and walk-through reports.

Appendix 1: Clearance Distance Derivation by the Gallet Equation

The Gallet Equation is a well-known method of computing the required strike distance for proper insulation coordination, and has the ability to take into account various air gap geometries, as well as non-standard atmospheric conditions. When the Gallet Equation and conservative probabilistic methods are combined, i.e. deterministic design, spark-over probabilities of 10^{-6} or less are achieved. This approach is well known for its conservatism and was used to design the first 500 kV and 765 kV lines in North America [1]. Thus, the deterministic design approach using the Gallet Equation is used for the standard to compute the minimum strike distance between transmission lines and the vegetation that may be present in or along the transmission corridor.

Method Explanation (Gallet Equation)

In 1975 G. Gallet published a benchmark paper that provided a method to compute the critical flashover voltage (CFO) of various air gap geometries [4]. The Gallet Equation uses various “gap factors” to take into account various air gap geometries. Various gap factor values are provided in [1]. If the vegetation in a transmission corridor, e.g. a tree, is assumed electrically to be a large structure then the CFO of such an air gap geometry can be computed for dry or wet conditions using a well established equation proposed by Gallet [1],[2],[4],

$$CFO_A = k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} \qquad (1)$$

where,

k_w is defined as the factor that takes into account wet or dry conditions (dry = 1.0 and wet = 0.96) and phase arrangement (multiply by 1.08 for outside phase), e.g. outside phase and wet conditions = (0.96)(1.08) = 1.037,

k_g is defined as the gap factor (1.3 for conductor to large structure),

D is the strike distance (m),

CFO_A is the CFO for the relative air density (kV).

δ is defined as the relative air density and is approximately equal to (2) where A is the altitude in km,

$$\delta = e^{-\frac{A}{8.6}} \tag{2}$$

$$m = 1.25G_0 \left(G_0 - 0.2\right) \tag{3}$$

$$G_0 = \frac{CFO_s}{500 \cdot D} \tag{4}$$

$$CFO_s = k_w \cdot k_g \cdot \frac{3400}{1 + \frac{8}{D}} \tag{5}$$

where CFO_S is the CFO for standard atmospheric conditions (kV). Using (1)-(5), the required CFO_A can be computed using an iterative process.

Once the CFO_A is known, deterministic methods can be used to determine the required clearance distance. If we let the maximum switching overvoltage be equal to the withstand voltage of the air gap (CFO_A - 3σ) then the CFO_A can be written as (6).

$$CFO_A = \frac{V_m}{1 - 3\left(\frac{\sigma}{CFO_A}\right)} \tag{6}$$

where

V_m is equal to the maximum switching overvoltage, i.e. the value that has a 0.135% chance of being exceeded,

σ is the standard deviation of the air gap insulation,

CFO_A is the critical flashover voltage of the air gap insulation under non-standard atmospheric conditions.

The ratio of σ to the CFO_A given in (6) can be assumed to be 0.05 (5%) [1]. Thus, (6) can be written as (7).

$$CFO_A = \frac{V_m}{0.85} \tag{7}$$

Substituting (7) into (1) we arrive at (8).

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1 + \frac{8}{D}} \tag{8}$$

Equation 8 relates the maximum transient overvoltage, V_m, to the air gap distance, D. Using (8) to compute the required clearance distance for the specified air gap geometry (conductor to large structure) results in a probability of flashover in the range of 10^{-6}.

Transient Overvoltage

In general, the worst case transient overvoltages occurring on a transmission line are caused by energizing or re-energizing the line with the latter being the extreme case if trapped charge is present. The intent of FAC-003 is to keep a transmission line that is *in service* from becoming de-energized (i.e. tripped out) due to sparkover from the line conductor to nearby vegetation. Thus, the worst case scenarios that are typically analyzed for insulation coordination purposes (e.g. line energization and re-energization) can be ignored. For the purposes of FAC-003-2, the worst case transient overvoltage then becomes the maximum value that can occur with the line energized. Determining a realistic value of transient overvoltage for this situation is difficult because the maximum transient overvoltage factors listed in the literature are based on a switching operation of the line in question. In other words, these maximum overvoltage values (e.g. the values listed in [2], [3] and [5]) are based on the assumption that the subject line is being energized, re-energized or de-energized. These operations, by their very nature, will create the largest transient overvoltages. Typical values of transient overvoltages of in-service lines, as such, are not readily available in the literature because the resulting level of overvoltage is negligible compared with the maximum (e.g. re-energizing a transmission line with trapped charge). A conservative value for the maximum transient overvoltage that can occur anywhere along the length of an in-service ac line is approximately 2.0 p.u.[2]. This value is a conservative estimate of the transient overvoltage that is created at the point of application (e.g. a substation) by switching a capacitor bank without a pre-insertion device (e.g. closing resistors). At voltage levels where capacitor banks are not very common (e.g. 362 kV), the maximum transient overvoltage of an “in-service” ac line are created by fault initiation on adjacent ac lines and shunt reactor bank switching. These transient voltages are usually 1.5 p.u. or less [2]. It is well known that these theoretical transient overvoltages will not be experienced at locations remote from the bus at which they were created; however, in order to be conservative, it will be assumed that all nearby ac lines are subjected to this same level of overvoltage. Thus, a maximum transient overvoltage factor of 2.0 p.u. for 302 kV and below and 1.4 p.u. for ac transmission lines 362 kV and above is used to compute the required clearance distances for vegetation management purposes.

The overvoltage characteristics of dc transmission lines vary somewhat from their ac counterparts. The referenced empirically derived transient overvoltage factor used to calculate the minimum clearance distances from dc transmission lines to vegetation for the purpose of FAC-003-2 will be 1.8 p.u.[3].

Example Calculation

An example calculation is presented below using the proposed method of computing the vegetation clearance distances. It is assumed that the line in question has a maximum operating voltage of 550 kV_{rms} line-to-line. Using a per unit transient overvoltage factor of 1.4, the result is a peak transient voltage of 629 kV_{crest}. It is further assumed that the line in question operates at a maximum altitude of 7000 feet (2.134 km) above sea level.

The required withstand voltage of the air gap must be equal to or greater than 629 kV_{crest}. Since the altitude is above sea level, (1) - (5) have to be iterated on to achieve the desired result. Equation (9) can be used as an initial guess for the clearance distance.

$$D_i = \frac{8}{\frac{3400 \cdot k_w \cdot k_g}{\left(\frac{V_m}{0.85}\right)} - 1} \tag{9}$$

For our case here, V_m is equal to 629 kV, k_w = 1.037 and k_g = 1.3. Thus,

$$D_i = \frac{8}{\frac{3400 \cdot k_w \cdot k_g}{\left(\frac{V_m}{0.85}\right)} - 1} = \frac{8}{\frac{3400 \cdot 1.037 \cdot 1.3}{\left(\frac{629}{0.85}\right)} - 1} = 1.535m \tag{10}$$

Using (2)-(5) and (8) the withstand voltage of the air gap is next computed. This value will then be compared to the maximum transient overvoltage.

$$CFO_S = k_w \cdot k_g \cdot \frac{3400}{1 + \frac{8}{D}} = 1.037 \cdot 1.3 \cdot \frac{3400}{1 + \frac{8}{1.535}} = 737.7kV \tag{11}$$

$$\delta = e^{-\frac{A}{8.6}} = e^{-\frac{2.134}{8.6}} = 0.78 \tag{12}$$

$$G_O = \frac{CFO_S}{500 \cdot D} = \frac{737.7}{(500) \cdot (1.535)} = 0.961 \tag{13}$$

$$m = 1.25 \cdot G_O (G_O - 0.2) = 1.25 \cdot 0.961(0.961 - 0.2) = 0.915 \tag{14}$$

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1 + \frac{8}{D}} = (0.85)(1.037)(1.3)(0.78)^{0.915} \left(\frac{3400}{1 + \frac{8}{1.535}} \right) = 499.8kV \tag{15}$$

The calculated V_m is less than 629 kV; thus, the clearance distance must be increased. A few iterations using (2)-(5) and (8) are required until the computed $V_m \geq 629$ kV. For this case it was found that D = 1.978 m (6.49 feet) yielded V_m = 629.3 kV. Using this clearance distance the following values were computed for the final iteration.

$$CFO_S = k_w \cdot k_g \cdot \frac{3400}{1+\frac{8}{D}} = 1.037 \cdot 1.3 \cdot \frac{3400}{1+\frac{8}{1.978}} = 908.5kV \tag{16}$$

$$\delta = e^{-\frac{A}{8.6}} = e^{-\frac{2.134}{8.6}} = 0.78 \tag{17}$$

$$G_O = \frac{CFO_S}{500 \cdot D} = \frac{908.5}{(500)\cdot(1.978)} = 0.919 \tag{18}$$

$$m = 1.25 \cdot G_O(G_O - 0.2) = 1.25 \cdot 0.919(0.919 - 0.2) = 0.825 \tag{19}$$

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} = (0.85)(1.037)(1.3)(0.78)^{0.825}\left(\frac{3400}{1+\frac{8}{1.978}}\right) = 629.3kV \tag{20}$$

Therefore, the minimum vegetation clearance distance for a maximum line to line ac operating voltage of 550 kV at 7000 feet above sea level is 1.978 m (6.49 feet). Table 1 provides calculated distances for various altitudes and maximum system operating ac voltages.

* Such lines are applicable to this standard only if PC has determined such per FAC-014 (refer to the Applicability Section above).

---

[7] The distances in this Table are the minimums required to prevent Flash-over; however prudent vegetation maintenance practices dictate that substantially greater distances will be achieved at time of vegetation maintenance.

[8] Where applicable lines are operated at nominal voltages other than those listed, The Transmission Owner should use the maximum system voltage to determine the appropriate clearance for that line.

North American Electric Reliability Corporation

Vegetation Management Standard Drafting Team
for NERC Project 2007-07

September 30, 2011

Disclaimer

This supporting document is supplemental to the reliability standard FAC-003-2 — Transmission Vegetation Management and does not contain mandatory requirements subject to compliance review.~~December 17, 2010~~

Throughout this document, for ready reference, there are "copies" in italic font of the wording in the Standard. Any "copy" of any part of the Standard in this document should be cross checked to the Standard and if any difference exists, then the Standard's exact wording should be considered the intended wording for this document.

Introduction

This document is intended to provide supplemental information and guidance for complying with the requirements of Reliability Standard FAC-003-2.

The purpose of the Standard is to improve the reliability of the electric transmission system by preventing those vegetation related outages that could lead to Cascading.

Compliance with the Standard is mandatory and enforceable.

Special Note: The Application of the Results-Based Approach to FAC-003-2

In its three-year assessment as the ERO, NERC acknowledged stakeholder comments and committed to:

i) addressing quality issues to ensure each reliability standard has a clear statement of purpose, and has outcome-focused requirements that are clear and measurable; and
ii) eliminating requirements that do not have an impact on bulk power system reliability.

In 2010, the Standards Committee approved a recommendation to use Project 2007-07 Vegetation Management as a first proof of concept for developing results-based standards.

~~The Standard Drafting Team (SDT) employed a defense-in-depth[1] strategy for FAC-003-2, where each requirement has a role in preventing~~This standard is not intended to address outages such as those due to vegetation fall-ins or blow-ins from outside the Right-of-Way, vandalism, human activities or acts of nature. Operating experience indicates that trees that have grown out of specification have contributed to Cascading, especially under heavy electrical loading conditions.

This standard utilizes three types of requirements to provide layers of protection to prevent vegetation related outages that could lead to Cascading~~. This portfolio of requirements was designed to achieve an overall defense-in-depth strategy and to comply with the quality objectives identified in the *Acceptance Criteria of a Reliability Standard* document.~~:

~~The SDT developed a portfolio of performance, risk, and competency-based mandatory reliability requirements to support an effective defense-in-depth strategy. Each Requirement was developed using one of the following requirement types:~~

a) Performance-based ~~-~~ — defines a particular reliability objective or outcome to be achieved. In its simplest form, a results-based requirement has four components: *who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome*?
b) Risk-based ~~-~~ — preventive requirements to reduce the risks of failure to acceptable tolerance levels. A risk-based reliability requirement should be framed as: who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome *that reduces a stated risk to the reliability of the bulk power system*?

~~[1] A defense-in-depth strategy for reliability standards recognizes that each requirement in the NERC standards has a role in preventing system failures, and that these roles are complementary and reinforcing. These prevention measures should be arranged in a series of defensive layers or walls. No single defensive layer provides complete protection from failure by itself. But taken together, with well-designed layers including performance, risk, and competency-based requirements, a defense-in-depth approach can be very effective in preventing future large scale power system failures.~~

c) Competency-based ~~-~~ — defines a minimum set of capabilities an entity needs to have to demonstrate it is able to perform its designated reliability functions. A competency-based reliability requirement should be framed as: *who, under what conditions (if any), shall have what capability, to achieve what particular result or outcome to perform an action to achieve a result or outcome or to reduce a risk to the reliability of the bulk power system*?

The defense-in-depth strategy for reliability standards development recognizes that each requirement in a NERC reliability standard has a role in preventing system failures, and that these roles are complementary and reinforcing. Reliability standards should not be viewed as a body of unrelated requirements, but rather should be viewed as part of a portfolio of requirements designed to achieve an overall defense-in-depth strategy and comport with the quality objectives of a reliability standard.

This NERC Vegetation Management Standard ("standard") uses a defense-in-depth approach to improve the reliability of the electric Transmission System by:

- Requiring that vegetation be managed to prevent vegetation encroachment inside the flash-over clearance (R1 and R2);
- Requiring documentation of the maintenance strategies, procedures, processes and specifications used to manage vegetation to prevent potential flash-over conditions including consideration of 1) conductor dynamics and 2) the interrelationships between vegetation growth rates, control methods and the inspection frequency (R3);
- Requiring timely notification to the appropriate control center of vegetation conditions that could cause a flash-over at any moment (R4);
- Requiring corrective actions to ensure that flash-over distances will not be violated due to work constrains such as legal injunctions (R5);
- Requiring inspections of vegetation conditions to be performed annually (R6); and
- Requiring that the annual work needed to prevent flash-over is completed (R7).

For this standard, the requirements have been developed as follows:

- Performance-based: Requirements 1 and 2
- Competency-based: Requirement 3
- Risk-based: Requirements 4, 5, 6 and 7

R3 serves as the first line of defense by ensuring that entities understand the problem they are trying to manage and have fully developed strategies and plans to manage the problem. R1, R2, and R7 serve as the second line of defense by requiring that entities carry out their plans and manage vegetation. R6, which requires inspections, may be either a part of the first line of defense (as input into the strategies and plans) or as a third line of defense (as a check of the first and second lines of defense). R4 serves as the final line of defense, as it addresses cases in which all the other lines of defense have failed.

Major outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations.

Adherence to the standard requirements for applicable lines on any kind of land or easement, whether they are Federal Lands, state or provincial lands, public or private lands, franchises, easements or lands owned in fee, will reduce and manage this risk. For the purpose of the standard the term "public lands" includes municipal lands, village lands, city lands, and a host of other governmental entities.

The standard addresses vegetation management along applicable overhead lines and does not apply to underground lines, submarine lines or to line sections inside an electric station boundary.

The standard focuses on transmission lines to prevent those vegetation related outages that could lead to Cascading. It is not intended to prevent customer outages due to tree contact with lower voltage distribution system lines. For example, localized customer service might be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. However, this standard is not written to address such isolated situations which have little impact on the overall electric transmission system.
Since vegetation growth is constant and always present, unmanaged vegetation poses an increased outage risk, especially when numerous transmission lines are operating at or near their Rating. This can present a significant risk of consecutive line failures when lines are experiencing large sags thereby leading to Cascading. Once the first line fails the shift of the current to the other lines and/or the increasing system loads will lead to the second and subsequent line failures as contact to the vegetation under those lines occurs. Conversely, most other outage causes (such as trees falling into lines, lightning, animals, motor vehicles, etc.) are not an interrelated function of the shift of currents or the increasing system loading. These events are not any more likely to occur during heavy system loads than any other time. There is no cause-effect relationship which creates the probability of simultaneous occurrence of other such events. Therefore these types of events are highly unlikely to cause large-scale grid failures. Thus, this standard places the highest priority on the management of vegetation to prevent vegetation grow-ins.

The drafting team reviewed and edited version 1 of FAC-003-1 to remove prescriptive and administrative language in order to distill the technical requirements down to their essential reliability content. ~~Text that~~ Explanatory text is ~~explanatory in nature is placed in a~~offered within two special ~~section of the standard entitled~~ sections, Background and Guideline and Technical Basis, to aid in ~~the~~ understanding ~~of~~ the standard and its requirements. ~~Furthermore,~~ Rationale text boxes and other text boxes are also inserted ~~alongside each requirement~~throughout the standard to ~~communicate~~aid understanding the sections. The Effective Dates section covers five special cases for lines that undergo specific transitions as or after the ~~foundation for~~ standard has reached the ~~requirement.~~

~~Disclaimer~~

~~This supporting document is supplemental to the reliability standard FAC-003-2 — Transmission Vegetation Management and does not contain mandatory requirements subject to compliance review.~~

general effective date.

Preface

The NERC Vegetation Management Standard Drafting Team (VM SDT) acknowledges those across the industry who contributed to the development of this Standard and companion Technical Reference document. ~~The~~This Technical Reference document is intended to provide supplemental explanatory background and guidance related to requirements contained in the Standard but does not in itself contain requirements subject to compliance review.

The ~~VM SDT believes that a well-designed and executed Transmission Vegetation Management Program (TVMP) will have few problems meeting the requirements of this Standard. While the~~ Standard requires ~~a TVMP~~ the Transmission Owner to ~~contain certain elements,~~have documentation of the maintenance strategies or procedures or processes or specifications it uses to be successful in managing vegetation. This allows the Transmission Owner to exercise substantial flexibility in designing ~~a TVMP~~its overall program to meet ~~local~~its specific needs provided ~~it~~that the Transmission Owner also meets the purpose of the Standard.

While there are many approaches to vegetation management, the VMSDT supports industry best practices contained in ANSI A300 (Part 7) – Integrated Vegetation Management (IVM) practices on Utility Rights-of-way, as well as the companion publication Best Management Practices – Integrated Vegetation Management, as an effective strategy to maintain compliance with this Standard. ANSI A300 (Part 7), approved by industry consensus in 2006, contains many elements needed for an effective ~~TVMP as required by~~vegetation management. Those elements are similar to the requirements in this Standard. One key element is the "wire zone – border zone" concept. Supported by over 50 years of continuous research, wire zone – border zone is a proven method to manage vegetation on transmission rights-of-ways and is an industry accepted best practice to help ensure electric system reliability.

The VM SDT believes that Transmission Owners who adopt and effectively implement IVM principles, particularly the "wire zone – border zone" concept, are far less likely to experience a vegetation caused outage than those who do not.

~~Definition of Terms~~Effective Dates & Special States of Transition

The first sentence of the Effective Dates section is standard language used in most NERC standards to cover the general effective date and is sufficient to cover the vast majority of situations. Five special cases are needed to cover effective dates for individual lines which undergo transitions after the general effective date. These special cases cover the effective dates for those lines which are initially becoming subject to the standard, those lines which are changing their applicability within the standard, and those lines which are changing in a manner that removes their applicability to the standard. The text for each of these five cases is copied from the standard and is shown below in italic font. An explanation of the need for each special exception follows each copied text section.

1. *A line operated below 200kV, designated by the Planning Coordinator as an element of an Interconnection Reliability Operating Limit (IROL) or designated by the Western Electricity Coordinating Council (WECC) as an element of a Major WECC Transfer Path, becomes subject to this standard the latter of: 1) 12 months after the date the Planning Coordinator or WECC initially designates the line as being an element of an IROL or an element of a Major WECC Transfer Path, or 2) January 1 of the planning year when the line is forecast to become an element of an IROL or an element of a Major WECC Transfer Path.*

Case 1 is needed because the Planning Coordinators may designate lines below 200 kV to become elements of an IROL or Major WECC Transfer Path in a future Planning Year (PY). For example, studies by the Planning Coordinator in 2011 may identify a line to have that designation beginning in PY 2021, ten years after the planning study is performed. It is not intended for the Standard to be immediately applicable to, or in effective for, that line until that future PY begins. The effective date provision for such lines ensures that the line will become subject to the standard on the January 1 of the PY specified with an allowance of at least 12 months for the Transmission Owner to make the necessary preparations to achieve compliance on that line. The table below has some explanatory examples of the application.

Date that Planning Study is completed	PY the line will become an IROL element	Date 1	Date 2	Effective Date The latter of Date 1 or Date 2
05/15/2011	2012	05/15/2012	01/01/2012	05/15/2012
05/15/2011	2013	05/15/2012	01/01/2013	01/01/2013
05/15/2011	2014	05/15/2012	01/01/2014	01/01/2014
05/15/2011	2021	05/15/2012	01/01/2021	01/01/2021

2. *A line operated below 200 kV currently subject to this standard as a designated element of an IROL or a Major WECC Transfer Path which has a specified date for the removal of such designation will no longer be subject to this standard effective on that specified date.*

Case 2 is needed because a line operating below 200kV designated as an element of an IROL or Major WECC Transfer Path may be removed from that designation due to system improvements, changes in generation, changes in loads or changes in studies and analysis of the network.

3. *A line operated at 200 kV or above, currently subject to this standard which is a designated element of an IROL or a Major WECC Transfer Path and which has a specified date for the removal of such designation will be subject to Requirement R2 and no longer be subject to Requirement R1 effective on that specified date*

Case 3 is needed because a line operating at 200 kV or above that once was designated as an element of an IROL or Major WECC Transfer Path may be removed from that designation due to system improvements, changes in generation, changes in loads or changes in studies and analysis of the network. Such changes result in the need to apply R1 to that line until that date is reached and then to apply R2 to that line thereafter.

4. *An existing transmission line operated at 200kV or higher which is newly acquired by an asset owner and which was not previously subject to this standard becomes subject to this standard 12 months after the acquisition date.*

Case 4 is needed because an existing line that is to be operated at 200 kV or above can be acquired by a Transmission Owner from a third party such as a Distribution Provider or other end-user who was using the line solely for local distribution purposes, but the Transmission owner, upon acquisition, is incorporating the line into the interconnected electrical energy transmission network which will thereafter make the line subject to the standard.

5. *An existing transmission line operated below 200kV which is newly acquired by an asset owner and which was not previously subject to this standard becomes subject to this standard 12 months after the acquisition date of the line if at the time of acquisition the line is designated by the Planning Coordinator as an element of an IROL or by WECC as an element of a Major WECC Transfer Path.*

Case 5 is needed because an existing line that is operated below 200 kV can be acquired by a Transmission Owner from a third party such as a Distribution Provider or other end-user who was using the line solely for local distribution purposes, but the Transmission owner, upon acquisition, is incorporating the line into the interconnected electrical energy transmission network. In this special case the line upon acquisition was designated as an element of an Interconnection Reliability Operating Limit (IROL) or an element of a Major WECC transfer Path.

Definition of Terms

Right-of-Way (ROW)*

-*The corridor of land under a transmission line(s) needed to operate the line(s). The width of the corridor is established by engineering or construction standards as documented in either construction documents, pre-2007 vegetation maintenance records, or by the blowout standard in effect when the line was built. The ROW width in no case exceeds the Transmission Owner's legal rights but may be less based on the aforementioned criteria.*

The current glossary definition of this NERC term is modified to address the issues set forth in Paragraph 734 of FERC Order 693.

The current NERC glossary definition of Right of Way has been modified to address the matter set forth in Paragraph 734 of FERC Order 693. The Order pointed out that Transmission Owners may in some cases own more property or rights than are needed to reliably operate transmission lines. This modified definition represents a slight but significant departure from the strict legal definition of "right of way" in that this definition is based on engineering and construction considerations that establish the width of a corridor from a technical basis. The pre-2007 maintenance records are included to allow the use of such vegetation widths if there were no engineering or construction standards that referenced the width of right of way to be maintained for vegetation on a particular line but the evidence exists in maintenance records for a width that was in fact maintained prior to this standard becoming mandatory. Such widths may be the only information available for lines that had limited or no vegetation easement rights and were typically maintained primarily to ensure public safety. This standard does not require additional easement rights to be purchased to satisfy a minimum right of way width that did not exist prior to this standard becoming mandatory.

This definition does not imply that danger tree rights beyond the constructed and maintained width are incorporated in the definition; therefore fall-ins from outside the ROW but within an area with danger tree rights would not be considered fall-ins from within the ROW.

Vegetation Inspection*

The systematic examination of vegetation conditions on a Right-of-Way and those vegetation conditions under the Transmission Owner's control that are likely to pose a hazard to the line(s) prior to the next planned maintenance or inspection. This may be combined with a general line inspection.

The current glossary definition of this NERC term is modified to allow both maintenance inspections and vegetation inspections to be performed concurrently.

Current definition of Vegetation Inspection: The systematic examination of a transmission corridor to document vegetation conditions.

The inspection includes the identification of any vegetation that may pose a threat to reliability prior to the next planned maintenance or inspection work, considering the current location of the conductor and other possible locations of the conductor due to sag and sway for rated conditions.

This definition allows both maintenance inspections and vegetation inspections to be performed concurrently.

* This is a modification to a defined term in the NERC glossary and will be incorporated into the NERC glossary of terms with final approval of this standard revision.

See the Guidelines and Technical Basis section on Requirement R6 contained within the Standard for more details on inspections.

Minimum Vegetation Clearance Distance (MVCD)
The calculated minimum distance stated in feet (meters) to prevent flash-over between conductors and vegetation, for various altitudes and operating voltages.

The MVCD is a calculated minimum distance that is derived from the Gallet Equations. This is a method has been in the design of high voltage transmission lines. Keeping vegetation away from high voltage conductors by this distance will prevent voltage flash-over to the vegetation. See the explanatory text below for Requirement R3 and associated Figures 1, 2 and 3. Details of the equations and an example calculation are provided in Appendix 1below of the Technical Reference document. Table 1in Appendix 1 below provides MVCD values for various voltages and altitudes.

Applicability of the Standard

4. Applicability

4.1. *Functional Entities:*
Transmission Owners

4.2. *Facilities:* *Defined below (referred to as "applicable lines"), including but not limited to those that cross lands owned by federal*[1]*, state, provincial, public, private, or tribal entities:*

4.2.1 *~~Overhead~~Each overhead transmission lines operated at 200kV or higher.*

4.2.2 *~~—Overhead~~ Each overhead transmission lines operated below 200kV ~~having been~~ identified as ~~included in the definition~~an element of an ~~Interconnection Reliability Operating Limit (~~IROL~~)~~ under NERC Standard FAC~~-~~-014 by the Planning Coordinator.*

4.2.3 *~~Overhead~~Each overhead transmission lines operated below 200 kV ~~having been~~ identified as ~~included in the definition~~an element of ~~one of the~~a Major WECC Transfer Paths in the Bulk Electric System by WECC.*

4.2.4 *~~This standard applies to~~*Each overhead transmission ~~*lines*~~line identified above (4.2.1 through 4.2.3) located outside the fenced area of the switchyard, station or substation and any portion of the spa*n of the transmission line that is crossing the substation fence.*

4.3. *Enforcement:* *The reliability obligations of the applicable entities and facilities are contained within the technical requirements of this standard~~. [Straw proposal]~~*

> **Rationale**
> ~~—~~The areas excluded in 4.2.4 were excluded based on comments from industry for reasons summarized as follows: 1) There is a very low risk from vegetation in this area. Based on an informal survey, no TOs reported such an event. 2) Substations, switchyards, and stations have many inspection and maintenance activities that are necessary for reliability. Those existing process manage the threat. As such, the formal steps in this standard are not well suited for this environment. 3) ~~The standard was written for Transmission Owners. Rolling the excluded areas into this standard will bring GO and DP into the standard, even though~~ NERC has ~~an initiative~~a project in place to address ~~this bigger registry issue.~~at a later date the

In Order 693, FERC discussed the 200 kV bright-line test of applicability. While FERC did not change the 200 kV bright~~-~~-line, the Commission remained concerned that there may be some transmission lines operating at lesser voltages that could have significant impact on the Bulk Electric System that should therefore be subject to this standard.

---
[1] EPAct 2005 section 1211c: *"Access approvals by Federal agencies"*.

NERC Standard FAC-014 has the stated purpose, "*To ensure that System Operating Limits (SOLs) used in the reliable planning and operation of the Bulk Electric System (BES) are determined based on an established methodology or methodologies.*" FAC-014 requires Reliability Coordinators, Planning Coordinators, and Transmission Planners to have a methodology to identify all lines that might comprise an IROL. Thus, these entities would identify sub-200 kV lines that qualify as part of an IROL and should be subject to FAC-003-2.

Although all three entities may prepare the list of elements, ~~FAC-003-2 presently does not specify that it is the~~ the list ~~from~~ as provided by the Planning Coordinator ~~that should be used by Transmission Owners~~function is the more appropriate choice for ~~FAC-003. However, the~~this Standard. The Time Horizon needed to plan vegetation management work does not lend itself to the operating horizon of a Reliability Coordinator. Additionally, the Planning Coordinator has a wider-area view than the Transmission Planner and could thus identify any elements of importance to a sub-set of its area that might be missed by a Transmission Planner.

Transmission Owners, who do not already get the list of circuits included in the definition of an IROL, can get them from the Planning Coordinator. Specifically R5 of FAC-014 specifies that "*The Reliability Coordinator, Planning Authority (Coordinator) and Transmission Planner shall each provide its SOLs and IROLs to those entities that have a reliability-related need for those limits and provide a written request that includes a schedule for delivery of those limits*"

Vegetation-related Sustained Outages that occur due to natural disasters are beyond the control of the Transmission Owner. These events are not classified as vegetation-related Sustained Outages and are therefore exempt from the Standard. Transmission lines are not designed to withstand the impacts of natural disasters such as flood, drought, earthquake, major storms, fire, hurricane, tornado, landslides, ice storms, etc. In the aftermath of catastrophic system damage from natural disasters the Transmission Owner's focus is on electric system restoration for public safety and critical support infrastructure.

Sustained Outages due to human or animal activity are beyond the control of the Transmission Owner. These outages are not classified as vegetation-related Sustained Outages and are therefore exempt from the Standard. Examples of these events may include new plantings by outside parties of tall vegetation under the transmission line planted since the last Vegetation Inspection, tree contacts with line initiated by vehicles, logging activities, etc.

The foregoing exemptions are addressed in a new footnote 2. Referred to collectively as force majeure events and activities, this footnote applies to requirements R1 and R2 in FAC-003-2.

The reliability objective of this NERC Vegetation Management Standard ("Standard") is to prevent vegetation-related outages which could lead to Cascading by effective vegetation maintenance while recognizing that certain outages such as those due to vandalism, human errors and acts of nature are not preventable. Operating experience clearly indicates that trees that have grown out of specification could contribute to a cascading grid failure, especially under heavy electrical loading conditions.

Serious outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations. To properly reduce and manage this risk, it is necessary to apply the Standard to applicable lines on any kind of land or easement, whether they are Federal Lands, state or provincial lands, public or private lands, franchises, easements or lands owned in fee. For the purposes of the Standard and this Technical Reference document, the term “public lands” includes municipal lands, village lands, city lands, and land owned by a host of other governmental entities.

The Standard addresses vegetation management along applicable overhead lines that serve to connect one electric station to another. However, it is not intended to be applied to lines sections inside the electric station fence or other boundary of an electric station, submarine or underground lines.

The Standard is intended to reduce the risk of Cascading involving vegetation. It is not intended to prevent customer outages from occurring due to tree contact with all transmission lines and voltages. For example, localized customer service might be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. However, this Standard is not written to address such isolated situations which have little impact on the overall Bulk Electric System.

Vegetation growth is constant and always present. Unmanaged vegetation ~~poses an increased outage risk when~~below numerous transmission lines that are operating at or near their Rating~~.~~ is highly problematic. This ~~poses a significant risk of~~situation has led to multiple subsequent line failures and Cascading. ~~On the other hand~~ Conversely, most other outage causes (such as trees falling into lines, lightning, animals, motor vehicles, etc.) are statistically intermittent. ~~The probability of occurrence of these~~ These events ~~is~~are not ~~dependent on~~any more likely to occur during heavy system loads~~.~~ than any other time. There is no cause-effect relationship which creates the probability of simultaneous occurrence of other such events. Therefore these types of events are highly unlikely to cause large-scale grid failures. Thus, this Standard’s emphasis is on vegetation grow-ins.

In preparing the original vegetation management standard in 2005, industry stakeholders set the threshold for applicability of the standard at 200kV. This was because an unexpected loss of lines operating at above 200kV has a higher probability of initiating a widespread blackout or cascading outages compared with lines operating at less than 200kV.

The original NERC Standard FAC-003-1 also allowed for application of the standard to “critical” circuits (critical from the perspective of initiating widespread blackouts or cascading outages) operating below 200kV. While the percentage of these circuits is relatively low, it remains a fact that there are sub-200kV circuits whose loss could contribute to a widespread outage. Given the very limited exposure and unlikelihood of a major event related to these lower-voltage lines, it would be an imprudent use of resources to apply the Standard to all sub-200kV lines. The drafting team, after evaluating several alternatives, selected the IROL and WECC Major Transfer Path criteria to determine applicable lines below 200 kV that are subject to this standard.

Requirements R1 and R2

R1. *Each Transmission Owner shall manage vegetation to prevent encroachments* ~~**of the types shown below,**~~ *into the Minimum Vegetation Clearance Distance (MVCD) of* ~~**any of**~~ *its applicable line(s)* ~~**identified as**~~*which are either an element of an* ~~**Interconnection Reliability Operating Limit (**~~*IROL*~~**) in the planning horizon by the Planning Coordinator;**~~*,* *or an element of a Major* ~~**Western Electricity Coordinating Council (**~~*WECC*~~**) transfer path(s);**~~ *Transfer Path; operating within its Rating and all Rated Electrical Operating Conditions*~~*.*~~ ~~[2]~~ *of the types shown below[3]:*

1. ~~*1.*~~ *An encroachment into the MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage[4],*
2. ~~*2.*~~ *An encroachment due to a fall-in from inside the Right-of-Way (ROW)*

Rationale for R1 and R2:
Lines with the highest significance to reliability are covered in R1; all other lines are covered in R2.

Rationale
~~The MVCD is a calculated minimum distance stated in feet (meters) to prevent flash-over between conductors and vegetation, for various altitudes and operating voltages. The distances in Table 2 were derived using a proven transmission design method. The~~ for the types of failure to manage vegetation which are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a ~~TO's~~Transmission Owner's vegetation maintenance program ~~since the encroachments listed require different~~:

1. This management failure is found by routine inspection or Fault event investigation, and ~~increasing levels~~is normally symptomatic of ~~skills~~unusual conditions in an otherwise sound program.

2. This management failure occurs when the height and ~~knowledge~~location of a side tree within the ROW is not adequately addressed by the program.

3. This management failure occurs when side

~~[2] This requirement does not apply to circumstances that are b~~ ~~this reliability standard, including natural disasters such as ea~~ ~~shear, fresh gale, major storms as defined either by the Trans~~ ~~storms, and floods; human or animal activity such as logging~~ ~~arboricultural activities or horticultural or agricultural activities, or removal or digging of vegetation. Nothing in this footnote should be construed to limit the Transmission Owner's right to exercise its full legal rights on the ROW.~~

[3] This requirement does not apply to circumstances that are beyond the control of a Transmission Owner subject to this reliability standard, including natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods; human or animal activity such as logging, animal severing tree, vehicle contact with tree, or installation, removal, or digging of vegetation. Nothing in this footnote should be construed to limit the Transmission Owner's right to exercise its full legal rights on the ROW.

[4] If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation.

that caused a vegetation-related Sustained Outage[5],

3. ~~3.~~ *An encroachment due to the blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained* ~~**Outage**~~ *Outage*[4],

4. ~~4.~~ *An encroachment due to* ~~**a grow-in**~~ *vegetation growth into the MVCD that caused a vegetation-related Sustained* ~~**Outage.**~~ *Outage*[4]*.*

2. ~~2.~~ *An encroachment due to a fall-in from inside the ROW that caused a vegetation-related Sustained* ~~**Outage**~~ *Outage*[4],

3. ~~3.~~ *An encroachment due to blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained* ~~**Outage**~~ *Outage*[4],

4. ~~4.~~ *An encroachment due to* ~~**a grow-in**~~ *vegetation growth into the MVCD that caused a vegetation-related Sustained* ~~***Outage. [VRF – Medium] [Time Horizon – Real-time]***~~ *Outage*[4]

M1. Each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R1. ~~Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-time observations of any MVCD encroachments.~~

~~If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation.~~

~~Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period. (R1)~~

[5] Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period.

~~***M2.*** Each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R2.~~ Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-time observations of any MVCD encroachments. (R1)

M2. Each~~If a later confirmation of a Fault by the~~ Transmission Owner ~~shows~~has evidence that ~~a~~it managed vegetation to prevent encroachment ~~within~~into the MVCD ~~has occurred from vegetation within the ROW, this shall be considered the equivalent~~as described in R2. Examples of acceptable forms of ~~a Real-time observation.~~

~~Multiple~~evidence may include dated attestations, dated reports containing no Sustained Outages ~~on an individual line, if caused by the same vegetation, will be reported as one outage regardless~~associated with encroachment types 2 through 4 above, or records confirming no Real-time observations of ~~the actual number of outages within a 24-hour period.~~any MVCD encroachments. (R2)

R1 and R2 are performance-based requirements. The reliability objective or outcome to be achieved is the prevention of vegetation encroachments within a minimum distance of transmission lines. Content-wise, R1 and R2 are the same requirements; however, they apply to different Facilities. Both R1 and R2 require each Transmission Owner to manage vegetation to prevent encroachment within the ~~Minimum Vegetation Clearance Distance ("~~MVCD~~")~~ of transmission lines. R1 is applicable to lines ~~"~~that are identified as an element of an ~~Interconnection Reliability Operating Limit (~~IROL~~)~~ or Major ~~Western Electricity Coordinating Council (~~WECC~~)~~ transfer path ~~(operating within Rating and Rated Electrical Operating Conditions) to avoid a Sustained Outage".~~. R2 ~~applies~~ is applicable to all other ~~applicable~~ lines that are not an element of an IROL ~~or~~, and not an element of a Major WECC Transfer Path.

The separation of applicability (between R1 and R2) recognizes that ~~an encroachment into the MVCD of an IROL or Major WECC Transfer Path transmission~~inadequate vegetation management for an applicable line that is an element of an IROL or Major WECC Transfer Path is a greater risk to the interconnected electric transmission system~~.~~ than applicable lines that are not an element of an IROL or a Major WECC Transfer Path. Applicable lines that are not an element of an IROL or Major WECC Transfer Path ~~are required to be clear of~~do require effective vegetation management, but these lines are comparatively less operationally significant. As a reflection of this difference in risk impact, the Violation Risk Factors (VRFs) are assigned as High for R1 and Medium for R2.

~~These requirements (~~R1 and R2~~)~~ state that if vegetation encroaches within the distances in Table 1 in Appendix 1 of this supplemental ~~Transmission Vegetation Management Standard FAC-003-2~~ Technical Reference document, it is in violation of the standard. Table ~~2~~1below, which is the same as Table 2 in the standard, tabulates the distances necessary to prevent spark-over based on the Gallet equations as described more fully in Appendix 1 below.

These requirements assume that transmission lines and their conductors are operating within their Rating. If a line conductor is intentionally or inadvertently operated beyond its Rating and Rated Electrical Operating Condition (potentially in violation of other standards), the occurrence of a clearance encroachment may occur solely due to that condition. For example, emergency actions taken by a Transmission Operator or Reliability Coordinator to protect an Interconnection may cause ~~the transmission line to sag more~~excessive sagging and ~~come closer to vegetation, potentially causing~~ an outage. Another example would be ice loading beyond the line's Rating and Rated Electrical Operating Condition. Such vegetation-related encroachments and outages are not ~~a violation~~violations of ~~these requirements~~this standard.

Evidence of ~~violation of Requirement R1 and R2~~failures to adequately manage vegetation include real-time observation of a vegetation encroachment into the MVCD (absent a Sustained Outage), or a vegetation-related encroachment resulting in a Sustained Outage due to a fall-in from inside the ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to the blowing together of ~~applicable~~the lines and vegetation located inside the ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to a grow-in. ~~If an investigation of~~ Faults which do not cause a ~~Fault by a Transmission Owner confirms that a~~Sustained outage and which are confirmed to have been caused by vegetation encroachment within the MVCD ~~occurred, then it shall be~~are considered the equivalent of a Real-time observation for violation severity levels.

With this approach, the VSLs ~~were defined~~for R1 and R2 are structured such that they directly correlate to the severity of a failure of a Transmission Owner to manage vegetation and to the corresponding performance level of the Transmission Owner's vegetation program's ability to meet the ~~goal~~objective of "preventing ~~a Sustained Outage~~the risk of those vegetation related outages that could lead to Cascading." Thus violation severity increases with a Transmission Owner's inability to meet this goal and its potential of leading to a Cascading event. The additional benefits of such a combination are that it simplifies the standard and clearly defines performance for compliance. A performance-based requirement of this nature will promote high quality, cost effective vegetation management programs that will deliver the overall end result of improved reliability to the system.

Multiple Sustained Outages on an individual line can be caused by the same vegetation. For example~~, a limb~~ initial investigations and corrective actions may ~~only partially break and intermittently contact a~~not identify and remove the actual outage cause then another outage occurs after the line is re-energized and previous high conductor temperatures return. Such events are considered to be a single vegetation-related Sustained Outage under the ~~Standard~~standard where the Sustained Outages occur within a 24 hour period.

The MVCD is a calculated minimum distance stated in feet (or meters) to prevent spark-over, for various altitudes and operating voltages that is used in the design of Transmission Facilities. Keeping vegetation from entering this space will prevent transmission outages.

If the TO has applicable lines operated at nominal voltage levels not listed in Table 2, then the TO should use the next largest clearance distance based on the next highest nominal voltage in the table to determine an acceptable distance.

Requirement R3

Rationale

The documentation provides a basis for evaluating the competency of the Transmission Owner's vegetation program. There may be many acceptable approaches to maintain clearances. Any approach must demonstrate that the Transmission Owner avoids vegetation-to-wire conflicts under all Rated Electrical Operating Conditions. See Figure 1 for an illustration of possible conductor locations.

R3. *Each Transmission Owner shall have documented maintenance strategies or procedures or processes or specifications it uses to prevent the encroachment of vegetation into the MVCD of its applicable transmission lines that ~~include(s)~~accounts for the following:*

3.1 *~~Accounts for the movement~~Movement of applicable ~~transmission~~ line conductors under their Facility Rating and all Rated Electrical Operating Conditions;*

3.2 *~~Accounts for the inter~~Inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency.*

~~[VRF – Lower] [Time Horizon – Long Term Planning]~~

M3. *The maintenance strategies or procedures or processes or specifications provided demonstrate that the Transmission Owner can prevent encroachment into the MVCD considering the factors identified in the requirement. (R3)*

Requirement R3 is a competency based requirement concerned with the maintenance strategies, procedures, processes, or specifications, a Transmission Owner uses for vegetation management.

An adequate transmission vegetation management program formally establishes the approach the Transmission Owner uses to plan and perform vegetation work to prevent transmission Sustained Outages and minimize risk to the ~~Transmission System.~~transmission system. The approach provides the basis for evaluating the intent, allocation of appropriate resources and the competency of the Transmission Owner in managing vegetation. There are many acceptable approaches to manage vegetation and avoid Sustained Outages. However, the Transmission Owner must be able to ~~state what~~show the documentation of its approach ~~is~~ and how it conducts work to maintain clearances.

An example of one approach commonly used by industry is ANSI Standard A300, part 7. However, regardless of the approach a utility uses to manage vegetation, any approach a Transmission Owner chooses to use will generally contain the following elements:

1. *the maintenance strategy used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that MVCD clearances are never violated.*
2. *the work methods that the Transmission Owner uses to control vegetation*
3. *a stated Vegetation Inspection frequency*
4. *an annual work plan*

The conductor's position in space at any point in time is continuously changing ~~as a~~in reaction to a number of different loading variables. Changes in vertical and horizontal conductor positioning are the result of thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation.

Physical loading applied to the conductor affects sag and sway by combining physical factors such as ice and wind loading. The movement of the transmission line conductor and the MVCD is illustrated in Figures 1, 2, and 3 below.

Conductor Dynamics

In order for a Transmission Owner to develop a specific maintenance approach, it is important to understand the dynamics of a line conductor's ~~movement.~~movements. This paper will first address the complexities inherent in observing and predicting conductor movement, particularly for field personnel. It will then present some examples of maintenance approaches which Transmission Owners may consider that take into account these complexities, ~~while resulting in~~and the practical approaches ~~for~~that can be utilized by field personnel.

Additionally, it is important the Transmission Owner consider all conductor locations, the MVCD, and vegetation growth between maintenance activities when developing a maintenance approach.

Understanding Conductor Position and Movement

The conductor's position in space at any point in time is continuously changing as a reaction to a number of different loading variables. Changes in vertical and horizontal conductor positioning are the result of thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation. Physical loading applied to the conductor affects sag and sway by combining physical factors such as ice and wind loading.

As a consequence of these loading variables, the conductor's position in space is dynamic and moving. When calculating the range of conductor positions, the Transmission Owner should use the same design criteria and assumptions that ~~the Transmission Owner uses when establishing~~are used to establish Ratings and ~~SOL,~~System Operating Limits (SOLs), as described in other standards. Typically, the greatest conductor ~~movement would be~~movements occur at mid-span. As the conductor moves through various positions, a spark-over zone surrounding the conductor moves with it. The radius of the spark-over zone may be found by referring to Table 1 ~~("Minimum Vegetation Clearance Distances") in the standard.~~below. For illustrations of this zone and conductor movements, Figures 1 ~~through~~, 2 and 3 below ~~demonstrate these concepts.~~are provided. At the time of making a field observation, however, it is very difficult to precisely know where the conductor is in relation to its wide range of all possible positions. Therefore, Transmission Owners must adopt maintenance approaches that account for this dynamic situation.

Selecting a Maintenance Approach

In order to maintain adequate separation between vegetation and transmission line conductors, the Transmission Owner must craft a maintenance strategy that keeps vegetation well away from the spark-over zone mentioned above. In fact, it is generally necessary to incorporate a variety of maintenance strategies. For example, one Transmission Owner may utilize a combination of routine cycles, traditional IVM techniques and long-term planning. Another Transmission Owner may place a higher reliance on frequent inspections and ~~quick~~follow-up remediation as opposed to a set cyclical approach. This variation of approaches is further warranted when factors, such as terrain, vegetation types, weather and climate, and any, environmental, legal ~~and~~or other land use constraints, ~~vegetation types, and climates, are~~must be considered in developing a Transmission Owner's specific approach to satisfying ~~this requirement~~R3.

The following ~~is a sample description of one combination of~~describes some strategies which may be utilized by a Transmission Owner. A Transmission Owner's basic maintenance approach in relatively flat terrain could be to remove all incompatible vegetation from the ~~right of way~~ROW if it has the right to do so and has no constraints. In mountainous terrain, however, this strategy could change to ~~one where the Transmission Owner manages~~managing vegetation based on vegetation-to-conductor clearances, since it might not be necessary to remove vegetation in a valley that is far below the conductors at maximum sag.
If faced with easement constraints ~~and assuming~~on a line design with sufficient ground clearance, the ~~Transmission Owner 's~~ approach could ~~then~~ be to allow vegetation such as fruit trees, but ~~perhaps~~ only up to a given height at maturity (~~perhaps~~for example 10 feet from the ground). If constraints cannot be overcome and if design clearances are sufficient, an exception to the Transmission Owner's 10-foot guideline might be made. ~~Finally, if the Transmission Owner has~~If an approach is chosen to ~~utilize~~manage vegetation~~ to conductor~~ based primarily on clearance ~~distance methods, the Transmission Owner~~distances it could ~~have~~include an inspection regimen ~~in place~~ to regularly ensure that~~ any~~ impending clearance problems are identified early for rectification.

ANSI A300 – Best Management Practices for Tree Care Operations

A description of ANSI A-300, part 7, is offered below to illustrate another maintenance approach that could be used in developing a comprehensive transmission vegetation management program.

Introduction

Integrated Vegetation Management (IVM) is a best management practice conveyed in the American National Standard for Tree Care Operations, Part 7 (ANSI 2006) and the International Society of Arboriculture *Best Management Practices: Integrated Vegetation Management* (Miller 2007). IVM is consistent with the requirements in FAC-003-02, and it provides practitioners with what industry experts consider to be appropriate techniques to apply to electric right-of-way projects in order to meet or exceed the Standard.

IVM is a system of managing plant communities whereby managers set objectives; identify compatible and incompatible vegetation; consider action thresholds; and evaluate, select and implement the most appropriate control method or methods to achieve set objectives. The choice of control method or methods should be based on the environmental impact and anticipated effectiveness; along with site characteristics, security, economics, current land use and other factors.

Planning and Implementation
Best management practices provide a systematic way of planning and implementing a vegetation management program. While designed primarily with transmission systems in mind, it is also applicable to distribution projects. As presented in ANSI A300 part 7 and the ISA best management practices, IVM consists of 6 elements:

1) Set Objectives
2) Evaluate the Site
3) Define Action Thresholds
4) Evaluate and Select Control Methods
5) Implement IVM
6) Monitor Treatment and Quality Assurance

The setting of objectives, defining action thresholds, and evaluating and selecting control methods all require decisions. The planning and implementation process is cyclical and continuous, because vegetation is dynamic and managers must have the flexibility to adjust their plans. Adjustments may be made at each stage as new information becomes available and circumstances evolve.

Set Objectives
Objectives should be clearly defined and documented. Examples of objectives can include promoting safety, preventing sustained outages caused by vegetation growing into electric facilities, maintaining regulatory compliance, protecting structures and security, restoring electric service during emergencies, maintaining access and clear lines of sight, protecting the environment, and facilitating cost effectiveness.

Objectives should be based on site factors, such as workload and vegetation type, in addition to human, equipment and financial resources. They will vary from utility to utility and project to project, depending on line voltage and criticality, as well as topographical, environmental, fiscal and political considerations. However, where it is appropriate, the overriding focus should be on environmentally-sound, cost effective control of species that potentially conflict with the electric facility, while promoting compatible, early successional, sustainable plant communities.

Work Load Evaluations
Work-load evaluations are inventories of vegetation that could have a bearing on management objectives. Work load assessments can capture a variety of vegetation characteristics, such as location, height, species, size and condition, hazard status, density and clearance from conductors. Assessments should be conducted considering voltage, conductor sag from ambient temperatures and loading, and the potential influence of wind on line sway.

Evaluate and Select Control Methods
Control methods are the process through which managers achieve objectives. The most suitable control method best achieves management objectives at a particular site. Many

cases call for a combination of methods. Managers have a variety of controls from which to choose, including manual, mechanical, herbicide and tree growth regulators, biological, and cultural options.

Manual Control Methods
Manual methods employ workers with hand-carried tools, including chainsaws, handsaws, pruning shears and other devices to control incompatible vegetation. The advantage of manual techniques is that they are selective and can be used where others may not be. On the other hand, manual techniques can be inefficient and expensive compared to other methods.

Mechanical Control Methods
Mechanical controls are done with machines. They are efficient and cost effective, particularly for clearing dense vegetation during initial establishment, or reclaiming neglected or overgrown right of way. On the other hand, mechanical control methods can be non-selective and disturb sensitive sites.

Tree Growth Regulator and Herbicide Control Methods
Tree growth regulators and herbicides can be effective for vegetation management. Tree growth regulators (TGRs) are designed to reduce growth rates by interfering with natural plant processes. TGRs can be helpful where removals are prohibited or impractical by reducing the growth rates of some fast-growing species.

Herbicides control plants by interfering with specific botanical biochemical pathways. Herbicide use can control individual plants that are prone to re-sprout or sucker after removal. When trees that re-sprout or sucker are removed without herbicide treatment, dense thickets develop, impeding access, swelling workloads, increasing costs, blocking lines-of-site, and deteriorating wildlife habitat. Treating suckering plants allows early successional, compatible species to dominate the right-of-way and out-compete incompatible species, ultimately reducing work.

Cultural Control Methods
Cultural methods modify habitat to discourage incompatible vegetation and establish and manage desirable, early successional plant communities. Cultural methods take advantage of seed banks of native, compatible species lying dormant on site. In the long run, cultural control is the most desirable method where it is applicable.

A cultural control known as cover-type conversion provides a competitive advantage to short-growing, early successional plants, allowing them to thrive and eventually out-compete unwanted tree species for sunlight, essential elements and water. The early successional plant community is relatively stable, tree-resistant and reduces the amount of work, including herbicide application, with each successive treatment.

Wire-Border Zone
The wire-border zone technique is a management philosophy that can be applied through cultural control. W.C. Bramble and W.R. Byrnes developed it in the mid-1980s out of research begun in 1952 on a transmission right-of-way in the Pennsylvania State Game Lands 33 Research and Demonstration project (Yahner and Hutnik (2004).

The wire zone is the section of a utility transmission right-of-way directly under the wires and extending outward about 10 feet on each side. The wire zone is managed to promote a low-growing plant community dominated by grasses, herbs and small shrubs (under 3 feet in height at maturity). The border zone is the remainder of the right-of-way. It is managed to establish small trees and tall shrubs (under 25 feet in height at maturity). When properly managed, diverse, tree-resistant plant communities develop in wire and border zones. The communities not only protect the electric facility and reduce long-term maintenance, but also enhance wildlife habitat, forest ecology and aesthetic values.

Although the wire-border zone is a best practice in many instances, it is not necessarily universally suitable. For example, standard wire-border zone prescriptions may be unnecessary where lines are high off the ground, such as across low valleys or canyons, so the technique can be modified without sacrificing reliability.

One way to accommodate variances in topography is to establish different regions based on wire height. For example, over canyon bottoms or other areas where conductors are 100 feet or more above the ground, only a few trees are likely to be tall enough to conflict with the lines. In those cases, trees that potentially interfere with the transmission lines can be removed selectively on a case-by-case basis.

In areas where the wire is lower, perhaps between 50-100 feet from the ground, a border zone community can be developed throughout the right-of-way. Note that in many cases, conductor attachment points are more than 50 feet off the ground, so a border zone community can be cultivated near structures. Where the line is less than 50 feet off the ground, managers could apply a full wire-border zone prescription.

An environmental advantage of this type of modification is stream protection. Streams often course through the valleys and canyons where lines are likely to be elevated. Leaving timber or border zone communities in canyon bottoms helps shelter this valuable habitat, enabling managers to achieve environmentally sensitive objectives.

Implement IVM

All laws and regulations governing IVM practices and specifications written by qualified vegetation managers must be followed. Integrated vegetation management control methods should be implemented on regular work schedules, which are based on established objectives and completed assessments. Work should progress systematically, using control measures determined to be best for varying conditions at specific locations along a right-of-way. Some considerations used in developing schedules include the importance and type of line, vegetation clearances, ~~work loads~~workloads, growth rate of predominant vegetation, geography, accessibility, and in some cases, time lapsed since the last scheduled work.

Clearances Following Work

Clearances following work should be sufficient to meet management objectives, including preventing trees from entering the Minimum Vegetation Clearance Distance, electric safety risks, service-reliability threats and cost.

Monitor Treatment and Quality Assurance

An effective program includes documented processes to evaluate results. Evaluations can involve quality assurance while work is underway and after it is completed. Monitoring for quality assurance should begin early to correct any possible miscommunication or misunderstanding on the part of crewmembers. Early and consistent observation and evaluation also provides an opportunity to modify the plan, if need be, in time for a successful outcome.

Utility vegetation management programs should have systems and procedures in place for documenting and verifying that vegetation management work was completed to specifications. Post-control reviews can be comprehensive or based on a statistically representative sample. This final review points back to the first step and the planning process begins again.

Summary of A-300 example

Integrated Vegetation Management offers among others, a systematic way of planning and implementing a vegetation management program as presented in ANSI A300 Part 7. This methodology enables a program to comply with the NERC *Transmission Vegetation Management Program* standard (FAC-003-2). Managers should select control options to best promote management objectives.

Vegetation Inspections

~~As with the ANSI A-300 example,~~ The ~~Transmission Owner's transmission vegetation management program (TVMP)~~standard in R6 establishes the frequency of vegetation inspections. These inspections can be used to "evaluate the site" as referred to in the second element of ANSI A300 Part 7. This necessary frequency may need to be less than the annually based ~~upon many factors. Such local and environmental factors may include~~on anticipated growth rates of the local vegetation, length of the growing season for the geographical area, limited ~~Rights of Way~~ROW width, rainfall amounts, etc.

Annual Work Plan

Requirement R7 of the Standard addresses the execution of the annual work plan. A comprehensive approach that exercises the full extent of legal rights is superior to incremental management in the long term because it reduces overall encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient at all locations on the ~~Right of Way~~ROW. Removal is superior to pruning. Removal minimizes the possibility of conflicts between energized conductors and vegetation. ~~Since~~When this is not ~~always~~ possible, the ~~Transmission Owner's~~ approach should be to use ~~its prescribed~~ vegetation maintenance methods to work towards or achieve the maximum use of the ~~Right of Way~~ROW.

Requirement R4

R4. *Each Transmission Owner, without any intentional time delay, shall notify the control center holding switching authority for the associated applicable transmission line when the Transmission Owner has confirmed the existence of a vegetation condition that is likely to cause a Fault at any moment.*

Rationale
~~To~~This is to ensure expeditious communication between the Transmission Owner and the control center when a critical situation is confirmed.

~~*[VRF – Medium] [Time Horizon – Real-time]*~~

M4. *Each Transmission Owner that has a confirmed vegetation condition likely to cause a Fault at any moment will have evidence that it notified the control center holding switching authority for the associated transmission line without any intentional time delay. Examples of evidence may include control center logs, voice recordings, switching orders, clearance orders and subsequent work orders. (R4)*

R4 is a risk-based requirement. It focuses on preventative actions to be taken by the Transmission Owner for the mitigation of Fault risk when a vegetation threat is confirmed. R4 involves the notification of potentially threatening vegetation conditions, without any intentional delay, to the control center holding switching authority for that specific transmission line. Examples of acceptable unintentional delays may include communication system problems (for example, cellular service or two-way radio disabled), crews located in remote field locations with no communication access, delays due to severe weather, etc.

Confirmation is key that a threat actually exists due to vegetation. This confirmation could be in the form of a Transmission Owner's employee who personally identifies such a threat in the field. Confirmation could also be made by sending out an employee to evaluate a situation reported by a landowner.

Vegetation-related conditions that warrant a response include vegetation that is near or encroaching into the MVCD (a grow-in issue) or vegetation that could fall into the transmission conductor (a fall-in issue). A knowledgeable verification of the risk would include an assessment of the possible sag or movement of the conductor while operating between no-load conditions and its rating.

The Transmission Owner has the responsibility to ensure the proper communication between field personnel and the control center to allow the control center to take the appropriate action until the vegetation threat is relieved. Appropriate actions may include a temporary reduction in the line loading, switching the line out of service, or positioning the system in recognition of the increasing risk of outage on that circuit. The notification of the threat should be communicated in terms of minutes or hours as opposed to a longer time frame for corrective action plans (see R5).

All potential grow-in or fall-in vegetation-related conditions will not necessarily cause a Fault at any moment. For example, some Transmission Owners may have a danger tree identification

program that identifies trees for removal with the potential to fall near the line. These trees would not require notification to the control center unless they pose an immediate fall-in threat.

Requirement R5

R5. *When a Transmission Owner is constrained from performing vegetation work on an applicable line operating within their Rating and all Rated Electrical Operating Conditions, and the constraint may lead to a vegetation encroachment into the MVCD ~~of its applicable transmission lines~~ prior to the implementation of the next annual work plan, then the Transmission Owner shall take corrective action to ensure continued vegetation management to prevent encroachments. ~~[VRF – Medium] [Time Horizon – Operations Planning]~~*

Rationale
Legal actions and other events may occur which result in constraints that prevent the Transmission Owner from performing planned vegetation maintenance work.
In cases where the transmission line is put at potential risk due to constraints, the intent is for the Transmission Owner to put interim measures in place, rather than do nothing.
The corrective action process is not intended to address situations where a planned work methodology cannot be performed but an alternate work methodology can be used.

M5. *Each Transmission Owner has evidence of the corrective action taken for each constraint where an applicable transmission line was put at potential risk. Examples of acceptable forms of evidence may include initially-planned work orders, documentation of constraints from landowners, court orders, inspection records of increased monitoring, documentation of the de-rating of lines, revised work orders, invoices, ~~and~~or evidence that a line was de-energized. (R5)*

R5 is a risk-based requirement. It focuses upon preventative actions to be taken by the Transmission Owner for the mitigation of Sustained Outage risk when temporarily constrained from performing vegetation maintenance. The intent of this requirement is to deal with situations that prevent the Transmission Owner from performing planned vegetation management work and, as a result, have the potential to put the transmission line at risk. Constraints to performing vegetation maintenance work as planned could result from legal injunctions filed by property owners, the discovery of easement stipulations which limit the Transmission Owner's rights, or other circumstances.

This requirement is not intended to address situations where the transmission line is not at potential risk and the work event can be rescheduled or re-planned using an alternate work methodology. For example, a land owner may prevent the planned use of chemicals on non-threatening, low growth vegetation but agree to the use of mechanical clearing. In this case the Transmission Owner is not under any immediate time constraint for achieving the management objective, can easily reschedule work using an alternate approach, and therefore does not need to take interim corrective action.

However, in situations where transmission line reliability is potentially at risk due to a constraint, the Transmission Owner is required to take an interim corrective action to mitigate the potential risk to the transmission line. A wide range of actions can be taken to address various situations. General considerations include:

- Identifying locations where the Transmission Owner is constrained from performing planned vegetation maintenance work which potentially leaves the transmission line at risk.
- Developing the specific action to mitigate any potential risk associated with not performing the vegetation maintenance work as planned.
- Documenting and tracking the specific action taken for each location.
- In developing the specific action to mitigate the potential risk to the transmission line the Transmission Owner could consider location specific measures such as modifying the inspection and/or maintenance intervals. Where a legal constraint would not allow any vegetation work, the interim corrective action could include limiting the loading on the transmission line.
- The Transmission Owner should document and track the specific corrective action taken at each location. This location may be indicated as one span, one tree or a combination of spans on one property where the constraint is considered to be temporary.

Requirement R6

R6. *Each Transmission Owner shall perform a Vegetation Inspection of 100% of its applicable ~~transmission~~ lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.) at least once per calendar year and with no more than 18 months between inspections on the same ROW.*[6]

~~*[VRF – Medium] [Time Horizon – Operations Planning]*~~

M6. *Each Transmission Owner has evidence that it conducted Vegetation Inspections of the transmission line ROW for all applicable ~~transmission~~ lines at least once per calendar year but with no more than 18 months between inspections on the same ROW. Examples of acceptable forms of evidence may include completed and dated work orders, dated invoices, or dated inspection records. (R6)*

Rationale
Inspections are used by Transmission Owners to assess the condition of the entire ROW. The information from the assessment can be used to determine risk, determine future work and evaluate recently-completed work. This requirement sets a minimum Vegetation Inspection frequency of once per calendar year but with no more than 18 months between inspections on the same ROW. Based upon average growth rates across North America and on common utility practice, this minimum frequency is reasonable. Transmission Owners should consider local and environmental factors that could warrant more frequent inspections.

R6 is a risk-based requirement. This requirement sets a minimum time period for completing Vegetation Inspections that fits general industry practice. In addition, the fact that Vegetation Inspections can be performed in conjunction with general line inspections further facilitates a Transmission Owner's ability to meet this requirement. However, the Transmission Owner may determine that more frequent inspections are needed to maintain reliability levels, dependent upon such factors as anticipated growth rates of the local vegetation, length of the growing season for the geographical area, limited ROW width, and rainfall amounts. Therefore it is expected that some transmission lines may be designated with a higher frequency of inspections.

~~The SDT~~Footnote 5 is added ~~footnote 3~~ to address the situation where a Transmission Owner through no fault of its own, would be unable to complete the vegetation inspection within the allotted time period. This would include the situation of mutual aid as well as disasters to the Transmission Owner's own system.

The VSL for Requirement R6 has VSL categories ranked by the percentage of the required ROW inspections completed. To calculate the percentage of inspection completion, the Transmission Owner may choose units such as: line miles or kilometers, circuit miles or kilometers, pole line miles, ROW miles, etc.

[6] When the Transmission Owner is prevented from performing a Vegetation Inspection within the timeframe in R6 due to a natural disaster, the TO is granted a time extension that is equivalent to the duration of the time the TO was prevented from performing the Vegetation Inspection.

For example, when a Transmission Owner operates 2,000 miles of ~~230 kV~~applicable transmission lines this Transmission Owner will be responsible for inspecting all the 2,000 miles of ~~230 kV transmission~~ lines at least once during the calendar year. If one of the included lines was 100 miles long, and if it was not inspected during the year, then the amount failed to inspect would be 100/2000 = 0.05 or 5%. ~~The "Low VSL" for R6 would apply in this example.~~

The “Low VSL” for R6 would apply in this example.

Requirement R7

Rationale
This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. ~~An annual vegetation work plan~~It allows ~~for work~~modifications to ~~be modified~~the planned work for changing conditions, taking into consideration anticipated growth of vegetation and all other environmental factors, provided that ~~the changes~~those modifications do not ~~violate the~~put the

R7. *Each Transmission Owner shall complete 100% of its annual vegetation work plan of applicable lines to ensure no vegetation encroachments occur within the MVCD. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made (provided they do not ~~put the transmission system at risk~~allow encroachment of ~~a~~ vegetation ~~encroachment~~into the MVCD) and must be documented. The percent completed calculation is based on the number of units actually completed divided by the number of units in the final amended plan (measured in units of choice - circuit, pole line, line miles or kilometers, etc.) Examples of reasons for modification to annual plan may include:*

- Change in expected growth rate/ environmental factors
- Circumstances that are beyond the control of a Transmission Owner[7]
- Rescheduling work between growing seasons
- Crew or contractor availability/ Mutual assistance agreements
- Identified unanticipated high priority work
- Weather conditions/Accessibility
- Permitting delays
- Land ownership changes/Change in land use by the landowner
- Emerging technologies

  ~~[VRF – Medium] [Time Horizon – Operations Planning]~~

M7. *Each Transmission Owner has evidence that it completed its annual vegetation work plan. Examples of acceptable forms of evidence may include a copy of the completed annual work plan (including modifications if any), dated work orders, dated invoices, or dated inspection records. (R7)*

R7 is a risk-based requirement. The Transmission Owner is required to implement ~~an annual~~its work plan for vegetation management to accomplish the purpose of this Standard. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made and documented provided they do not put the transmission system at risk. The

[7] ~~circumstances~~Circumstances that are beyond the control of a Transmission Owner include but are not limited to natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, ice storms, floods, or major storms as defined either by the TO or an applicable regulatory body~~, ice storms, and floods; arboricultural, horticultural or agricultural activities~~.

annual work plan requirement is not intended to necessarily require a "span-by-span", or even a "line-by-line" detailed description of all work to be performed. It is only intended to require that the Transmission Owner provide evidence of annual planning and execution of a vegetation management maintenance approach which successfully prevents encroachment of vegetation into the MVCD.

For example, when a Transmission Owner identifies 1,000 miles of applicable transmission lines to be completed in the TO's annual plan, the Transmission Owner will be responsible completing those identified miles. If a TO makes a modification to the annual plan that does not put the transmission system at risk of an encroachment the annual plan may be modified. If 100 miles of the annual plan is deferred until next year the calculation to determine what percentage was completed for the current year would be: 1000 – 100 (deferred miles) = 900 modified annual plan, or 900 / 900 = 100% completed annual miles. If a TO only completed 875 of the total 1000 miles with no acceptable documentation for modification of the annual plan the calculation for failure to complete the annual plan would be: 1000 – 875 = 125 miles failed to complete then, 125 miles (not completed) / 1000 total annual plan miles = 12.5% failed to complete.

The ability to modify the work plan allows the Transmission Owner to change priorities or treatment methodologies during the year as conditions or situations dictate. For example recent line inspections may identify unanticipated high priority work, weather conditions (drought) could make herbicide application ineffective during the plan year, or a major storm could require redirecting local resources away from planned maintenance or work may be deferred to a subsequent year because of slower-than-expected growth. This situation may also include complying with mutual assistance agreements by moving resources off the Transmission Owner's system to work on another system. Any of these examples could result in acceptable deferrals or additions to the annual work plan. Modifications to the annual work plan must always ensure the reliability of the electric Transmission system.

In general, the vegetation management maintenance approach should use the full extent of the Transmission Owner's legal rights on the ROW. A comprehensive approach that exercises the full extent of legal rights on the ROW is superior to incremental management in the long term because it reduces the overall potential for encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient.

When developing the annual work plan~~,~~ the Transmission Owner should allow time for ~~reasonable and predictable~~ procedural requirements to obtain permits to work on federal, state, provincial, public, tribal lands. In some cases~~,~~ the lead time for obtaining permits may necessitate preparing work plans more than a year prior to ~~the~~work start ~~of work.~~dates. Transmission Owners may also need to consider those special landowner requirements as documented in easement instruments.

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. Therefore, deferrals or relevant changes to the annual plan shall be documented. Depending on the planning and documentation format used by the Transmission Owner, evidence of successful annual work plan execution could consist of signed-off work orders, signed contracts, printouts from work management systems, spreadsheets of planned versus completed work, timesheets, work inspection reports, or paid invoices. Other evidence may include photographs and walk-through reports.

Appendix 1: Clearance Distance Derivation by the Gallet Equation

The Gallet Equation is a well-known method of computing the required strike distance for proper insulation coordination, and has the ability to take into account various air gap geometries, as well as non-standard atmospheric conditions. When the Gallet Equation and conservative probabilistic methods are combined, i.e. deterministic design, ~~sparkover~~spark-over probabilities of 10^{-6} or less are achieved. This approach is well known for its conservatism and was used to design the first 500 kV and 765 kV lines in North America [1]. Thus, the deterministic design approach using the Gallet Equation is used for the standard to compute the minimum strike distance between transmission lines and the vegetation that may be present in or along the transmission corridor.

Method Explanation (Gallet Equation)

In 1975 G. Gallet published a benchmark paper that provided a method to compute the critical flashover voltage (CFO) of various air gap geometries [4]. The Gallet Equation uses various "gap factors" to take into account various air gap geometries. Various gap factor values are provided in [1]. If the vegetation in a transmission corridor, e.g. a tree, is assumed electrically to be a large structure then the CFO of such an air gap geometry can be computed for dry or wet conditions using a well established equation proposed by Gallet [1],[2],[4],

$$CFO_A = k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} \qquad (1)$$

where,

k_w	is defined as the factor that takes into account wet or dry conditions (dry = 1.0 and wet = 0.96) and phase arrangement (multiply by 1.08 for outside phase), e.g. outside phase and wet conditions = (0.96)(1.08) = 1.037,
k_g	is defined as the gap factor (1.3 for conductor to large structure),
D	is the strike distance (m),
CFO_A	is the CFO for the relative air density (kV).
δ	is defined as the relative air density and is approximately equal to (2) where A is the altitude in km,

$$\delta = e^{-\frac{A}{8.6}} \qquad (2)$$

$$m = 1.25G_0\left(G_0 - 0.2\right) \qquad (3)$$

$$G_0 = \frac{CFO_s}{500 \cdot D} \qquad (4)$$

$$CFO_S = k_w \cdot k_g \cdot \frac{3400}{1+\frac{8}{D}} \tag{5}$$

where CFO_S is the CFO for standard atmospheric conditions (kV). Using (1)-(5), the required CFO_A can be computed using an iterative process.

Once the CFO_A is known, deterministic methods can be used to determine the required clearance distance. If we let the maximum switching overvoltage be equal to the withstand voltage of the air gap (CFO_A - 3σ) then the CFO_A can be written as (6).

$$CFO_A = \frac{V_m}{1-3\left(\frac{\sigma}{CFO_A}\right)} \tag{6}$$

where

V_m is equal to the maximum switching overvoltage, i.e. the value that has a 0.135% chance of being exceeded,

σ is the standard deviation of the air gap insulation,

CFO_A is the critical flashover voltage of the air gap insulation under non-standard atmospheric conditions.

The ratio of σ to the CFO_A given in (6) can be assumed to be 0.05 (5%) [1]. Thus, (6) can be written as (7).

$$CFO_A = \frac{V_m}{0.85} \tag{7}$$

Substituting (7) into (1) we arrive at (8).

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} \tag{8}$$

Equation 8 relates the maximum transient overvoltage, V_m, to the air gap distance, D. Using (8) to compute the required clearance distance for the specified air gap geometry (conductor to large structure) results in a probability of flashover in the range of 10^{-6}.

Transient Overvoltage

In general, the worst case transient overvoltages occurring on a transmission line are caused by energizing or re-energizing the line with the latter being the extreme case if trapped charge is present. The intent of FAC-003 is to keep a transmission line that is *in service* from becoming de-energized (i.e. tripped out) due to sparkover from the line conductor to nearby vegetation. Thus, the worst case scenarios that are typically analyzed for insulation coordination purposes (e.g. line energization and re-energization) can be ignored. For the purposes of FAC-003-2, the worst case transient overvoltage then becomes the maximum value that can occur with the line energized. Determining a realistic value of transient overvoltage for this situation is difficult because the maximum transient overvoltage factors listed in the literature are based on a

switching operation of the line in question. In other words, these maximum overvoltage values (e.g. the values listed in [2], [3] and [5]) are based on the assumption that the subject line is being energized, re-energized or de-energized. These operations, by their very nature, will create the largest transient overvoltages. Typical values of transient overvoltages of in-service lines, as such, are not readily available in the literature because the resulting level of overvoltage is negligible compared with the maximum (e.g. re-energizing a transmission line with trapped charge). A conservative value for the maximum transient overvoltage that can occur anywhere along the length of an in-service ac line is approximately 2.0 p.u.[2]. This value is a conservative estimate of the transient overvoltage that is created at the point of application (e.g. a substation) by switching a capacitor bank without a pre-insertion device (e.g. closing resistors). At voltage levels where capacitor banks are not very common (e.g. 362 kV), the maximum transient overvoltage of an "in-service" ac line are created by fault initiation on adjacent ac lines and shunt reactor bank switching. These transient voltages are usually 1.5 p.u. or less [2]. It is well known that these theoretical transient overvoltages will not be experienced at locations remote from the bus at which they were created; however, in order to be conservative, it will be assumed that all nearby ac lines are subjected to this same level of overvoltage. Thus, a maximum transient overvoltage factor of 2.0 p.u. for ~~242~~302 kV and below and 1.4 p.u. for ac transmission lines 362 kV and above is used to compute the required clearance distances for vegetation management purposes.

The overvoltage characteristics of dc transmission lines vary somewhat from their ac counterparts. The referenced empirically derived transient overvoltage factor used to calculate the minimum clearance distances from dc transmission lines to vegetation for the purpose of FAC-003-2 will be 1.8 p.u.[3].

Example Calculation

An example calculation is presented below using the proposed method of computing the vegetation clearance distances. It is assumed that the line in question has a maximum operating voltage of 550 kV_{rms} line-to-line. Using a per unit transient overvoltage factor of 1.4, the result is a peak transient voltage of 629 kV_{crest}. It is further assumed that the line in question operates at a maximum altitude of 7000 feet (2.134 km) above sea level.

The required withstand voltage of the air gap must be equal to or greater than 629 kV_{crest}. Since the altitude is above sea level, (1) - (5) have to be iterated on to achieve the desired result. Equation (9) can be used as an initial guess for the clearance distance.

$$D_i = \frac{8}{\dfrac{3400 \cdot k_w \cdot k_g}{\left(\dfrac{V_m}{0.85}\right)} - 1} \tag{9}$$

For our case here, V_m is equal to 629 kV, k_w = 1.037 and k_g = 1.3. Thus,

$$D_i = \frac{8}{\dfrac{3400 \cdot k_w \cdot k_g}{\left(\dfrac{V_m}{0.85}\right)} - 1} = \frac{8}{\dfrac{3400 \cdot 1.037 \cdot 1.3}{\left(\dfrac{629}{0.85}\right)} - 1} = 1.535m \tag{10}$$

Using (2)-(5) and (8) the withstand voltage of the air gap is next computed. This value will then be compared to the maximum transient overvoltage.

$$CFO_S = k_w \cdot k_g \cdot \frac{3400}{1+\frac{8}{D}} = 1.037 \cdot 1.3 \cdot \frac{3400}{1+\frac{8}{1.535}} = 737.7kV \quad (11)$$

$$\delta = e^{-\frac{A}{8.6}} = e^{-\frac{2.134}{8.6}} = 0.78 \quad (12)$$

$$G_O = \frac{CFO_S}{500 \cdot D} = \frac{737.7}{(500)\cdot(1.535)} = 0.961 \quad (13)$$

$$m = 1.25 \cdot G_O (G_O - 0.2) = 1.25 \cdot 0.961(0.961 - 0.2) = 0.915 \quad (14)$$

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} = (0.85)(1.037)(1.3)(0.78)^{0.915}\left(\frac{3400}{1+\frac{8}{1.535}}\right) = 499.8kV \quad (15)$$

The calculated V_m is less than 629 kV; thus, the clearance distance must be increased. A few iterations using (2)-(5) and (8) are required until the computed $V_m \geq 629$ kV. For this case it was found that D = 1.978 m (6.49 feet) yielded V_m = 629.3 kV. Using this clearance distance the following values were computed for the final iteration.

$$CFO_S = k_w \cdot k_g \cdot \frac{3400}{1+\frac{8}{D}} = 1.037 \cdot 1.3 \cdot \frac{3400}{1+\frac{8}{1.978}} = 908.5kV \quad (16)$$

$$\delta = e^{-\frac{A}{8.6}} = e^{-\frac{2.134}{8.6}} = 0.78 \quad (17)$$

$$G_O = \frac{CFO_S}{500 \cdot D} = \frac{908.5}{(500)\cdot(1.978)} = 0.919 \quad (18)$$

$$m = 1.25 \cdot G_O (G_O - 0.2) = 1.25 \cdot 0.919(0.919 - 0.2) = 0.825 \quad (19)$$

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} = (0.85)(1.037)(1.3)(0.78)^{0.825}\left(\frac{3400}{1+\frac{8}{1.978}}\right) = 629.3kV \quad (20)$$

Therefore, the minimum vegetation clearance distance for a maximum line to line ac operating voltage of 550 kV at 7000 feet above sea level is 1.978 m (6.49 feet). Table 1 provides calculated distances for various altitudes and maximum system operating ac voltages.

A. Introduction

1. **Title:** **Transmission Vegetation Management Program**

2. **Number:** FAC-003-1

3. **Purpose:** To improve the reliability of the electric transmission systems by preventing outages from vegetation located on transmission rights-of-way (ROW) and minimizing outages from vegetation located adjacent to ROW, maintaining clearances between transmission lines and vegetation on and along transmission ROW, and reporting vegetation-related outages of the transmission systems to the respective Regional Reliability Organizations (RRO) and the North American Electric Reliability Council (NERC).

4. **Applicability:**

   4.1. Transmission Owner.

   4.2. Regional Reliability Organization.

   4.3. This standard shall apply to all transmission lines operated at 200 kV and above and to any lower voltage lines designated by the RRO as critical to the reliability of the electric system in the region.

5. **Effective Dates:**

   5.1. One calendar year from the date of adoption by the NERC Board of Trustees for Requirements 1 and 2.

   5.2. Sixty calendar days from the date of adoption by the NERC Board of Trustees for Requirements 3 and 4.

B. Requirements

R1. The Transmission Owner shall prepare, and keep current, a formal transmission vegetation management program (TVMP). The TVMP shall include the Transmission Owner's objectives, practices, approved procedures, and work specifications[1].

R1.1. The TVMP shall define a schedule for and the type (aerial, ground) of ROW vegetation inspections. This schedule should be flexible enough to adjust for changing conditions. The inspection schedule shall be based on the anticipated growth of vegetation and any other environmental or operational factors that could impact the relationship of vegetation to the Transmission Owner's transmission lines.

R1.2. The Transmission Owner, in the TVMP, shall identify and document clearances between vegetation and any overhead, ungrounded supply conductors, taking into consideration transmission line voltage, the effects of ambient temperature on conductor sag under maximum design loading, and the effects of wind velocities on conductor sway. Specifically, the Transmission Owner shall establish clearances to be achieved at the time of vegetation management work identified herein as Clearance 1, and shall also establish and maintain a set of clearances identified herein as Clearance 2 to prevent flashover between vegetation and overhead ungrounded supply conductors.

R1.2.1. Clearance 1 — The Transmission Owner shall determine and document appropriate clearance distances to be achieved at the time of transmission vegetation management work based upon local conditions and the expected time frame in which the Transmission Owner plans to return for future

[1] ANSI A300, Tree Care Operations – Tree, Shrub, and Other Woody Plant Maintenance – Standard Practices, while not a requirement of this standard, is considered to be an industry best practice.

vegetation management work. Local conditions may include, but are not limited to: operating voltage, appropriate vegetation management techniques, fire risk, reasonably anticipated tree and conductor movement, species types and growth rates, species failure characteristics, local climate and rainfall patterns, line terrain and elevation, location of the vegetation within the span, and worker approach distance requirements. Clearance 1 distances shall be greater than those defined by Clearance 2 below.

R1.2.2. Clearance 2 — The Transmission Owner shall determine and document specific radial clearances to be maintained between vegetation and conductors under all rated electrical operating conditions. These minimum clearance distances are necessary to prevent flashover between vegetation and conductors and will vary due to such factors as altitude and operating voltage. These Transmission Owner-specific minimum clearance distances shall be no less than those set forth in the Institute of Electrical and Electronics Engineers (IEEE) Standard 516-2003 (*Guide for Maintenance Methods on Energized Power Lines*) and as specified in its Section 4.2.2.3, Minimum Air Insulation Distances without Tools in the Air Gap.

R1.2.2.1 Where transmission system transient overvoltage factors are not known, clearances shall be derived from Table 5, IEEE 516-2003, phase-to-ground distances, with appropriate altitude correction factors applied.

R1.2.2.2 Where transmission system transient overvoltage factors are known, clearances shall be derived from Table 7, IEEE 516-2003, phase-to-phase voltages, with appropriate altitude correction factors applied.

R1.3. All personnel directly involved in the design and implementation of the TVMP shall hold appropriate qualifications and training, as defined by the Transmission Owner, to perform their duties.

R1.4. Each Transmission Owner shall develop mitigation measures to achieve sufficient clearances for the protection of the transmission facilities when it identifies locations on the ROW where the Transmission Owner is restricted from attaining the clearances specified in Requirement 1.2.1.

R1.5. Each Transmission Owner shall establish and document a process for the immediate communication of vegetation conditions that present an imminent threat of a transmission line outage. This is so that action (temporary reduction in line rating, switching line out of service, etc.) may be taken until the threat is relieved.

R2. The Transmission Owner shall create and implement an annual plan for vegetation management work to ensure the reliability of the system. The plan shall describe the methods used, such as manual clearing, mechanical clearing, herbicide treatment, or other actions. The plan should be flexible enough to adjust to changing conditions, taking into consideration anticipated growth of vegetation and all other environmental factors that may have an impact on the reliability of the transmission systems. Adjustments to the plan shall be documented as they occur. The plan should take into consideration the time required to obtain permissions or permits from landowners or regulatory authorities. Each Transmission Owner shall have systems and procedures for documenting and tracking the planned vegetation management work and ensuring that the vegetation management work was completed according to work specifications.

R3. The Transmission Owner shall report quarterly to its RRO, or the RRO's designee, sustained transmission line outages determined by the Transmission Owner to have been caused by vegetation.

R3.1. Multiple sustained outages on an individual line, if caused by the same vegetation, shall be reported as one outage regardless of the actual number of outages within a 24-hour period.

R3.2. The Transmission Owner is not required to report to the RRO, or the RRO's designee, certain sustained transmission line outages caused by vegetation: (1) Vegetation-related outages that result from vegetation falling into lines from outside the ROW that result from natural disasters shall not be considered reportable (examples of disasters that could create non-reportable outages include, but are not limited to, earthquakes, fires, tornados, hurricanes, landslides, wind shear, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods), and (2) Vegetation-related outages due to human or animal activity shall not be considered reportable (examples of human or animal activity that could cause a non-reportable outage include, but are not limited to, logging, animal severing tree, vehicle contact with tree, arboricultural activities or horticultural or agricultural activities, or removal or digging of vegetation).

R3.3. The outage information provided by the Transmission Owner to the RRO, or the RRO's designee, shall include at a minimum: the name of the circuit(s) outaged, the date, time and duration of the outage; a description of the cause of the outage; other pertinent comments; and any countermeasures taken by the Transmission Owner.

R3.4. An outage shall be categorized as one of the following:

R3.4.1. Category 1 — Grow-ins: Outages caused by vegetation growing into lines from vegetation inside and/or outside of the ROW;

R3.4.2. Category 2 — Fall-ins: Outages caused by vegetation falling into lines from inside the ROW;

R3.4.3. Category 3 — Fall-ins: Outages caused by vegetation falling into lines from outside the ROW.

R4. The RRO shall report the outage information provided to it by Transmission Owner's, as required by Requirement 3, quarterly to NERC, as well as any actions taken by the RRO as a result of any of the reported outages.

C. Measures

M1. The Transmission Owner has a documented TVMP, as identified in Requirement 1.

M1.1. The Transmission Owner has documentation that the Transmission Owner performed the vegetation inspections as identified in Requirement 1.1.

M1.2. The Transmission Owner has documentation that describes the clearances identified in Requirement 1.2.

M1.3. The Transmission Owner has documentation that the personnel directly involved in the design and implementation of the Transmission Owner's TVMP hold the qualifications identified by the Transmission Owner as required in Requirement 1.3.

M1.4. The Transmission Owner has documentation that it has identified any areas not meeting the Transmission Owner's standard for vegetation management and any mitigating measures the Transmission Owner has taken to address these deficiencies as identified in Requirement 1.4.

M1.5. The Transmission Owner has a documented process for the immediate communication of imminent threats by vegetation as identified in Requirement 1.5.

M2. The Transmission Owner has documentation that the Transmission Owner implemented the work plan identified in Requirement 2.

M3. The Transmission Owner has documentation that it has supplied quarterly outage reports to the RRO, or the RRO's designee, as identified in Requirement 3.

M4. The RRO has documentation that it provided quarterly outage reports to NERC as identified in Requirement 4.

D. Compliance

1. Compliance Monitoring Process

1.1. Compliance Monitoring Responsibility

RRO

NERC

1.2. Compliance Monitoring Period and Reset

One calendar Year

1.3. Data Retention

Five Years

1.4. Additional Compliance Information

The Transmission Owner shall demonstrate compliance through self-certification submitted to the compliance monitor (RRO) annually that it meets the requirements of NERC Reliability Standard FAC-003-1. The compliance monitor shall conduct an on-site audit every five years or more frequently as deemed appropriate by the compliance monitor to review documentation related to Reliability Standard FAC-003-1. Field audits of ROW vegetation conditions may be conducted if determined to be necessary by the compliance monitor.

2. Levels of Non-Compliance

2.1. Level 1:

2.1.1. The TVMP was incomplete in one of the requirements specified in any subpart of Requirement 1, or;

2.1.2. Documentation of the annual work plan, as specified in Requirement 2, was incomplete when presented to the Compliance Monitor during an on-site audit, or;

2.1.3. The RRO provided an outage report to NERC that was incomplete and did not contain the information required in Requirement 4.

2.2. Level 2:

2.2.1. The TVMP was incomplete in two of the requirements specified in any subpart of Requirement 1, or;

2.2.2. The Transmission Owner was unable to certify during its annual self-certification that it fully implemented its annual work plan, or documented deviations from, as specified in Requirement 2.

2.2.3. The Transmission Owner reported one Category 2 transmission vegetation-related outage in a calendar year.

2.3. Level 3:

2.3.1. The Transmission Owner reported one Category 1 or multiple Category 2 transmission vegetation-related outages in a calendar year, or;

2.3.2. The Transmission Owner did not maintain a set of clearances (Clearance 2), as defined in Requirement 1.2.2, to prevent flashover between vegetation and overhead ungrounded supply conductors, or;

2.3.3. The TVMP was incomplete in three of the requirements specified in any subpart of Requirement 1.

2.4. Level 4:

2.4.1. The Transmission Owner reported more than one Category 1 transmission vegetation-related outage in a calendar year, or;

2.4.2. The TVMP was incomplete in four or more of the requirements specified in any subpart of Requirement 1.

E. Regional Differences

None Identified.

Version History

Version	Date	Action	Change Tracking
Version 1	TBA	1. Added “Standard Development Roadmap.” 2. Changed “60” to “Sixty” in section A, 5.2. 3. Added “Proposed Effective Date: April 7, 2006” to footer. 4. Added “Draft 3: November 17, 2005” to footer.	01/20/06

Standard FAC-003-1	Proposed Standard FAC-003-2 RBS Draft 4	Observations
Definitions of Terms **Right of Way** A corridor of land on which electric lines may be located. The Transmission Owner may own the land in fee, own an easement, or have certain franchise, prescription, or license rights to construct and maintain lines.	**Definitions of Terms Used in Standard** **Right-of-Way (ROW)** The corridor of land under a transmission line(s) needed to operate the line(s). The width of the corridor is established by engineering or construction standards as documented in either construction documents, pre-2007 vegetation maintenance records, or by the blowout standard in effect when the line was built. The ROW width in no case exceeds the Transmission Owner's legal rights but may be less based on the aforementioned criteria. The current glossary definition of this NERC term is modified to address the issues set forth in Paragraph 734 of FERC Order 693.	This definition is intended to more clearly recognize the establishment of the Right of Way thought documentation.
Vegetation Inspection The systematic examination of a transmission corridor to document vegetation conditions.	**Vegetation Inspection** The systematic examination of vegetation conditions on a Right-of-Way and those vegetation conditions under the Transmission Owner's control that are likely to pose a hazard to the line(s) prior to the next planned maintenance or inspection. This may be combined with a general line inspection.	This definition is intended to explain the reason for Vegetation Inspections, and to make clear that entities may perform other inspections at the same time as the Vegetation Inspection.

Standard FAC-003-1	Proposed Standard FAC-003-2 RBS Draft 4	Observations
	The current glossary definition of this NERC term is modified to allow both maintenance inspections and vegetation inspections to be performed concurrently. Current definition of Vegetation Inspection: The systematic examination of a transmission corridor to document vegetation conditions.	
	Minimum Vegetation Clearance Distance (MVCD) The calculated minimum distance stated in feet (meters) to prevent flash-over between conductors and vegetation, for various altitudes and operating voltages.	This definition was added to ensure a consistent understanding of the phrase.
3. Purpose: To improve the reliability of the electric transmission systems by preventing outages from vegetation located on transmission rights-of-way (ROW) and minimizing outages from vegetation located adjacent to ROW, maintaining clearances between transmission lines and vegetation on and along transmission ROW, and	**3. Purpose:** To maintain a reliable electric transmission system by using a defense-in-depth strategy to manage vegetation located on transmission rights of way (ROW) and minimize encroachments from vegetation located adjacent to the ROW, thus preventing the risk of those vegetation-related outages that could lead to Cascading.	Results based purpose, driven by Needs and Goals. NEED: To maintain a reliable electric transmission system , preventing the risk of those vegetation-related outages that could lead to Cascading. GOAL: To manage vegetation located on transmission rights of way (ROW) and minimize encroachments from vegetation located adjacent to the ROW

Standard FAC-003-1	Proposed Standard FAC-003-2 RBS Draft 4	Observations
reporting vegetation related outages of the transmission systems to the respective Regional Reliability Organizations (RRO) and the North American Electric Reliability Council (NERC).		
4. Applicability: **4.1.** Transmission Owner **4.2.** Regional Reliability Organization **4.3.** This Standard shall apply to all transmission lines operated at 200 kV and above and to any lower voltage lines designated by the RRO as critical to the reliability of the electric system in the region.	4.1. Functional Entities: 4.1.1 Transmission Owners 4.2. Facilities: Defined below (referred to as "applicable lines"), including but not limited to those that cross lands owned by federal , state, provincial, public, private, or tribal entities: 4.2.1. Each overhead transmission line operated at 200kV or higher. 4.2.2. Each overhead transmission line operated below 200kV identified as an element of an IROL under NERC Standard FAC-014 by the Planning Coordinator. 4.2.3. Each overhead transmission line operated below 200 kV identified as an element of a Major WECC Transfer Path in the Bulk Electric System by WECC. 4.2.4. Each overhead transmission line identified above (4.2.1 through 4.2.3) located outside the fenced area of the switchyard, station or substation and any portion of the span of the transmission line that is crossing the substation fence.	4.1.1 replaces 4.1. 4.2 has been removed, as the requirements related to the RRO have been addressed in the compliance section of the standard. 4.2 replaces 4.3. This is superior, as it raises the bar on what lines need to be included within the applicability of this standard. To the extent the areas not covered in 4.2.4 need to be addressed, they should do so under another project and possibly in a separate standard, as the requirements for vegetation management performed in these areas by the GO and DP may be somewhat different than those performed by a Transmission Owner.

Standard FAC-003-1	Proposed Standard FAC-003-2 RBS Draft 4	Observations
	Rationale The areas excluded in 4.2.4 were excluded based on comments from industry for reasons summarized as follows: 1) There is a very low risk from vegetation in this area. Based on an informal survey, no TOs reported such an event. 2) Substations, switchyards, and stations have many inspection and maintenance activities that are necessary for reliability. Those existing process manage the threat. As such, the formal steps in this standard are not well suited for this environment. 3) NERC has a project in place to address at a later date the applicability of this standard to Generation Owners. 4) Specifically addressing the areas where the standard does and does not apply makes the standard clearer.	

R1. The Transmission Owner shall prepare, and keep current, a formal transmission vegetation management program (TVMP). The TVMP shall include the Transmission Owner's objectives, practices, approved procedures, and work specifications**1**.	**R3.** Each Transmission Owner shall have documented maintenance strategies or procedures or processes or specifications it uses to prevent the encroachment of vegetation into the MVCD of its applicable lines that include(s) the following: **Rationale** The documentation provides a basis for evaluating the competency of the Transmission Owner's vegetation program. There may be many acceptable approaches to maintain clearances. Any approach must demonstrate that the Transmission Owner avoids vegetation-to-wire conflicts under all Ratings and all Rated Electrical Operating Conditions. See Figure 1 for an illustration of possible conductor locations.	R3 replaces R1.
R1.1. The TVMP shall define a schedule for and the type (aerial, ground) of ROW vegetation inspections. This schedule should be flexible enough to adjust for changing conditions. The inspection schedule shall be based on the anticipated growth of vegetation	R6. Each Transmission Owner shall perform a Vegetation Inspection of 100% of its applicable transmission lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.) at least once per calendar year and with no more than 18	R6 replaces R1.1. R6 is superior because it requires entities to take action (perform the inspection), rather than just create a schedule.

and any other environmental or operational factors that could impact the relationship of vegetation to the Transmission Owner's transmission lines.	calendar months between inspections on the same ROW.1 **Rationale** Inspections are used by Transmission Owners to assess the condition of the entire ROW. The information from the assessment can be used to determine risk, determine future work and evaluate recently-completed work. This requirement sets a minimum Vegetation Inspection frequency of once per calendar year but with no more than 18 months between inspections on the same ROW. Based upon average growth rates across North America and on common utility practice, this minimum frequency is reasonable. Transmission Owners should consider local and environmental factors that could warrant more frequent inspections.	
R1.2. The Transmission Owner, in the TVMP, shall identify and document clearances between vegetation and any overhead, ungrounded supply conductors, taking into consideration transmission line voltage, the effects of ambient temperature on conductor sag under maximum design	**R3.** Each Transmission Owner shall have documented maintenance strategies or procedures or processes or specifications it uses to prevent the encroachment of vegetation into the MVCD of its applicable lines that include(s)accounts for the following	Requirement R3 and Parts 3.1 and 3.2 replace the concept of "Clearance 1," as discussed in R1.2 and R1.2.1.

[1] When the Transmission Owner is prevented from performing a Vegetation Inspection within the timeframe in R6 due to a natural disaster, the TO is granted a time extension that is equivalent to the duration of the time the TO was prevented from performing the Vegetation Inspection.

loading, and the effects of wind velocities on conductor sway. Specifically, the Transmission Owner shall establish clearances to be achieved at the time of vegetation management work identified herein as Clearance 1, and shall also establish and maintain a set of clearances identified herein as Clearance 2 to prevent flashover between vegetation and overhead ungrounded supply conductors. **R1.2.1.** Clearance 1 — The Transmission Owner shall determine and document appropriate clearance distances to be achieved at the time of transmission vegetation management work based upon local conditions and the expected time frame in which the Transmission Owner plans to return for future vegetation management work. Local conditions may include, but are not limited to: operating voltage, appropriate vegetation management techniques, fire risk, reasonably anticipated tree and conductor movement, species types and growth rates, species failure characteristics, local climate and rainfall patterns, line terrain and elevation, location of the vegetation within the span, and worker approach distance requirements. Clearance 1 distances shall be greater than those defined by Clearance 2 below.	**3.1** Movement of applicable line conductors under their Rating and all Rated Electrical Operating Conditions; **3.2** Inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency.	

R1.2.2. Clearance 2 — The Transmission Owner shall determine and document specific radial clearances to be maintained between vegetation and conductors under all rated electrical operating conditions. These minimum clearance distances are necessary to prevent flashover between vegetation and conductors and will vary due to such factors as altitude and operating voltage. These Transmission Owner-specific minimum clearance distances shall be no less than those set forth in the Institute of Electrical and Electronics Engineers (IEEE) Standard 516-2003 (*Guide for Maintenance Methods on Energized Power Lines*) and as specified in its Section 4.2.2.3, Minimum Air Insulation Distances without Tools in the Air Gap. **R1.2.2.1** Where transmission system transient overvoltage factors are not known, clearances shall be derived from Table 5, IEEE 516-2003, phase-to-ground distances, with appropriate altitude correction factors applied. **R1.2.2.2** Where transmission system	**R1.** Each Transmission Owner shall manage vegetation to prevent encroachments into the MVCD of its applicable line(s) which are either an element of an IROL, or an element of a Major WECC Transfer Path; operating within its Rating and all Rated Electrical Operating Conditions of the types shown below[2] [*Violation Risk Factor: High*] [*Time Horizon: Real-time*]: 1. An encroachment into the MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage **R2.** Each Transmission Owner shall manage vegetation to prevent encroachments into the MVCD of its applicable line(s) which are <u>not</u> either an element of an IROL, or an element of a Major WECC Transfer Path; operating within its Rating and all Rated Electrical Operating Conditions of the types shown below[2] [*Violation Risk Factor:*	R1 item 1 and R2 item 2 replace Clearance 2 with the Gallet Equations. These are performance based, and superior to the existing standard, as they require the entities to perform an action (manage vegetation) rather than creating a document.

[2] This requirement does not apply to circumstances that are beyond the control of a Transmission Owner subject to this reliability standard, including natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods; human or animal activity such as logging, animal severing tree, vehicle contact with tree, or installation, removal, or digging of vegetation. Nothing in this footnote should be construed to limit the Transmission Owner's right to exercise its full legal rights on the ROW.

[3] If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation.

transient overvoltage factors are known, clearances shall be derived from Table 7, IEEE 516-2003, phase-to-phase voltages, with appropriate altitude correction factors applied.	*Medium*] [*Time Horizon: Real-time*]: 1. An encroachment into the MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage[3],	
R1.3. All personnel directly involved in the design and implementation of the TVMP shall hold appropriate qualifications and training, as defined by the Transmission Owner, to perform their duties.		R1.3 is ambiguous (what is "appropriate") and unenforceable (what if the Transmission Owner defines no qualifications or training), and was not included in the new version of the standard.
R1.4. Each Transmission Owner shall develop mitigation measures to achieve sufficient clearances for the protection of the transmission facilities when it identifies locations on the ROW where the Transmission Owner is restricted from attaining the clearances specified in Requirement 1.2.1.		R5 replaces R1.4. It is superior because it requires the Transmission Owner to take action (take corrective action), rather than to simply develop mitigation measures.
	R5. When a Transmission Owner is constrained from performing vegetation work on applicable transmission lines operating within their Rating and all Rated Electrical Operating Conditions, and the constraint may lead to a vegetation encroachment into the MVCD prior to the implementation of the next annual work plan, then the Transmission Owner shall take corrective action to ensure continued vegetation management to prevent encroachments	

	Rationale Legal actions and other events may occur which result in constraints that prevent the Transmission Owner from performing planned vegetation maintenance work. In cases where the transmission line is put at potential risk due to constraints, the intent is for the Transmission Owner to put interim measures in place, rather than do nothing. The corrective action process is not intended to address situations where a planned work methodology cannot be performed but an alternate work methodology can be used.	
R1.5. Each Transmission Owner shall establish and document a process for the immediate communication of vegetation conditions that present an imminent threat of a transmission line outage. This is so that action (temporary reduction in line rating, switching line out of service, etc.) may be taken until the threat is relieved.	**R4.** Each Transmission Owner, without any intentional time delay, shall notify the control center holding switching authority for the associated applicable line when the Transmission Owner has confirmed the existence of a vegetation condition that is likely to cause a Fault at any moment. *[VRF – Medium] [Time Horizon – Real-time]*	R4 replaces R1.5. It is superior because it requires the Transmission Owner to take action (notify the control center) rather than document a process.

	Rationale This is to ensure expeditious communication between the Transmission Owner and the control center when a critical situation is confirmed.	
R2. The Transmission Owner shall create and implement an annual plan for vegetation management work to ensure the reliability of the system. The plan shall describe the methods used, such as manual clearing, mechanical clearing, herbicide treatment, or other actions. The plan should be flexible enough to adjust to changing conditions, taking into consideration anticipated growth of vegetation and all other environmental factors that may have an impact on the reliability of the transmission systems. Adjustments to the plan shall be documented as they occur. The plan should take into consideration the time required to obtain permissions or permits from landowners or regulatory authorities. Each Transmission Owner shall have systems and procedures for documenting and tracking the planned vegetation management work and ensuring that the vegetation management work was completed according to work specifications.	**R7.** Each Transmission Owner shall complete 100% of its annual vegetation work plan of applicable lines to ensure no vegetation encroachments occur within the MVCD. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made (provided they do not allow encroachment of vegetation into the MVCD) and must be documented. The percent completed calculation is based on the number of units actually completed divided by the number of units in the final amended plan (measured in units of choice - circuit, pole line, line miles or kilometers, etc.) Examples of reasons for modification to annual plan may include • Change in expected growth rate/ environmental factors • Circumstances that are beyond the control of a Transmission Owner[3] • Rescheduling work between growing seasons • Crew or contractor availability/ Mutual assistance agreements	R7 replaces R2. It is superior because it requires entities to takes specific action (complete 100% of its plan) rather than more generic language (implement its plan). Entities that do not have a plan would be unable to meet this requirement, as they would have no evidence to demonstrate compliance.

[3] Circumstances that are beyond the control of a Transmission Owner include but are not limited to natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, ice storms, floods, or major storms as defined either by the TO or an applicable regulatory body.

	• Identified unanticipated high priority work • Weather conditions/Accessibility • Permitting delays • Land ownership changes/Change in land use by the landowner • Emerging technologies **Rationale** This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. It allows modifications to the planned work for changing conditions, taking into consideration anticipated growth of vegetation and all other environmental factors, provided that those modifications do not put the transmission system at risk of a vegetation encroachment.	
R3. The Transmission Owner shall report quarterly to its RRO, or the RRO's designee, sustained transmission line outages determined by the Transmission Owner to have been caused by vegetation. **R3.1.** Multiple sustained outages on an individual line, if caused by the same vegetation, shall be reported as one outage regardless of the actual number of outages within a 24-hour period. **R3.2.** The Transmission Owner is not required to report to the RRO, or the RRO's designee, certain sustained transmission line outages caused by vegetation: (1) Vegetation related	**Periodic Data Submittal:** The Transmission Owner will submit a quarterly report to its Regional Entity, or the Regional Entity's designee, identifying all Sustained Outages of applicable lines operated within their Rating and all Rated Electrical Operating Conditions as determined by the Transmission Owner to have been caused by vegetation, except as excluded in footnote 2, and including as a minimum the following: o The name of the circuit(s), the date, time and duration of the outage; the voltage of the circuit; a description of the cause of the outage; the category associated with the Sustained	Moved to compliance section of standard.

outages that result from vegetation falling into lines from outside the ROW that result from natural disasters shall not be considered reportable (examples of disasters that could create non-reportable outages include, but are not limited to, earthquakes, fires, tornados, hurricanes, landslides, wind shear, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods), and (2) Vegetation-related outages due to human or animal activity shall not be considered reportable (examples of human or animal activity that could cause a non-reportable outage include, but are not limited to, logging, animal severing tree, vehicle contact with tree, arboricultural activities or horticultural or agricultural activities, or removal or digging of vegetation). **R3.3.** The outage information provided by the Transmission Owner to the RRO, or the RRO's designee, shall include at a minimum: the name of the circuit(s) outaged, the date, time and duration of the outage; a description of the cause of the outage; other pertinent comments; and any countermeasures taken by the Transmission Owner. **R3.4.** An outage shall be categorized as one of the following: **R3.4.1.** Category 1 — Grow-ins: Outages caused by vegetation growing into lines from vegetation inside and/or outside of the ROW; **R3.4.2.** Category 2 — Fall-ins: Outages caused by vegetation falling into lines from inside the ROW; **R3.4.3.** Category 3 — Fall-ins: Outages caused by vegetation falling into lines from	Outage; other pertinent comments; and any countermeasures taken by the Transmission Owner. A Sustained Outage is to be categorized as one of the following: o Category 1A — Grow-ins: Sustained Outages caused by vegetation growing into applicable lines, that are identified as an element of an IROL or Major WECC Transfer Path, by vegetation inside and/or outside of the ROW; o Category 1B — Grow-ins: Sustained Outages caused by vegetation growing into applicable lines, but are not identified as an element of an IROL or Major WECC Transfer Path, by vegetation inside and/or outside of the ROW; o Category 2A — Fall-ins: Sustained Outages caused by vegetation falling into applicable lines that are identified as an element of an IROL or Major WECC Transfer Path, from within the ROW; o Category 2B — Fall-ins: Sustained Outages caused by vegetation falling into applicable lines, but are not identified as an element of an IROL or Major WECC Transfer Path, from within the ROW; o Category 3 — Fall-ins: Sustained Outages caused by vegetation falling into applicable lines from outside the ROW; o Category 4A — Blowing together: Sustained Outages caused by vegetation and applicable lines that are identified as an element of an IROL or Major WECC Transfer Path, blowing together from within the ROW. o Category 4B — Blowing together: Sustained	

outside the ROW. **R4.** The RRO shall report the outage information provided to it by Transmission Owner's, as required by Requirement 3, quarterly to NERC, as well as any actions taken by the RRO as a result of any of the reported outages.	Outages caused by vegetation and applicable lines, but are not identified as an element of an IROL or Major WECC Transfer Path, blowing together from within the ROW. The Regional Entity will report the outage information provided by Transmission Owners, as per the above, quarterly to NERC, as well as any actions taken by the Regional Entity as a result of any of the reported Sustained Outages.	
	R1. Each Transmission Owner shall manage vegetation to prevent encroachments into the MVCD of its applicable line(s) which are either an element of an IROL, or an element of a Major WECC Transfer Path; operating within their Rating and all Rated Electrical Operating Conditions of the types shown below[2]: 1. An encroachment into the MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage[3] , 2. An encroachment due to a fall-in from inside the ROW that caused a vegetation-related Sustained Outage[4] , 3. An encroachment due to the blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained Outage[4], 4. An encroachment due to vegetation growth into the MVCD that caused a vegetation-related Sustained Outage[4].	New requirement.

	Rationale Lines with the highest significance to reliability are covered in R1; all other lines are covered in R2. Rationale for the types of failure to manage vegetation which are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a Transmission Owner's vegetation maintenance program: 1. This management failure is found by routine inspection or Fault event investigation, and is normally symptomatic of unusual conditions in an otherwise sound program. 2. This management failure occurs when the height and location of a side tree within the ROW is not adequately addressed by the program. 3. This management failure occurs when side growth is not adequately addressed and may be indicative of an unsound program. 4. This management failure is usually indicative of a program that is not addressing the most fundamental dynamic of vegetation management, (i.e. a grow-in under the line). If this type of failure is pervasive on multiple	
	R2. Each Transmission Owner shall manage	New requirement.

	vegetation to prevent encroachments into the MVCD of its applicable line(s) which are not either an element of an IROL, or an element of a Major WECC Transfer Path; operating within its Rating and all Rated Electrical Operating Conditions of the types shown below[2] [Violation Risk Factor: Medium] [Time Horizon: Real-time]: 1. An encroachment into the MVCD, observed in Real-time, absent a Sustained Outage[3], 2. An encroachment due to a fall-in from inside the ROW that caused a vegetation-related Sustained Outage[4], 3. An encroachment due to blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained Outage[4], 4. An encroachment due to vegetation growth into the MVCD that caused a vegetation-related Sustained Outage[4]	

	Rationale Lines with the highest significance to reliability are covered in R1; all other lines are covered in R2. Rationale for the types of failure to manage vegetation which are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a Transmission Owner's vegetation maintenance program: 1. This management failure is found by routine inspection or Fault event investigation, and is normally symptomatic of unusual conditions in an otherwise sound program. 2. This management failure occurs when the height and location of a side tree within the ROW is not adequately addressed by the program. 3. This management failure occurs when side growth is not adequately addressed and may be indicative of an unsound program. 4. This management failure is usually indicative of a program that is not addressing the most fundamental dynamic of vegetation management, (i.e. a grow-in under the line). If this type of failure is pervasive on multiple lines, it provides a mechanism for a Cascade.	

[2] This requirement does not apply to circumstances that are beyond the control of a Transmission Owner subject to this reliability standard, including natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods; human or animal activity such as logging, animal severing tree, vehicle contact with tree, or installation, removal, or digging of vegetation. Nothing in this footnote should be construed to limit the Transmission Owner's right to exercise its full legal rights on the ROW.

[3] If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation.

[4] Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period.

Project 2007-07 Vegetation Management

New and Modified Definitions

The following definitions are proposed as part of project 2007-07. They have been provided separately for ease of reference.

Right-of-Way (ROW)

Current

A corridor of land on which electric lines may be located. The Transmission Owner may own the land in fee, own an easement, or have certain franchise, prescription, or license rights to construct and maintain lines.

Proposed

The corridor of land under a transmission line(s) needed to operate the line(s). The width of the corridor is established by engineering or construction standards as documented in either construction documents, pre-2007 vegetation maintenance records, or by the blowout standard in effect when the line was built. The ROW width in no case exceeds the Transmission Owner’s legal rights but may be less based on the aforementioned criteria.

Redline

~~A~~ The corridor of land ~~on which electric~~ under a transmission line(s) needed to operate the line(s). The width of the corridor is established by engineering or construction standards as documented in either construction documents, pre-2007 vegetation maintenance records, or by the blowout standard in effect when the line was built.~~s may be located.~~ The ROW width in no case exceeds the s may be located. Transmission Owner’s legal rights but may be less based on the aforementioned criteria. ~~may own the land in fee, own an easement, or have certain franchise, prescription, or license rights to construct and maintain lines.~~

Vegetation Inspection

Current

The systematic examination of a transmission corridor to document vegetation conditions.

Proposed

The systematic examination of vegetation conditions on a Right-of-Way and those vegetation conditions under the Transmission Owner’s control that are likely to pose a hazard to the line(s) prior to the next planned maintenance or inspection. This may be combined with a general line inspection.

Redline
The systematic examination of vegetation conditions on a Right-of-Way and those vegetation conditions under the Transmission Owner's control that are likely to pose a hazard to the line(s) prior to the next planned maintenance or inspection. This may be combined with a general line inspection.~~a transmission corridor to document vegetation conditions.~~

Minimum Vegetation Clearance Distance (MVCD)
Proposed (new)
The calculated minimum distance stated in feet (meters) to prevent flash-over between conductors and vegetation, for various altitudes and operating voltages.

NERC
NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Project 2007-07 Vegetation Management

Consideration of Issues and Directives

Project 2007-07 Vegetation Management		
Issue or Directive	**Source**	**Consideration of Issue or Directive**
We will not direct NERC to submit a modification to the general limitation on applicability as proposed in the NOPR. However, we will require the ERO to address the proposed modification through its Reliability Standards development process. As explained in the NOPR, the Commission is concerned that the bright-line applicability threshold of 200 kV will exclude a significant number of transmission lines that could impact Bulk-Power System reliability. Although the regional reliability organizations are given discretion to designate lower voltage lines under the proposed Reliability Standard, none have designated any operationally significant lines even though there are lower voltage lines involving IROL as suggested by Progress and SERC. We continue to be concerned that this approach will not prospectively result in the inclusion of all transmission lines that could impact Bulk-Power System reliability.	FERC Order 693, P706	The standard applies to the following facilities, including but not limited to those that cross lands owned by federal, state, provincial, public, private, or tribal entities: 1 - Each overhead transmission line operated at 200kV or higher. 2 - Overhead transmission line operated below 200kV identified as an element of an IROL under NERC Standard FAC-014 by the Planning Coordinator. 3 - Each overhead transmission line operated below 200 kV identified as an element of a Major WECC Transfer Path in the Bulk Electric System by WECC. 4 - Each overhead transmission line identified above located outside the fenced area of the switchyard, station or substation and any portion of the span of the transmission line that is crossing the substation fence.

In proposing to require the ERO to modify the Reliability Standard to apply to Bulk-Power System transmission lines that have an impact on reliability as determined by the ERO, we did not intend to make this Reliability Standard applicable to fewer facilities than it currently is with the 200 kV bright line applicability, but to extend the applicability to lower voltage facilities that have an impact on reliability. We support the suggestions by Progress Energy, SERC and MISO to limit applicability to lower voltage lines associated with IROL and these suggestions should be part of the input to the Reliability Standards development process. Similarly, the ERO should evaluate the suggestions proposed by LPPC, APPA and Avista.	FERC Order 693, P706	The standard applies to the following facilities, including but not limited to those that cross lands owned by federal, state, provincial, public, private, or tribal entities: 1 - Each overhead transmission line operated at 200kV or higher. 2 - Overhead transmission line operated below 200kV identified as an element of an IROL under NERC Standard FAC-014 by the Planning Coordinator. 3 - Each overhead transmission line operated below 200 kV identified as an element of a Major WECC Transfer Path in the Bulk Electric System by WECC. 4 - Each overhead transmission line identified above located outside the fenced area of the switchyard, station or substation and any portion of the span of the transmission line that is crossing the substation fence.
Accordingly, the Commission directs the ERO to develop a Reliability Standard that defines the minimum clearance needed to avoid sustained vegetation-related outages that would apply to transmission lines crossing both federal land and non-federal land.	FERC Order 693, P732	The standard includes Minimum Vegetation Clearance Distances based on the Gallet equations, as specified in FAC-003 Table 2. The standard applies to facilities that meet specific criteria, including (but not limited to) those that cross lands owned by federal, state, provincial, public, private, or tribal entities.

The Commission also directs the ERO to collect outage data for transmission outages of lines that cross both federal and non-federal lands, analyze it, and use the results of this analysis and information to develop a Reliability Standard that would apply to transmission lines crossing both federal and non-federal land.	FERC Order 693, P732	The ERO is currently collecting and publishing all outage data related to FAC-003. This data is received through quarterly reporting and self reporting of violations. Additionally, the TADS initiative is currently collecting data on all automatic interruptions, including those caused by vegetation, both on and off the right of way. This action is equally applicable to federal and non-federal lands. The SDT has requested the TADS project team to modify its database to include fields to identify Federal and non-Federal land transmission facilities such that this data can be collected.

We recognize that many commenters would like a more precise definition for the applicability of this Reliability Standard, and we direct the ERO to develop an acceptable definition that covers facilities that impact reliability but balances extending the applicability of this standard against unreasonably increasing the burden on transmission owners.	FERC Order 693, P708	The standard applies to all Transmission Owners, for the following facilities, including but not limited to those that cross lands owned by federal, state, provincial, public, private, or tribal entities: 1 - Each overhead transmission line operated at 200kV or higher. 2 - Overhead transmission line operated below 200kV identified as an element of an IROL under NERC Standard FAC-014 by the Planning Coordinator. 3 - Each overhead transmission line operated below 200 kV identified as an element of a Major WECC Transfer Path in the Bulk Electric System by WECC. 4 - Each overhead transmission line identified above located outside the fenced area of the switchyard, station or substation and any portion of the span of the transmission line that is crossing the substation fence.

FirstEnergy and Xcel suggest that if the applicability of this Reliability Standard is expanded, the Commission should allow flexibility in complying with this Reliability Standard for lower-voltage facilities, or allow lower-voltage facilities one year before the Reliability Standard is implemented. The ERO should consider these comments when determining when it would request that the modification of this Reliability Standard to go into effect.	FERC Order 693, P709	The Implementation Plan requests that the standard become effective as follows: "The first calendar day of the first calendar quarter one year after the date of the order approving the standard from applicable regulatory authorities where such explicit approval is required. Where no regulatory approval is required, the standard becomes effective on the first calendar day of the first calendar quarter one year after Board of Trustees adoption." Additionally, the Implementation Plan proposes four transition cases to address specific situations.
The Commission continues to be concerned with leaving complete discretion to the transmission owners in determining inspection cycles, which limits the effectiveness of the Reliability Standard. Accordingly, the Commission directs the ERO to develop compliance audit procedures, using relevant industry experts, which would identify appropriate inspection cycles based on local factors. These inspection cycles are to be used in compliance auditing of FAC-003-1 by the ERO or Regional Entity to ensure such inspection cycles and vegetation management requirements are properly met by the responsible entities.	FERC Order 693, P721	The VM SDT has tightened the Inspection Cycle requirement. Minimum inspection frequency of once per calendar year is now required.

FirstEnergy suggests that rights-of-way be defined to encompass the required clearance areas instead of the corresponding legal rights, and that the standards should not require clearing the entire right-of-way when the required clearance for an existing line does not take up the entire right-of-way. The Commission believes this suggestion is reasonable and should be addressed by the ERO. Accordingly, the Commission directs the ERO to address this suggestion in the Reliability Standards development process.	FERC Order 693, P734	The VMSDT developed a new definition of Active Transmission Line ROW for inclusion in NERC Glossary. This definition includes the statement "The ROW width in no case exceeds the Transmission Owner's legal rights but may be less based on the aforementioned criteria." The Standard does not require the clearing the entire legal easement for a particular parcel of land to ensure reliability. Rather, the Standard requires vegetation maintenance to adequately prevent outages from vegetation on the right of way but also requires the TO to prevent encroachment within the MVCD.
It was pointed out that an entity did not need to be registered as a TO for FAC-003-1 to apply to them, only that they have transmission lines operated at 200 kV and above. This could include radial lines as well as generation leads at the 200kV and above level. This could mean functions other than TO would require FAC-003-1 to be in the audit scope. How are you looking at the applicability of FAC-003-1 as it applies to DPs, LSEs, GOs etc. This could be applicable to many entities registered in multiple regions.	NERC Audit Observation Team	This is currently addressed through entity registration and is also being addressed through Project 2010-07 Generator Requirements at the Transmission Interface
TO's shall demonstrate compliance through self certification. Compliance monitoring shall conduct an on-site audit every five years or more frequently as deemed appropriate. Does this over-ride the six year audit cycle for TO's?	NERC Audit Observation Team	The standard has been updated with the most current compliance information, eliminating this potential concern.

With regards to the vegetation management standard, what type of event would trigger a compliance investigation?	NERC Audit Observation Team	This question is outside the scope of the drafting team's work.
Format inconsistencies	Version 0 Team	The proposed standard has been formatted consistently.
RA vs. RRO	Version 0 Team	The proposed standard no longer refers to RAs or RROs. Additional, the Planning Coordinator has replaced the Region in a number of areas in which discretion might be required (e.g., identifying the criticality of an element).
Too weak on compliance	Version 0 Team	The Compliance section of the proposed standard now includes Time Horizons, Violation Severity Levels, and Violation Risk Factors to support a stronger position regarding compliance.

NERC
NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Violation Risk Factor and Violation Severity Level Assignments

Project 2007-07 Vegetation Management

This document provides the drafting team's justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for each requirement in FAC-003-2 Vegetation Management.

Each primary requirement is assigned a VRF and a set of one or more VSLs. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the ERO Sanction Guidelines.

Justification for Assignment of Violation Risk Factors

The SDT applied the following NERC criteria when developing these VRFs:

High Risk Requirement
A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement
A requirement that, if violated, could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. However, violation of a medium risk requirement is unlikely to lead to bulk electric system instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to bulk electric system instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system. A planning requirement that is administrative in nature.

The SDT also considered consistency with the FERC Violation Risk Factor Guidelines for setting VRFs:[1]

Guideline (1) — Consistency with the Conclusions of the Final Blackout Report

The Commission seeks to ensure that Violation Risk Factors assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System.

In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:[2]

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief.

Guideline (2) — Consistency within a Reliability Standard

The Commission expects a rational connection between the sub-Requirement Violation Risk Factor assignments and the main Requirement Violation Risk Factor assignment.

[1] North American Electric Reliability Corp., 119 FERC ¶ 61,145, order on reh'g and compliance filing, 120 FERC ¶ 61,145 (2007) ("VRF Rehearing Order").

[2] Id. at footnote 15.

Guideline (3) — Consistency among Reliability Standards

The Commission expects the assignment of Violation Risk Factors corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) — Consistency with NERC's Definition of the Violation Risk Factor Level

Guideline (4) was developed to evaluate whether the assignment of a particular Violation Risk Factor level conforms to NERC's definition of that risk level.

Guideline (5) — Treatment of Requirements that Co-mingle More Than One Obligation

Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

The following discussion addresses how the SDT considered FERC's VRF Guidelines 2 through 5. The team did not address Guideline 1 directly because of an apparent conflict between Guidelines 1 and 4. Whereas Guideline 1 identifies a list of topics that encompass nearly all topics within NERC's Reliability Standards and implies that these requirements should be assigned a "High" VRF, Guideline 4 directs assignment of VRFs based on the impact of a specific requirement to the reliability of the system. The SDT believes that Guideline 4 is reflective of the intent of VRFs in the first instance and therefore concentrated its approach on the reliability impact of the requirements.

VRF Justification

VRF for FAC-003-2, Requirements R1:

The SDT assigned this requirement a VRF of High.

- FERC's Guideline 2 — Consistency within a Reliability Standard. The Requirement states transmission owners must manage vegetation for lines that represent a significant risk of cascading, instability, or separation. The VRF is only applied at the Requirement level and each Requirement Part is treated equally.
- FERC's Guideline 3 — Consistency among Reliability Standards. The requirement mandates measurable performance with regard to vegetation management to ensure that the risk of cascading, separation, and instability is minimized. Other requirements with similar performance based outcomes that could lead to cascading, instability, or separation carry a High VRF.

- FERC's Guideline 4 — Consistency with NERC's Definition of a VRF. IROLs and Major WECC Transfer Paths by definition have an increased potential for leading to cascading, separation, or instability. Therefore this requirement was assigned a High VRF.
- FERC's Guideline 5 — Treatment of Requirements that Co-mingle More Than One Objective. The requirement contains only one objective (to manage vegetation of lines that carry increased risk of instability, cascading, or separation) and only one VRF was assigned.

VRF for FAC-003-2, Requirements R2:

The SDT assigned this requirement a VRF of Medium.

- FERC's Guideline 2 — Consistency within a Reliability Standard. The Requirement states transmission owners must manage vegetation for lines that do not represent a significant risk of cascading, instability, or separation. The VRF is only applied at the Requirement level and each Requirement Part is treated equally.
- FERC's Guideline 3 — Consistency among Reliability Standards. The requirement mandates measurable performance with regard to vegetation management to ensure that the risk of equipment damage is minimized. Other requirements similar performance based outcomes that could lead to equipment damage carry a Medium VRF.
- FERC's Guideline 4 — Consistency with NERC's Definition of a VRF. Lines that are not IROLs and Major WECC Transfer Paths by definition have less potential for leading to cascading, separation, or instability. Therefore this requirement was assigned a Medium VRF.
- FERC's Guideline 5 — Treatment of Requirements that Co-mingle More Than One Objective. The requirement contains only one objective (to manage vegetation of lines that carry minimal risk instability, cascading, or separation) and only one VRF was assigned.

VRF for FAC-003-2, Requirements R3:

The SDT assigned this requirement a VRF of Lower.

- FERC's Guideline 2 — Consistency within a Reliability Standard. The Requirement mandates the Transmission Owner to have documented strategies, procedures, processes, or specifications. The VRF is only applied at the Requirement level and each Requirement Part is treated equally.
- FERC's Guideline 3 — Consistency among Reliability Standards. This requirement calls for an entity to have documented strategies, procedures, processes, or specifications. This requirement is administrative in nature, and is consistent with other standards requiring documentation.
- FERC's Guideline 4 — Consistency with NERC's Definition of a VRF. Failure to have a document is not likely to directly affect the electrical state or the capability of the bulk electric system, or the

ability to effectively monitor and control the bulk electric system. Development of the documents is a requirement that is administrative in nature and is in a planning time frame that, if violated, would not, under emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the bulk electric system, or the ability to effectively monitor, control, or restore the bulk electric system.. Therefore this requirement was assigned a Lower VRF.

- FERC's Guideline 5 — Treatment of Requirements that Co-mingle More Than One Objective. R2 contains only one objective which is to have documents(s). Since the requirement is to have a documents, only one VRF was assigned.

VRF for FAC-003-2, Requirements R4:

The SDT assigned this requirement a VRF of Medium.

- FERC's Guideline 2 — Consistency within a Reliability Standard. The Requirement specifies that transmission owners must report vegetation conditions that are likely to cause a Fault to the control center holding switching authority for the associated line. The VRFs are only applied at the Requirement level and there are no Requirement Parts for separate consideration.
- FERC's Guideline 3 — Consistency among Reliability Standards. The requirement mandates notifications that could hinder the ability to effectively monitor and control the bulk electric system. Other requirements that address with similar outcomes are also assigned Medium VRFs.
- FERC's Guideline 4 — Consistency with NERC's Definition of a VRF. Failure to report vegetation conditions may affect the ability to effectively monitor and control the bulk electric system Therefore this requirement was assigned a Medium VRF.
- FERC's Guideline 5 — Treatment of Requirements that Co-mingle More Than One Objective. The requirement contains only one objective (to report) , and only one VRF was assigned.

VRF for FAC-003-2, Requirements R5:

The SDT assigned this requirement a VRF of Medium.

- FERC's Guideline 2 — Consistency within a Reliability Standard. The Requirement mandates that a Transmission Owner, when constrained from performing vegetation work that may lead to a vegetation encroachment into the MVCD prior to the implementation of the next annual work plan, must take corrective action to ensure continued vegetation management to prevent encroachments. The VRF is only applied at the Requirement level and there are no Requirement Parts for separate consideration.
- FERC's Guideline 3 — Consistency among Reliability Standards. The requirement mandates corrective action that, if not taken, could directly affect the electrical state or the capability of the bulk electric system. Other requirements with similar outcomes are also assigned Medium VRFs.

- FERC's Guideline 4 — Consistency with NERC's Definition of a VRF. Failure to take corrective action could directly affect the electrical state or the capability of the bulk electric system, or the ability to effectively monitor and control the bulk electric system. Therefore this requirement was assigned a Medium VRF.
- FERC's Guideline 5 — Treatment of Requirements that Co-mingle More Than One Objective. The requirement contains only one objective (to take corrective action), and only one VRF was assigned.

VRF for FAC-003-2, Requirements R6:

The SDT assigned this requirement a VRF of Medium.

- FERC's Guideline 2 — Consistency within a Reliability Standard. The Requirement specifies that the transmission owner must perform a Vegetation Inspection of 100% of its lines at least once per calendar year. The VRFs are only applied at the Requirement level and there are no Requirement Parts for separate consideration.
- FERC's Guideline 3 — Consistency among Reliability Standards. The requirement mandates inspections that, if not performed, could affect the ability to effectively monitor and control the bulk electric system. Other requirements with similar outcomes are also assigned Medium VRFs.
- FERC's Guideline 4 — Consistency with NERC's Definition of a VRF. Failure to perform an inspection could affect the ability to effectively monitor and control the bulk electric system. Therefore this requirement was assigned a lower VRF.
- FERC's Guideline 5 — Treatment of Requirements that Co-mingle More Than One Objective. The requirement contains only one objective (to perform a Vegetation inspection), and only one VRF was assigned.

VRF for FAC-003-2, Requirements R7:

The SDT assigned this requirement a VRF of Medium.

- FERC's Guideline 2 — Consistency within a Reliability Standard. The Requirement specifies that the Transmission Owner must complete 100% of its annual vegetation work plan. The VRFs are only applied at the Requirement level and there are no Requirement Parts for separate consideration.
- FERC's Guideline 3 — Consistency among Reliability Standards. The requirement mandates completion of work that, if not completed, could affect the electrical state or the capability of the bulk electric system. Other requirements with similar outcomes are also assigned Medium VRFs.
- FERC's Guideline 4 — Consistency with NERC's Definition of a VRF. Failure to complete the annual vegetation work plan could affect the electrical state or the capability of the bulk electric system. Therefore this requirement was assigned a lower VRF.

- FERC's Guideline 5 — Treatment of Requirements that Co-mingle More Than One Objective. The Requirement contains only one objective (to complete 100% of the annual vegetation work plan), and only one VRF was assigned.

Justification for Assignment of Violation Severity Levels

In developing the VSLs, the SDT anticipated the evidence that would be reviewed during an audit, and developed its VSLs based on the noncompliance an auditor may find during a typical audit. The SDT based its assignment of VSLs on the following NERC criteria:

Lower	Moderate	High	Severe
Missing a minor element (or a small percentage) of the required performance The performance or product measured has significant value as it almost meets the full intent of the requirement.	Missing at least one significant element (or a moderate percentage) of the required performance. The performance or product measured still has significant value in meeting the intent of the requirement.	Missing more than one significant element (or is missing a high percentage) of the required performance or is missing a single vital component. The performance or product has limited value in meeting the intent of the requirement.	Missing most or all of the significant elements (or a significant percentage) of the required performance. The performance measured does not meet the intent of the requirement or the product delivered cannot be used in meeting the intent of the requirement.

FERC's VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement meet the FERC Guidelines for assessing VSLs:

Guideline 1: Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

> Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of non-compliance were used.

Guideline 2: Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a “binary” type requirement must be a “Severe” VSL.

Do not use ambiguous terms such as “minor” and “significant” to describe noncompliant performance.

Guideline 3: Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

Guideline 4: Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations

. . . unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the “default” for penalty calculations.

VSLs for FAC-003-2 Requirement R1:

R#	Compliance with NERC's VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R1	Meets NERC's VSL guidelines. There is an incremental aspect to the violation and the VSLs follow the guidelines for incremental violations..	This is a new requirement, and accordingly cannot lower the current level of compliance.	The proposed VSL does not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.	The proposed VSL uses the same terminology as used in the associated requirement, and is, therefore, consistent with the requirement.	The VSL is based on a single violation and not cumulative violations.

VSLs for FAC-003-2 Requirement R2:

R#	Compliance with NERC's VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R2.	Meets NERC's VSL guidelines. There is an incremental aspect to the violation and the VSLs follow the guidelines for incremental violations.	This is a new requirement, and accordingly cannot lower the current level of compliance.	The proposed VSL does not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.	The proposed VSL uses the same terminology as used in the associated requirement, and is, therefore, consistent with the requirement.	The VSL is based on a single violation and not cumulative violations.

VSLs for FAC-003-3 Requirement R3

R#	Compliance with NERC's Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R3.	Meets NERC's VSL guidelines. There is an incremental aspect to the violation and the VSLs follow the guidelines for incremental violations.	The previous standard graded the VSLs based on the completeness of the TVMP. The new VSL is structured similarly, but has omitted the "Low" level, effectively raising the minimum level of compliance.	The proposed VSLs do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.	The proposed VSLs use the same terminology as used in the associated requirement, and are, therefore, consistent with the requirement.	The VSLs are based on a single violation and not cumulative violations.

VSLs for FAC-003-3 Requirement R4:

R#	Compliance with NERC's Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R4.	Meets NERC's VSL guidelines. There is an incremental aspect to the violation and the VSLs follow the guidelines for incremental violations.	The previous standard does not require actual communication, while the new standard does. Accordingly, this should be treated as a new requirement, and therefore cannot lower the current level of compliance.	The proposed VSLs do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.	The proposed VSLs use the same terminology as used in the associated requirement, and are, therefore, consistent with the requirement.	The VSLs are based on a single violation and not cumulative violations.

VSLs for FAC-003-3 Requirement R5:

R#	Compliance with NERC's Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R5.	Meets NERC's VSL guidelines - Severe: The performance or product measured does not substantively meet the intent of the requirement.	The only VSL is Severe, and therefore, the VSL cannot result in a lower level of compliance.	The proposed VSLs do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.	The proposed VSLs use the same terminology as used in the associated requirement, and are, therefore, consistent with the requirement.	The VSLs are based on a single violation and not cumulative violations.

VSLs for FAC-003-3 Requirement R6:

R#	Compliance with NERC's Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R6.	Meets NERC's VSL guidelines. There is an incremental aspect to the violation and the VSLs follow the guidelines for incremental violations.	The previous standard does not require actual inspections, while the new standard does. Accordingly, this should be treated as a new requirement, and therefore cannot lower the current level of compliance.	The proposed VSLs do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.	The proposed VSLs use the same terminology as used in the associated requirement, and are, therefore, consistent with the requirement.	The VSLs are based on a single violation and not cumulative violations.

VSLs for FAC-003-3 Requirement R7:

R#	Compliance with NERC's Revised VSL Guidelines	Guideline 1 Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance	Guideline 2 Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties Guideline 2a: The Single Violation Severity Level Assignment Category for "Binary" Requirements Is Not Consistent Guideline 2b: Violation Severity Level Assignments that Contain Ambiguous Language	Guideline 3 Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement	Guideline 4 Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations
R7.	Meets NERC's VSL guidelines. There is an incremental aspect to the violation and the VSLs follow the guidelines for incremental violations.	The VSLs in the previous standard were focused on completeness of the document, with the "Severe" VSL only reserved for entities that did not have or implement their plan. The proposed VSLs are graded based on the amount of the plan completed, giving a clear indication that partial completion is still a violation, establishing a level of compliance in excess of what was established previously.	The proposed VSLs do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations.	The proposed VSLs use the same terminology as used in the associated requirement, and are, therefore, consistent with the requirement.	The VSLs are based on a single violation and not cumulative violations.

NERC
NORTH AMERICAN ELECTRIC
RELIABILITY CORPORATION

Technical, Policy and Regulatory Issues Addressed by FAC-003 SDT

Q1: FERC generally requires that revised standards provide an adequate level of reliability in a manner that is at least as effective and efficient as the previously balloted and approved version of the standard. How does draft Standard FAC-003-2 meet this objective? Please provide specific explanation of how the portfolio of proposed requirements provides a defense-in-depth strategy for ensuring bulk power system reliability that is equally efficient and effective to or superior to the current Standard, FAC-003-1 — Transmission Vegetation Management Program. A specific explanation of how each requirement, when combined with the other requirements of the draft standard, contributes to a defense-in-depth strategy will be helpful.

A1: This Standard is more effective and efficient in ensuring an adequate level of reliability than FAC-003-1 because it has the following attributes.

- It removes the “fill-in-the-blank” ambiguity previously contained in FAC-003-1.
- It separates performance requirements (R1, R2, R4, R5, R6, and part of R7) from documentation requirements (R3 and the remainder of R7), and minimizes the burden of those documentation requirements.
- It has explicit and therefore clearer expectations to manage vegetation to: 1) prevent observable vegetation encroachments inside the Minimum Vegetation Clearance Distance (MVCD) and 2) prevent a confirmed Fault even in the absence of a Sustained Outage (R1, R2).
- It places more emphasis on those lines that pose the greatest risk to the reliability of the interconnected transmission system. This is accomplished by converting the previous FAC-00301 R1 into the new R1 and R2 and assigning the high VRF to the more important lines in R1.
- It requires the management of vegetation to prevent encroachments by specific types, which are indicative of the quality of that management. Those quality-related encroachment types also allow more specificity for determining the severity level of a violation.
- It establishes a clear, industry proven method for flash-over distance (clearance) that is not subject to external standards established for other purposes (through use of the Gallet Equations to establish the MCVD).
- It has an unambiguous expectation for Vegetation Inspection intervals.

- It separates inspections and communications of imminent threats into individual and clearer requirements that can be appropriately weighted by VRFs and VSLs (both of these items were previously addressed in sub-requirements of FAC-003-1 R1).
- It correctly moves reporting obligations from the requirements section (FAC-003-1 R3) to the Additional Compliance Information Section.
- It has additional supporting text in the Background, Rationale, and Guidelines and Technical Basis sections to aid the industry in using the Standard and understanding conductor dynamics and the interrelationship of vegetation growth, inspection frequencies, and vegetation control methods.
- It requires vegetation be managed with equal rigor over all lands regardless of the ownership of those lands.

This standard utilizes three types of requirements to provide layers of protection to prevent vegetation related outages that could lead to Cascading:

a) Performance-based — defines a particular reliability objective or outcome to be achieved. In its simplest form, a results-based requirement has four components: *who, under what conditions (if any), shall perform what action, to achieve what particular bulk power system performance result or outcome*?

b) Risk-based — preventive requirements to reduce the risks of failure to acceptable tolerance levels. A risk-based reliability requirement should be framed as: *who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome that reduces a stated risk to the reliability of the bulk power system*?

c) Competency-based — defines a minimum set of capabilities an entity needs to have to demonstrate it is able to perform its designated reliability functions. A competency-based reliability requirement should be framed as: *who, under what conditions (if any), shall have what capability, to achieve what particular result or outcome to perform an action to achieve a result or outcome or to reduce a risk to the reliability of the bulk power system*?

The defense-in-depth strategy for reliability standards development recognizes that each requirement in a NERC reliability standard has a role in preventing system failures, and that these roles are complementary and reinforcing. Reliability standards should not be viewed as a body of unrelated requirements, but rather should be viewed as part of a portfolio of requirements designed to achieve an overall defense-in-depth strategy and comport with the quality objectives of a reliability standard.

This NERC Vegetation Management Standard ("standard") uses a defense-in-depth approach to improve the reliability of the electric Transmission System by:

- Requiring that vegetation be managed to prevent vegetation encroachment inside the flash-over clearance (R1 and R2);

- Requiring documentation of the maintenance strategies, procedures, processes and specifications used to manage vegetation to prevent potential flash-over conditions including consideration of 1) conductor dynamics and 2) the interrelationships between vegetation growth rates, control methods and the inspection frequency (R3);
- Requiring timely notification to the appropriate control center of vegetation conditions that could cause a flash-over at any moment (R4);
- Requiring corrective actions to ensure that flash-over distances will not be violated due to work constrains such as legal injunctions (R5);
- Requiring inspections of vegetation conditions to be performed annually (R6); and
- Requiring that the annual work needed to prevent flash-over is completed (R7).

For this standard, the requirements have been developed as follows:

- Performance-based: Requirements 1 and 2
- Competency-based: Requirement 3
- Risk-based: Requirements 4, 5, 6 and 7

R3 serves as the first line of defense by ensuring that entities understand the problem they are trying to manage and have fully developed strategies and plans to manage the problem. R1, R2, and R7 serve as the second line of defense by requiring that entities carry out their plans and manage vegetation. R6, which requires inspections, may be either a part of the first line of defense (as input into the strategies and plans) or as a third line of defense (as a check of the first and second lines of defense). R4 serves as the final line of defense, as it addresses cases in which all the other lines of defense have failed.

Q2: The primary FERC directive in Order 693 is that the standard should specify minimum clearances to avoid Sustained Outages under all applicable conditions. Where in the Revised FAC-003-2 are references made to the 'all applicable conditions' issues? Is it understood that the revised standard is intended to protect facilities during emergency conditions?

A2: There are numerous references in the Standard to ensure that facilities are protected for all applicable conditions, including emergency conditions and conditions that would prevent the entity from carrying out its annual work plan. Those references are provided below along with a conclusion answer.

- See R1 and R2 which include the phrase "...operating within its **Rating and all Rated Electrical Operating Conditions.**"**(***Emphasis added)*
- Also see R3 which states:

"Each Transmission Owner shall have documented maintenance strategies or procedures or processes or specifications it uses to prevent the encroachment of vegetation into the MVCD of its applicable lines that include(s) the following:

- 3.1 Accounts for the movement of applicable line conductors under their **Rating and all Rated Electrical Operating Conditions;** "

- Also see R5 which states "When a Transmission Owner is **constrained** from performing vegetation work on applicable lines operating within its **Rating and all Rated Electrical Operating Conditions,** and the constraint may lead to a vegetation encroachment into the MVCD prior to the implementation of the next annual work plan, then the Transmission Owner **shall take corrective action** to ensure continued vegetation management to prevent encroachments**.**"

- Also see **Periodic Data Submittal:** The Transmission Owner will submit a quarterly report to its Regional Entity, or the Regional Entity's designee, identifying all Sustained Outages of applicable lines operated within their **Rating and all Rated Electrical Operating Conditions**

- Also see **Guideline and Technical Basis** discussion for Requirements R1, R2 and R3, which reinforces the concept that applicable line clearances are to be observed throughout a line's **Rating and under all Rated electrical Operating Conditions.**

The MVCD is the minimum clearance needed under all **Rating and Rated Electrical Operating Conditions**. The **Rated Electrical Operating Condition** is defined in the glossary as "the specified or reasonably anticipated conditions under which the electrical system or an individual electrical circuit is intend/designed to operate.' As such if there is an emergency rating for a line, it would be covered by this standard.

Q3: Cost and cost effectiveness management have been raised as issues by stakeholders, state regulators and some FERC commissioners. How will the Revised FAC-003-2 affect companies' abilities to perform ROW maintenance in the most cost effective manner that does not compromise reliability? Will the Revised FAC-003-2 facilitate or restrict companies from ensuring cost effective ROW maintenance compared to FAC-003-1?

A3: This is a Results Based Standard. It addresses core rules to ensure an adequate level of reliability and removes fill-in-the-blank requirements, as well as requirements for excessive documentation. It allows efficiency in Vegetation Inspections by allowing them to be combined with other line inspections, and it focuses more on "what" to do than "how" to do it. Altogether, this allows the applicable entity the latitude to choose the most cost effective methods to achieve compliance.

Q4: FAC-003-1 identifies two clearances in R1.2.1 and R1.2.2: a clearance to be achieved when performing vegetation management work (Clearance 1), and a minimum clearance to prevent flashover (Clearance 2). Revised FAC-003-2 only identifies the minimum clearance to prevent flashover (based on the Gallet equations), and does not identify a clearance to be achieved when performing vegetation management work. How does the new standard ensure that vegetation management work is performed that would provide a similar level of performance as is currently required? Does the removal of Clearance 1 provide public interest benefits or cost savings that should be considered by regulatory authorities and other stakeholders? i.e., there is a trade off from C1 & C2 to MVCD so how do we find comfort with this?

A4: The MVCD was chosen to replace Clearance 2 because it defines the distance that will prevent a flash-over based on tested and proven principles. The FAC-003-1 Clearance 2 was inappropriately based on worker safety considerations; FAC-003 is not a worker safety standard. The Revised FAC-003-2 is now based on science, and not on another ANSI safety standard which may change for reasons beyond the scope of this Standard.

Clearance 1 is an entity-specific fill-in-the blank requirement; as such, it was removed.

R3 requires that the entity's documented maintenance strategies must account for the movement of the conductors under their Rating(s) and all Rated Electrical Operating Conditions. This is superior to the previous Clearance 1, as it leaves the necessary latitude for the applicable entity to exercise its full easement rights to manage vegetation at the time the work is performed (through methods such as use of herbicides or mechanical means, which may result in the complete elimination of the vegetation). Such exercise of full easements rights is often more efficient than pruning to a Clearance 1. In some cases property owners have incorrectly interpreted Clearance 1 as a limitation on the applicable entities' vegetation management rights. Such incorrect interpretations can exacerbate the execution of best work practices. If an applicable entity was not exercising its full rights due to external pressures or due to the assumption that Clearance 1 was fully sufficient at the time of maintenance, that entity is now (under FAC-003-2) relieved of that assumption, which will lead more directly to the consideration of the most cost effective vegetation management method(s).

FAC-003-2 Requirement R5 states that when the applicable entity is constrained from performing vegetation work that may lead to an encroachment into the MVCD prior to the implementation of the next annual work plan that the entity shall take corrective *action to ensure continued vegetation management to prevent encroachments.* This ensures that the clearance obtained at the time work is performed will be fully adequate.

R6 requires an Annual Inspection which by its definition is "The systematic examination of vegetation conditions on a Right-of-Way and those vegetation conditions under the Transmission Owner's control that are likely to pose a hazard to the line(s) prior to the next planned maintenance or inspection". Therefore this inspection will identify annually those vegetation conditions that require attention regardless of how, when or to what clearance distance the work was last performed. As such the required inspection provides the mechanism to allow the applicable entity to address any work that must be performed even in advance of the next planned maintenance. Requirement R7 requires that the work plan be executed to ensure that no vegetation encroachments occur within the MVCD.

Therefore, separately and collectively R3, R5, R6 and R7 are superior to the previous requirement to establish a Clearance 1.

Q5: FAC-003-1 R1.3 required a transmission vegetation management program that mandated personnel involved in the establishment of the TVMP hold appropriate qualifications and training. How is this requirement addressed in the Revised FAC-003-2 or otherwise addressed in other NERC reliability standards?

A5: The FAC-003-1 requirement for "appropriate" qualifications and training was ambiguous and therefore removed. Applicable entities (as well as contractors that are retained by applicable entities to perform vegetation management) are subject to numerous state and federal environmental and worker safety regulations related to right of way work. Imposing additional NERC requirements for "appropriate" qualifications and training on personnel and contractors that may perform right of way maintenance is not helpful to reliability, and overly burdensome. To the extent such personnel qualifications are needed, they would be better addressed in the PER standards.

Q6: In one respect, revised FAC-003-2 appears to reduce applicability of the Standard. Section 4.2.4 indicates the Standard only applies to those transmission lines "outside the fenced area of the switchyard, station or substation or any portion of the span the transmission line that is crossing the substation fence." These areas are currently within the scope of FAC-003-1, and removing them from the Standard would appear to create a reliability gap. Is this correct? How is this reliability gap addressed?

A6: Transmission line right of way maintenance programs do not normally extend inside those fenced areas, and some of those areas require special access permissions for entry. There are no reported or known vegetation related outages that have occurred in those areas. The fenced areas under lines are typically either paved or maintained as grassy areas. The lines within fenced areas are usually very short in length as compared to the miles of line outside the fenced areas. The lands within the fenced area are typically held fee-simple, precluding the need for special easements to maintain vegetation. That land is typically maintained such that buses, switchgear, ground-mat grids, touch and step potentials mitigation, and switchyard maintenance are of highest priority and therefore tree growth is not allowed. The maintenance of those fenced areas is often performed by other specialized contractors that do not maintain transmission line Right-of-Way. The ownership of the line often changes at the switchyard fence. For all those reasons it is neither necessary nor practical to have this Standard apply inside those areas based on the premise that such a limitation would lower the bar or create a reliability gap.

Q7: Revised FAC-003-2 has a minimum inspection cycle requirement. Order 693 did not ask for a minimum inspection cycle. What is the technical need for this requirement? Does the addition of this requirement provide reliability benefits that offset changes to other requirements?

A7: In 693 the Commission noted its concern about minimizing outages and expressed support for a realistic inspection cycle. The Commission further directed the ERO to develop compliance audit procedures, using relevant industry experts, which would identify appropriate inspection cycles based on local factors. However, the Commission also expressed its support for a realistic inspection cycle and expressed concern when entities performed inspections on cycles of less than every 3 years or even "as needed". The Commission expressed concern with leaving complete discretion to the transmission owners in determining inspection cycles which could limit the effectiveness of the Reliability Standard.

The Team received industry feedback regarding their desire to perform vegetation surveys in conjunction with other line inspections, which are typically annual surveys. The Team then chose to request industry to comment on the adequacy of annual Vegetation Inspections with the condition that the Vegetation Inspection could be performed in conjunction with other inspections. Industry comments were highly supportive of this approach.

The annual inspection cycle requirement is viewed by the Team as realistic, clear, unambiguous, easily performed, and not overly burdensome, since inspections can be performed aerially, on the ground, and in conjunction with other inspections. Regional Entities can develop Regional Standards or supplements to require increased frequencies in their regions if they determine that their regional vegetation growth rates justify such an increase.

Development of compliance audit procedures that account for local factors was considered and vetted by the Team. The Team concluded that the substantial variability in local factors would place undue burden on the ERO to develop continent-wide compliance audit procedures that would be clear and unambiguous. Furthermore the Team felt that waiting on the development of audit procedures and the implementation of those audit procedures could place Applicable Transmission Lines at greater risk than the proposed annual inspection cycle in FAC-003-2 which will provide a timelier "find-and-fix" solution to emerging problems with existing corrective and preventative maintenance processes. The Team suggests that the Annual Inspection requirement will ensure that applicable entities "find those conditions...likely to pose a hazard to the line prior to the next planned maintenance or inspection." This alternative approach accomplishes the reliability objective targeted by the Commission of identifying appropriate inspection cycles based on local factors.

Q8: Revised FAC-003-2 requires in R7 that the Transmission Owner "complete 100% of its annual vegetation work plan of applicable lines." What is required to be included in the plan? How does this differ from what is required under FAC-003-1 R1 and R2?

A8: The annual work plan will need to include the planned vegetation maintenance work necessary to ensure no vegetation encroachments occur within the MVCD. Regarding how this approach differs from FAC-003-1 Requirement 1 (which is about the documentation of practices and is silent on annual work planning), FAC-003-2 addresses similar documentation in Requirement R3. As far as how this approach differs from R2 in FAC-003-1, this FAC-003-2 Requirement 7 is not about details of creation of a plan with prescriptive descriptions of "how to" contents; it focuses instead on the necessary end results: specifically, work execution necessary to ensure no vegetation encroachments occur within the MVCD.

R7 continues to allow adjustments or modifications to the work plan and gives various examples to aid users of the Standard.

Q9: It appears that the SDT based the VSLs for R1 and R2 on the reliability consequences of an encroachment, rather than whether or not an encroachment occurred. NERC standards address consequences as an aspect of risk through the Violation Risk Factor, rather than the VSL. Why is the team choosing to attempt to address reliability consequences in both the VRF and the VSL?

A9: The action verb in R1 and R2 is to "manage." The Subject Matter Experts on the team, with industry feedback, recognized that the types of encroachments provide a valuable method to determine the effectiveness of a vegetation program's ability to manage vegetation effectively.

The most egregious vegetation management failure, and the most predictable, is to allow vegetation that is directly under the line to continue growing until it contacts the conductor. An entity that is unable to meet this obligation either does not have a vegetation program of significant value or doers but is not implementing it faithfully.

The next most obvious vegetation management failure mode would be vegetation that has grown adjacent to the line sufficiently close such that the line and vegetation could be blown together. In this case, the entity is likely implementing a relatively effective program, but was unable to identify this particular risk.

Less obvious and less predictable vegetation management failures are caused by falling trees that are tall enough to lodge into the line and cause a Sustained Outage. This is due to the challenges in predicting the various causes for and the numerous ways that trees fail (decay, erosion, defects, excavation, wind forces) and fall and the likely direction (up to 360 degrees available) that the tree will fall. An entity can have a very effective program, but fail to mitigate a risk of such occurrence.

Along with the difficulties just stated, it is deemed an even lesser vegetation maintenance failure to not find and remove every single tree before it has grown just enough to fall near the line and cause a brief Fault when it falls; or growth that reaches within the MVCD, but has not caused a fault. Again, an entity can have a very effective program, but fail to mitigate a risk of such occurrence.

Accordingly, the Team believes that the type and result of encroachment is indicative of an entity's overall performance and ability to "manage" vegetation.

Q10: Revised FAC-003-2 under R1 assigns a high VRF to those lines that are part of an IROL and/or are a WECC transfer path. Encroachment violations for all other lines are assigned a Medium VRF under R2. In the previous version of the standard, all lines were subject to the same requirements (i.e., the clearances were specified for all lines in R1.2, and clearances for all lines were expected to be maintained under R2). Splitting these elements into two different requirements, with two different VRFs, may create the perception that FAC-003-2 is "lowering the bar" by either reducing performance requirements or reducing potential penalties. How does the standard ensure that this "lowering" of the bar will not occur? Alternately, if this "lowering" is intentional, why is this reduction in expected performance or penalties reasonable and in the public interest?

A10: The reliability risk incurred by the outage of a transmission line within the interconnected transmission network is higher for some lines than for others. NERC's VRF definitions indicate that a High Violation Risk Factor is only appropriate for:

> A requirement that, if violated, could directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to bulk electric system instability, separation, or a cascading sequence of failures, or could place the bulk electric system at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

In FERC's May 18, 2007 Order on Violation Risk Factors, FERC identified Guideline 5, which states that where a single requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment must not be "watered down" to reflect the lower risk level associated with the less important objective. By not drawing a distinction between those lines with the ability to cause instability, separation, and cascading and those that do not, the previous standard co-mingled these objectives, and appropriately had a VRF of High assigned. However, the Team has chosen to eliminate that co-mingling, has split the requirement, and has accordingly assigned the appropriate VRFs to the separate requirements.

From a practical perspective, FAC-003-2 continues to find applicable entities in violation for all the types of encroachments that they were subject to in FAC-003-1. FAC-003-2 requires all of the sub-200 kV IROL and WECC Major Transfer Path lines be included in the applicability, which provide more specificity than what was required in the previous version of the standard. There is now a clear inclusion of violations for those Faults confirmed-after-the-fact, as well as for confirmed MVCD encroachments that are found and removed prior to a Fault. Given the VRF definitions, FERC's guidance, and the above additional considerations, the Team believes FAC-003-2 continues to require an appropriate level of performance.

Standards Announcement

Project 2007-07 Vegetation Management
Now Open: Recirculation Ballot October 4-13, 2011

Now available

Project 2007-07 – Vegetation Management
A recirculation ballot window for FAC-003-2 – Transmission Vegetation Management and its associated implementation plan is open through **8 p.m. on Thursday, October 13, 2011**.

Instructions
Members of the ballot pool associated with this project may log in and submit their votes.

In the recirculation ballot, votes are counted by exception. Only members of the ballot pool may cast a ballot; all ballot pool members may change their prior votes. A ballot pool member who failed to cast a ballot during the last ballot window may cast a ballot in the recirculation ballot window. If a ballot pool member does not participate in the recirculation ballot, that member's last vote cast in the successive ballot that ended on February 28, 2011 will be carried over and used to determine if there are sufficient affirmative votes for this standard to pass.

Background
FAC-003-1 is being revised to address several fill-in-the-blank requirements, directives from Order 693, and issues raised by stakeholders. A successive ballot closed in February 2011 and achieved a quorum of 79.28% and an approval of 79.34%. The drafting team has posted its consideration of comments from the successive ballot and has been working to address a set of questions posed by Standards Committee chairman Allen Mosher, aimed at documenting the technical justification for the proposed requirements and verifying that the team has addressed the associated directives from Order 693

Documents for this project, including clean and redline to the last posted versions of the standard, implementation plan, and technical reference and the drafting team's responses to the technical, policy, and regulatory questions posed by Chairman Mosher have been posted on the project webpage.

Next Steps
Voting results will be posted and announced after the ballot window closes. If the recirculation ballot achieves a quorum and ballot pool approval, the standard will be presented to the NERC Board of Trustees for adoption.

Standards Process
The Standard Processes Manual contains all the procedures governing the standards development process.

The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

For more information or assistance, please contact Monica Benson, Standards Process Administrator, at monica.benson@nerc.net or at 404-446-2560.

Project 2007-07 Transmission Vegetation Management Recirculation Ballot Results

Now available

Ballot Results for FAC-003-2 Transmission Vegetation Management
A recirculation ballot on revisions to FAC-003-2 – Transmission Vegetation Management concluded on Thursday, October 13, 2011. The standard was approved by the associated ballot pool.

Voting statistics for the standard are listed in the table below, and the Ballot Results Web page provides a link to the detailed results.

Standard	Ballot Results
FAC-003-2 – Transmission Vegetation Management	Quorum: 87.17% Approval: 86.25 %

Next Steps

The standard will be presented to the NERC Board of Trustees for adoption.

Background

FAC-003-1 is being revised to address several fill-in-the-blank requirements, directives from Order 693, and issues raised by stakeholders. A successive ballot closed in February 2011 and achieved a quorum of 79.28% and an approval of 79.34%. The drafting team has posted its consideration of comments from the successive ballot and has posted answers to a set of questions posed by Standards Committee chairman Allen Mosher.

Documents for this project, including clean and redline to the last posted versions of the standard, implementation plan, and technical reference and the drafting team's responses to the technical, policy, and regulatory questions posed by Chairman Mosher have been posted on the project webpage.

Exhibit H

Standard Drafting Team Roster for NERC Standards Development Project 2007-07 Vegetation Management

VMSDT Bios

Ron Adams is General Manager, Right of Way Management at Duke Energy in Charlotte, NC. His current responsibilities include operational management of both Transmission and Distribution Rights of Way, which consist of over 100,000 miles of overhead T&D facilities. He has held many positions in his 26 year career, such as Substation Engineer, Industrial Marketing Specialist, Power Quality Engineer, Technical Services Manager, Manager of Design Engineering, Manager Engineering, Transmission Construction Manager, Transmission Operations Manager, and previously Director Vegetation Management Carolinas.

Mr. Adams is a Senior Member of IEEE, a former EPRI Innovator Award recipient for his Power Quality work, and a former Chair of the Canadian Electricity Association Work Group for Substation Life Cycle Management. He holds a Bachelor of Science degree in Electrical Engineering from Clemson University, and is a registered professional engineer in the states of North and South Carolina.

Tom Anderson is presently Lead Forester of Lincoln Electric System's Vegetation Management Team. Tom has worked at Lincoln Electric System (LES) since 1974. He has been involved with or supervised the installation and maintenance of LES's overhead and underground facilities at all distribution and transmission line voltages, and coordinated and completed LES's first TVMP and annual work plans for compliance with FAC-003-1. Mr. Anderson has supervised Locating and Troubleshooting Technicians and Thermography Technicians, and has also served as Trainer of Apprentice Line Technicians, 1st Class Line Technicians, and T&D Dispatchers.

Mr. Anderson has served as President of the International Brotherhood of Electrical Workers (IBEW) Local 1536 for 12 years. He has competed in the IBEW International Lineman Rodeo, and as a part of the LES team, has been awarded First Place for Underground Splicing. He has also been judge of the "Hurt Man Rescue" for several years in the American Public Power Association Line Technician Rodeo.

Mr. Anderson has served on the Board of Advisors for the Northeast Community College in Norfolk, Nebraska. During this period, Tom attempted to develop an Associate Degree program for Line Clearance Arborists, recognizing that the industry needs better trained and qualified personnel n this area.

Mr. Anderson has Bachelor of Arts degrees in Human Resources and in Industrial Management from Doane College. He also has an Associate of Arts degree in Computer Programming from Southeast Community College System, and is a NERC Certified Operator for LES transmission system.

Paul S. Beaulieu is a Professional Engineer with Finley Engineering Company. He has been involved in the electric utility industry for the past 28 years. Prior to joining Finley, he worked with Kansas City Power & Light (Great Plains Energy), a Midwest investor owned utility.

Mr. Beaulieu's has significant experience with design and construction of transmission, substation, and distribution projects ranging from 12 kV to 345kV, to managing transmission, (69kV and above) construction and maintenance resources over 47 counties across two states. His broad range of design experience for 34kV through 345kV transmission system projects includes: route selection, right of way descriptions, implementation and usage of transmission line design software, NESC code compliance determination, transmission line strength and loading profiles, structure and foundation design, bill of material and construction contracts and specifications. Additionally, he has provided the mechanical/civil design for 34 kV through 345kV substations including plans for grading and drainage, roadways, manholes and duct banks, foundations, apparatus layout, structure specifications, yard and interior lighting, lightning protection, station grounding, fencing design, control house development including foundation design, electrical layout, HVAC, plumbing, and house material specifications.

Mr. Beaulieu has also provided leadership to an efficiently run construction and maintenance organization. He had oversight responsibility for C&M activities, GIS integration, and Transmission Vegetation Management for 3,400 miles of transmission lines. Ultimately, he was responsible for new transmission construction and maintenance projects including ongoing asset management programs of the systems with an estimated plant value of $700 Million, assuring proper Project Scope and Cost Development and Project Management and Closeout.

Mr. Beaulieu earned his Master of Science in Mechanical and Aerospace Engineering from the University of Missouri Columbia (Emphasis Material Science, Fatigue and Fracture Mechanics) and his Bachelor of Science in Mechanical Engineering from the University of Missouri Kansas City. Additionally he earned an Associates of Science in Drafting Technology from Longview Community College.

Stephen Cieslewicz is President and Chief Consultant at CN Utility Consulting Inc. With more than 30 years of industry experience, Mr. Cieslewicz has established himself as a leading expert in utility vegetation management (UVM). This includes designing and running one of the nation's largest UVM programs (PG&E), managing large scale UVM related research projects, performing the industry's largest UVM benchmarking, and researching laws and regulations applicable to UVM. In working with utilities, regulators and service providers around the world, Mr. Cieslewicz has been directly involved in the bulk of tree and power line issues of note. He was a principal UVM investigator for the Joint U.S./Canada Power Systems Outage Task Force, a principal author of all UVM related reports following the August 14, 2003 blackout, and has been directly involved with the crafting or interpretation of UVM standards, best practices, and laws and regulations throughout the US and abroad.

An ISA Certified Arborist and Utility Specialist, Mr. Cieslewicz has testified as an expert at many significant legal, regulatory and legislative hearings. He is a past president of the Utility Arborist Association (UAA) and a recipient of numerous awards, including the UAA Utility Arborist Award, UAA President's Award, and certificates of appreciation from the U.S. and Canadian governments. Mr. Cieslewicz is also a well known speaker and author on UVM issues, and was recently selected by Green Media (publisher of Arbor Age, Landscape and Irrigation, Outdoor Power Equipment and Sports Turf) as one of eight most influential people in the green industry.

Orville Cocking is currently the Section Manager of the Transmission Line Maintenance Group at Consolidated Edison of New York, overseeing Transmission Line Maintenance and the Transmission Vegetation Management Program (TVMP). He has spent the last six years working in positions of increasing responsibilities in Central Engineering and Transmission Operations. He spent the 9 years prior to joining Consolidated Edison performing structural analysis of transmission and other unique structures as an engineering consultant.

Mr. Cocking has a Bachelor of Science degree in Civil Engineering, and is a licensed professional engineer in the states of New York, Delaware, and New Jersey.

Richard Dearman is a Senior Advisor on NERC Compliance at the Tennessee Valley Authority. Mr. Dearman has held numerous positions in engineering, maintenance and management within transmission and distribution since 1971. He has supported FEMA with investigations of disaster recovery claims on three occasions in Minnesota, Illinois, and Tennessee. In 1997, Mr. Dearman led a team within TVA that resulted in the reorganization and centralization of the TVA right-of-way maintenance program. He was assigned the management responsibility for the program at that that time, and held that position until April 2010. The interruption rate due to vegetation related outages declined to record low levels under Mr. Dearman's management. His 17 years management experience in transmission line right of way maintenance culminated in responsibility for TVA's full program oversight for over 17,000 miles of transmission lines with annual expenditures in excess of $19M in FY 2009.

Mr. Dearman served on the NERC Outage Investigation Team as a transmission industry expert/representative to perform field investigations of tree related interruptions that were associated with the August 14, 2003 blackout. He was the first Chairman of the SERC Vegetation Management Subcommittee inn 2004, and held that position for 5 years.

Mr. Dearman has participated in two industry peer reviews of transmission system vegetation maintenance programs sponsored by the North American Transmission Forum, and has led an EPRI project to reduce Human Errors in Switching Safety and Reliability. He has also led numerous safety and human performance improvement initiatives, projects, and investigations at TVA. He is well known within TVA for his investigative abilities to determine causes for transmission system interruptions, including (but not limited to) suspected and actual vegetation related outages.

Mr. Dearman holds a Bachelor of Science degree in Electrical Engineering, as well as an Master in Business Administration degree, and is a Registered Professional Engineer

Randall F. Gann

Randall Gann is the Manager of Power Delivery Contract Services for Alabama Power Company. He has held this position for the past 10 years. Part of Mr. Gann's responsibilities while holding this position has included vegetation management for 70,000 miles of distribution voltage lines and over 10,000 miles of transmission voltage lines. Prior to this, Mr. Gann held positions as Manager of Transmission Line Design and Transmission Line Construction for 8 years. He has worked the remainder of his career in various supervisory and engineering positions for Alabama Power Company in distribution and transmission operations and maintenance; and also Nuclear Generation Construction. Mr. Gann has over 40 years experience with the Southern Company, and is a member of the Vegetation Management Sub-Committee reporting to the SERC Operating Committee.

Mr. Gann holds a Bachelor of Science degree from Auburn University in Electrical Engineering and is a registered Professional Engineer in the State of Alabama.

Jeff Hackman is Manager – Transmission Operations for Ameren. In this role, he has responsibility for Transmission and Balancing Authority Operations, EMS support for Operations, Transmission Construction and Maintenance, Transmission Vegetation Management, Transmission Design, and Transmission Project Management. Mr. Hackman has been with Ameren or its predecessor companies since 1980. He has held many positions with increasing responsibility in transmission planning, design, and operations. Mr. Hackman has also held supervisory or management positions in distribution line design and distribution operations, including overhead and underground maintenance and construction activities. He has also performed studies to support power plant operation, and was responsible for engineering and design for distribution gas service in one of Ameren's divisions.

Mr. Hackman has conducted research and published/presented papers on insulation degradation and insulator design to prevent flashover in contaminated environments. He was the Missouri Society of Professional Engineers – St Louis Chapter "Young Engineer of the Year," and is currently a Senior Member of the IEEE. Hackman received earned his Bachelor of Science degree in Electrical Engineering from the University of Missouri – Rolla (now Missouri University of Science & Technology), and a Master of Arts degree in Business Administration from Webster University. He is a registered professional engineer in Missouri.

David Morrell is a Utility Environmental Analyst with the New York State Department of Public Service (the Department). He holds an Associate of Applied Science degree in Land Management and a Bachelor of Science in Forestry degree, with a specialization in Forest Resource Management.

Mr. Morrell has been with the NYS Department of Public Service for 21 years. Much of this time has been spent overseeing NY's Investor Owned Utilities ROW vegetation management programs pursuant to the Departments regulations. Mr. Morrell served on the first NERC vegetation standard drafting team, has written a number of the Departments recent regulations pertaining to ROW management, sits on ROW management training committees, and has authored a number of peer reviewed papers regarding issues in ROW management. Mr. Morell worked in the utility industry in the areas of T&D vegetation management and inspection for 5 years prior to joining the Department.

Mr. Morrell is a Certified ROW Pesticide Applicator and has received Departmental awards and recognitions for outstanding performance.

John Pinney is currently the Lead Transmission Forester for Progress Energy Florida, and been involved in utility vegetation management for the past 16 years. He is in charge of Progress Energy Florida's transmission vegetation management program and responsible the associated compliance program and documentation. Additionally, Mr. Pinney has worked for two utilities in the past in supervisory and management roles related to vegetation management for transmission and distribution.

A certified arborist, Mr. Pinney also holds membership in the International Society of Arboriculture and the Utility Arborists Association, and holds a pesticide applicators license in the state of Florida.

John Schechter is Manager of American Electric Power's Protection & Control Engineering office in Columbus, Ohio. Mr. Schechter has been with American Electric Power (AEP) or its operating companies since 1980. He has held many positions with increasing responsibility over the past thirty years, in areas of substation operation, construction, maintenance, and engineering. Mr. Schechter has also held supervisory or managerial positions in distribution line design, distribution service dispatching, and overhead and underground distribution maintenance and construction. For five years, he was responsible for the asset condition and forestry program for AEP's 35,000-mile transmission system, including over 8,000 miles of line operating above 200kV, and was accountable to state regulatory commission staff for the performance and compliance of AEP's transmission line assets.

Mr. Schechter served on the ECAR VM task force and has conducted presentations to promote vegetation standards at compliance workshops conducted by ERCOT, Southwest Power Pool and ReliabilityFirst. Mr. Schechter received his Bachelor of Science degree in electrical engineering from the University of Cincinnati, his Master of Science degree in electric power systems engineering from The Ohio State University, and his Master of Business Administration degree from the University of Notre Dame. He is a registered professional engineer in the states of Indiana and Ohio.

John Tamsberg is currently Manager of Transmission Vegetation Management for Florida Power and Light (FPL), where he manages the vegetation on 6,700 miles of Transmission in Florida and at 950 miles for NextEra Energy at sites across the US and Canada. Prior to his 25 years at FPL, Mr. Tamsberg spent 15 years working in state government, managing timber for the South Carolina Commission of Forestry and working for the Florida Division of Forestry in forest management, urban forestry and fire suppression.

With over 40 year's total experience in forestry and vegetation management, Mr. Tamsberg has served on a number of Urban Forestry and Landscape Advisory Boards. He served the International Society of Arboriculture on the Certification Test Committee, is past president of the Florida Urban Forestry Council, and is currently a member of the Arborist Certification Ethics Committee.

Mr. Tamsberg has a Bachelor of Science degree in Forestry from Clemson University, and is a Certified Arborist.

Stephen Tankersley is Operations Manager of Pacific Gas and Electric Company's (PG&E) Vegetation Management Department. He has been with PG&E for 34 years, holding a variety of positions of increasing responsibility in Engineering & Construction, Project Management, Financial and Business Systems Process Engineering, and most recently Vegetation Management, where he has served in his current position since 1999.

Mr. Tankersley has significant previous expertise in formal project/program management; process engineering; utility construction productivity; and computer systems design, development and implementation; and has used this expertise building PG&E's UVM program.

PG&E has one of the largest UVM programs in the nation, covering 70,000 sq. miles with 114,000 miles of overhead distribution and 20,000 miles of transmission, and operates under the strictest UVM regulatory environment in the country. Mr. Tankersley is a frequent speaker on topics related to UVM business operations, operating UVM programs in California's regulatory environment, and building effective UVM programs, and frequently contributes to UVM industry publications. Most recently, the Utility Arborist Association published an article by Mr. Tankerlsey discussing "Best Management Practices for Project Management Applied to Utility Vegetation Management."

Ron Turley is currently a Special Programs Manager for the Western Area Power Administration. He has 30 years experience in the electrical utility industry with the U.S. Department of Energy. Turley has over 28 years of management experience overseeing various combinations of engineering, construction and maintenance functions for high voltage transmission and substation facilities interconnecting Federal hydroelectric generation facilities such as Hoover, Glen Canyon and Flaming Gorge Dams in the Colorado River drainage basin. One of his current responsibilities involves the development and management of a vegetation management program for Western's Rocky Mountain Region which involves over 5000 miles of high voltage transmission across seven western states.

Mr. Turley was appointed by former Colorado Governor Ritter and retained by current Governor Hickenlooper on the Colorado Governor's Forest Health Advisory Council. He has frequently served as a technical industry expert to the Department of the Agriculture, U.S. Forest Service and Department of the Interior, Bureau of Land Management. Turley also serves on a number of other public organizations involved with the management of declining forest health and wildland fire issues affecting forested landscapes across the western United States and Canada. Mr. Turley holds a Bachelor of Science degree in Biological Science from the State University of New York at Binghamton and a Master of Science degree in Civil Engineering from Colorado State University.

Gary White is a Vegetation Management Program Manager – Forester for Oncor Electric Delivery LLC. Oncor's T&D system consists of approximately 113,000 miles of distribution facilities and 15,000 miles of transmission. For the last six years, Mr. White has been in the Asset Management – Maintenance Strategy and Planning workgroup responsible for VM strategy and planning. Prior to this position, Mr. White held various positions within Oncor's Vegetation Management workgroup for 24 years. He worked for a national line clearance company for 4 years prior to joining Oncor.

Mr. White holds a Bachelor of Science-Forestry degree from Stephen F. Austin State University. He holds a Texas Department of Agriculture Non Commercial Applicators license. He is a member of the International Society of Arboriculture (ISA) and a Certified Arborist and Utility Specialist through the ISA. He is a member of the Utility Arborists Association and a charter member and past president of the International Society of Arboriculture -Texas Chapter.

Phil Whitmer is the Transmission Compliance Manager for Georgia Power Company. He joined Georgia Power in 1980. During his career, he served ten years in Distribution Engineering, seven years in Industrial Marketing, six years in Transmission Line and Substation Maintenance, eight years in Transmission System Operations, and one year in Compliance.

Mr. Whitmer holds a Bachelor of Science degree in Electrical Engineering from the Georgia Institute of Technology and a Master in Business Administration degree from Augusta State University. He also obtained his Certified Energy Manager certification in 1996.

Ken Wright is Lead Superintendent, Transmission Maintenance at Tucson Electric Power Company (TEP) in Tucson, AZ. His current responsibilities include Transmission Line Maintenance in Arizona and New Mexico and Distribution Line Vegetation Management in Arizona. He has held several positions in his 35 year career at TEP, including Substation Civil Engineer, Gas Engineer, Transmission Engineer, Superintendent-Transmission Line C&M, Civil & Transmission Engineering Manager and T & D Construction & Maintenance Manager.

Taking an early retirement in 1996, Mr. Wright opened and managed the Tucson Office for Engineering Consultants, Inc. and returned to TEP in 2002 to head up the Transmission Line Design, Maintenance and Construction Department. Mr. Wright is a member of the American Society of Civil Engineers. He is a Registered Civil Engineer and Registered Land Surveyor in Arizona, sits on two Boards of Director for non-profit organizations, and holds a Bachelor of Science degree in Civil Engineering from The University of Arizona.

Disclaimer

This supporting document is supplemental to the reliability standard FAC-003-2 — Transmission Vegetation Management and does not contain mandatory requirements subject to compliance review. Throughout this document, for ready reference, there are “copies” in italic font of the wording in the Standard. Any “copy” of any part of the Standard in this document should be cross checked to the Standard and if any difference exists, then the Standard’s exact wording should be considered the intended wording for this document.

Introduction

This document is intended to provide supplemental information and guidance for complying with the requirements of Reliability Standard FAC-003-2.

The purpose of the Standard is to improve the reliability of the electric transmission system by preventing those vegetation related outages that could lead to Cascading.

Compliance with the Standard is mandatory and enforceable.

Special Note: The Application of the Results-Based Approach to FAC-003-2

In its three-year assessment as the ERO, NERC acknowledged stakeholder comments and committed to:

i) addressing quality issues to ensure each reliability standard has a clear statement of purpose, and has outcome-focused requirements that are clear and measurable; and
ii) eliminating requirements that do not have an impact on bulk power system reliability.

In 2010, the Standards Committee approved a recommendation to use Project 2007-07 Vegetation Management as a first proof of concept for developing results-based standards.

This standard is not intended to address outages such as those due to vegetation fall-ins or blow-ins from outside the Right-of-Way, vandalism, human activities or acts of nature. Operating experience indicates that trees that have grown out of specification have contributed to Cascading, especially under heavy electrical loading conditions.

This standard utilizes three types of requirements to provide layers of protection to prevent vegetation related outages that could lead to Cascading:

a) Performance-based — defines a particular reliability objective or outcome to be achieved. In its simplest form, a results-based requirement has four components: *who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome*?
b) Risk-based — preventive requirements to reduce the risks of failure to acceptable tolerance levels. A risk-based reliability requirement should be framed as: who, under what conditions (if any), shall perform what action, to achieve what particular result or outcome *<u>that reduces a stated risk to the reliability of the bulk power system</u>*?
c) Competency-based — defines a minimum set of capabilities an entity needs to have to demonstrate it is able to perform its designated reliability functions. A competency-based reliability requirement should be framed as: *who, under what conditions (if any), shall have what capability, to achieve what particular result or outcome to perform an action to achieve a result or outcome or to reduce a risk to the reliability <u>of the bulk power system</u>*?

The defense-in-depth strategy for reliability standards development recognizes that each requirement in a NERC reliability standard has a role in preventing system failures, and that these roles are complementary and reinforcing. Reliability standards should not be viewed as a body of unrelated requirements, but rather should be viewed as part of a portfolio of requirements designed to achieve an overall defense-in-depth strategy and comport with the quality objectives of a reliability standard.

This NERC Vegetation Management Standard ("standard") uses a defense-in-depth approach to improve the reliability of the electric Transmission System by:

- Requiring that vegetation be managed to prevent vegetation encroachment inside the flash-over clearance (R1 and R2);
- Requiring documentation of the maintenance strategies, procedures, processes and specifications used to manage vegetation to prevent potential flash-over conditions including consideration of 1) conductor dynamics and 2) the interrelationships between vegetation growth rates, control methods and the inspection frequency (R3);
- Requiring timely notification to the appropriate control center of vegetation conditions that could cause a flash-over at any moment (R4);
- Requiring corrective actions to ensure that flash-over distances will not be violated due to work constrains such as legal injunctions (R5);
- Requiring inspections of vegetation conditions to be performed annually (R6); and
- Requiring that the annual work needed to prevent flash-over is completed (R7).

For this standard, the requirements have been developed as follows:

- Performance-based: Requirements 1 and 2
- Competency-based: Requirement 3
- Risk-based: Requirements 4, 5, 6 and 7

R3 serves as the first line of defense by ensuring that entities understand the problem they are trying to manage and have fully developed strategies and plans to manage the problem. R1, R2, and R7 serve as the second line of defense by requiring that entities carry out their plans and manage vegetation. R6, which requires inspections, may be either a part of the first line of defense (as input into the strategies and plans) or as a third line of defense (as a check of the first and second lines of defense). R4 serves as the final line of defense, as it addresses cases in which all the other lines of defense have failed.

Major outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations. Adherence to the standard requirements for applicable lines on any kind of land or easement, whether they are Federal Lands, state or provincial lands, public or private lands, franchises, easements or lands owned in fee, will reduce and manage this risk. For the purpose of the standard the term "public lands" includes municipal lands, village lands, city lands, and a host of other governmental entities.

The standard addresses vegetation management along applicable overhead lines and does not apply to underground lines, submarine lines or to line sections inside an electric station boundary.

The standard focuses on transmission lines to prevent those vegetation related outages that could lead to Cascading. It is not intended to prevent customer outages due to tree contact with lower voltage distribution system lines. For example, localized customer service might be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. However, this standard is not written to address such isolated situations which have little impact on the overall electric transmission system.
Since vegetation growth is constant and always present, unmanaged vegetation poses an increased outage risk, especially when numerous transmission lines are operating at or near their Rating. This can present a significant risk of consecutive line failures when lines are experiencing large sags thereby leading to Cascading. Once the first line fails the shift of the current to the other lines and/or the increasing system loads will lead to the second and subsequent line failures as contact to the vegetation under those lines occurs. Conversely, most other outage causes (such as trees falling into lines, lightning, animals, motor vehicles, etc.) are not an interrelated function of the shift of currents or the increasing system loading. These events are not any more likely to occur during heavy system loads than any other time. There is no cause-effect relationship which creates the probability of simultaneous occurrence of other such events. Therefore these types of events are highly unlikely to cause large-scale grid failures. Thus, this standard places the highest priority on the management of vegetation to prevent vegetation grow-ins.

The drafting team reviewed and edited version 1 of FAC-003-1 to remove prescriptive and administrative language in order to distill the technical requirements down to their essential reliability content. Explanatory text is offered within two special sections, <u>Background</u> and <u>Guideline and Technical Basis</u>, to aid in understanding the standard and its requirements. <u>Rationale</u> text boxes and other text boxes are also inserted throughout the standard to aid understanding the sections. The <u>Effective Dates</u> section covers five special cases for lines that undergo specific transitions as or after the standard has reached the general effective date.

Preface

The NERC Vegetation Management Standard Drafting Team (VM SDT) acknowledges those across the industry who contributed to the development of this Standard and companion Technical Reference document. This Technical Reference document is intended to provide supplemental explanatory background and guidance related to requirements contained in the Standard but does not in itself contain requirements subject to compliance review.

The Standard requires the Transmission Owner to have documentation of the maintenance strategies or procedures or processes or specifications it uses to be successful in managing vegetation. This allows the Transmission Owner to exercise substantial flexibility in designing its overall program to meet its specific needs provided that the Transmission Owner also meets the purpose of the Standard.

While there are many approaches to vegetation management, the VMSDT supports industry best practices contained in ANSI A300 (Part 7) – Integrated Vegetation Management (IVM) practices on Utility Rights-of-way, as well as the companion publication Best Management Practices – Integrated Vegetation Management, as an effective strategy to maintain compliance with this Standard. ANSI A300 (Part 7), approved by industry consensus in 2006, contains many elements needed for an effective vegetation management. Those elements are similar to the requirements in this Standard. One key element is the "wire zone – border zone" concept. Supported by over 50 years of continuous research, wire zone – border zone is a proven method to manage vegetation on transmission rights-of-ways and is an industry accepted best practice to help ensure electric system reliability.

The VM SDT believes that Transmission Owners who adopt and effectively implement IVM principles, particularly the "wire zone – border zone" concept, are far less likely to experience a vegetation caused outage than those who do not.

Effective Dates & Special States of Transition

The first sentence of the Effective Dates section is standard language used in most NERC standards to cover the general effective date and is sufficient to cover the vast majority of situations. Five special cases are needed to cover effective dates for individual lines which undergo transitions after the general effective date. These special cases cover the effective dates for those lines which are initially becoming subject to the standard, those lines which are changing their applicability within the standard, and those lines which are changing in a manner that removes their applicability to the standard. The text for each of these five cases is copied from the standard and is shown below in italic font. An explanation of the need for each special exception follows each copied text section.

1. *A line operated below 200kV, designated by the Planning Coordinator as an element of an Interconnection Reliability Operating Limit (IROL) or designated by the Western Electricity Coordinating Council (WECC) as an element of a Major WECC Transfer Path, becomes subject to this standard the latter of: 1) 12 months after the date the Planning Coordinator or WECC initially designates the line as being an element of an IROL or an element of a Major WECC Transfer Path, or 2) January 1 of the planning year when the line is forecast to become an element of an IROL or an element of a Major WECC Transfer Path.*

Case 1 is needed because the Planning Coordinators may designate lines below 200 kV to become elements of an IROL or Major WECC Transfer Path in a future Planning Year (PY). For example, studies by the Planning Coordinator in 2011 may identify a line to have that designation beginning in PY 2021, ten years after the planning study is performed. It is not intended for the Standard to be immediately applicable to, or in effective for, that line until that future PY begins. The effective date provision for such lines ensures that the line will become subject to the standard on the January 1 of the PY specified with an allowance of at least 12 months for the Transmission Owner to make the necessary preparations to achieve compliance on that line. The table below has some explanatory examples of the application.

Date that Planning Study is completed	PY the line will become an IROL element	Date 1	Date 2	Effective Date The latter of Date 1 or Date 2
05/15/2011	2012	05/15/2012	01/01/2012	05/15/2012
05/15/2011	2013	05/15/2012	01/01/2013	01/01/2013
05/15/2011	2014	05/15/2012	01/01/2014	01/01/2014
05/15/2011	2021	05/15/2012	01/01/2021	01/01/2021

2. *A line operated below 200 kV currently subject to this standard as a designated element of an IROL or a Major WECC Transfer Path which has a specified date for the removal of such designation will no longer be subject to this standard effective on that specified date.*

Case 2 is needed because a line operating below 200kV designated as an element of an IROL or Major WECC Transfer Path may be removed from that designation due to system improvements, changes in generation, changes in loads or changes in studies and analysis of the network.

3. *A line operated at 200 kV or above, currently subject to this standard which is a designated element of an IROL or a Major WECC Transfer Path and which has a specified date for the removal of such designation will be subject to Requirement R2 and no longer be subject to Requirement R1 effective on that specified date*

Case 3 is needed because a line operating at 200 kV or above that once was designated as an element of an IROL or Major WECC Transfer Path may be removed from that designation due to system improvements, changes in generation, changes in loads or changes in studies and analysis of the network. Such changes result in the need to apply R1 to that line until that date is reached and then to apply R2 to that line thereafter.

4. *An existing transmission line operated at 200kV or higher which is newly acquired by an asset owner and which was not previously subject to this standard becomes subject to this standard 12 months after the acquisition date.*

Case 4 is needed because an existing line that is to be operated at 200 kV or above can be acquired by a Transmission Owner from a third party such as a Distribution Provider or other end-user who was using the line solely for local distribution purposes, but the Transmission owner, upon acquisition, is incorporating the line into the interconnected electrical energy transmission network which will thereafter make the line subject to the standard.

5. *An existing transmission line operated below 200kV which is newly acquired by an asset owner and which was not previously subject to this standard becomes subject to this standard 12 months after the acquisition date of the line if at the time of acquisition the line is designated by the Planning Coordinator as an element of an IROL or by WECC as an element of a Major WECC Transfer Path.*

Case 5 is needed because an existing line that is operated below 200 kV can be acquired by a Transmission Owner from a third party such as a Distribution Provider or other end-user who was using the line solely for local distribution purposes, but the Transmission owner, upon acquisition, is incorporating the line into the interconnected electrical energy transmission network. In this special case the line upon acquisition was designated as an element of an Interconnection Reliability Operating Limit (IROL) or an element of a Major WECC transfer Path.

Definition of Terms

Right-of-Way (ROW)*

The corridor of land under a transmission line(s) needed to operate the line(s). The width of the corridor is established by engineering or construction standards as documented in either construction documents, pre-2007 vegetation maintenance records, or by the blowout standard in effect when the line was built. The ROW width in no case exceeds the Transmission Owner's legal rights but may be less based on the aforementioned criteria.

The current glossary definition of this NERC term is modified to address the issues set forth in Paragraph 734 of FERC Order 693.

The current NERC glossary definition of Right of Way has been modified to address the matter set forth in Paragraph 734 of FERC Order 693. The Order pointed out that Transmission Owners may in some cases own more property or rights than are needed to reliably operate transmission lines. This modified definition represents a slight but significant departure from the strict legal definition of "right of way" in that this definition is based on engineering and construction considerations that establish the width of a corridor from a technical basis. The pre-2007 maintenance records are included to allow the use of such vegetation widths if there were no engineering or construction standards that referenced the width of right of way to be maintained for vegetation on a particular line but the evidence exists in maintenance records for a width that was in fact maintained prior to this standard becoming mandatory. Such widths may be the only information available for lines that had limited or no vegetation easement rights and were typically maintained primarily to ensure public safety. This standard does not require additional easement rights to be purchased to satisfy a minimum right of way width that did not exist prior to this standard becoming mandatory.

This definition does not imply that danger tree rights beyond the constructed and maintained width are incorporated in the definition; therefore fall-ins from outside the ROW but within an area with danger tree rights would not be considered fall-ins from within the ROW.

Vegetation Inspection*

The systematic examination of vegetation conditions on a Right-of-Way and those vegetation conditions under the Transmission Owner's control that are likely to pose a hazard to the line(s) prior to the next planned maintenance or inspection. This may be combined with a general line inspection.

The inspection includes the identification of any vegetation that may pose a threat to reliability

The current glossary definition of this NERC term is modified to allow both maintenance inspections and vegetation inspections to be performed concurrently.

Current definition of Vegetation Inspection: The systematic examination of a transmission corridor to document vegetation conditions.

prior to the next planned maintenance or inspection work, considering the current location of the conductor and other possible locations of the conductor due to sag and sway for rated conditions.

This definition allows both maintenance inspections and vegetation inspections to be performed concurrently.

* This is a modification to a defined term in the NERC glossary and will be incorporated into the NERC glossary of terms with final approval of this standard revision.

See the Guidelines and Technical Basis section on Requirement R6 contained within the Standard for more details on inspections.

Minimum Vegetation Clearance Distance (MVCD)

The calculated minimum distance stated in feet (meters) to prevent flash-over between conductors and vegetation, for various altitudes and operating voltages.

The MVCD is a calculated minimum distance that is derived from the Gallet Equations. This is a method has been in the design of high voltage transmission lines. Keeping vegetation away from high voltage conductors by this distance will prevent voltage flash-over to the vegetation. See the explanatory text below for Requirement R3 and associated Figures 1, 2 and 3. Details of the equations and an example calculation are provided in Appendix 1below of the Technical Reference document. Table 1in Appendix 1 below provides MVCD values for various voltages and altitudes.

Applicability of the Standard

4. Applicability

4.1. ***Functional Entities:***
Transmission Owners

4.2. ***Facilities:*** *Defined below (referred to as "applicable lines"), including but not limited to those that cross lands owned by federal*[1]*, state, provincial, public, private, or tribal entities:*

4.2.1 *Each overhead transmission lines operated at 200kV or higher.*

4.2.2 *Each overhead transmission lines operated below 200kV identified as an element of an IROL under NERC Standard FAC-014 by the Planning Coordinator.*

4.2.3 *Each overhead transmission lines operated below 200 kV identified as an element of a Major WECC Transfer Paths in the Bulk Electric System by WECC.*

4.2.4 Each overhead transmission line identified above (4.2.1 through 4.2.3) located outside the fenced area of the switchyard, station or substation and any portion of the span *of the transmission line that is crossing the substation fence.*

4.3. ***Enforcement:*** *The reliability obligations of the applicable entities and facilities are contained within the technical requirements of this standard*

Rationale

The areas excluded in 4.2.4 were excluded based on comments from industry for reasons summarized as follows: 1) There is a very low risk from vegetation in this area. Based on an informal survey, no TOs reported such an event. 2) Substations, switchyards, and stations have many inspection and maintenance activities that are necessary for reliability. Those existing process manage the threat. As such, the formal steps in this standard are not well suited for this environment. 3) NERC has a project in place to address at a later date the applicability of this standard to Generation Owners. 4) Specifically addressing the areas where the standard does and does not apply makes the standard clearer.

In Order 693, FERC discussed the 200 kV bright-line test of applicability. While FERC did not change the 200 kV bright-line, the Commission remained concerned that there may be some transmission lines operating at lesser voltages that could have significant impact on the Bulk Electric System that should therefore be subject to this standard.

[1] EPAct 2005 section 1211c: *"Access approvals by Federal agencies".*

NERC Standard FAC-014 has the stated purpose, "*To ensure that System Operating Limits (SOLs) used in the reliable planning and operation of the Bulk Electric System (BES) are determined based on an established methodology or methodologies.*" FAC-014 requires Reliability Coordinators, Planning Coordinators, and Transmission Planners to have a methodology to identify all lines that might comprise an IROL. Thus, these entities would identify sub-200 kV lines that qualify as part of an IROL and should be subject to FAC-003-2.

Although all three entities may prepare the list of elements, the list as provided by the Planning Coordinator function is the more appropriate choice for this Standard. The Time Horizon needed to plan vegetation management work does not lend itself to the operating horizon of a Reliability Coordinator. Additionally, the Planning Coordinator has a wider-area view than the Transmission Planner and could thus identify any elements of importance to a sub-set of its area that might be missed by a Transmission Planner.

Transmission Owners, who do not already get the list of circuits included in the definition of an IROL, can get them from the Planning Coordinator. Specifically R5 of FAC-014 specifies that "*The Reliability Coordinator, Planning Authority (Coordinator) and Transmission Planner shall each provide its SOLs and IROLs to those entities that have a reliability-related need for those limits and provide a written request that includes a schedule for delivery of those limits*"

Vegetation-related Sustained Outages that occur due to natural disasters are beyond the control of the Transmission Owner. These events are not classified as vegetation-related Sustained Outages and are therefore exempt from the Standard. Transmission lines are not designed to withstand the impacts of natural disasters such as flood, drought, earthquake, major storms, fire, hurricane, tornado, landslides, ice storms, etc. In the aftermath of catastrophic system damage from natural disasters the Transmission Owner's focus is on electric system restoration for public safety and critical support infrastructure.

Sustained Outages due to human or animal activity are beyond the control of the Transmission Owner. These outages are not classified as vegetation-related Sustained Outages and are therefore exempt from the Standard. Examples of these events may include new plantings by outside parties of tall vegetation under the transmission line planted since the last Vegetation Inspection, tree contacts with line initiated by vehicles, logging activities, etc.

The foregoing exemptions are addressed in a new footnote 2. Referred to collectively as force majeure events and activities, this footnote applies to requirements R1 and R2 in FAC-003-2.

The reliability objective of this NERC Vegetation Management Standard ("Standard") is to prevent vegetation-related outages which could lead to Cascading by effective vegetation maintenance while recognizing that certain outages such as those due to vandalism, human errors and acts of nature are not preventable. Operating experience clearly indicates that trees that have grown out of specification could contribute to a cascading grid failure, especially under heavy electrical loading conditions.

Serious outages and operational problems have resulted from interference between overgrown vegetation and transmission lines located on many types of lands and ownership situations. To properly reduce and manage this risk, it is necessary to apply the Standard to applicable lines on any kind of land or easement, whether they are Federal Lands, state or provincial lands, public or private lands, franchises, easements or lands owned in fee. For the purposes of the Standard and this Technical Reference document, the term “public lands” includes municipal lands, village lands, city lands, and land owned by a host of other governmental entities.

The Standard addresses vegetation management along applicable overhead lines that serve to connect one electric station to another. However, it is not intended to be applied to lines sections inside the electric station fence or other boundary of an electric station, submarine or underground lines.

The Standard is intended to reduce the risk of Cascading involving vegetation. It is not intended to prevent customer outages from occurring due to tree contact with all transmission lines and voltages. For example, localized customer service might be disrupted if vegetation were to make contact with a 69kV transmission line supplying power to a 12kV distribution station. However, this Standard is not written to address such isolated situations which have little impact on the overall Bulk Electric System.

Vegetation growth is constant and always present. Unmanaged vegetation below numerous transmission lines that are operating at or near their Rating is highly problematic. This situation has led to multiple subsequent line failures and Cascading. Conversely, most other outage causes (such as trees falling into lines, lightning, animals, motor vehicles, etc.) are statistically intermittent. These events are not any more likely to occur during heavy system loads than any other time. There is no cause-effect relationship which creates the probability of simultaneous occurrence of other such events. Therefore these types of events are highly unlikely to cause large-scale grid failures. Thus, this Standard’s emphasis is on vegetation grow-ins.

In preparing the original vegetation management standard in 2005, industry stakeholders set the threshold for applicability of the standard at 200kV. This was because an unexpected loss of lines operating at above 200kV has a higher probability of initiating a widespread blackout or cascading outages compared with lines operating at less than 200kV.

The original NERC Standard FAC-003-1 also allowed for application of the standard to “critical” circuits (critical from the perspective of initiating widespread blackouts or cascading outages) operating below 200kV. While the percentage of these circuits is relatively low, it remains a fact that there are sub-200kV circuits whose loss could contribute to a widespread outage. Given the very limited exposure and unlikelihood of a major event related to these lower-voltage lines, it would be an imprudent use of resources to apply the Standard to all sub-200kV lines. The drafting team, after evaluating several alternatives, selected the IROL and WECC Major Transfer Path criteria to determine applicable lines below 200 kV that are subject to this standard.

Requirements R1 and R2

R1. Each Transmission Owner shall manage vegetation to prevent encroachments into the Minimum Vegetation Clearance Distance (MVCD) of its applicable line(s) which are either an element of an IROL, or an element of a Major WECC Transfer Path; operating within its Rating and all Rated Electrical Operating Conditions of the types shown below[2]:

1. An encroachment into the MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage[3],
2. An encroachment due to a fall-in from inside the Right-of-Way (ROW) that caused a vegetation-related Sustained Outage[4],
3. An encroachment due to the blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained Outage[4],
4. An encroachment due to vegetation growth into the MVCD that caused a vegetation-related Sustained Outage[4].

R2. Each Transmission Owner shall manage vegetation to prevent encroachments into the MVCD of its applicable line(s) which are not either an element of an IROL, or an element of a Major WECC Transfer

Rationale for R1 and R2:

Lines with the highest significance to reliability are covered in R1; all other lines are covered in R2.

Rationale for the types of failure to manage vegetation which are listed in order of increasing degrees of severity in non-compliant performance as it relates to a failure of a Transmission Owner's vegetation maintenance program:

1. This management failure is found by routine inspection or Fault event investigation, and is normally symptomatic of unusual conditions in an otherwise sound program.

2. This management failure occurs when the height and location of a side tree within the ROW is not adequately addressed by the program.

3. This management failure occurs when side growth is not adequately addressed and may be indicative of an unsound program.

4. This management failure is usually indicative of a program that is not addressing the most fundamental dynamic of vegetation management, (i.e. a grow-in under the line). If this type of failure is pervasive on multiple lines, it provides a mechanism for a Cascade.

[2] This requirement does not apply to circumstances that are beyond the control of a Transmission Owner subject to this reliability standard, including natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, wind shear, fresh gale, major storms as defined either by the Transmission Owner or an applicable regulatory body, ice storms, and floods; human or animal activity such as logging, animal severing tree, vehicle contact with tree, or installation, removal, or digging of vegetation. Nothing in this footnote should be construed to limit the Transmission Owner's right to exercise its full legal rights on the ROW.

[3] If a later confirmation of a Fault by the Transmission Owner shows that a vegetation encroachment within the MVCD has occurred from vegetation within the ROW, this shall be considered the equivalent of a Real-time observation.

[4] Multiple Sustained Outages on an individual line, if caused by the same vegetation, will be reported as one outage regardless of the actual number of outages within a 24-hour period.

Path; operating within its Rating and all Rated Electrical Operating Conditions of the types shown below[2]:

1. An encroachment into the MVCD as shown in FAC-003-Table 2, observed in Real-time, absent a Sustained Outage[3],
2. An encroachment due to a fall-in from inside the ROW that caused a vegetation-related Sustained Outage[4],
3. An encroachment due to blowing together of applicable lines and vegetation located inside the ROW that caused a vegetation-related Sustained Outage[4],
4. An encroachment due to vegetation growth into the MVCD that caused a vegetation-related Sustained Outage[4]

M1. Each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R1. Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-time observations of any MVCD encroachments. (R1)

M2. Each Transmission Owner has evidence that it managed vegetation to prevent encroachment into the MVCD as described in R2. Examples of acceptable forms of evidence may include dated attestations, dated reports containing no Sustained Outages associated with encroachment types 2 through 4 above, or records confirming no Real-time observations of any MVCD encroachments. (R2)

R1 and R2 are performance-based requirements. The reliability objective or outcome to be achieved is the prevention of vegetation encroachments within a minimum distance of transmission lines. Content-wise, R1 and R2 are the same requirements; however, they apply to different Facilities. Both R1 and R2 require each Transmission Owner to manage vegetation to prevent encroachment within the MVCD of transmission lines. R1 is applicable to lines that are identified as an element of an IROL or Major WECC transfer path. R2 is applicable to all other lines that are <u>not</u> an element of an IROL, and <u>not</u> an element of a Major WECC Transfer Path.

The separation of applicability (between R1 and R2) recognizes that inadequate vegetation management for an applicable line that is an element of an IROL or Major WECC Transfer Path is a greater risk to the interconnected electric transmission system than applicable lines that are not an element of an IROL or a Major WECC Transfer Path. Applicable lines that are not an element of an IROL or Major WECC Transfer Path do require effective vegetation management, but these lines are comparatively less operationally significant. As a reflection of this difference in risk impact, the Violation Risk Factors (VRFs) are assigned as High for R1 and Medium for R2.

R1 and R2 state that if vegetation encroaches within the distances in Table 1 in Appendix 1 of this supplemental Technical Reference document, it is in violation of the standard. Table 1below, which is the same as Table 2 in the standard, tabulates the distances necessary to prevent spark-over based on the Gallet equations as described more fully in Appendix 1 below.

These requirements assume that transmission lines and their conductors are operating within their Rating. If a line conductor is intentionally or inadvertently operated beyond its Rating and Rated Electrical Operating Condition (potentially in violation of other standards), the occurrence of a clearance encroachment may occur solely due to that condition. For example, emergency actions taken by a Transmission Operator or Reliability Coordinator to protect an Interconnection may cause excessive sagging and an outage. Another example would be ice loading beyond the line's Rating and Rated Electrical Operating Condition. Such vegetation-related encroachments and outages are not violations of this standard.

Evidence of failures to adequately manage vegetation include real-time observation of a vegetation encroachment into the MVCD (absent a Sustained Outage), or a vegetation-related encroachment resulting in a Sustained Outage due to a fall-in from inside the ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to the blowing together of the lines and vegetation located inside the ROW, or a vegetation-related encroachment resulting in a Sustained Outage due to a grow-in. Faults which do not cause a Sustained outage and which are confirmed to have been caused by vegetation encroachment within the MVCD are considered the equivalent of a Real-time observation for violation severity levels.

With this approach, the VSLs for R1 and R2 are structured such that they directly correlate to the severity of a failure of a Transmission Owner to <u>manage</u> vegetation and to the corresponding performance level of the Transmission Owner's vegetation program's ability to meet the objective of "preventing the risk of those vegetation related outages that could lead to Cascading." Thus violation severity increases with a Transmission Owner's inability to meet this goal and its potential of leading to a Cascading event. The additional benefits of such a combination are that it simplifies the standard and clearly defines performance for compliance. A performance-based requirement of this nature will promote high quality, cost effective vegetation management programs that will deliver the overall end result of improved reliability to the system.

Multiple Sustained Outages on an individual line can be caused by the same vegetation. For example initial investigations and corrective actions may not identify and remove the actual outage cause then another outage occurs after the line is re-energized and previous high conductor temperatures return. Such events are considered to be a single vegetation-related Sustained Outage under the standard where the Sustained Outages occur within a 24 hour period.

The MVCD is a calculated minimum distance stated in feet (or meters) to prevent spark-over, for various altitudes and operating voltages that is used in the design of Transmission Facilities. Keeping vegetation from entering this space will prevent transmission outages.

If the TO has applicable lines operated at nominal voltage levels not listed in Table 2, then the TO should use the next largest clearance distance based on the next highest nominal voltage in the table to determine an acceptable distance.

Requirement R3

> **Rationale**
>
> The documentation provides a basis for evaluating the competency of the Transmission Owner's vegetation program. There may be many acceptable approaches to maintain clearances. Any approach must demonstrate that the Transmission Owner avoids vegetation-to-wire conflicts under all Rated Electrical Operating Conditions. See Figure 1 for an illustration of possible conductor locations.

R3. *Each Transmission Owner shall have documented maintenance strategies or procedures or processes or specifications it uses to prevent the encroachment of vegetation into the MVCD of its applicable transmission lines that accounts for the following:*

3.1 *Movement of applicable line conductors under their Facility Rating and all Rated Electrical Operating Conditions;*

3.2 *Inter-relationships between vegetation growth rates, vegetation control methods, and inspection frequency.*

M3. *The maintenance strategies or procedures or processes or specifications provided demonstrate that the Transmission Owner can prevent encroachment into the MVCD considering the factors identified in the requirement. (R3)*

Requirement R3 is a competency based requirement concerned with the maintenance strategies, procedures, processes, or specifications, a Transmission Owner uses for vegetation management.

An adequate transmission vegetation management program formally establishes the approach the Transmission Owner uses to plan and perform vegetation work to prevent transmission Sustained Outages and minimize risk to the transmission system. The approach provides the basis for evaluating the intent, allocation of appropriate resources and the competency of the Transmission Owner in managing vegetation. There are many acceptable approaches to manage vegetation and avoid Sustained Outages. However, the Transmission Owner must be able to show the documentation of its approach and how it conducts work to maintain clearances.

An example of one approach commonly used by industry is ANSI Standard A300, part 7.

However, regardless of the approach a utility uses to manage vegetation, any approach a Transmission Owner chooses to use will generally contain the following elements:

1. *the maintenance strategy used (such as minimum vegetation-to-conductor distance or maximum vegetation height) to ensure that MVCD clearances are never violated.*
2. *the work methods that the Transmission Owner uses to control vegetation*
3. *a stated Vegetation Inspection frequency*

4. *an annual work plan*

The conductor's position in space at any point in time is continuously changing in reaction to a number of different loading variables. Changes in vertical and horizontal conductor positioning are the result of thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation. Physical loading applied to the conductor affects sag and sway by combining physical factors such as ice and wind loading. The movement of the transmission line conductor and the MVCD is illustrated in Figures 1, 2, and 3 below.

Conductor Dynamics

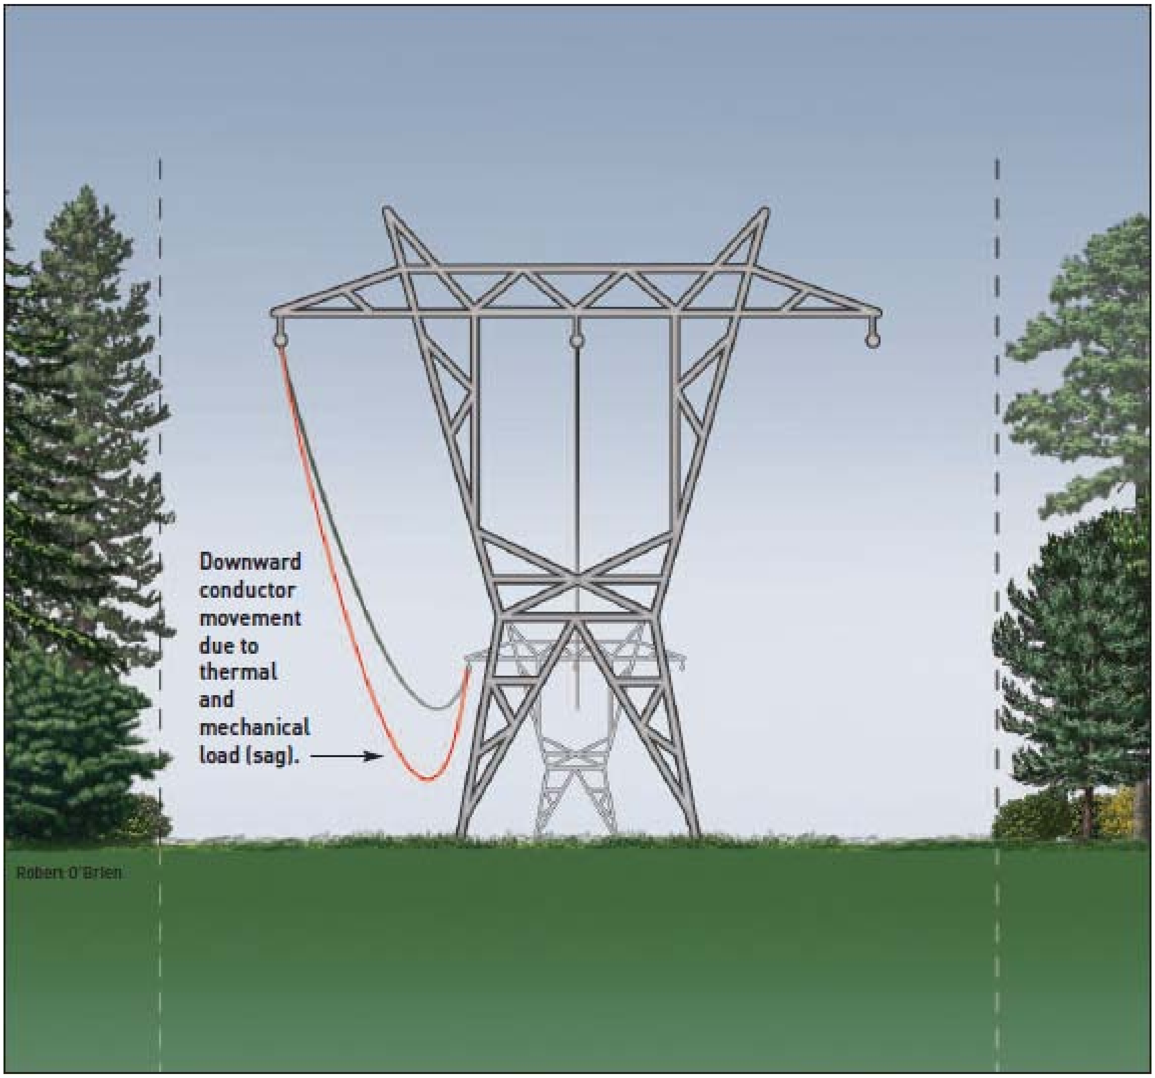
In order for a Transmission Owner to develop a specific maintenance approach, it is important to understand the dynamics of a line conductor's movements. This paper will first address the complexities inherent in observing and predicting conductor movement, particularly for field personnel. It will then present some examples of maintenance approaches which Transmission Owners may consider that take into account these complexities, and the practical approaches that can be utilized by field personnel.

Additionally, it is important the Transmission Owner consider all conductor locations, the MVCD, and vegetation growth between maintenance activities when developing a maintenance approach.

Understanding Conductor Position and Movement

The conductor's position in space at any point in time is continuously changing as a reaction to a number of different loading variables. Changes in vertical and horizontal conductor positioning are the result of thermal and physical loads applied to the line. Thermal loading is a function of line current and the combination of numerous variables influencing ambient heat dissipation including wind velocity/direction, ambient air temperature and precipitation. Physical loading applied to the conductor affects sag and sway by combining physical factors such as ice and wind loading.

As a consequence of these loading variables, the conductor's position in space is dynamic and moving. When calculating the range of conductor positions, the Transmission Owner should use the same design criteria and assumptions that are used to establish Ratings and System Operating Limits (SOLs), as described in other standards. Typically, the greatest conductor movements occur at mid-span. As the conductor moves through various positions, a spark-over zone surrounding the conductor moves with it. The radius of the spark-over zone may be found by referring to Table 1 below. For illustrations of this zone and conductor movements, Figures 1, 2 and 3 below are provided. At the time of making a field observation, however, it is very difficult to precisely know where the conductor is in relation to its wide range of all possible positions. Therefore, Transmission Owners must adopt maintenance approaches that account for this dynamic situation.



Downward conductor movement due to thermal and mechanical load (sag).

Figure 2

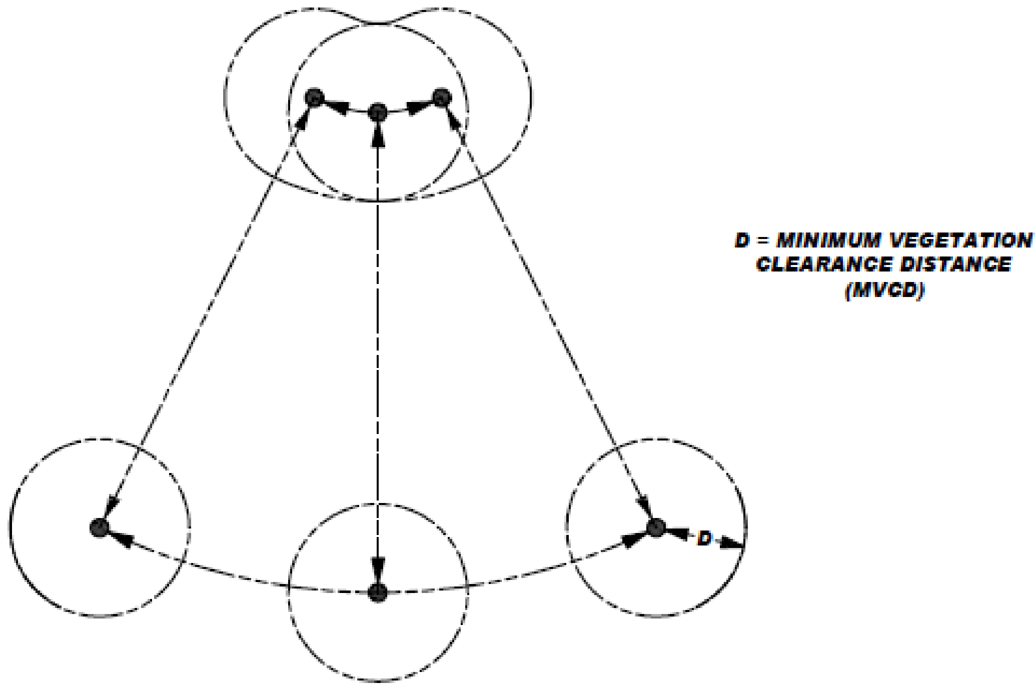

Figure 3

A cross-section view of a single conductor at a given point along the span is shown with six possible conductor positions due to movement resulting from thermal and mechanical loading.

Selecting a Maintenance Approach

In order to maintain adequate separation between vegetation and transmission line conductors, the Transmission Owner must craft a maintenance strategy that keeps vegetation well away from the spark-over zone mentioned above. In fact, it is generally necessary to incorporate a variety of maintenance strategies. For example, one Transmission Owner may utilize a combination of routine cycles, traditional IVM techniques and long-term planning. Another Transmission Owner may place a higher reliance on frequent inspections and follow-up remediation as opposed to a set cyclical approach. This variation of approaches is further warranted when factors, such as terrain, vegetation types, weather and climate, and any, environmental, legal or other land use constraints, must be considered in developing a Transmission Owner's specific approach to satisfying R3.

The following describes some strategies which may be utilized by a Transmission Owner. A Transmission Owner's basic maintenance approach in relatively flat terrain could be to remove all incompatible vegetation from the ROW if it has the right to do so and has no constraints. In mountainous terrain, however, this strategy could change to managing vegetation based on vegetation-to-conductor clearances, since it might not be necessary to remove vegetation in a valley that is far below the conductors at maximum sag.

If faced with easement constraints on a line design with sufficient ground clearance, the approach could be to allow vegetation such as fruit trees, but only up to a given height at maturity (for example 10 feet from the ground). If constraints cannot be overcome and if design clearances are sufficient, an exception to the Transmission Owner's 10-foot guideline might be made. If an approach is chosen to manage vegetation based primarily on clearance distances it could include an inspection regimen to regularly ensure that impending clearance problems are identified early for rectification.

ANSI A300 – Best Management Practices for Tree Care Operations

A description of ANSI A-300, part 7, is offered below to illustrate another maintenance approach that could be used in developing a comprehensive transmission vegetation management program.

Introduction

Integrated Vegetation Management (IVM) is a best management practice conveyed in the American National Standard for Tree Care Operations, Part 7 (ANSI 2006) and the International Society of Arboriculture *Best Management Practices: Integrated Vegetation Management* (Miller 2007). IVM is consistent with the requirements in FAC-003-02, and it provides practitioners with what industry experts consider to be appropriate techniques to apply to electric right-of-way projects in order to meet or exceed the Standard.

IVM is a system of managing plant communities whereby managers set objectives; identify compatible and incompatible vegetation; consider action thresholds; and evaluate, select and implement the most appropriate control method or methods to achieve set objectives. The choice of control method or methods should be based on the environmental impact and anticipated effectiveness; along with site characteristics, security, economics, current land use and other factors.

Planning and Implementation

Best management practices provide a systematic way of planning and implementing a vegetation management program. While designed primarily with transmission systems in mind, it is also applicable to distribution projects. As presented in ANSI A300 part 7 and the ISA best management practices, IVM consists of 6 elements:

1) Set Objectives
2) Evaluate the Site
3) Define Action Thresholds
4) Evaluate and Select Control Methods
5) Implement IVM
6) Monitor Treatment and Quality Assurance

The setting of objectives, defining action thresholds, and evaluating and selecting control methods all require decisions. The planning and implementation process is cyclical and continuous, because vegetation is dynamic and managers must have the flexibility to adjust their plans. Adjustments may be made at each stage as new information becomes available and circumstances evolve.

Set Objectives

Objectives should be clearly defined and documented. Examples of objectives can include promoting safety, preventing sustained outages caused by vegetation growing into electric facilities, maintaining regulatory compliance, protecting structures and security, restoring electric service during emergencies, maintaining access and clear lines of sight, protecting the environment, and facilitating cost effectiveness. Objectives should be based on site factors, such as workload and vegetation type, in addition to human, equipment and financial resources. They will vary from utility to utility and project to project, depending on line voltage and criticality, as well as topographical, environmental, fiscal and political considerations. However, where it is appropriate, the overriding focus should be on environmentally-sound, cost effective control of species that potentially conflict with the electric facility, while promoting compatible, early successional, sustainable plant communities.

Work Load Evaluations

Work-load evaluations are inventories of vegetation that could have a bearing on management objectives. Work load assessments can capture a variety of vegetation characteristics, such as location, height, species, size and condition, hazard status, density and clearance from conductors. Assessments should be conducted considering voltage, conductor sag from ambient temperatures and loading, and the potential influence of wind on line sway.

Evaluate and Select Control Methods

Control methods are the process through which managers achieve objectives. The most suitable control method best achieves management objectives at a particular site. Many cases call for a combination of methods. Managers have a variety of controls from which to choose, including manual, mechanical, herbicide and tree growth regulators, biological, and cultural options.

Manual Control Methods

Manual methods employ workers with hand-carried tools, including chainsaws, handsaws, pruning shears and other devices to control incompatible vegetation. The advantage of manual techniques is that they are selective and can be used where others may not be. On the other hand, manual techniques can be inefficient and expensive compared to other methods.

Mechanical Control Methods

Mechanical controls are done with machines. They are efficient and cost effective, particularly for clearing dense vegetation during initial establishment, or reclaiming neglected or overgrown right of way. On the other hand, mechanical control methods can be non-selective and disturb sensitive sites.

Tree Growth Regulator and Herbicide Control Methods

Tree growth regulators and herbicides can be effective for vegetation management. Tree growth regulators (TGRs) are designed to reduce growth rates by interfering with natural plant processes. TGRs can be helpful where removals are prohibited or impractical by reducing the growth rates of some fast-growing species.

Herbicides control plants by interfering with specific botanical biochemical pathways. Herbicide use can control individual plants that are prone to re-sprout or sucker after removal. When trees that re-sprout or sucker are removed without herbicide treatment, dense thickets develop, impeding access, swelling workloads, increasing costs, blocking lines-of-site, and deteriorating wildlife habitat. Treating suckering plants allows early successional, compatible species to dominate the right-of-way and out-compete incompatible species, ultimately reducing work.

Cultural Control Methods

Cultural methods modify habitat to discourage incompatible vegetation and establish and manage desirable, early successional plant communities. Cultural methods take advantage of seed banks of native, compatible species lying dormant on site. In the long run, cultural control is the most desirable method where it is applicable.

A cultural control known as cover-type conversion provides a competitive advantage to short-growing, early successional plants, allowing them to thrive and eventually out-compete unwanted tree species for sunlight, essential elements and water. The early successional plant community is relatively stable, tree-resistant and reduces the amount of work, including herbicide application, with each successive treatment.

Wire-Border Zone

The wire-border zone technique is a management philosophy that can be applied through cultural control. W.C. Bramble and W.R. Byrnes developed it in the mid-1980s out of research begun in 1952 on a transmission right-of-way in the Pennsylvania State Game Lands 33 Research and Demonstration project (Yahner and Hutnik (2004).

The wire zone is the section of a utility transmission right-of-way directly under the wires and extending outward about 10 feet on each side. The wire zone is managed to promote a low-growing plant community dominated by grasses, herbs and small shrubs (under 3 feet in height at maturity). The border zone is the remainder of the right-of-way. It is managed to establish small trees and tall shrubs (under 25 feet in height at maturity). When properly managed, diverse, tree-resistant plant communities develop in wire and border zones. The communities not only protect the electric facility and reduce long-term maintenance, but also enhance wildlife habitat, forest ecology and aesthetic values.

Although the wire-border zone is a best practice in many instances, it is not necessarily universally suitable. For example, standard wire-border zone prescriptions may be unnecessary where lines are high off the ground, such as across low valleys or canyons, so the technique can be modified without sacrificing reliability.

One way to accommodate variances in topography is to establish different regions based on wire height. For example, over canyon bottoms or other areas where conductors are 100 feet or more above the ground, only a few trees are likely to be tall enough to conflict with the lines. In those cases, trees that potentially interfere with the transmission lines can be removed selectively on a case-by-case basis.

In areas where the wire is lower, perhaps between 50-100 feet from the ground, a border zone community can be developed throughout the right-of-way. Note that in many cases, conductor attachment points are more than 50 feet off the ground, so a border zone community can be cultivated near structures. Where the line is less than 50 feet off the ground, managers could apply a full wire-border zone prescription.

An environmental advantage of this type of modification is stream protection. Streams often course through the valleys and canyons where lines are likely to be elevated. Leaving timber or border zone communities in canyon bottoms helps shelter this valuable habitat, enabling managers to achieve environmentally sensitive objectives.

Implement IVM

All laws and regulations governing IVM practices and specifications written by qualified vegetation managers must be followed. Integrated vegetation management control methods should be implemented on regular work schedules, which are based on established objectives and completed assessments. Work should progress systematically, using control measures determined to be best for varying conditions at specific locations along a right-of-way. Some considerations used in developing schedules include the importance and type of line, vegetation clearances, workloads, growth rate of predominant vegetation, geography, accessibility, and in some cases, time lapsed since the last scheduled work.

Clearances Following Work

Clearances following work should be sufficient to meet management objectives, including preventing trees from entering the Minimum Vegetation Clearance Distance, electric safety risks, service-reliability threats and cost.

Monitor Treatment and Quality Assurance

An effective program includes documented processes to evaluate results. Evaluations can involve quality assurance while work is underway and after it is completed. Monitoring for quality assurance should begin early to correct any possible miscommunication or misunderstanding on the part of crewmembers. Early and consistent observation and evaluation also provides an opportunity to modify the plan, if need be, in time for a successful outcome.

Utility vegetation management programs should have systems and procedures in place for documenting and verifying that vegetation management work was completed to specifications. Post-control reviews can be comprehensive or based on a statistically representative sample. This final review points back to the first step and the planning process begins again.

Summary of A-300 example

Integrated Vegetation Management offers among others, a systematic way of planning and implementing a vegetation management program as presented in ANSI A300 Part 7. This methodology enables a program to comply with the NERC *Transmission Vegetation Management Program* standard (FAC-003-2). Managers should select control options to best promote management objectives.

Vegetation Inspections

The standard in R6 establishes the frequency of vegetation inspections. These inspections can be used to “evaluate the site” as referred to in the second element of ANSI A300 Part 7. This necessary frequency may need to be less than the annually based on anticipated growth rates of the local vegetation, length of the growing season for the geographical area, limited ROW width, rainfall amounts, etc.

Annual Work Plan

Requirement R7 of the Standard addresses the execution of the annual work plan. A comprehensive approach that exercises the full extent of legal rights is superior to incremental management in the long term because it reduces overall encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient at all locations on the ROW. Removal is superior to pruning. Removal minimizes the possibility of conflicts between energized conductors and vegetation. When this is not possible, the approach should be to use vegetation maintenance methods to work towards or achieve the maximum use of the ROW.

Requirement R4

R4. *Each Transmission Owner, without any intentional time delay, shall notify the control center holding switching authority for the associated applicable transmission line when the Transmission Owner has confirmed the existence of a vegetation condition that is likely to cause a Fault at any moment.*

Rationale

This is to ensure expeditious communication between the Transmission Owner and the control center when a critical situation is confirmed.

M4. *Each Transmission Owner that has a confirmed vegetation condition likely to cause a Fault at any moment will have evidence that it notified the control center holding switching authority for the associated transmission line without any intentional time delay. Examples of evidence may include control center logs, voice recordings, switching orders, clearance orders and subsequent work orders. (R4)*

R4 is a risk-based requirement. It focuses on preventative actions to be taken by the Transmission Owner for the mitigation of Fault risk when a vegetation threat is confirmed. R4 involves the notification of potentially threatening vegetation conditions, without any intentional delay, to the control center holding switching authority for that specific transmission line. Examples of acceptable unintentional delays may include communication system problems (for example, cellular service or two-way radio disabled), crews located in remote field locations with no communication access, delays due to severe weather, etc.

Confirmation is key that a threat actually exists due to vegetation. This confirmation could be in the form of a Transmission Owner's employee who personally identifies such a threat in the field. Confirmation could also be made by sending out an employee to evaluate a situation reported by a landowner.

Vegetation-related conditions that warrant a response include vegetation that is near or encroaching into the MVCD (a grow-in issue) or vegetation that could fall into the transmission conductor (a fall-in issue). A knowledgeable verification of the risk would include an assessment of the possible sag or movement of the conductor while operating between no-load conditions and its rating.

The Transmission Owner has the responsibility to ensure the proper communication between field personnel and the control center to allow the control center to take the appropriate action until the vegetation threat is relieved. Appropriate actions may include a temporary reduction in the line loading, switching the line out of service, or positioning the system in recognition of the increasing risk of outage on that circuit. The notification of the threat should be communicated in terms of minutes or hours as opposed to a longer time frame for corrective action plans (see R5).

All potential grow-in or fall-in vegetation-related conditions will not necessarily cause a Fault at any moment. For example, some Transmission Owners may have a danger tree identification program that identifies trees for removal with the potential to fall near the line. These trees would not require notification to the control center unless they pose an immediate fall-in threat.

Requirement R5

R5. *When a Transmission Owner is constrained from performing vegetation work on an applicable line operating within their Rating and all Rated Electrical Operating Conditions, and the constraint may lead to a vegetation encroachment into the MVCD prior to the implementation of the next annual work plan, then the Transmission Owner shall take corrective action to ensure continued vegetation management to prevent encroachments.*

M5. *Each Transmission Owner has evidence of the corrective action taken for each constraint where an applicable transmission line was put at potential risk. Examples of acceptable forms of evidence may include initially-planned work orders, documentation of constraints from landowners, court orders, inspection records of increased monitoring, documentation of the de-rating of lines, revised work orders, invoices, or evidence that a line was de-energized. (R5)*

Rationale

Legal actions and other events may occur which result in constraints that prevent the Transmission Owner from performing planned vegetation maintenance work.

In cases where the transmission line is put at potential risk due to constraints, the intent is for the Transmission Owner to put interim measures in place, rather than do nothing.

The corrective action process is not intended to address situations where a planned work methodology cannot be performed but an alternate work methodology can be used.

R5 is a risk-based requirement. It focuses upon preventative actions to be taken by the Transmission Owner for the mitigation of Sustained Outage risk when temporarily constrained from performing vegetation maintenance. The intent of this requirement is to deal with situations that prevent the Transmission Owner from performing planned vegetation management work and, as a result, have the potential to put the transmission line at risk. Constraints to performing vegetation maintenance work as planned could result from legal injunctions filed by property owners, the discovery of easement stipulations which limit the Transmission Owner’s rights, or other circumstances.

This requirement is not intended to address situations where the transmission line is not at potential risk and the work event can be rescheduled or re-planned using an alternate work methodology. For example, a land owner may prevent the planned use of chemicals on non-threatening, low growth vegetation but agree to the use of mechanical clearing. In this case the Transmission Owner is not under any immediate time constraint for achieving the management objective, can easily reschedule work using an alternate approach, and therefore does not need to take interim corrective action.

However, in situations where transmission line reliability is potentially at risk due to a constraint, the Transmission Owner is required to take an interim corrective action to mitigate the potential risk to the transmission line. A wide range of actions can be taken to address various situations. General considerations include:

- Identifying locations where the Transmission Owner is constrained from performing planned vegetation maintenance work which potentially leaves the transmission line at risk.
- Developing the specific action to mitigate any potential risk associated with not performing the vegetation maintenance work as planned.
- Documenting and tracking the specific action taken for each location.
- In developing the specific action to mitigate the potential risk to the transmission line the Transmission Owner could consider location specific measures such as modifying the inspection and/or maintenance intervals. Where a legal constraint would not allow any vegetation work, the interim corrective action could include limiting the loading on the transmission line.
- The Transmission Owner should document and track the specific corrective action taken at each location. This location may be indicated as one span, one tree or a combination of spans on one property where the constraint is considered to be temporary.

Requirement R6

R6. *Each Transmission Owner shall perform a Vegetation Inspection of 100% of its applicable lines (measured in units of choice - circuit, pole line, line miles or kilometers, etc.) at least once per calendar year and with no more than 18 months between inspections on the same ROW.*[5]

M6. *Each Transmission Owner has evidence that it conducted Vegetation Inspections of the transmission line ROW for all applicable lines at least once per calendar year but with no more than 18 months between inspections on the same ROW. Examples of acceptable forms of evidence may include completed and dated work orders, dated invoices, or dated inspection records. (R6)*

Rationale

Inspections are used by Transmission Owners to assess the condition of the entire ROW. The information from the assessment can be used to determine risk, determine future work and evaluate recently-completed work. This requirement sets a minimum Vegetation Inspection frequency of once per calendar year but with no more than 18 months between inspections on the same ROW. Based upon average growth rates across North America and on common utility practice, this minimum frequency is reasonable. Transmission Owners should consider local and environmental factors that could warrant more frequent inspections.

R6 is a risk-based requirement. This requirement sets a minimum time period for completing Vegetation Inspections that fits general industry practice. In addition, the fact that Vegetation Inspections can be performed in conjunction with general line inspections further facilitates a Transmission Owner's ability to meet this requirement. However, the Transmission Owner may determine that more frequent inspections are needed to maintain reliability levels, dependent upon such factors as anticipated growth rates of the local vegetation, length of the growing season for the geographical area, limited ROW width, and rainfall amounts. Therefore it is expected that some transmission lines may be designated with a higher frequency of inspections.

Footnote 5 is added to address the situation where a Transmission Owner through no fault of its own, would be unable to complete the vegetation inspection within the allotted time period. This would include the situation of mutual aid as well as disasters to the Transmission Owner's own system.

[5] When the Transmission Owner is prevented from performing a Vegetation Inspection within the timeframe in R6 due to a natural disaster, the TO is granted a time extension that is equivalent to the duration of the time the TO was prevented from performing the Vegetation Inspection.

The VSL for Requirement R6 has VSL categories ranked by the percentage of the required ROW inspections completed. To calculate the percentage of inspection completion, the Transmission Owner may choose units such as: line miles or kilometers, circuit miles or kilometers, pole line miles, ROW miles, etc.

For example, when a Transmission Owner operates 2,000 miles of applicable transmission lines this Transmission Owner will be responsible for inspecting all the 2,000 miles of lines at least once during the calendar year. If one of the included lines was 100 miles long, and if it was not inspected during the year, then the amount failed to inspect would be 100/2000 = 0.05 or 5%.

The "Low VSL" for R6 would apply in this example.

Requirement R7

R7. *Each Transmission Owner shall complete 100% of its annual vegetation work plan of applicable lines to ensure no vegetation encroachments occur within the MVCD. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made (provided they do not allow encroachment of vegetation into the MVCD) and must be documented. The percent completed calculation is based on the number of units actually completed divided by the number of units in the final amended plan (measured in units of choice - circuit, pole line, line miles or kilometers, etc.) Examples of reasons for modification to annual plan may include:*

- Change in expected growth rate/ environmental factors
- Circumstances that are beyond the control of a Transmission Owner[6]
- Rescheduling work between growing seasons
- Crew or contractor availability/ Mutual assistance agreements
- Identified unanticipated high priority work
- Weather conditions/Accessibility
- Permitting delays
- Land ownership changes/Change in land use by the landowner
- Emerging technologies

Rationale

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. It allows modifications to the planned work for changing conditions, taking into consideration anticipated growth of vegetation and all other environmental factors, provided that those modifications do not put the transmission system at risk of a vegetation encroachment.

M7. *Each Transmission Owner has evidence that it completed its annual vegetation work plan. Examples of acceptable forms of evidence may include a copy of the completed annual work plan (including modifications if any), dated work orders, dated invoices, or dated inspection records. (R7)*

R7 is a risk-based requirement. The Transmission Owner is required to implement its work plan for vegetation management to accomplish the purpose of this Standard. Modifications to the work plan in response to changing conditions or to findings from vegetation inspections may be made and documented provided they do not put the transmission system at risk. The annual

[6] Circumstances that are beyond the control of a Transmission Owner include but are not limited to natural disasters such as earthquakes, fires, tornados, hurricanes, landslides, ice storms, floods, or major storms as defined either by the TO or an applicable regulatory body.

work plan requirement is not intended to necessarily require a “span-by-span”, or even a “line-by-line” detailed description of all work to be performed. It is only intended to require that the Transmission Owner provide evidence of annual planning and execution of a vegetation management maintenance approach which successfully prevents encroachment of vegetation into the MVCD.

For example, when a Transmission Owner identifies 1,000 miles of applicable transmission lines to be completed in the TO’s annual plan, the Transmission Owner will be responsible completing those identified miles. If a TO makes a modification to the annual plan that does not put the transmission system at risk of an encroachment the annual plan may be modified. If 100 miles of the annual plan is deferred until next year the calculation to determine what percentage was completed for the current year would be: 1000 – 100 (deferred miles) = 900 modified annual plan, or 900 / 900 = 100% completed annual miles. If a TO only completed 875 of the total 1000 miles with no acceptable documentation for modification of the annual plan the calculation for failure to complete the annual plan would be: 1000 – 875 = 125 miles failed to complete then, 125 miles (not completed) / 1000 total annual plan miles = 12.5% failed to complete.

The ability to modify the work plan allows the Transmission Owner to change priorities or treatment methodologies during the year as conditions or situations dictate. For example recent line inspections may identify unanticipated high priority work, weather conditions (drought) could make herbicide application ineffective during the plan year, or a major storm could require redirecting local resources away from planned maintenance or work may be deferred to a subsequent year because of slower-than-expected growth. This situation may also include complying with mutual assistance agreements by moving resources off the Transmission Owner’s system to work on another system. Any of these examples could result in acceptable deferrals or additions to the annual work plan. Modifications to the annual work plan must always ensure the reliability of the electric Transmission system.

In general, the vegetation management maintenance approach should use the full extent of the Transmission Owner’s legal rights on the ROW. A comprehensive approach that exercises the full extent of legal rights on the ROW is superior to incremental management in the long term because it reduces the overall potential for encroachments, and it ensures that future planned work and future planned inspection cycles are sufficient.

When developing the annual work plan the Transmission Owner should allow time for procedural requirements to obtain permits to work on federal, state, provincial, public, tribal lands. In some cases the lead time for obtaining permits may necessitate preparing work plans more than a year prior to work start dates. Transmission Owners may also need to consider those special landowner requirements as documented in easement instruments.

This requirement sets the expectation that the work identified in the annual work plan will be completed as planned. Therefore, deferrals or relevant changes to the annual plan shall be documented. Depending on the planning and documentation format used by the Transmission Owner, evidence of successful annual work plan execution could consist of signed-off work orders, signed contracts, printouts from work management systems, spreadsheets of planned

versus completed work, timesheets, work inspection reports, or paid invoices. Other evidence may include photographs and walk-through reports.

Appendix 1: Clearance Distance Derivation by the Gallet Equation

The Gallet Equation is a well-known method of computing the required strike distance for proper insulation coordination, and has the ability to take into account various air gap geometries, as well as non-standard atmospheric conditions. When the Gallet Equation and conservative probabilistic methods are combined, i.e. deterministic design, spark-over probabilities of 10^{-6} or less are achieved. This approach is well known for its conservatism and was used to design the first 500 kV and 765 kV lines in North America [1]. Thus, the deterministic design approach using the Gallet Equation is used for the standard to compute the minimum strike distance between transmission lines and the vegetation that may be present in or along the transmission corridor.

Method Explanation (Gallet Equation)

In 1975 G. Gallet published a benchmark paper that provided a method to compute the critical flashover voltage (CFO) of various air gap geometries [4]. The Gallet Equation uses various "gap factors" to take into account various air gap geometries. Various gap factor values are provided in [1]. If the vegetation in a transmission corridor, e.g. a tree, is assumed electrically to be a large structure then the CFO of such an air gap geometry can be computed for dry or wet conditions using a well established equation proposed by Gallet [1],[2],[4],

$$CFO_A = k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} \qquad (1)$$

where,

k_w	is defined as the factor that takes into account wet or dry conditions (dry = 1.0 and wet = 0.96) and phase arrangement (multiply by 1.08 for outside phase), e.g. outside phase and wet conditions = (0.96)(1.08) = 1.037,
k_g	is defined as the gap factor (1.3 for conductor to large structure),
D	is the strike distance (m),
CFO_A	is the CFO for the relative air density (kV).
δ	is defined as the relative air density and is approximately equal to (2) where A is the altitude in km,

$$\delta = e^{-\frac{A}{8.6}} \qquad (2)$$

$$m = 1.25G_0\left(G_0 - 0.2\right) \qquad (3)$$

$$G_0 = \frac{CFO_s}{500 \cdot D} \qquad (4)$$

$$CFO_s = k_w \cdot k_g \cdot \frac{3400}{1 + \frac{8}{D}} \qquad (5)$$

where CFO_S is the CFO for standard atmospheric conditions (kV). Using (1)-(5), the required CFO_A can be computed using an iterative process.

Once the CFO_A is known, deterministic methods can be used to determine the required clearance distance. If we let the maximum switching overvoltage be equal to the withstand voltage of the air gap (CFO_A - 3σ) then the CFO_A can be written as (6).

$$CFO_A = \frac{V_m}{1 - 3\left(\frac{\sigma}{CFO_A}\right)} \qquad (6)$$

where

V_m is equal to the maximum switching overvoltage, i.e. the value that has a 0.135% chance of being exceeded,

σ is the standard deviation of the air gap insulation,

CFO_A is the critical flashover voltage of the air gap insulation under non-standard atmospheric conditions.

The ratio of σ to the CFO_A given in (6) can be assumed to be 0.05 (5%) [1]. Thus, (6) can be written as (7).

$$CFO_A = \frac{V_m}{0.85} \qquad (7)$$

Substituting (7) into (1) we arrive at (8).

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1 + \frac{8}{D}} \qquad (8)$$

Equation 8 relates the maximum transient overvoltage, V_m, to the air gap distance, *D*. Using (8) to compute the required clearance distance for the specified air gap geometry (conductor to large structure) results in a probability of flashover in the range of 10^{-6}.

Transient Overvoltage

In general, the worst case transient overvoltages occurring on a transmission line are caused by energizing or re-energizing the line with the latter being the extreme case if trapped charge is present. The intent of FAC-003 is to keep a transmission line that is *in service* from becoming de-energized (i.e. tripped out) due to sparkover from the line conductor to nearby vegetation. Thus, the worst case scenarios that are typically analyzed for insulation coordination purposes (e.g. line energization and re-energization) can be ignored. For the purposes of FAC-003-2, the worst case transient overvoltage then becomes the maximum value that can occur with the line energized. Determining a realistic value of transient overvoltage for this situation is difficult because the maximum transient overvoltage factors listed in the literature are based on a switching operation of the line in question. In other words, these maximum overvoltage values (e.g. the values listed in [2], [3] and [5]) are based on the assumption that the subject line is being energized, re-energized or de-energized. These operations, by their very nature, will create the largest transient overvoltages. Typical values of transient overvoltages of in-service lines, as such, are not readily available in the literature because the resulting level of overvoltage is negligible compared with the maximum (e.g. re-energizing a transmission line with trapped charge). A conservative value for the maximum transient overvoltage that can occur anywhere along the length of an in-service ac line is approximately 2.0 p.u.[2]. This value is a conservative estimate of the transient overvoltage that is created at the point of application (e.g. a substation) by switching a capacitor bank without a pre-insertion device (e.g. closing resistors). At voltage levels where capacitor banks are not very common (e.g. 362 kV), the maximum transient overvoltage of an “in-service” ac line are created by fault initiation on adjacent ac lines and shunt reactor bank switching. These transient voltages are usually 1.5 p.u. or less [2]. It is well known that these theoretical transient overvoltages will not be experienced at locations remote from the bus at which they were created; however, in order to be conservative, it will be assumed that all nearby ac lines are subjected to this same level of overvoltage. Thus, a maximum transient overvoltage factor of 2.0 p.u. for 302 kV and below and 1.4 p.u. for ac transmission lines 362 kV and above is used to compute the required clearance distances for vegetation management purposes.

The overvoltage characteristics of dc transmission lines vary somewhat from their ac counterparts. The referenced empirically derived transient overvoltage factor used to calculate the minimum clearance distances from dc transmission lines to vegetation for the purpose of FAC-003-2 will be 1.8 p.u.[3].

Example Calculation

An example calculation is presented below using the proposed method of computing the vegetation clearance distances. It is assumed that the line in question has a maximum operating voltage of 550 kV_{rms} line-to-line. Using a per unit transient overvoltage factor of 1.4, the result is a peak transient voltage of 629 kV_{crest}. It is further assumed that the line in question operates at a maximum altitude of 7000 feet (2.134 km) above sea level.

The required withstand voltage of the air gap must be equal to or greater than 629 kV_{crest}. Since the altitude is above sea level, (1) - (5) have to be iterated on to achieve the desired result. Equation (9) can be used as an initial guess for the clearance distance.

$$D_i = \frac{8}{\frac{3400 \cdot k_w \cdot k_g}{\left(\frac{V_m}{0.85}\right)} - 1} \tag{9}$$

For our case here, V_m is equal to 629 kV, k_w = 1.037 and k_g = 1.3. Thus,

$$D_i = \frac{8}{\frac{3400 \cdot k_w \cdot k_g}{\left(\frac{V_m}{0.85}\right)} - 1} = \frac{8}{\frac{3400 \cdot 1.037 \cdot 1.3}{\left(\frac{629}{0.85}\right)} - 1} = 1.535m \tag{10}$$

Using (2)-(5) and (8) the withstand voltage of the air gap is next computed. This value will then be compared to the maximum transient overvoltage.

$$CFO_S = k_w \cdot k_g \cdot \frac{3400}{1+\frac{8}{D}} = 1.037 \cdot 1.3 \cdot \frac{3400}{1+\frac{8}{1.535}} = 737.7kV \tag{11}$$

$$\delta = e^{-\frac{A}{8.6}} = e^{-\frac{2.134}{8.6}} = 0.78 \tag{12}$$

$$G_O = \frac{CFO_S}{500 \cdot D} = \frac{737.7}{(500) \cdot (1.535)} = 0.961 \tag{13}$$

$$m = 1.25 \cdot G_O(G_O - 0.2) = 1.25 \cdot 0.961(0.961 - 0.2) = 0.915 \tag{14}$$

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} = (0.85)(1.037)(1.3)(0.78)^{0.915}\left(\frac{3400}{1+\frac{8}{1.535}}\right) = 499.8kV \tag{15}$$

The calculated V_m is less than 629 kV; thus, the clearance distance must be increased. A few iterations using (2)-(5) and (8) are required until the computed $V_m \geq$ 629 kV. For this case it was found that D = 1.978 m (6.49 feet) yielded V_m = 629.3 kV. Using this clearance distance the following values were computed for the final iteration.

$$CFO_S = k_w \cdot k_g \cdot \frac{3400}{1+\frac{8}{D}} = 1.037 \cdot 1.3 \cdot \frac{3400}{1+\frac{8}{1.978}} = 908.5kV \tag{16}$$

$$\delta = e^{-\frac{A}{8.6}} = e^{-\frac{2.134}{8.6}} = 0.78 \tag{17}$$

$$G_O = \frac{CFO_S}{500 \cdot D} = \frac{908.5}{(500)\cdot(1.978)} = 0.919 \tag{18}$$

$$m = 1.25 \cdot G_O (G_O - 0.2) = 1.25 \cdot 0.919(0.919 - 0.2) = 0.825 \tag{19}$$

$$V_m = 0.85 \cdot k_w \cdot k_g \cdot \delta^m \cdot \frac{3400}{1+\frac{8}{D}} = (0.85)(1.037)(1.3)(0.78)^{0.825}\left(\frac{3400}{1+\frac{8}{1.978}}\right) = 629.3kV \tag{20}$$

Therefore, the minimum vegetation clearance distance for a maximum line to line ac operating voltage of 550 kV at 7000 feet above sea level is 1.978 m (6.49 feet). Table 1 provides calculated distances for various altitudes and maximum system operating ac voltages.

Table 1 — Minimum Vegetation Clearance Distances (MVCD)[7]

* Such lines are applicable to this standard only if PC has determined such per FAC-014 (refer to the Applicability Section above).

---

[7] The distances in this Table are the minimums required to prevent Flash-over; however prudent vegetation maintenance practices dictate that substantially greater distances will be achieved at time of vegetation maintenance.

[8] Where applicable lines are operated at nominal voltages other than those listed, The Transmission Owner should use the maximum system voltage to determine the appropriate clearance for that line.
